configured to receive the RAR message from the eNodeB by monitoring a RAR message window, wherein a position of the RAR message window is configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

[00132] Example 12 includes the apparatus of any of Examples 1-11, further configured to receive a preamble from the eNodeB prior to receiving the RAR message, wherein the preamble functions to improve a downlink synchronization accuracy.

[00133] Example 13 includes the apparatus of any of Examples 1-12, wherein the RAR message received at the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

[00134] Example 14 includes the apparatus of any of Examples 1-13, wherein: the RAR message is received at the UE via a physical downlink control channel (PDCCH), wherein the UE is configured to monitor the PDCCH using a cyclic redundancy check (CRC) scrambled by a random-access radio network temporary identifier (RA-RNTI); or the RAR message is received at the UE via a physical downlink shared channel (PDSCH) that is scheduled by the PDCCH.

[00135] Example 15 includes the apparatus of any of Examples 1-14, wherein: a gap between a last subframe for a RAR message transmission and a starting subframe of the mission critical communication in uplink is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling; and a gap between a last subframe of the mission critical communication in uplink and a starting subframe of an acknowledgement (ACK) or a negative acknowledgement (NACK) transmission is predefined or configured by higher layers via one of: the MIB, the SIB, or dedicated RRC signaling.

[00136] Example 16 includes the apparatus of any of Examples 1-15, wherein the UE includes at least one of an antenna, a touch sensitive display screen, a speaker, a microphone, a graphics processor, an application processor, a baseband processor, an internal memory, a non-volatile memory port, and combinations thereof.

[00137] Example 17 includes an apparatus of a base station operable to receive mission

critical communications from a user equipment (UE), the apparatus comprising one or more processors and memory configured to: receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI); transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message; and transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00138] Example 18 includes the apparatus of Example 17, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00139] Example 19 includes the apparatus of any of Examples 17-18, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

[00140] Example 20 includes the apparatus of any of Examples 17-19, wherein: the PRACH signal is received from the UE with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device

identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE; and the RAR message transmitted to the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

[00141] Example 21 includes the apparatus of any of Examples 17-20, wherein the RAR message is transmitted to the UE via a physical downlink control channel (PDCCH) or a physical downlink shared channel (PDSCH).

[00142] Example 22 includes at least one machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, the instructions when executed perform the following: transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI); receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI; and receiving, using the at least one processor of the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00143] Example 23 includes the at least one machine readable storage medium of Example 22, wherein the UE is configured to initiate performance of the mission critical

communication when in a radio resource control (RRC) idle mode.

[00144] Example 24 includes the at least one machine readable storage medium of any of Examples 22-23, wherein the first TTI is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00145] Example 25 includes the at least one machine readable storage medium of any of Examples 22-24, further comprising instructions which when executed perform the following: performing repeated transmissions of the repeatedly transmit the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and performing repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB.

[00146] Various techniques, or certain aspects or portions thereof, may take the form of program code (i.e., instructions) embodied in tangible media, such as floppy diskettes, compact disc-read-only memory (CD-ROMs), hard drives, non-transitory computer readable storage medium, or any other machine-readable storage medium wherein, when the program code is loaded into and executed by a machine, such as a computer, the machine becomes an apparatus for practicing the various techniques. A non-transitory computer readable storage medium can be a computer readable storage medium that does not include signal. In the case of program code execution on programmable computers, the computing device may include a processor, a storage medium readable by the processor (including volatile and non-volatile memory and/or storage elements), at least one input device, and at least one output device. The volatile and non-volatile memory and/or storage elements may be a random-access memory (RAM), erasable programmable read only memory (EPROM), flash drive, optical drive, magnetic hard drive, solid state drive, or other medium for storing electronic data. The node and wireless device may also include a transceiver module (i.e., transceiver), a counter module (i.e., counter), a processing module (i.e., processor), and/or a clock module (i.e., clock) or timer module (i.e., timer). One or more programs that may implement or utilize

the various techniques described herein may use an application programming interface (API), reusable controls, and the like. Such programs may be implemented in a high level procedural or object oriented programming language to communicate with a computer system. However, the program(s) may be implemented in assembly or machine language, if desired. In any case, the language may be a compiled or interpreted language, and combined with hardware implementations.

[00147] As used herein, the term "circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

[00148] It should be understood that many of the functional units described in this specification have been labeled as modules, in order to more particularly emphasize their implementation independence. For example, a module may be implemented as a hardware circuit comprising custom very-large-scale integration (VLSI) circuits or gate arrays, off-the-shelf semiconductors such as logic chips, transistors, or other discrete components. A module may also be implemented in programmable hardware devices such as field programmable gate arrays, programmable array logic, programmable logic devices or the like.

[00149] Modules may also be implemented in software for execution by various types of processors. An identified module of executable code may, for instance, comprise one or more physical or logical blocks of computer instructions, which may, for instance, be organized as an object, procedure, or function. Nevertheless, the executables of an identified module may not be physically located together, but may comprise disparate instructions stored in different locations which, when joined logically together, comprise the module and achieve the stated purpose for the module.

[00150] Indeed, a module of executable code may be a single instruction, or many instructions, and may even be distributed over several different code segments, among

different programs, and across several memory devices. Similarly, operational data may be identified and illustrated herein within modules, and may be embodied in any suitable form and organized within any suitable type of data structure. The operational data may be collected as a single data set, or may be distributed over different locations including over different storage devices, and may exist, at least partially, merely as electronic signals on a system or network. The modules may be passive or active, including agents operable to perform desired functions.

[00151] Reference throughout this specification to "an example" or “exemplary” means that a particular feature, structure, or characteristic described in connection with the example is included in at least one embodiment of the present technology. Thus, appearances of the phrases "in an example" or the word “exemplary” in various places throughout this specification are not necessarily all referring to the same embodiment.

[00152] As used herein, a plurality of items, structural elements, compositional elements, and/or materials may be presented in a common list for convenience. However, these lists should be construed as though each member of the list is individually identified as a separate and unique member. Thus, no individual member of such list should be construed as a de facto equivalent of any other member of the same list solely based on their presentation in a common group without indications to the contrary. In addition, various embodiments and example of the present technology may be referred to herein along with alternatives for the various components thereof. It is understood that such embodiments, examples, and alternatives are not to be construed as defacto equivalents of one another, but are to be considered as separate and autonomous representations of the present technology.

[00153] Furthermore, the described features, structures, or characteristics may be combined in any suitable manner in one or more embodiments. In the following description, numerous specific details are provided, such as examples of layouts, distances, network examples, etc., to provide a thorough understanding of embodiments of the technology. One skilled in the relevant art will recognize, however, that the technology can be practiced without one or more of the specific details, or with other methods, components, layouts, etc. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid obscuring aspects of the

technology.

[00154] While the forgoing examples are illustrative of the principles of the present technology in one or more particular applications, it will be apparent to those of ordinary skill in the art that numerous modifications in form, usage and details of implementation can be made without the exercise of inventive faculty, and without departing from the principles and concepts of the technology. Accordingly, it is not intended that the technology be limited, except as by the claims set forth below.

CLAIMS

What is claimed is:

1. An apparatus of a user equipment (UE) operable to perform mission critical communications with an eNodeB, the apparatus comprising one or more processors and memory configured to:

transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI);

receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication; and

perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

2. The apparatus of claim 1, further configured to receive, from the eNodeB, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

3. The apparatus of claim 1, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and the second TTI is approximately 0.1 to

0.2 ms.

4. The apparatus of claim 1, wherein the first TTI is associated with a first partition of a low band and the second TTI is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

5. The apparatus of any of claims 1 to 4, wherein the UE is configured to:

perform repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and

perform repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB,

wherein a maximum number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling,

wherein the UE performs a random back off and reinitiates a procedure for performing the mission critical communication when the maximum number of repetitions for a defined transmission is reached.

6. The apparatus of claim 1, wherein the UE is configured to:

repeatedly transmit the PRACH signal to the eNodeB in accordance with a fixed number of repetitions; and

repeatedly perform the mission critical communication with the eNodeB in accordance with a fixed number of repetitions,

wherein the fixed number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

7. The apparatus of claim 1, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

8. The apparatus of claim 1, wherein a plurality of signatures, time resources and frequency resources are reserved for transmitting the PRACH signal from the UE to trigger the mission critical communication.

9. The apparatus of claim 1, wherein the PRACH signal is communicated to the eNodeB with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE.

10. The apparatus of claim 1, wherein the PRACH signal is transmitted from the UE to the eNodeB in accordance with a maximum transmit power.

11. The apparatus of claim 1, wherein the UE is configured to receive the RAR message from the eNodeB by monitoring a RAR message window, wherein a position of the RAR message window is configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

12. The apparatus of claim 1, further configured to receive a preamble from the eNodeB prior to receiving the RAR message, wherein the preamble functions to improve a downlink synchronization accuracy.

13. The apparatus of claim 1, wherein the RAR message received at the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type

communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

14. The apparatus of claim 1, wherein:

the RAR message is received at the UE via a physical downlink control channel (PDCCH), wherein the UE is configured to monitor the PDCCH using a cyclic redundancy check (CRC) scrambled by a random-access radio network temporary identifier (RA-RNTI); or

the RAR message is received at the UE via a physical downlink shared channel (PDSCH) that is scheduled by the PDCCH.

15. The apparatus of any of claims 6 to 14, wherein:

a gap between a last subframe for a RAR message transmission and a starting subframe of the mission critical communication in uplink is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling; and

a gap between a last subframe of the mission critical communication in uplink and a starting subframe of an acknowledgement (ACK) or a negative acknowledgement (NACK) transmission is predefined or configured by higher layers via one of: the MIB, the SIB, or dedicated RRC signaling.

16. The apparatus of claim 1, wherein the UE includes at least one of an antenna, a touch sensitive display screen, a speaker, a microphone, a graphics processor, an application processor, a baseband processor, an internal memory, a non-volatile memory port, and combinations thereof.

17. An apparatus of a base station operable to receive mission critical communications from a user equipment (UE), the apparatus comprising one or more processors and memory configured to:

receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the

eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI);

transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message; and

transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

18. The apparatus of claim 17, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

19. The apparatus of claim 17, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

20. The apparatus of any of claims 17 to 19, wherein:

the PRACH signal is received from the UE with a scheduling request (SR),

wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE; and

the RAR message transmitted to the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

21. The apparatus of claim 17, wherein the RAR message is transmitted to the UE via a physical downlink control channel (PDCCH) or a physical downlink shared channel (PDSCH).

22. At least one machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, the instructions when executed perform the following:

transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI);

receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI; and

receiving, using the at least one processor of the UE, an acknowledgement

(ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

23. The at least one machine readable storage medium of claim 22, wherein the UE is configured to initiate performance of the mission critical communication when in a radio resource control (RRC) idle mode.

24. The at least one machine readable storage medium of claim 22, wherein the first TTI is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

25. The at least one machine readable storage medium of any of claims 22 to 24, further comprising instructions which when executed perform the following:

performing repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and

performing repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB.

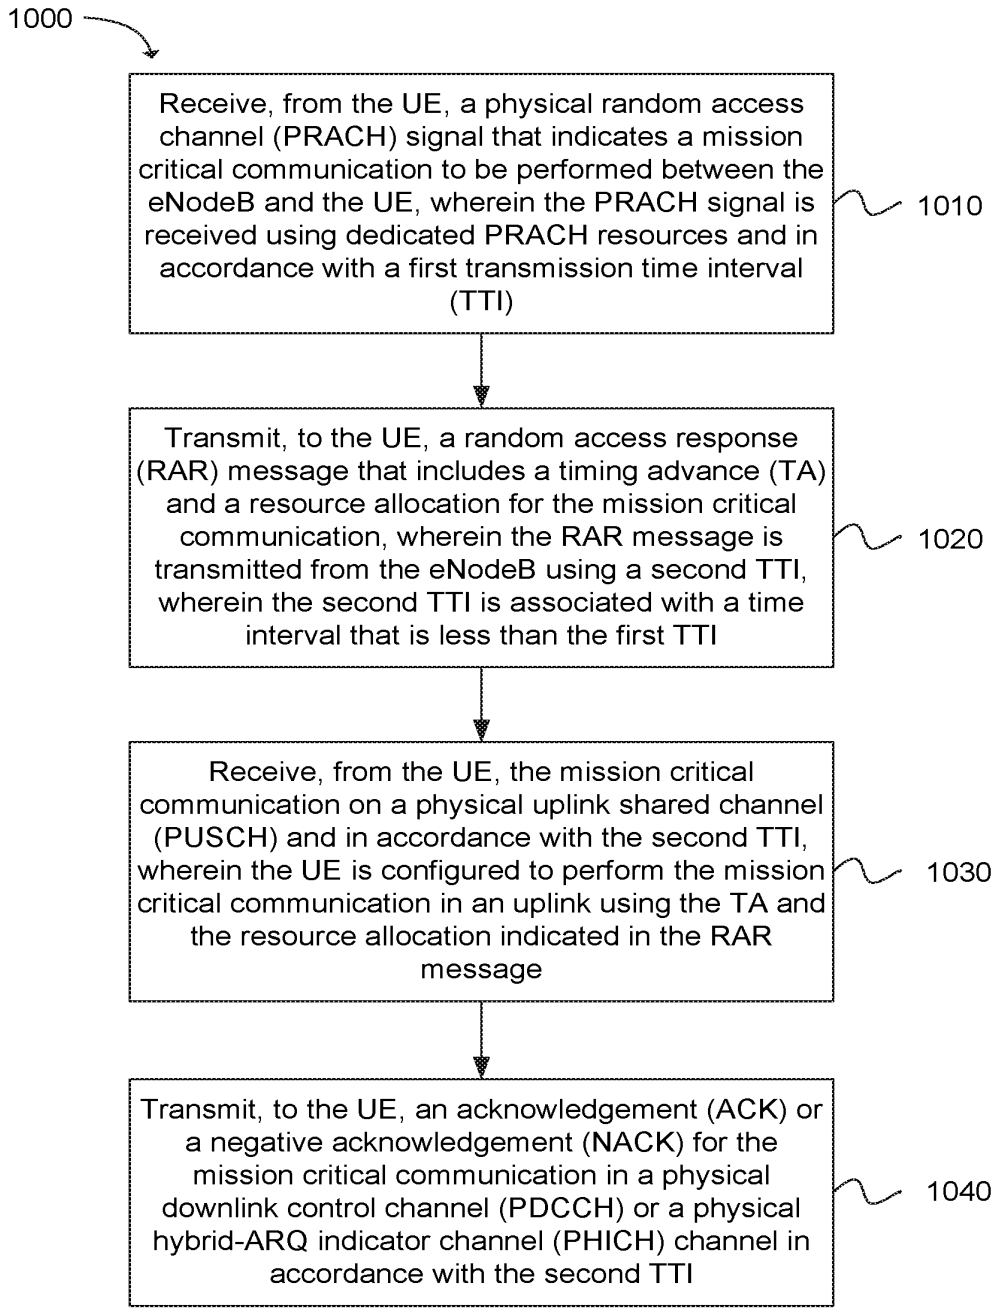
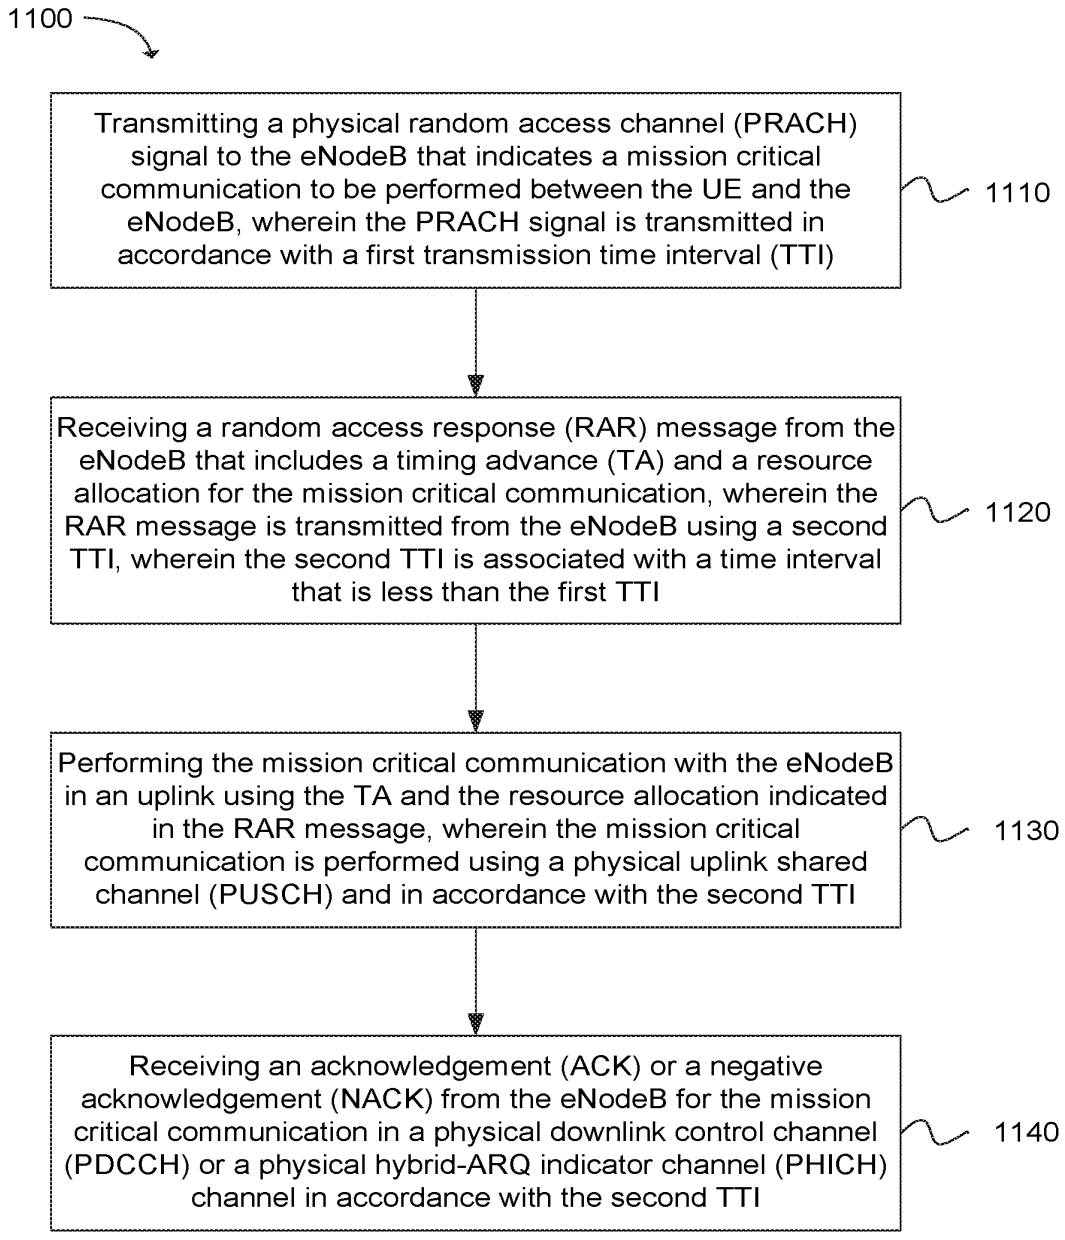
900
Transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI)
910
Receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
920
Decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication
930
Perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI
940

FIG. 9



1000
Receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI)
1010
Transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
1020
Receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message
1030
Transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI
1040

FIG. 10



1100
Transmitting a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI)
1110
Receiving a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
1120
Performing the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI
1130
Receiving an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI

(54) **Title**: DEVICE AND METHODS FOR MULTIPLEXING TRANSMISSIONS WITH DIFFERENT TTI DURATION

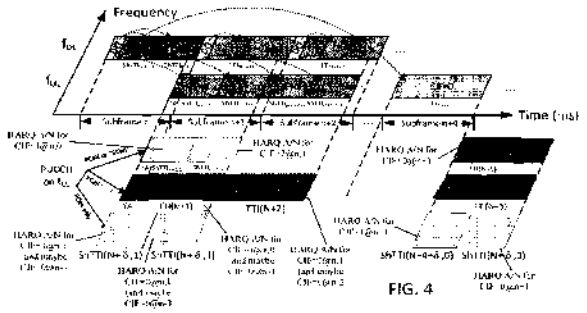

FIG. 4

(57) **Abstract**: A wireless transmit/receive unit, WTRU and methods of using a WTRU within a wireless communications network include communicating with a serving cell in the wireless communications network and determining, based on downlink control information whether the WTRU shall transmit with a first transmission time interval, TTI, length, using a first set of transmission resources, or a second TTI length, using a second set of transmission resources. Alternatively, determining based on said DCI, that the serving cell has indicated that the WTRU should use a first TTI on a physical uplink channel to communicate with the serving cell, or whether said DCI indicates that the WTRU should use a second TTI that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation.

DEVICE AND METHODS FOR MULTIPLEXING TRANSMISSIONS WITH DIFFERENT TTI DURATION

BACKGROUND

[0001] In a wireless communication network, such as a Long Term Evolution (LTE) system or New Radio (NR), a wireless transmit/receive unit (WTRU) device may access resources of the communication system. Latency associated with transmission of data in a communication system may have one or more latency components. A latency component may be the time to perform the transmission of a transport block, which time may be referred to as a Transmission Time Interval (TTI). Such TTI may be tied to a specific numerology associated with the transmission method and to a specific number of transmission symbols associated with the transmission. Other latency components may include processing time at a receiver, e.g., time decoding a transmission, transmission of feedback (e.g. ACK or NACK) and/or one or more retransmissions with one or more latency components.

SUMMARY

[0002] Systems, methods, and instrumentalities are disclosed for multiplexing transmissions with different durations, for example transmissions that are associated with different TTI lengths. Latency may be reduced (e.g., in an LTE system and/or in a NR system), for example, by multiplexing transmissions with different TTI durations or associated with different transmission numerologies. TTI duration may be modeled based on defining one or more cell(s) for a given carrier frequency, for example that may be associated with different TTI lengths and/or transmission durations. For example, the different transmission durations may be achieved by time-shifting one or more of the cells. In order to support signaling techniques that allow for concurrent and/or complementary scheduling of transmissions associated with different duration, a logical structure for the physical layer resources (e.g., a cell, a spectrum block, etc.) may configured to correspond to a secondary cell ("SCell"). A primary cell ("PCell") may logically maintain a first transmission duration (e.g., a first TTI length such as a legacy TTI length). The SCell may be configured with a second transmission duration (e.g., a second TTI length or a shortened TTI length). One or more of a PCell or an SCell may be configured with either the legacy or shortened TTI length (e.g., a shorter duration TTI (ShTTI).

[0003] By associating different TTI lengths with different cells, the LTE carrier aggregation framework can be utilized to support multiplexing of transmissions of different durations. For example, carrier aggregation signaling, including cross-carrier scheduling mechanisms, can be used to different scheduling grants and assignments of varying length. For example, a WTRU may determine a TTI duration (e.g., first or second TTI length) applicable to a transmission. For example, a WTRU may determine a TTI duration using cross-carrier scheduling. A WTRU may be configured to associate a given cell identity (e.g., servCellID) with a given transmission duration. Different cell identities (e.g., different servCellIDs) may be associated with different transmission durations/different TTI lengths. When a WTRU receives scheduling information applicable to a given cell identity, the WTRU may determine the associated TTI length based on the configuration received for that cell identity.

[0004] A WTRU may determine a TTI length and/or transmission duration based on one or more parameters and/or received fields. For example, a WTRU may associate a given TTI duration with a given transmission mode (TM). A TTI duration may be indicated by a Carrier Indicator Field (CIF), for example where certain values of the CIF are associated with SCells configured with a given TTI durations such as a ShTTI. The CIF may also be referred to as a Carrier Indicator Field (CIF). The TTI duration may be indicated by a field that indicates a set of resources such as a set of PRBs, a carrier, a serving cell of the WTRU's configuration, and/or a spectrum block. A TTI duration may be determined from an identity of a PRB subset associated with the transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using a medium access control (MAC) Activation/Deactivation control element. MAC Activation/Deactivation CE may be used to toggle between first and second TTIs (e.g. legacy TTI and ShTTIs) or between slot-based ShTTIs and/or may be used to determine zero, one or more TTI (e.g. ShTTI) period(s) within a subframe.

[0005] HARQ processing may be performed according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. An exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA) formats and/or (e.g. legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g. legacy) format, although, for example, interpretation of fields such as the CIF and/or fields that indicate the PRBs applicable for the transmission may be different than the interpretations of the first

(e.g. legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. Physical random access channel (PRACH) resources and/or physical downlink control channel (PDCCH) order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g. a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0006] A method of using a wireless transmit/receive unit within a wireless communications network that is capable of aggregating different sets of physical layer resources (e.g., such as carrier aggregation, for example) may include communicating with a serving cell in the wireless communications network and determining that the serving cell has indicated that the WTRU should use a first transmission time interval on a physical uplink channel to communicate with the serving cell. The method may also include determining whether downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel). The method may further include communicating with the wireless communications network using the second transmission time interval.

[0007] The method may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g, on the physical uplink channel) comprises determining based on a carrier indicator field in received downlink control information.

[0008] The method may include communicating with the wireless communications network using the second transmission time interval comprises communicating with the serving cell using the second transmission time interval.

[0009] The method may include wherein communicating with the wireless communications network using the second transmission time interval includes communicating with a secondary cell using the second transmission time interval.

[0010] The method may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a third

transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network. The shorten transmission time interval may correspond to at least one of at least one symbol or at least one resource block. The first transmission time interval may be one millisecond.

[0011] The method may include determining a time to transmit with the second transmission time interval based on the downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment). The time to transmit may defined by a time partition (e.g., a slot in a subframe and/or one or more time symbols, (e.g., OFDM symbols), an arrangement of symbols, a min-slot, or other time for a sub-carrier spacing).

[0012] The method may include determining whether a first downlink control information (e.g., using carrier aggregation fields such as the CIF) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel) or whether the WTRU should transmit using carrier aggregation comprises determining with cross-carrier scheduling.

[0013] A wireless transmit/receive unit (WTRU) for use within a wireless communications network that is capable of carrier aggregation may have a processor having executable instructions that communicate with a serving cell in the wireless communications network and determine that the serving cell has indicated that the WTRU should use a first transmission time interval on an uplink channel (e.g., physical uplink channel) to communicate with the serving cell. The processor instructions may include determining whether a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel). The WTRU processor instructions may include communicating with the wireless communications network using the second transmission time interval.

[0014] The WTRU processor instructions that determine that a first downlink control information (e.g, carrier aggregation field such as the CIF) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel) may comprise determining based on a carrier indicator field in received downlink control information.

[0015] The WTRU processor executable instructions that communicate with the wireless communications network using the second transmission time interval may comprise communicating with the serving cell using the second transmission time interval.

[0016] The WTRU processor executable instructions that communicate with the wireless communications network using the second transmission time interval may comprise communicating with a secondary cell using the second transmission time interval.

[0017] The WTRU processor executable instructions may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network. The shorten transmission time interval may correspond to at least one of at least one symbol or at least one resource block. The first transmission time interval may be one millisecond.

[0018] The WTRU processor executable instructions may include determining a time to transmit with the second transmission time interval based on the downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment). The time to transmit may be defined by a slot in a subframe.

[0019] The WTRU processor executable instructions that determine whether a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel).

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] FIG. 1A is a system diagram of an example communications system in which disclosed subject matter may be implemented.

[0021] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used in a communications system.

[0022] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0023] FIG. 1D is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0024] FIG. 1E is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0025] FIG. 2 shows an example of DL physical layer channels.

[0026] FIG. 3 shows an example of UL physical layer channels.

[0027] FIG. 4 is an example of scheduling with time-shifted cells.

DETAILED DESCRIPTION

[0028] A detailed description of illustrative embodiments will now be described with reference to the various figures. Although this description provides a detailed example of possible implementations, it should be noted that the details are intended to be exemplary and in no way limit the scope of the application.

[0029] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, for example voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, for example code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0030] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, and/or 102d (which generally or collectively may be referred to as WTRU 102), a radio access network (RAN) 103/104/105, a core network 106/107/109, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include a user equipment (WTRU), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0031] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to

one or more communication networks, for example the core network 106/107/109, the Internet 110, and/or the networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0032] The base station 114a may be part of the RAN 103/104/105, which may also include other base stations and/or network elements (not shown), for example a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In an embodiment, the base station 114a may employ multiple-input multiple output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0033] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 115/116/117, which may be any suitable wireless communication link (e.g. radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 115/116/117 may be established using any suitable radio access technology (RAT).

[0034] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, for example CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 103/104/105 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 115/116/117 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0035] In an embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 115/116/117 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0036] In an embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), New Radio (NR) and the like. The descriptions and example provided herein apply to any of the air interface and communications standards that have been implemented although the terminology may differ among them for the functional components.

[0037] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, for example a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In an embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet an embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (e.g. WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106/107/109.

[0038] The RAN 103/104/105 may be in communication with the core network 106/107/109, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106/107/109 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, for example user authentication. Although not shown in FIG. 1A, it will be appreciated that the RAN 103/104/105 and/or the core network 106/107/109 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 103/104/105 or a different RAT. For example, in addition to being connected to the RAN 103/104/105, which may be utilizing an E-UTRA radio technology, the core network 106/107/109 may also be in communication with a RAN (not shown) employing a GSM radio technology.

[0039] The core network 106/107/109 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The

PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, for example the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include a core network connected to one or more RANs, which may employ the same RAT as the RAN 103/104/105 or a different RAT.

[0040] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0041] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment. Also, embodiments contemplate that the base stations 114a and 114b, and/or the nodes that base stations 114a and 114b may represent, for example but not limited to transceiver station (BTS), a Node-B, a site controller, an access point (AP), a home node-B, an evolved home node-B (eNodeB), a home evolved node-B (HeNB), a home evolved node-B gateway, and proxy nodes, among others, may include some or each of the elements depicted in FIG. 1B and described herein.

[0042] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the

transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0043] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (e.g. the base station 114a) over the air interface 115/116/117. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In an embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet an embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0044] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (e.g. multiple antennas) for transmitting and receiving wireless signals over the air interface 115/116/117.

[0045] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, for example UTRA and IEEE 802.11, for example.

[0046] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (e.g. a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, for example the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In an embodiment, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, for example on a server or a home computer (not shown).

[0047] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (e.g. nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0048] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (e.g. longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 115/116/117 from a base station (e.g. base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0049] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0050] FIG. 1C is a system diagram of the RAN 103 and the core network 106 according to an embodiment. As noted above, the RAN 103 may employ a UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 115. The RAN 103 may also be in communication with the core network 106. As shown in FIG. 1C, the RAN 103 may include Node-Bs 140a, 140b, 140c, which may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 115. The Node-Bs 140a, 140b, 140c may each be associated with a particular cell (not shown) within the RAN 103. The RAN 103 may also include RNCs 142a, 142b. It will be appreciated that the RAN 103 may include any number of Node-Bs and RNCs while remaining consistent with an embodiment.

[0051] As shown in FIG. 1C, the Node-Bs 140a, 140b may be in communication with the RNC 142a. Additionally, the Node-B 140c may be in communication with the RNC142b. The Node-Bs 140a, 140b, 140c may communicate with the respective RNCs 142a, 142b via an Iub interface. The RNCs 142a, 142b may be in communication with one another via an Iur interface.

Each of the RNCs 142a, 142b may be configured to control the respective Node-Bs 140a, 140b, 140c to which it is connected. In addition, each of the RNCs 142a, 142b may be configured to carry out or support other functionality, for example outer loop power control, load control, admission control, packet scheduling, handover control, macro diversity, security functions, data encryption, and the like.

[0052] The core network 106 shown in FIG. 1C may include a media gateway (MGW) 144, a mobile switching center (MSC) 146, a serving GPRS support node (SGSN) 148, and/or a gateway GPRS support node (GGSN) 150. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0053] The RNC 142a in the RAN 103 may be connected to the MSC 146 in the core network 106 via an IuCS interface. The MSC 146 may be connected to the MGW 144. The MSC 146 and the MGW 144 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices.

[0054] The RNC 142a in the RAN 103 may also be connected to the SGSN 148 in the core network 106 via an IuPS interface. The SGSN 148 may be connected to the GGSN 150. The SGSN 148 and the GGSN 150 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between and the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0055] As noted above, the core network 106 may also be connected to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0056] FIG. 1D is a system diagram of the RAN 104 and the core network 107 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 107.

[0057] The RAN 104 may include eNode-Bs 160a, 160b, 160c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 160a, 160b, 160c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 160a, 160b, 160c may implement MIMO technology. Thus, the eNode-B 160a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0058] Each of the eNode-Bs 160a, 160b, 160c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1D, the eNode-Bs 160a, 160b, 160c may communicate with one another over an X2 interface.

[0059] The core network 107 shown in FIG. 1D may include a mobility management gateway (MME) 162, a serving gateway 164, and a packet data network (PDN) gateway 166. While each of the foregoing elements are depicted as part of the core network 107, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0060] The MME 162 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 162 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 162 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, for example GSM or WCDMA.

[0061] The serving gateway 164 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via the S1 interface. The serving gateway 164 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 164 may also perform other functions, for example anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0062] The serving gateway 164 may also be connected to the PDN gateway 166, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0063] The core network 107 may facilitate communications with other networks. For example, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 107 may include, or may communicate with, an IP gateway (e.g. an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 107 and the PSTN 108. In addition, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to

the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0064] FIG. 1E is a system diagram of the RAN 105 and the core network 109 according to an embodiment. The RAN 105 may be an access service network (ASN) that employs IEEE 802.16 radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 117. As will be further discussed below, the communication links between the different functional entities of the WTRUs 102a, 102b, 102c, the RAN 105, and the core network 109 may be defined as reference points.

[0065] As shown in FIG. 1E, the RAN 105 may include base stations 180a, 180b, 180c, and an ASN gateway 182, though it will be appreciated that the RAN 105 may include any number of base stations and ASN gateways while remaining consistent with an embodiment. The base stations 180a, 180b, 180c may each be associated with a particular cell (not shown) in the RAN 105 and may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 117. In one embodiment, the base stations 180a, 180b, 180c may implement MIMO technology. Thus, the base station 180a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a. The base stations 180a, 180b, 180c may also provide mobility management functions, for example handoff triggering, tunnel establishment, radio resource management, traffic classification, quality of service (QoS) policy enforcement, and the like. The ASN gateway 182 may serve as a traffic aggregation point and may be responsible for paging, caching of subscriber profiles, routing to the core network 109, and the like.

[0066] The air interface 117 between the WTRUs 102a, 102b, 102c and the RAN 105 may be defined as an R1 reference point that implements the IEEE 802.16 specification. In addition, each of the WTRUs 102a, 102b, 102c may establish a logical interface (not shown) with the core network 109. The logical interface between the WTRUs 102a, 102b, 102c and the core network 109 may be defined as an R2 reference point, which may be used for authentication, authorization, IP host configuration management, and/or mobility management.

[0067] The communication link between each of the base stations 180a, 180b, 180c may be defined as an R8 reference point that includes protocols for facilitating WTRU handovers and the transfer of data between base stations. The communication link between the base stations 180a, 180b, 180c and the ASN gateway 182 may be defined as an R6 reference point. The R6 reference point may include protocols for facilitating mobility management based on mobility events associated with each of the WTRUs 102a, 102b, 102c.

[0068] As shown in FIG. 1E, the RAN 105 may be connected to the core network 109. The communication link between the RAN 105 and the core network 109 may defined as an R3 reference point that includes protocols for facilitating data transfer and mobility management capabilities, for example. The core network 109 may include a mobile IP home agent (MIP-HA) 184, an authentication, authorization, accounting (AAA) server 186, and a gateway 188. While each of the foregoing elements are depicted as part of the core network 109, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0069] The MIP-HA may be responsible for IP address management, and may enable the WTRUs 102a, 102b, 102c to roam between different ASNs and/or different core networks. The MIP-HA 184 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices. The AAA server 186 may be responsible for user authentication and for supporting user services. The gateway 188 may facilitate interworking with other networks. For example, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. In addition, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0070] Although not shown in FIG. 1E, it will be appreciated that the RAN 105 may be connected to other ASNs and the core network 109 may be connected to other core networks. The communication link between the RAN 105 the other ASNs may be defined as an R4 reference point, which may include protocols for coordinating the mobility of the WTRUs 102a, 102b, 102c between the RAN 105 and the other ASNs. The communication link between the core network 109 and the other core networks may be defined as an R5 reference, which may include protocols for facilitating interworking between home core networks and visited core networks.

[0071] Systems, methods, and instrumentalities are disclosed for multiplexing transmissions with different durations, for example such as transmission that utilize different TTI lengths. Latency reduction for some transmissions may achieved, for example, by multiplexing transmissions with different TTI durations. Although examples may be described with respect to multiplexing of an LTE legacy TTI (e.g., 1 ms) with a shortened TTI length (e.g., less than 1 ms), the techniques described herein may be generally applicable to the multiplexing of other

types of transmissions that are of different/varying lengths. For example, the examples may be described with respect to transmissions that contain one transport block (TB), but the examples may be equally applicable to transmissions that include a portion of a TB, transmissions that contain multiple TBs, etc. Thus, as may be appreciated, although specific examples herein may be described with respect to multiplexing transmissions associated with a "legacy" 1 ms TTI with transmissions that are less than 1 ms, these examples are not limited to the specific embodiments described and may be applied to transmissions of varying length that include varying amounts of data. Additionally, although examples may be described with respect to multiplexing shorter than 1 ms transmissions into a legacy LTE system that utilizes a legacy TTI length of 1 ms, the techniques may be applied to other types of transmission configurations, for example such as the NR system that may be utilized for 5G cellular communications.

[0072] Transmissions of different length may be realized in multiple ways and be consistent with this disclosure. For example, multiple TTI lengths may be defined, and the system may be configured to multiplex transmissions associated with the different TTI lengths over a common set of transmission resources. In example, rather than or in addition to defining different TTI lengths, transmissions of different durations may be supported, for example where one or more of the transmissions durations may or may not correspond to a TTI. Transmission duration may be defined in a number of ways, for example an amount of time over which the transmission occurs, (e.g., a specific duration or a time partition), a number of symbols over which the transmission occurs (e.g., 14 OFDM symbols, 12 OFDM symbols, 1 OFDM symbol, etc.), a slot, a minislot, a time partition for a sub-carrier spacing, and/or in terms of a specific numerology associated with the transmissions. For example, the numerology may be defined based on one or more of a sub-carrier spacing (e.g., different sub-carrier spacing may lead to different time durations for a symbol), a symbol length, a waveform type, etc.

[0073] Examples may also be described with respect to one or more cells. However, the techniques described herein may be equally applicable to other types of resource partitions. For example, in LTE cells may be defined based on certain OFDM time-frequency resources that are defined for a certain operating band for the cell. However, the multiplexing techniques described herein may be applied to physical resources that may or may not be defined using the cell construct. For example, the techniques described herein may apply of a subset of the physical resources in a cell and/or to physical resources that are not defined using the cell construct.

[0074] In order to TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency, e.g. in an LTE system such as a legacy LTE system. A "logical" cell structure may correspond to an SCell (e.g., a legacy SCell). A PCell may logically maintain

a TTI (e.g., a first TTI such as a legacy TTI that may be 1 ms) or may be (e.g. also) configured with a second duration TTI (e.g., a shorter duration TTI (ShTTI) that may be less than 1 ms).

[0075] In an example, a WTRU may determine a TTI duration (e.g. first or second TTI) applicable to a transmission. A determination may be, for example, a function of one or more facts, factors, and/or parameters. For example, a WTRU may determine a TTI duration using cross-carrier scheduling information. A WTRU may associate a certain TTI duration with a certain cell identity (e.g. servCellID). A WTRU may associate a certain TTI duration with certain a transmission mode (TM). A TTI duration may be indicated by a CIF included in DCI. For example, a first cell identity (e.g., servCellID = 1) may be associated with a first TTI duration and a second cell identity (e.g., servCellID = 2) may be associated with a second TTI duration. When the CIF field indicates that the received DCI is applicable to the first cell identity (e.g., CIF = '001' - servCellID = 1), the WTRU may determine that the scheduled transmission is associated with the first TTI duration. When the CIF field indicates that the received DCI is applicable to the second cell identity (e.g., CIF = '010' - servCellID = 2), the WTRU may determine that the scheduled transmission is associated with the second TTI duration. In this matter, carrier aggregation signaling methods may be reused/reinterpreted in order to support multiple TTI length.

[0076] A TTI duration may be determined from an identity of a PRB subset associated with the transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using MAC Activation/Deactivation. MAC Activation/Deactivation may be used to toggle between first and second TTIs (e.g. between a legacy TTI and one or more ShTTIs). For example, a WTRU may utilize a first TTI length for a first cell prior to receiving MAC Activation/Deactivation control element. Upon receiving the MAC Activation/Deactivation control element for the first cell, the WTRU may toggle to a second TTI length. In an example, the MAC Activation/Deactivation control element may be used to toggle between different slots used for a ShTTI transmission in a legacy suframe. For example, the MAC Activation/Deactivation control element may be used to switch between the first and second slots for the shortened TTI transmission. MAC Activation/Deactivation may be used to determine zero, one or more ShTTIs period(s) within a subframe.

[0077] HARQ processing may remain according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. In an example, an exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA)

formats and/or (e.g., legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g., legacy) format, although, for example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different than the first (e.g., legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. PRACH resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g., a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0078] A device may access resources of a communication system. Latency associated with transmission of data may have one or more latency components. A latency component may be the time to perform the transmission of a transport block, which time may be referred to as a Transmission Time Interval (TTI). A latency component may be processing time at a receiver, e.g., time decoding a transmission. Receiver processing time may be tied to implementation complexity and may be accounted for using a fixed timing relationship between different events associated with the transmission of a data unit. A timing relationship may be fixed, for example, when time-division duplex (TDD) is used for a carrier and/or synchronous Hybrid ARQ (HARQ) operation (e.g., such as for LTE in the uplink).

[0079] There may be additional latency components, for example, when a transmission is not successfully decoded. For example, additional components may include transmission of feedback (e.g. HARQ ACK or NACK), processing time at the receiver and/or one or more retransmissions with one or more latency components.

[0080] Latency components may be measured in integer multiples of a basic time interval (BTI). For example, latency components may be measured in TTIs, e.g., in LTE.

[0081] Latency in wireless networks may be caused by multiple factors. Latency may be affected, e.g., at lower layers, by a need for highly reliable transmissions, which may be obtained using HARQ. One or more retransmissions may affect the latency of a transmission, for example, given that retransmissions may not be performed in adjacent time periods.

[0082] A WTRU may incur processing time, for example, for downlink (DL) transmission, to determine whether a transmission was decoded properly, which may lead to a time interval between reception of a DL transmission and transmission of an ACK or NACK. An eNB may

incur processing time, for example, to determine whether an ACK or NACK was transmitted by the WTRU and/or whether a retransmission is required. A similar consumption of processing time may occur for uplink (UL) transmissions. Processing times may be cumulative. There may be a tradeoff between latency and implementation complexity.

[0083] A system (e.g. LTE) may accommodate processing times in a timing relationship between a first transmission for a transport block and its corresponding ACK-NACK HARQ response for downlink and/or uplink operation and possible retransmission.

[0084] Time Division Duplex (TDD) and Frequency Division Duplex (FDD) DL scheduling timing may be the same, such that a WTRU may receive a scheduling grant for a DL transmission in the same subframe or transmission time interval (TTI).

[0085] A WTRU may transmit a corresponding Physical UL Shared Channel (PUSCH), e.g., in subframe n+4, for example, upon detection of a Physical DL Control Channel PDCCH or enhanced PDCCH (EPDCCH) with UL Downlink Control Information (DCI) format and/or Physical Hybrid ARQ Indicator Channel (PHICH) transmission in subframe n, e.g., in an FDD UL transmission intended for the WTRU. A HARQ ACK/NACK response for a DL or UL transmission in subframe n may be provided in subframe n+4.

[0086] A WTRU may transmit a corresponding PUSCH in subframe n+k, for example, upon detection of a (E)PDCCH with UL DCI format and/or PHICH transmission in subframe n, e.g., for a UL transmission in a TDD system intended for the WTRU. The value of k may depend on the TDD UL/DL configuration, the subframe where the UL DCI and/or PHICH was transmitted and/or the PHICH resource and the MSB or LSB of the UL index in the (E)PDCCH, e.g., in TDD UL/DL configuration 0. A HARQ ACK/NACK response for a DL or UL transmission in subframe n may be provided in subframe n+k, where k may depend on the value of n and the TDD UL/DL configuration. Bundling may be used to provide HARQ for multiple transmissions in one instance.

[0087] Processing time available to a WTRU may depend, for example, on the value of the timing advance or on the distance between the WTRU and the eNB. In an example, an LTE system may have a distance of 100km between a WTRU and an eNB, which may correspond to a (e.g. a maximum) timing advance of 0.67ms. In an example, there may be approximately 2.3 ms left for terminal processing. An eNB may have, for example, 3 ms processing time available, which may be on the same order as that of the terminal.

[0088] FIG. 2 shows an example of DL physical layer channels. In a DL example with reference to the example shown in FIG. 2, there may be three channel areas in a subframe to support DL Shared Channel (DL-SCH) and UL-SCH. Three channel areas may comprise a PDCCH (which may include Physical Control Format Indicator Channel (PCFICH) and PHICH),

a Physical DL Shared Channel (PDSCH) and an EPDCCH. An EPDCCH may include scheduling information for a WTRU while taking advantage of the benefits of the PDSCH region, such as beamforming gain and frequency domain Inter-Cell Interference Coordination (ICIC) and/or improving PDCCH capacity.

[0089] FIG. 3 shows an example of UL physical layer channels. In a UL example with reference to the example shown in FIG. 3, there may be two channel areas in a subframe to support DL-SCH and UL-SCH. Two channel areas may comprise a PUSCH and a PDSCH. These channel areas may be transmitted in different RBs in each time slot (e.g. frequency hopping of PUSCH), for example, to increase robustness in frequency selective channels.

[0090] A transmission time interval (TTI) duration may be based on and/or defined by one or more symbols. A TTI duration may be defined in terms of a number of OFDM symbols. For example, a TTI duration may be defined as an entire (legacy) subframe and/or a pair of physical resource blocks (PRBs). In the legacy 1 ms TTI length, there may be 14 OFDM symbols for normal cyclic prefix and 12 OFDM symbols for extended cyclic prefix. For example when multiplexing ShTTI transmissions with legacy TTI transmissions of 1 ms, a ShTTI may be made as short as a single ODFM symbol. Symbol-based categorization may be referred to as symbol-based TTI durations.

[0091] A TTI duration may be based on time-varying symbol duration. TTI durations may have a fixed number of symbols (e.g., 14 symbols) while symbol duration may vary in time. For example, variable time symbol-based TTI duration may be achieved by modifying subcarrier spacing. In an example, a first TTI duration may be achieved with a first subcarrier spacing and a second TTI duration may be achieved with a second subcarrier spacing. Different bandwidth portions (e.g. PRBs) of a carrier may support different subcarrier spacing, thus enabling different TTI duration for different bandwidth portions (e.g. PRBs). Multiplexing transmissions associated with different sub-carrier spacing and/or symbol duration may be applicable to 5G systems such as NR. Such techniques may also be used in LTE-Advanced.

[0092] A TTI duration may be based on a time slot. A TTI duration may be defined in terms of a time slot (e.g. 7 OFDM symbols for normal cyclic prefix and 6 OFDM symbols for extended cyclic prefix). For example, if a ShTTI is defined as the length of one slot, two ShTTI transmissions may be time multiplexed into a legacy 1 ms TTI length.

[0093] A TTI duration may be based on time. A TTI duration may be defined in terms of a time value (e.g. 1ms legacy TTI or a 100ms ShTTI).

[0094] A TTI duration may be based on a hybrid, such as a combination of forgoing TTI duration bases. In an example of a hybrid method of achieving variable TTI durations, a different number of symbols and different symbol durations may be used.

[0095] Latency may be improved. It may be beneficial to decrease the TTI duration of different channels. A decrease in TTI duration may enable a decrease in WTRU processing time and may permit a WTRU to begin processing data sooner. Such a scenario may enable a shorter HARQ timeline. Different channels may have different TTI durations. A TTI duration shorter than one subframe for one or more of the EPDCCH, PDSCH, PUCCH, PDSCH, etc. may be provided. Effective HARQ feedback for PDSCH and PUSCH transmissions using shorter than (e.g., legacy 1ms) subframe TTI durations may be provided. Shorter TTIs may be referred to as ShTTI.

[0096] ShTTI and/or a combination of TTI and ShTTI may be supported for a given WTRU, for example, to minimize the impact of other aspects related to WTRU transmissions, such as scheduling (e.g., formats of DCIs), HARQ (e.g., related processing/process identities), feedback formats and determination of an applicable TTI duration. For example, the configuration of ShTTIs and/or the signaling of DCI for ShTTIs may utilize certain signaling originally defined for purposes of carrier aggregation in order to limit the amount of complexity at the WTRU and/or facilitated TTI length multiplexing in a backwards compatible manner. One or more latency components may be reduced, for example, to minimize the impact on WTRU implementations.

[0097] A WTRU may (e.g., based on a determination) operate with a one or more TTI durations, such as subframe TTI duration (e.g., 1 ms), a timeslot TTI duration (e.g., 0.5 ms), a symbol-based TTI duration (e.g., one or more OFDM symbols in duration), and/or other shorter than 1 ms TTI durations. In an example, a WTRU may be configured to operate with specific but different TTI duration configuration in downlink and uplink. In an example, a WTRU may be configured to permit the same TTI duration configuration to be used in downlink and uplink for applicable transmissions. For example, if the WTRU receives a configuration that indicates a first cell is associated with a first TTI duration in the downlink, the WTRU may determine that the uplink TTI duration is also the first TTI duration unless the configuration indicates otherwise.

[0098] A TTI duration may be WTRU specific. A WTRU may operate with a TTI duration during a given period. A WTRU may be configured to operate according to one or more of a plurality of possible TTI durations and may operate with the one or more TTI durations for a specific period of time, e.g., based on an L3 (e.g., radio resource control (RRC)) reconfiguration. A TTI duration may be fixed (e.g. statically, semi-statically or dynamically) for a (e.g. every) transmission to and from a WTRU.

[0099] Multiple TTI durations may be concurrently configured and/or used. A WTRU may be configured to operate for transmissions of different TTI durations concurrently. Different TTI durations may be based on, for example, semi-static allocation (e.g. configuration of a subset of frames/subframes dedicated to different TTI durations based on a semi-persistent grant or assignment) and/or dynamic allocation (e.g. based on detection and/or reception of downlink control signaling).

[0100] A TTI duration may be cell/cell group (CG)-specific. Configuration may be applicable per cell of a WTRU's configuration, for a subset of cells of a WTRU's configuration, and/or for all cells of the same timing advance group (TAG) and/or all cells of the same cell group (CG). For example, upon adding a new cell, the TTI duration may be defined for the new cell. As an example, if the WTRU adds an SCell, the SCell configuration may indicated that the WTRU is to utilize a shortened TTI duration for the SCell. The HARQ instances associated with a specific MAC entity may be configured with a similar configuration for TTI duration. A similar or same configuration for TTI duration may be used, for example, for cells associated with the same channel(s) (e.g. PUCCH, PUSCH) for uplink control signaling.

[0101] TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency. Modeling may enable co-existence between WTRUs operating according to different TTI durations, e.g. in legacy LTE systems. A "logical" cell structure may correspond to the use of one or more serving cell(s). Serving cells may include secondary cells, such as an SCell type or a PSCell type defined for LTE CA. A PCell may logically maintain a first (e.g., legacy) TTI such as 1 ms or may be (e.g., also) configured as a ShTTI.

[0102] Multiple serving cells may be associated with a specific TTI duration. A WTRU may support multiple TTI durations based on one or more functions and/or characteristic associated to a serving cell.

[0103] A WTRU may determine the duration of a downlink control region, e.g., according to a first (e.g., legacy) behavior for LTE. A reception of PDCCH may be a first (e.g., legacy) behavior for downlink subframes. In an example, the first ShTTI in a subframe may include a control region, e.g., in case of slot-based operation, such as two slots of 7 symbols where the first slot include 1-3 symbols for PDCCH. In an example, the ShTTI duration may exclude the control region, e.g., in case of symbol-based ShTTIs. In an example, an offset in time or in symbol from the start of a subframe may be used to indicate the start of an ShTTI (e.g., in the DCI).

[0104] In an example, a WTRU may operate on a given carrier frequency (e.g., for downlink and/or uplink) according to at least one of the following: TTI duration per Transmission

Mode (TM), TTI duration per Serving Cell Identity (servCellID), and/or TTI duration per Serving Cell.

[0105] In an example of TTI duration per Transmission Mode (TM), a WTRU may be configured with multiple transmission modes (TM), e.g., one for each applicable TTI duration.

[0106] In an example of TTI duration per Serving Cell Identity (servCellID), a WTRU may be configured with multiple serving cell identities (e.g., servCellIDs), e.g., one for each applicable TTI duration.

[0107] In an example of TTI duration per Serving Cell, a WTRU may be configured with multiple serving cells for a given carrier frequency, e.g. one for each applicable TTI duration.

[0108] Combinations may be made using different types of serving cells. For example, a WTRU may be configured according to any of the following examples or other examples.

[0109] In a first case or example, a WTRU may be configured with one PCell and one SCell (or PSCell). A WTRU may perform a transmission associated with a PCell using a first ShTTI and a transmission associated with the SCell/PSCell using a second ShTTI. A WTRU may transmit Uplink Control Information (UCI) for a transmission associated with a specific cell using the uplink resources associated with the concerned cell (e.g., according to a first (e.g. legacy) behavior or processing time associated with the ShTTI), for example, when an SCell is configured with PUCCH resources or when the WTRU is configured with PSCell. A WTRU may perform the transmission of UCI using resources of the PCell (e.g., according to a first (e.g., legacy) behavior), for example, otherwise. In either case or other cases, a WTRU may transmit UCI using the TTI applicable to the uplink configuration of the concerned cell or according to the ShTTI applicable the received transmission.

[0110] In a second case or example, a WTRU may be configured with one PCell and two SCells. A WTRU may perform a transmissions associated with a PCell using a first TTI (e.g., a legacy 1ms TTI) and a transmission associated with an SCell using a second TTI (e.g., an ShTTI). A WTRU may transmit UCI for a transmission associated with a specific cell using the uplink resources associated with the concerned cell (e.g., according to a first (e.g., legacy) behavior or processing time associated with the ShTTI), for example, when an SCell is configured with PUCCH resources. A WTRU may perform the transmission of UCI using resources of the PCell (e.g., according to a first (e.g., legacy) behavior), for example, otherwise. In either case or other cases, a WTRU may transmit UCI using the TTI applicable to the uplink configuration of the concerned cell or according to the ShTTI applicable to the received transmission.

[0111] In a third case or example, a WTRU may be configured with one PCell and multiple SCells. A configuration may be a generalization of either of the first and second examples,

whereby more than two TTI durations may be supported (e.g., within a first (e.g., legacy) subframe).

[0112] In an example involving a PSCell, a different Cell Radio Network Temporary Identifier (C-RNTI) than that applicable for a PCell may indicate the duration of the TTI. Examples presented and other examples may be used separately or in combination. Other realizations and/or combinations are possible.

[0113] Examples for handling of downlink control region for case 1 with slot-based operation are described.

[0114] A WTRU may be configured with a (e.g., DL) control region of zero symbols for a serving cell used for the purpose of ShTTI, e.g., for the serving cell that corresponds to a second slot in case of slot-based operation. A WTRU may determine that a serving cell is configured for the purpose of ShTTI, for example, based on reception of signaling that indicates such value for the duration of the control region. A WTRU may determine that a serving cell is configured as an ShTTI for the second slot, for example, based on reception of signaling that indicates such value for the duration of the control region. A WTRU may determine that a PCell configuration is used for ShTTI for the first slot.

[0115] Different procedures or algorithms may be used to determine applicable TTI duration, e.g., independent of modeling. For example, a WTRU may determine the TTI duration (e.g. legacy duration such as 1ms or shorter (e.g., ShTTI)) applicable to a transmission as a function of one or more of the following: (a) a WTRU may determine TTI duration using cross-carrier scheduling; (b) a WTRU may associate a TTI duration with a serving cell identity; (c) a TTI duration may be indicated by a Carrier Indicator Field (CIF); (d) a TTI duration may be indicated by C-RNTI applicable to control signaling associated with the allocation of resources; (e) a TTI duration may be determined from the identity of a PRB subset applicable to the transmissions and/or to the time-shifted cell within the entire subset of PRBs for the carrier frequency; (f) a MAC Activation/Deactivation may be used to determine the applicable TTI duration and/or the identity of the slot/period applicable to a transmission within a subframe. A MAC Activation/Deactivation may be used, for example, to toggle between multiple TTIs (e.g. a legacy TTI and one or more ShTTIs), toggle between slot-based ShTTIs and/or to determine zero, one or more ShTTIs period(s) within a subframe.

[0116] HARQ processing may be used (e.g., according to a first (e.g., legacy) behavior) for time-shifted cell(s), although, in an example, timing-relationships may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may reuse LTE CA formats, first (e.g., legacy) subframe-based timing relationships and/or timing relationship associated with the HARQ

process. DCI signaling may reuse a first (e.g., legacy) format, although, in an example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with the HARQ process. Physical Random Access Channel (PRACH) resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted according to the shift applied to the TTI associated with a cell, for example, when such time shift is relative to the PCell timing (e.g., the PCell remains the DL timing reference for such SCell with the additional offset corresponding to the start of the ShTTI for those cells).

[0117] Any procedure or algorithm that may operate with or indicate a TTI duration may be applicable as a procedure or algorithm to operate with or to indicate a subcarrier spacing.

[0118] Support may be provided for transmissions with different TTI duration. A WTRU may be configured for operation with the LTE physical layer. A WTRU may be configured, for example, for operation according to a first (e.g., legacy) LTE behavior or for operation together with a 5gFLEX configuration, e.g., a configuration that supports a physical layer operating with other variants of potentially filtered OFDM transmissions, such as Universal Filtered OFDM (UF-OFDM), Filtered Based OFDM (FB-OFDM), etc.

[0119] In an example of LTE FDD, a radio frame may consist of 10 subframes of 1ms each with a TTI of 1ms. Each TTI may consist of two 0.5ms slots of 7 symbols for a configuration with a normal cyclic prefix. In the downlink, there may be 8 asynchronous HARQ processes numbered 0-7 that may be addressed by means of downlink DCI. In the uplink, there may be 8 synchronous HARQ processes per RTT, which identity may be tied to the subframe timing. A WTRU may be configured for 1 to 3 symbols at the beginning of the first slot used for control signaling (PDCCH). Control signaling may span the entire bandwidth for a given cell. A TTI duration may be fixed, e.g., at 1ms, as an aspect of the LTE physical layer.

[0120] Different cells of a WTRU's configuration may be (e.g. explicitly) associated with a TTI duration/offset shift. Support for different TTI durations may be realized, for example, by maintaining a unique association between a cell and a TTI duration in a WTRU's configuration. Timing associated with the cell (e.g. a cell of the LTE CA SCell type) may be shifted and/or offset in time with respect to the timing of a reference cell. A reference cell may be the PCell of the WTRU's configuration. The PCell may be considered to have a zero time shift, e.g., by default. In an example of dual connectivity, a PSCell may be considered to have a zero time shift (e.g., by

default), for example, when a secondary group of cells is configured and when the PSCell is used as the timing reference.

[0121] In an example, a time-shifted/TTI duration/offset shift may be associated with an identity. For example, a time-shifted cell may be configured with a serving cell identity, with an offset in time relative to the start of a cell-specific subframe (e.g. where timing may be based on the PCell used as a downlink timing reference) and with a TTI duration (e.g. shorter than a first (e.g. legacy) timing that may be referred to as a shorter TTI or ShTTI).

[0122] TTI duration may be a configuration aspect of a WTRU, such as part of a configured transmission mode associated with the physical layer configuration for the cell.

[0123] Cells using a timing relationship may be configured as part of the same timing advance group (TAG). Cells (e.g., SCells) in a secondary TAG (STAG) supporting ShTTIs may use one of the cells in the same TAG as a timing reference (e.g., a cell used may be a configuration aspect of a WTRU) or may use the PCell as the timing reference (e.g., otherwise).

[0124] Support may be provided for multiplexing transmissions in a cell and/or for a specific WTRU. Support for transmissions using different TTI duration may be for concurrent transmissions in the same cell. For example, transmission may correspond to a single TTI duration for each WTRU at any given time while some WTRUs may have different TTI duration than other WTRUs. Support may be for transmissions for a given WTRU within the same subframe (e.g., within a first (e.g., legacy) subframe such as 1 ms) where different transmissions may be performed according to different TTI durations by the concerned WTRU.

[0125] Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0126] An ShTTI-based transmission mode (TM) and cell timing configuration may be provided. For example, a WTRU may be configured with a PCell (e.g., according to first (e.g., legacy) behavior). For example, a WTRU may operate on a PCell carrier frequency using a first TM (e.g., a TM in the range of 1-10) associated with a first TTI duration (e.g., legacy 1ms). The WTRU may receive a RRC Connection Reconfiguration message that may reconfigure the WTRU according to at least one of the following: the WTRU may reconfigure the PCell and/or may configure at least one SCell.

[0127] In an example of reconfiguring a PCell, the WTRU may reconfigure the PCell such that a second TTI (e.g., ShTTI) of a duration shorter than previously used by the WTRU for the PCell is supported. For example, the WTRU may reconfigure (or add) a TM associated to the PCell. For example, a TM (e.g., TM = 11) may be associated with a TTI duration different than previously used by the WTRU for the PCell.

[0128] For example, a WTRU may configure a TTI duration according to one of the following. In an example, an ShTTI duration may be equal to 1 slot (0.5ms). This may be applicable, for example, to the first case. In another example, an ShTTI may be a duration expressed as an integer multiple of 1 symbol. A duration may include the control region, for example, when the configuration includes a start offset for the ShTTI and such offset is equal to zero. In another example, an ShTTI may be a duration expressed as an integer value in time, e.g. 100 μs or 125μs. Whether an ShTTI duration may include the control region may be determined as a function the value of a start offset for the ShTTI when applicable. A control region may be a separate aspect of a WTRU's configuration for a cell when an offset is equal to a non-zero value.

[0129] For example, a TM may support transmissions in (e.g., only in) the first slot of a first (e.g., legacy) subframe for the concerned ShTTI duration. A WTRU may determine an aspect as a function of the type of cell (e.g., PCell) associated with the TM. A TM may support WTRU-specific demodulation reference signals (e.g., DM-RS) such that their location and density may be better suited for ShTTI operation.

[0130] In an example of reconfiguring a PCell, transmissions on the PCell using a first (e.g., legacy) TTI such as 1ms may be enabled. This may be applicable, for example, in the second case, e.g., when a WTRU may be configured such that PCell operation supports transmissions using a first (e.g. legacy) 1ms TTI and one or more SCells support operation using ShTTI.

[0131] A WTRU may configure a PCell with an additional cell identity to the PCell in the PCell's configuration such that DCI may indicate, for example, "CIF=0" for a transmission on PCell using a first TTI (e.g., 1ms) and "CIF=1" for a transmission on PCell using a second TTI (e.g. a slot-based ShTTI of 0.5ms or similar). This may be applicable, for example, in the first case.

[0132] In an example of reconfiguring at least one SCell, the WTRU may configure an SCell such that an associated TTI duration (e.g., ShTTI) is less than that of a first (e.g., legacy) subframe duration (e.g., less than 1ms). For example, the WTRU may configure a TM associated with the SCell. For example, a TM (e.g., TM = 11) may be associated with a TTI duration similar to that of the PCell (e.g., ShTTI). For example, a ShTTI duration may be equal to 1 slot (0.5ms). This may be applicable, for example, in the first case. A TM (e.g., TM = 11+x) may be (e.g. alternatively) associated with a TTI duration different than that of the PCell, for example, when the TTI duration of such SCell may differ from that of the PCell.

[0133] Combinations of slot-based TTI (e.g., 0.5ms for a PCell) and non slot-based TTIs (e.g., 5 SCells of 100ms each) may be applicable for a given WTRU. Another example may be of a WTRU configured with symbol-based TTIs such that a different number of symbols may be used for each of the control regions (e.g,. 3 symbols), the TTI duration for the PCell (e.g., 5 symbols)

and for a number of SCells of x symbols in duration (e.g., 3 SCells each 2 symbols in TTI duration). Other combinations and/or other values are possible.

[0134] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0135] TTI duration may be determined as a function of a Carrier Indicator Field (CIF) in a DCI on PDCCH. A TTI duration may be signaled as a function of the indicated cell identity in the DCI (e.g., by CIF or similar for a given carrier frequency of the WTRU's configuration). A determination or indication may be achieved, for example, by associating a second identity with a cell of the WTRU's configuration or by duplication of a serving cell configuration for a given carrier frequency. The WTRU may determine that the DCI of a given transmission (e.g., PDDCH transmission, serving cell transmission, received downlink control information, or scheduling information) has indicated that the WTRU should use a first transmission time interval on a physical uplink channel to communicate with the serving cell. For example, the determination may be based on the CIF field of the DCI, as the CIF may refer to a serving cell identity that has been configured to utilize the first transmission time interval. In this manner, downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) may be re-used for scheduling of transmissions associated with the first TTI length. Similarly, the WTRU may determine that the DCI of a given transmission (e.g., PDDCH transmission, serving cell transmission, received downlink control information, or scheduling information) has indicated that the WTRU should use a second transmission time interval on a physical uplink channel to communicate with a second serving cell. For example, the determination may be based on the CIF field of the DCI, as the CIF may refer to the second serving cell identity and the second serving cell may have been configured to utilize the second transmission time interval. One or more of the first or second transmission time intervals may correspond a shortened TTI that is less than the legacy transmission time interval. The first and second serving cells may configured to utilize the same frequency band and/or carrier frequency.

[0136] In an example using slot-based TTI duration, a WTRU may be configured with a PCell with CIF=0, an SCell with CIF=1 and an SCell with CIF=2 for a given carrier frequency. Both SCells may be configured with carrier aggregation cross-carrier scheduling such that scheduling information for the associated resources may be received on the PDCCH associated with the PCell. A WTRU may receive signaling that schedules a transmission on such PDCCH. A WTRU may determine that a TTI duration is according to first (e.g., legacy) operation (e.g., 1ms), for example, when the WTRU determines that the CIF applicable to the transmission is that

of the PCell. The WTRU may determine that the transmission is applicable to the first slot of the concerned subframe, for example, when the WTRU determines that the CIF=1. The WTRU may determine that the transmission is for the second slot of the concerned subframe, for example, when CIF=2.

[0137] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0138] A start offset for ShTTI may be a function of CIF in the DCI on PDCCH. In an example, determination of the applicable location in time (e.g., slot in the subframe, applicable starting symbol and/or all applicable symbols or similar) may be enabled for a transmission, for example, when a TTI duration shorter than that of the subframe duration is configured for a given cell.

[0139] A start offset or applicable location in time may be based on signaling received by the WTRU. The WTRU may perform such determination as a function of the indicated cell identity in the DCI, e.g., by Carrier Indicator Field (CIF) or similar for a given carrier frequency of the WTRU's configuration. An indication or determination may be achieved, for example, by associating a specific offset in the subframe with an identity of a cell of the WTRU's configuration or by configuring multiple serving cells for a given carrier frequency each with a different identity and a different offset.

[0140] For example, an offset may indicate one of a first slot or a second slot of a cell-specific subframe or it may indicate an offset in terms of a starting symbol in a subframe or an offset in absolute time (e.g. 500ms). An offset may be applied from the start of a cell-specific subframe. An offset may implicitly indicate a TTI duration (or vice-versa).

[0141] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0142] A TTI duration may be a function of PRB(s) for a transmission. In an example, a WTRU may be configured such that a number of PRBs (e.g. a subset of the total set of system-specific PRBs for the concerned carrier frequency) may be associated with a cell of the WTRU's configuration for which the WTRU is operating with shorter than 1ms TTI duration e.g. configured with ShTTI.

[0143] A WTRU may determine an applicable TTI duration as a function of the PRB(s) indicated by the scheduling information. A PRB may correspond to the starting PRB for the resource allocation for the transmission. A set of PRBs may correspond to a range of PRBs. A

WTRU may use the TTI duration associated with a set of PRB(s), for example, when such range includes (e.g., only includes) PRB(s) associated with the concerned set. A WTRU may (e.g., otherwise) use a different TTI duration (e.g., a first (e.g. legacy) TTI duration, such as 1ms, or a configured duration), for example, when such range includes PRBs associated with different sets of PRBs or when such range does not include PRBs associated with any such sets. Sets of PRBs may be a configuration aspect of a WTRU's configuration. For example, a serving cell may be associated with a set of one or more PRBs, for example, when a serving cell is configured for ShTTI operation for a carrier frequency. A WTRU may use the TTI duration associated with such a cell or associated with the concerned PRBs. Scheduling information may be received dynamically in a DCI on PDCCH. Scheduling information may be semi-statically configured. For example, an entire (e.g., system-specific) set of PRBs for a PCell configured with a first (e.g., legacy) operation may be 110 PRBs. A WTRU may (e.g., alternatively) be configured with one or more subsets of PRBs, where each set may be associated with a specific TTI duration.

[0144] A WTRU may (e.g., first) determine the cell configured with ShTTI applicable to the transmission and/or the duration of the TTI (e.g., determining as described herein) and may determine the set of applicable PRBs therefrom (e.g., determining using a configuration of sets of PRBs as discussed herein).

[0145] Example procedures (e.g., operation) may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU. For example, a procedure may be associated with a transmission mode for downlink and/or uplink. For example, a procedure may be associated with a serving cell of the WTRU's configuration. For example, a WTRU may determine that a configuration is specific to a serving cell of a WTRU's configuration, e.g., a determination may be made that a TTI configuration applies to both DL and UL frequencies. For example, a WTRU may determine that a configuration is specific to a specific direction of a configuration for a given serving cell of the WTRU's configuration, e.g., a determination may be made that a TTI configuration is provided separately for the DL direction and for the UL direction.

[0146] A determination may be made about the start offset time for a transmission. Cell de-activation may control availability of ShTTI. In an example, a first (e.g., legacy) cell activation-deactivation mechanism (e.g., procedure or algorithm) may control the duration (e.g., first or second TTI such as a legacy TTI or an ShTTI duration) of a transmission, e.g., by activating and deactivating the transmission. A WTRU may associate an activation state with an ShTTI, a slot and/or a resource.

[0147] In an example, a WTRU configured using ShTTI cells may receive a first (e.g., legacy) MAC activation/deactivation control element. A WTRU may use the activation/deactivation element as a mechanism to determine the availability of the ShTTI. For example, a WTRU may use a first (e.g., 1ms) TTI duration, e.g., when the WTRU is configured with a single SCell with ShTTI and when the SCell is in a deactivated state when the WTRU determines that it needs to perform a transmission. A WTRU may (e.g., otherwise) use a second TTI duration (e.g., ShTTI) for a transmission, e.g., when the SCell is active. The WTRU may perform a transmission using the second TTI duration (e.g. ShTTI), for example, according to scheduling information independently of the scheduled slot. This example may be extended to apply to the case where a symbol-based TTI duration is used instead of a time duration such as transmission slots.

[0148] In an example where multiple SCells may be used to indicate slot-based transmissions, a WTRU may determine that a first TTI duration is applicable when all cells configured with ShTTI are in a deactivated state. A WTRU may determine (e.g., otherwise) the applicable slot based on the activation state associated with each SCell and associated with each slot. This example may be extended to apply to the case where a symbol-based TTI duration is used, e.g., instead of using time duration such as transmission slots.

[0149] A WTRU may transmit HARQ feedback and/or other Uplink Control Information (UCI) (e.g. CQI, PMI, RI or similar), for example, taking into consideration the configuration of the TTI duration.

[0150] A TTI duration applicable to the transmission of UCI may be a function of at least one of the following: scheduling information, configuration information, TTI applicable to a serving cell, a default configuration for UCI transmission, etc.

[0151] Scheduling information may indicate whether a WTRU has resources for a PUSCH transmission and (e.g., if so) the TTI duration associated with such transmission, which may be determined according to procedures described herein.

[0152] Configuration information may indicate whether a WTRU is configured for simultaneous PUSCH and PUCCH transmission.

[0153] A TTI may be applicable to a serving cell associated with a UCI transmission in the subframe for the concerned UCI transmission.

[0154] A TTI may be applicable (e.g., in duration and/or offset) to a serving cell associated with a UCI transmission in the subframe for a downlink transmission pertaining to the feedback (e.g., in case of HARQ A/N feedback).

[0155] A default configuration for the transmission of UCI may be, for example, for the transmission of UCI on PUCCH (e.g., always a first TTI such as 1 ms TTI on PCell).

[0156] Further examples are provided below.

[0157] An applicable resource may be a PUSCH or PUCCH resource. A WTRU may determine a physical channel to perform the transmission of UCI using any technique, procedure or algorithm. For example, a WTRU may determine that UCI may be included in a PUSCH transmission when the transmission is scheduled, when simultaneous PUSCH and PUCCH transmissions are not configured or on a PUCCH transmission (e.g., otherwise).

[0158] An applicable resource may be a PUSCH resource. A WTRU may perform the transmission of UCI on a PUSCH transmission according to a TTI duration associated with a PUSCH transmission, which may be determined using procedures described herein.

[0159] An applicable resource may be a PUCCH resource. A WTRU may determine that a PUCCH resource may be used for transmission of UCI according to any technique, procedure or algorithm applicable to LTE CA. For example, selection of a resource may be based on the first CCE of the DCI that scheduled a downlink transmission or based on a configuration (e.g. PUCCH format 3 or similar). Bundling and/or multiplexing may be applied, for example, when configured.

[0160] An applicable TTI may be function of the type of transmissions on the carrier frequency PUSCH or PUCCH. Transmission of UCI may use the principles of LTE CA whereby UCI corresponding to transmission on different cells, e.g., including time-shifted cells, maybe multiplexed on a single transmission using a format that supports the required number of information bits (e.g., PUCCH format 3).

[0161] A PUCCH transmission may be performed on a PCell with a first (e.g., 1 ms TTI), where the first TTI may be a fixed TTI. A WTRU may perform PUCCH transmission on resources of an applicable serving cell (e.g., a PCell) according to a TTI duration associated with a concerned (e.g., pertinent) PCell, which may be determined using procedures described herein. In an example, a WTRU may transmit HARQ feedback using a single PUCCH transmission, which may use resources associated with a PCell (e.g. using a 1ms TTI duration), for example, when a WTRU has HARQ A/N feedback to transmit for two slot-based time-shifted cells using PUCCH on the PCell according to a configuration for a given carrier frequency where the PCell uses a first (e.g., 1ms) TTI.

[0162] A PUCCH transmission may be performed on a PCell with alignment in time with TTI being reported. A WTRU may perform PUCCH transmission on resources of an applicable serving cell (e.g. a PCell) according to a TTI duration associated with transmission(s) for which feedback is transmitted. A WTRU may have, for example, HARQ A/N feedback to transmit for

two slot-based time-shifted cells using PUCCH on the PCell according to a configuration for a given carrier frequency. In an example, a WTRU may transmit in the first slot a HARQ feedback for a transmission associated with the first slot and may transmit the HARQ feedback for the other transmission in the second slot for the concerned subframe.

[0163] A PUCCH transmission may be performed on a PCell with TTI/ShTTI of the PCell. A WTRU may perform a PUCCH transmission on resources of an applicable serving cell (e.g. a PCell) according to a TTI duration associated with the PCell, which may be determined using procedures described herein. A PCell may be (e.g., otherwise) configured with a default TTI, such as a first (e.g., 1 ms) TTI or an ShTTI. A WTRU may have HARQ A/N feedback to transmit for two slot-based time-shifted cells using PUCCH on the PCell, e.g., according to a configuration for a given carrier frequency where the PCell uses ShTTI in the concerned subframe (e.g., based on a configuration aspect and/or an activation state such as ShTTI activated for a time-shifted SCell for the concerned subframe). In an example, a WTRU may transmit HARQ feedback using a single PUCCH transmission, which may use resources associated with the PCell using a ShTTI duration with an offset applicable to the PCell.

[0164] A WTRU may transmit HARQ A/N feedback, for example, based on an applicable WTRU processing time for a concerned (e.g., pertinent) HARQ process in a given subframe.

[0165] Processing time associated with a HARQ process may be specific to a TTI associated with a transmissions for a concerned process. Processing time may be specific to a serving cell, a transmission mode or may be indicated by DCI (e.g., from servCellID or CIF) associated with such transmissions for a concerned HARQ process. In an example, HARQ processing time may be the same for all HARQ processes associated with a serving cell configured with a specific TTI (e.g., an ShTTI). Processing time may be a fixed value (e.g., 1ms), a multiple of an ShTTI, etc. Processing time may be determined for a transmission using ShTTI in subframe, the first available occasion in subframe n+2, where an occasion may correspond to a PUCCH or a PUSCH transmission with duration according to a first TTI or second TTI (e.g., ShTTI).

[0166] Systems, methods, and instrumentalities have been disclosed for multiplexing transmissions with different TTI duration. Latency may be reduced (e.g., in an LTE system), for example, by multiplexing transmissions with different TTI durations. TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency. A "logical" cell structure may correspond to an SCell. A PCell may logically maintain a TTI (e.g,. a first TTI) or may be configured with a second duration TTI (e.g., a shorter duration TTI (ShTTI)).

[0167] In an example, a WTRU may determine a TTI duration (e.g., first or second TTI) applicable to a transmission. For example, a WTRU may determine a TTI duration using cross-

carrier scheduling. A WTRU may associate a TTI duration with a cell identity (e.g. servCellID). A WTRU may associate a TTI duration with a transmission mode (TM). A TTI duration may be indicated by Carrier Indicator Field (CIF). A TTI duration may be determined from an identity of a PRB subset applicable to transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using MAC Activation/Deactivation. MAC Activation/Deactivation may be used to toggle between first and second TTIs (e.g. legacy TTI and ShTTIs) or between slot-based ShTTIs and/or may be used to determine zero, one or more TTI (e.g. ShTTI) period(s) within a subframe.

[0168] HARQ processing may be performed according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. An exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA) formats and/or (e.g., legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g., legacy) format, although, for example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different than the first (e.g., legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. PRACH resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g. a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0169] A different TTI may be used in LTE R14 and NR. Multiple serving cells may be configured on the same carrier for a single WTRU. There may be an association between a serving cell and a TTI duration (or more generally – a numerology-related aspect). A WTRU can be configured with multiple such cells on a given carrier to support (*e.g.*, dynamically) a change in transmission duration. A field in downlink control signaling (DCI), *e.g.*, on a downlink control channel (*e.g.*, PDCCH), such as the CIF field in a DCI, may be used to dynamically schedule specific TTI durations for same or later subframes, for UL or DL transmissions.

[0170] The WTRU may be configured with a plurality of transmission methods, where at least two of the configured transmission methods differ in at least the applicable TTI duration.

[0171] A transmission may be associated with a transmission timing (start offset) relative to a timing reference.

[0172] A WTRU transmission mode may be indicated in downlink control information (DCI) signaling.

[0173] WTRU transmissions may be configured for each of a plurality of PRBs in the WTRU's configuration. Each of a plurality of PRBs may correspond to a serving cell of the WTRU's configuration. Each of a plurality of PRBs may correspond to a given carrier.

[0174] An applicable transmission duration/timing may be determined from a serving cell ID indicated in DCI signaling.

[0175] The WTRU may determine the set of resources, transmission duration, and/or uplink control information for a transmission based on a previous combination of received downlink signaling and received transmission duration.

[0176] A WTRU may determine whether a control region (*e.g.*, single control region) (*e.g.*, single level PDCCH) or multiple control regions (*e.g.*, multi-level PDCCH) are applicable and whether they are a function of the PDCCH configuration applicable to the concerned cell(s). A WTRU can determine the location of CCEs with respect to the timing reference (*e.g.*, in support of either self-scheduling or cross-TTI scheduling).

[0177] A WTRU may support mini-slots (*e.g.*, 125usec), slots (*e.g.*, 0.5ms), subframe (*e.g.*, 1ms) and multi-slots (*e.g.*, Multiples of other durations), and transmission durations and use different (*e.g.*, shortened) TTI's based on these time allocations. This may provide a low latency mode, a throughput mode and/or a coverage mode.

[0178] FIG. 4 depicts a scheduling example with time shifted-cells. As shown, there is a frequency axis and a time axis. In Fig. 4, the time is measured in milliseconds and divided into subframes. Other time units can be used such as slots, minislots, symbols, and PRB lengths. The frequency axis shows downlink (DL) and uplink (UL) transmissions. The time axis shows subframes. N, n+1, N=3, etc.... As shown for the DL frequency, for one or more subframes, the WTRU may receive DCI. For subframe n, the DCI may indicate two allocations, for example two ShTTI allocations (*e.g.*, $ShTTI_{DL(n,0)}$ and $ShTTI_{DL(n,1)}$). As an example, setting the CIF equal to 1 may indicate that the allocation is for $ShTTI_{DL(n,0)}$ and setting the CIF equal to 2 may indicate the allocation is for $ShTTI_{DL(n,1)}$. Other values of the CIF may be used to indicate no ShTTI transmissions and/or different transmission durations. For example, the DCI in Subframe

n+1 may indicate that for DL subframe n+1, the transmission has a duration corresponding to the entire subframe by using the value CIF=0 (*see e.g.*, a $TTI_{DL(N+1)}$).

[0179] A similar signaling mechanism can be used for indicating different durations of uplink transmissions. For example, DCI in DL subframe n may indicate that the WTRU has recieved two uplink grants. For example, a first grant for subframe n+1 may be indicate a CIF=1, which may be configured to correspond to $ShTTI_{(n+an\ offset,0)}$, while a CIF equal to 2 may indicate a grant for $ShTTI_{(n+an\ offset,0)}$. Similarly, a different value of the CIF (*e.g.*, CIF = 0) in this example may indicate that the transmissions duration spans an entire legacy TTI as illustrated in FIG. 4. Thus, by associating different CIF values with different transmission durations, the DCI may be used to indicate different transmission durations by referencing the different CIF values. Although the CIF field is used for purposes of illustration, other DCI fields may be used and may have values mapped to/associated with transmissions of different duration.

[0180] FIG. 4 also shows for an example of the PUCCH on the uplink frequency. For the PCell or SCell there may be a HARQ A/N for CIF = 1 at (n, 0) and a HARQ A/N for CIF = 2 at n, 1. For the PCell, (*e.g.*, PCell only), there may be a HARQ A/N for CIF = 0 at (n, 0) or CIF = 0 at n-3. Also, for the PCell, (*e.g.*, PCell only), there may be a HARQ A/N for CIF = 1 at (n, 0) or CIF = 0 at n-3 for the $ShTTI_{(n+?,\ 0)}$ and HARQ A/N for CIF = 2 at (n, 1) or CIF = 0 at n-3 for the $ShTTI_{(n+?,\ 1)}$.

[0181] FIG. 4 shows an example with time shifted cells with an offset of symbols. In this example, the symbol offset is based on CIF. FIG. 4 shows a single HARQ addressing space per TTI duration and start offset in a given subframe. MAC activation/deactivation may be applied by a HARQ process space or CIF value. FIG. 4 also shows a UCI example with time-shifted cells. The first CCE of the DCI on the example channel, PDCCH, may be used for legacy PUCCH resource allocation at TTI or ShTTI. Configured LTE CA PUCCH, PUCCH on an SCell, and/or ARI may be used for UCI using different TTIs. As shown, the WTRU interprets the DCI TTI indication differently in the FIG. 4 example for SCells and PCells to use ShTTI for the SCells. FIG. 4 also shows an example of the frequency being the same for the PCell and SCell. The FIG. 4 example dynamically varies the scheduled TTI for a WTRU and uses the appropriate HARQ signaling. Also, resource allocation for associated control information is resolved and there is flexibility to adapt different time offsets in a subframe and with different ShTTIs.

[0182] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element may be used alone or in any combination with the other features and elements. In addition, the methods described herein

may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, WTRU, terminal, base station, RNC, or any host computer.

CLAIMS

What Is Claimed:

1. A method implemented by a wireless transmit/receive unit (WTRU) for supporting transmissions of different durations, the method comprising:

receiving a first configuration associated with a first set of transmission resources, the first configuration indicating a first transmission time interval (TTI) length for use with the first set of transmission resources;

receiving a second configuration associated with a second set of transmission resources, the second configuration indicating a second transmission time interval (TTI) length for use with the second set of transmission resources;

receiving downlink control information (DCI), wherein the DCI comprises a field that indicates whether the DCI is applicable to first set of transmission resources or the second set of transmission resources; and

determining that a transmission associated with the DCI utilizes the first TTI length on condition that the field indicates that the DCI is applicable to the first set of transmission resources or that the transmission associated with the DCI utilizes the second TTI length on condition that the field indicates that the DCI is applicable to the second set of transmission resources.

2. The method of claim 1, wherein the first set of transmission resources correspond to a first serving cell and the second set of transmission resources correspond to a second serving cell.

3. The method of claim 2, wherein the field corresponds to a carrier indicator field.

4. The method of claim 2, wherein the first serving cell and the second serving cell are associated with the same carrier frequency.

5. The method of claim 2, wherein each of the first and second serving cells are configured as secondary cells (SCells).

6. The method of claim 2, wherein the first serving cell corresponds to a primary cell (PCell), the second serving cells is configured as a secondary cells (SCell), the first TTI length corresponds to 1 millisecond (ms), and the second TTI length corresponds to less than 1 ms.

7. The method of claim 1, wherein the DCI further comprises a physical resource block (PRB) assignment field, and the PRB assignment field is interpreted differently depending on whether the transmission is associated with the first TTI length or the second TTI length.

8. The method as in claim 1, wherein at least the second configuration is received via a radio resource control (RRC) message, and the DCI is received via a physical downlink control channel.

9. The method as in claim 1, wherein a hybrid automatic repeat request timing used for the transmission is dependent on whether the transmission is associated with the first TTI length or the second TTI length.

10. A method implemented by a wireless transmit/receive unit (WTRU) for supporting transmissions of different durations, the method comprising:

receiving downlink control information from a first serving cell in the wireless communications network;

determining that the received downlink control information indicates that the WTRU should use a first transmission time interval to transmit data information to the first serving cell;

determining whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is different than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation; and

communicating with the wireless communications network using the second transmission time interval.

11. The method of claim 10, wherein determining that the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel comprises determining based on a carrier indicator field in the received downlink control information.

12. The method of claim 10, wherein communicating with the wireless communications network using the second transmission time interval comprises communicating with the first serving cell using the second transmission time interval.

13. The method of claim 10, wherein communicating with the wireless communications network using the second transmission time interval comprises communicating with a secondary cell using the second transmission time interval.

14. The method of claim 10, further comprising determining that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network.

15. The method of claim 10, wherein the shorten transmission time interval corresponds to at least one of at least one symbol or at least one resource block.

16. The method of claim 10, wherein the first transmission time interval is one millisecond.

17. The method of claim 10, wherein the first transmission time interval is greater than the first transmission time interval.

18. The method of claim 10, wherein the first transmission time interval corresponds to a first sub-carrier spacing and the second transmission time interval corresponds to a second subcarrier spacing.

19. The method of claim 10, wherein the first transmission time interval corresponds to a first number of transmission symbols and the second transmission time interval corresponds to a second number of transmission symbols.

20. The method of claim 10, further comprising the WTRU communicating with the first serving cell and a second serving cell using the same carrier frequency.

21. The method of claim 10, further comprising determining a time to transmit with the second transmission time interval based on the received downlink control information.

22. The method of claim 21, wherein the time to transmit is defined by a slot in a subframe.

23. The method of claim 10, wherein determining whether the received downlink control information indicates that the WTRU should use a second transmission time interval that

is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation comprises determining with cross-carrier scheduling.

24. A wireless transmit/receive unit (WTRU) for use within a wireless communications network that is capable of carrier aggregation, comprising:

a processor having executable instructions that:

determine that downlink control information from a first serving cell in the wireless communications network has been received;

determine that the received downlink control information indicates that the WTRU should use a first transmission time interval to transmit data information to the first serving cell;

determine whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is different than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation; and

communicate with the wireless communications network using the second transmission time interval.

25. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine that the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel comprises determining based on a carrier indicator field in the received downlink control information.

26. The WTRU of claim 24, wherein the executable instructions that communicate with the wireless communications network using the second transmission time interval comprise communicating with the first serving cell using the second transmission time interval.

27. The WTRU of claim 24, wherein the executable instructions that communicate with the wireless communications network using the second transmission time interval comprise communicating with a secondary cell using the second transmission time interval.

28. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network.

29. The WTRU of claim 24, wherein the shorten transmission time interval corresponds to at least one of at least one symbol or at least one resource block.

30. The WTRU of claim 24, wherein the first transmission time interval is one millisecond.

31. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine a time to transmit with the second transmission time interval based on the received downlink control information.

32. The WTRU of claim 31, wherein the time to transmit is defined by a slot in a subframe.

33. The WTRU of claim 24, wherein the executable instructions that determine whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation comprise determining with cross-carrier scheduling.

34. The WTRU of claim 24, wherein the first transmission time interval is greater than the first transmission time interval.

35. The method of claim 24, wherein the first transmission time interval corresponds to a first sub-carrier spacing and the second transmission time interval corresponds to a second subcarrier spacing.

36. The method of claim 24, wherein the first transmission time interval corresponds to a first number of transmission symbols and the second transmission time interval corresponds to a second number of transmission symbols.

37. The method of claim 24, further comprising the WTRU communicating with the first serving cell and a second serving cell using the same carrier frequency.

(54) Title: METHOD AND DEVICE FOR PAGING A MACHINE TO MACHINE DEVICE

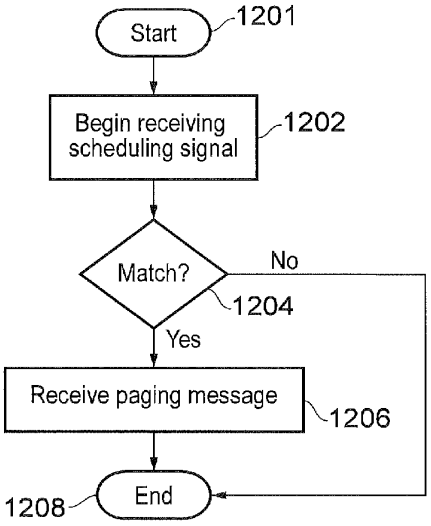

FIG. 12

(57) Abstract: A terminal device for use with a wireless telecommunications network comprising: a transceiver; and a controller. Receiving, during one of a plurality of periodic paging occasions associated with the terminal, a paging scheduling signal for one or more terminal devices, each paging occasion being associated with a value of a characteristic of the scheduling signal which is unique to that paging occasion. Determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the of periodic paging occasions associated with the terminal device; and control the transceiver to receive the paging message scheduled by the received scheduling message.

METHOD AND DEVICE FOR PAGING A MACHINE TO MACHINE DEVICE

BACKGROUND

Field of Disclosure

The present disclosure relates to a terminal device, infrastructure equipment, methods and integrated circuitry for use with a wireless telecommunications network.

Description of Related Art

The "background" description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description which may not otherwise qualify as prior art at the time of filing, are neither expressly or impliedly admitted as prior art against the present disclosure.

Third and fourth generation wireless communications systems, such as those based on the third generation project partnership (3GPP) defined UMTS and Long Term Evolution (LTE) architecture are able to support sophisticated services such as instant messaging, video calls as well as high speed internet access. For example, with the improved radio interface and enhanced data rates provided by LTE systems, a user is able to enjoy high data rate applications such as mobile video streaming and mobile video conferencing that would previously only have been available via a fixed line data connection. The demand to deploy third and fourth generation networks is therefore strong and the coverage area of these networks, i.e. geographic locations where access to the networks is possible, is expected to increase rapidly. However, whilst fourth generation networks can support communications at high data rate and low latencies from devices such as smart phones and tablet computers, it is expected that future wireless communications networks will need to support communications to and from a much wider range of devices, including reduced complexity devices, machine type communication devices, devices which require little or no mobility, high resolution video displays and virtual reality headsets. As such, supporting such a wide range of communications devices can represent a technical challenge for a wireless communications network.

A current technical area of interest to those working in the field of wireless and mobile communications is known as "The Internet of Things" or IoT for short. The 3GPP has proposed to develop technologies for supporting narrow band (NB)-IoT using an LTE or 4G wireless access interface and wireless infrastructure. Such IoT devices are expected to be low complexity and inexpensive devices requiring infrequent communication of relatively low bandwidth data. It is also expected that there will be an extremely large number of IoT devices which would need to be supported in a cell of the wireless

communications network. Furthermore such NB-IoT devices are likely to be deployed indoors and /or in remote locations making radio communications challenging.

SUMMARY OF THE DISCLOSURE

According to a first embodiment, the present technique provides a terminal device for use with a wireless telecommunications network, the terminal device comprising: a transceiver; and a controller operable: to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network; to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

According to the first embodiment, the present technique also provides infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising: a transceiver; and a controller operable: to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

According to a second embodiment, the present technique provides a terminal device for use with a wireless telecommunications network, the terminal device comprising: a transceiver; and a controller operable: to control the transceiver to begin receiving, during one of a plurality of periodic paging

occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

According to the second embodiment, the present technique also provides infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising: a transceiver; and a controller operable: to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

The foregoing paragraphs have been provided by way of general introduction, and are not intended to limit the scope of the following claims. The described embodiments, together with further advantages, will be best understood by reference to the following detailed description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete appreciation of the disclosure and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings wherein like reference numerals designate identical or corresponding parts throughout the several views, and wherein:

Figure 1 is a schematic block diagram illustrating an example of a mobile telecommunication system;

Figure 2 is a schematic representation illustrating a frame structure of a downlink of a wireless access interface according to an LTE standard;

Figure 3 is a schematic representation illustrating a frame structure of an uplink of wireless access interface according to an LTE standard;

DETAILED DESCRIPTION OF THE EMBODIMENTS

Conventional Communications System

Figure 1 provides a schematic diagram illustrating some basic functionality of a mobile telecommunications network / system 100 operating in accordance with LTE principles and which may be adapted to implement embodiments of the disclosure as described further below. Various elements of Figure 1 and their respective modes of operation are well-known and defined in the relevant standards administered by the 3GPP (RTM) body, and also described in many books on the subject, for example, Holma H. and Toskala A [1]. It will be appreciated that operational aspects of the telecommunications network which are not specifically described below may be implemented in accordance with any known techniques, for example according to the relevant standards.

The network 100 includes a plurality of base stations 101 connected to a core network 102. Each base station provides a coverage area 103 (i.e. a cell) within which data can be communicated to and from communications devices 104. Data is transmitted from base stations 101 to communications devices 104 within their respective coverage areas 103 via a radio downlink. Data is transmitted from communications devices 104 to the base stations 101 via a radio uplink. The uplink and downlink

communications are made using radio resources that are licenced for exclusive use by the operator of the network 100. The core network 102 routes data to and from the communications devices 104 via the respective base stations 101 and provides functions such as authentication, mobility management, charging and so on. Communications devices may also be referred to as mobile stations, user equipment (UE), user device, mobile radio, terminal device and so forth. Base stations may also be referred to as transceiver stations / infrastructure equipment / NodeBs / eNodeBs (eNB for short), and so forth.

Wireless communications systems such as those arranged in accordance with the 3GPP defined Long Term Evolution (LTE) architecture use an orthogonal frequency division modulation (OFDM) based interface for the radio downlink (so-called OFDMA) and a single carrier frequency division multiple access scheme (SC-FDMA) on the radio uplink.

Figure 2 provides a simplified schematic diagram of the structure of a downlink of a wireless access interface that may be provided by or in association with the eNB of Figure 1 when the communications system is operating in accordance with the LTE standard. In LTE systems the wireless access interface of the downlink from an eNB to a UE is based upon an orthogonal frequency division multiplexing (OFDM) access radio interface. In an OFDM interface the resources of the available bandwidth are divided in frequency into a plurality of orthogonal subcarriers and data is transmitted in parallel on a plurality of orthogonal subcarriers, where bandwidths between 1.4MHz and 20MHz bandwidth may be divided into 128 to 2048 orthogonal subcarriers for example. Each subcarrier bandwidth may take any value but in LTE it is conventionally fixed at 15kHz. However it has been proposed in the future [2][3] to provide also a reduced subcarrier spacing of 3.75 kHz for certain parts of the LTE wireless access interface for the uplink. As shown in Figure 2, the resources of the wireless access interface are also temporally divided into frames where a frame 200 lasts 10ms and is subdivided into 10 subframes 201 each with a duration of 1ms. Each subframe is formed from 14 OFDM symbols and is divided into two slots each of which comprise six or seven OFDM symbols depending on whether a normal or extended cyclic prefix is being utilised between OFDM symbols for the reduction of inter symbol interference. The resources within a slot may be divided into resources blocks 203 each comprising 12 subcarriers for the duration of one slot and the resources blocks further divided into resource elements 204 which span one subcarrier for one OFDM symbol, where each rectangle 204 represents a resource element. More details of the downlink structure of the LTE wireless access interface are provided in Annex 1.

Figure 3 provides a simplified schematic diagram of the structure of an uplink of an LTE wireless access interface that may be provided by or in association with the eNB of Figure 1. In LTE networks the uplink wireless access interface is based upon a single carrier frequency division multiplexing FDM (SC-FDM) interface and downlink and uplink wireless access interfaces may be provided by frequency division duplexing (FDD) or time division duplexing (TDD), where in TDD implementations subframes switch

between uplink and downlink subframes in accordance with predefined patterns. However, regardless of the form of duplexing used, a common uplink frame structure is utilised. The simplified structure of Figure 3 illustrates such an uplink frame in an FDD implementation. A frame 300 is divided in to 10 subframes 301 of 1ms duration where each subframe 301 comprises two slots 302 of 0.5ms duration. Each slot is then formed from seven OFDM symbols 303 where a cyclic prefix 304 is inserted between each symbol in a manner equivalent to that in downlink subframes. In Figure 3 a normal cyclic prefix is used and therefore there are seven OFDM symbols within a subframe, however, if an extended cyclic prefix were to be used, each slot would contain only six OFDM symbols. The resources of the uplink subframes are also divided into resource blocks and resource elements in a similar manner to downlink subframes. More details of the LTE uplink represented in Figure 3 are provided in Annex 1.

Narrowband Internet of Things

As explained above, it has been proposed to develop an adaptation of a mobile communications network to accommodate narrow band communications within an existing wireless access interface which has been developed to provide broadband wireless communications. For example, in 3GPP a project relating to improvements to LTE wireless access interfaces to provide for a Narrowband Internet of Things (NB-IoT) was agreed [2]. This project is aimed at improved indoor coverage, support for massive number of low throughput devices, low delay sensitivity, ultra-low device cost, low device power consumption and (optimised) network architecture. An example of such a device is a smart meter. It has been proposed that an NB-IoT communications system supports a bandwidth of only 180 kHz and can have three operational modes:

1. 'Stand-alone operation' utilizing for example the spectrum currently being used by GERAN systems as a replacement of one or more GSM carriers
2. 'Guard band operation' utilizing the unused resource blocks within a LTE carrier's guard-band
3. 'In-band operation' utilizing resource blocks within a normal LTE carrier

Figure 4 provides an example schematic block diagram of a terminal device or UE 104 and an infrastructure equipment or eNB 101 according to embodiments of the present technique. As shown in Figure 4, the UE 104 includes a transmitter 401 and a receiver 402 (which together form a transceiver) which are controlled by a controller 403. The UE 104 also comprises a storage medium 420 for storing data. Correspondingly, the eNB 101 includes a transmitter 411 and a receiver 412 (which together form a transceiver) which are controlled by a controller 413 (which can also implement a scheduler function). The eNB 101 also comprises a storage medium 422 for storing data. As explained above, the UE 104 transmits and receives signals to and from the eNB 101 via a wireless access interface provided by the

eNB as part of the wireless communications network. Each of the UE 104 and eNB 101 are configured to exchange signals with each other using NB-IoT.

One of the objectives of NB-IoT is to provide extended coverage of up to 20 dB. The main mechanism to extend coverage is to perform numerous repetitions of a message to be received at a receiving device, such that the receiver can accumulate the signal energy over the repetitive samples in order for it to have an increased signal-to-noise ratio (SNR), which increases the likelihood of successful decoding of the message at the receiving device. Such a mechanism is known as coverage enhancement (CE).

Coverage enhancement (CE) may have several levels. For example, it may provide one of 5 dB, 15 dB and 20 dB additional coverage enhancement. In NB-IoT, the CE levels may be referred to as the targeted MCL (Max Coupling Loss, the achievable coupling loss (accounting for, for example, path loss, feeder losses and/or antenna gains) between transmitter and receiver) of, for example, 144 dB, 154 dB and 164 dB (so that the higher the targeted MCL, the greater the additional coverage enhancement).

As previously mentioned, repetitions of a signal so that a receiver can accumulate energy of the signal over numerous repetitive samples is the basic method used for coverage enhancement. The number of repetitions required is dependent upon the CE level. Thus, a UE at a lower CE level, such as at 144 dB, MCL requires less repetition compared to one at a higher CE level, such as at 154 dB MCL. The power spectral density, PSD (mW/Hz) of a transmission also affects the number of repetitions required, that is, the larger the PSD, the less the required number of repetitions.

The NB-PDCCH (Narrow Band Physical Downlink Control Channel) is a control channel that is used to schedule downlink resources (downlink grant) and uplink resources (uplink grant) for a NB-PDSCH (Narrow Band Physical Downlink Shared Channel) and a NB-PUSCH (Narrow Band Physical Uplink Shared Channel) that carry data traffic. An NB-PDCCH search space consists of multiple NB-PDCCH candidates wherein each candidate has a specific starting time, set of subcarriers, a defined number of repetitions and an aggregation level (the aggregation level relating to the number of frequency resources occupied by the candidate such that when the candidate occupies a higher number of frequency resources, the aggregation level is higher, and when the candidate occupies a lower number of frequency resources, the aggregation level is lower). Candidates that have a larger number of repetitions and a higher aggregation level are more robust and can reach a UE at poorer coverage compared to candidates that have a smaller number of repetitions and a lower aggregation level.

The eNB uses one of the candidates in the search space to carry the NB-PDCCH. The UE is not aware which candidate is used and so it must blind decode all the candidates in the search space in order to find the candidate used by the eNB for the NB-PDCCH. An example of a typical NB-PDCCH search space is

shown in Figure 5. Here, the search space has 4 repetition levels {R1, R2, R3, R4} where R4 = 2×R3 = 4×R2 = 8×R1. It should be appreciated that an NB-PDCCH search space with other repetition levels is also possible. As an example the eNB can use any of the 15 candidates (labelled as C1 to C15) to carry the NB-PDCCH and the UE has to blind decode for all 15 candidates. The max repetition R_{MAX} (in Figure 5, R_{MAX} = R4) of the search space is assigned to the UE based on the UE's radio condition. Thus, for example, if the UE is in a poorer quality radio coverage location, then the eNB can configure a search space with a larger value of R_{MAX}, and if the UE is in a better quality radio coverage location, then the eNB can configure a search space with a smaller value of R_{MAX}. Typically, a set of NB-PDCCH search spaces is predefined in which each NB-PDCCH search space of the set consists of a set of candidates and a value of R_{MAX}. The UE is then assigned one NB-PDCCH search space in the set of NB-PDCCH search spaces. The maximum repetition R_{MAX} of an NB-PDCCH search space can be selected from the set of values {1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048}, for example.

In NB-IoT, paging is performed when a UE is in idle mode. More specifically, when in idle mode, the UE monitors an NB-PDCCH CSS (Common Search Space) which, in the case that a paging message is to be transmitted to the UE, contains an NB-PDCCH that schedules that paging message (the paging message being carried by an NB-PDSCH). In order to reduce power consumption, the UE monitors the NB-PDCCH CSS during each of a plurality of periodic Paging Occasions (PO) rather than constantly monitoring the NB-PDCCH CCS. The PO occurs periodically for a particular UE (or particular group of UEs), wherein the period is configured by the network, for example. In an embodiment, the network can configure multiple POs in which the specific PO that a UE monitors depends on an identifier of that that UE (UE-ID), for example, the UE's International Mobile Subscriber Identifity (IMSI). This enables the network to spread the paging load. For example in Figure 6, the eNB configures four POs where each PO has a period T_{PO}. The UE thus wakes up every T_{PO} ms to monitor for possible paging. The PO is assigned to the UE based on the UE's ID, using a **MOD** function of the number of POs, for example (thus, in the case of Figure 6, the PO assigned to a particular UE is given by UE_ID **MOD** 4).

As described previously, repetition of the paging CSS can reach 2048. A problem with this is that a PO can overlap another PO, causing confusion for UEs reading the PO. For example in Figure 7, two POs are configured. PO 1 begins at time t_1, where UE 1 belonging to this PO will start monitoring for NB-PDCCH in the paging CSS. This paging CSS ends at time t_3. If the repetition of NB-PDCCH is very long (for example, if the paging CSS ending at time t_3 has the structure shown in Figure 5, and the NB-PDDCH is received via the candidate C15 with the largest number of repetitions) , it will overlap into PO 2 at time t_2. At time t_2 UE 2 belonging to PO 2 will start monitoring for NB-PDCCH and will start to accumulate repetition samples from the NB-PDCCH intended for UE 1 (belong to PO 1). If UE 2 is in a better radio condition than UE 1, it may decode the NB-PDCCH and start to accumulate and decode the corresponding NB-PDSCH containing the paging message. UE 2 will not find any paging indication in

this paging message and would waste battery power accumulating and decoding the NB-PDSCH. This is because the paging message contains an identifier of each UE to be paged. If a paging message is not intended for UE 2, then the identifier of UE 2 will not be included in the paging message and thus UE 2 will not be paged. However, since UE 2 has received the NB-PDCCH during its paging occasion, it will still attempt to read the paging message scheduled by the NB-PDCCH by accumulating and decoding the NB-PDSCH, thus wasting battery power. It should be noted that the NB-PDSCH is also repeated.

It should also be appreciated that if the PO period T_{PO} is shorter than the NB-PDCCH repetition, the PO may overlap itself, as shown in an example in Figure 8, in which the NB-PDCCH for PO 1 starts at time t_1 but the repetition doesn't end till time t_4. It overlaps the next PO 1 at time t_3. In this scenario, the UE belonging to PO 1 is confused as to whether to continue accumulating samples from the previous PO 1 (started at time t_1) or start a new accumulation starting at time t_3. Furthermore, in an embodiment, the NB-PDSCH starting subframe is indicated in the downlink control information (DCI) of the NB-PDCCH, this NB-PDSCH starting subframe being defined relative to the end of the NB-PDCCH that schedules this NB-PDSCH. In order to determine the end of an NB-PDCCH transmission, the repetition of the NB-PDCCH is indicated in the DCI of that NB-PDCCH. For example, in Figure 5, if candidate C11 is used to carry the NB-PDCCH (including the DCI), then the NB-PDSCH scheduled by the NB-PDCCH will start at k subframes after time t_6 (t_6 marking the end of the NB-PDCCH carried by candidate C11) where k is indicated in the DCI. Since the UE can decode a message with less repetition when it has a good radio condition, however, the UE may decode C11 at time t_5 and mistake candidate C11 for candidate C5. The UE will thereby use the wrong reference point for the start of the NB-PDSCH. To avoid this, the repetition of the NB-PDCCH is indicated in the DCI so that the UE will not mistake candidate C11 for C5. However, this does not solve the problem shown in Figure 8 in which the search space overlaps itself. In this case, although the UE will know the repetition of the NB-PDCCH from the DCI information, the UE does not know whether the NP-PDCCH repetitions started at time t_1 or at time t_3. This causes confusion at the UE regarding the candidates.

In LTE Release-13 eMTC (enhanced Machine Type Communication), the POs are separated far apart so that they do not overlap. This is possible because the repetition used in this case is not as large as that used in NB-IoT. Furthermore, eMTC can use different narrowbands for different groups of UEs and avoid overlapping. In contrast, only the anchor NB-IoT can contain the paging CSS and paging message, and therefore problem of overlapping of the NB-PDCCH between different POs requires a new solution.

In an embodiment of the present technique, an indicator is used to distinguish one PO from another. The UE belonging to a PO then uses this indicator to determine whether the NB-PDCCH belongs to it or to another PO.

In one embodiment, the said indicator is a PO index in the DCI (carried by the NB-PDCCH). A new field in the DCI would indicate which PO the DCI (that is, the NB-PDCCH) belongs to. The UE, after accumulating the NB-PDCCH, will then decode the DCI and check the PO index to see whether it matches the PO that the UE belongs to.

In another embodiment, different versions of the same PO are also indicated in the DCI. This is to help overcome the issue of uncertainty at the UE regarding when the search space starts when a NB-PDCCH repetition is larger than the PO period T_{PO} (as described in Figure 8). For example, in Figure 8, PO 1 at time t_1 can be version 1 and PO 1 at time t_3 can be version 2, these versions being distinguishable from each other by the PO identifier in the DCI so the UE is clear where the search space starts. This helps to avoid confusion of the candidates in the search space.

In another embodiment the starting time of the CSS is indicated in the DCI. This is similar to indicating the PO index (which indirectly indicates the starting time of the CSS). After decoding the DCI, the UE will determine whether the starting time of the decoded NB-PDCCH belongs to the CSS that starts at its PO or another PO. If the CSS starts at a time belonging to another PO, the UE can discard the decoded DCI.

In another embodiment, a different P-RNTI (Paging Radio Network Temporary Identifier) is used for one or more of each respective PO and each respective PO version. The P-RNTI of each respective PO and/or each respective PO version can be signalled either explicitly or implicitly (that is, derived from a reference P-RNTI). For example, in the case that a different P-RNTI is used for each respective PO, the eNB may signal a single reference P-RNTI and PO 1 will use this P-RNTI, PO 2 will use this reference P-RNTI + 1, PO 3 will use P-RNTI + 2, and so on.

In another embodiment, a scrambling applied to the NB-PDCCH is dependent upon the PO. The UE then applies a descrambler depending upon which PO it belongs to. A different scrambling may be applied to each respective PO (so as to distinguish, for example, PO 1 from PO 2, but not distinguish between different versions of PO 1 or PO 2). Alternatively, or in addition, a different scrambling may be applied to each respective PO version (so that different versions of, for example, PO 1 or PO 2 may be distinguished from each other).

It will be appreciated that various features of these embodiments may be combined as appropriate. For example, it may be the case that each respective PO is distinguished by a different scrambling, but then each version of that PO is further distinguished in the DCI.

In another embodiment of the present technique, two or more different NB-PDCCH search spaces (that is, Common Search Spaces) are configured wherein at least one of these search spaces has max repetition $R1_{MAX}$ greater than the time between two adjacent POs T_S (thus potentially causing the overlapping issue described in Figure 7) whilst the remaining search spaces have max repetition $R2_{MAX}$ smaller than T_S. In this way the search space with $R1_{MAX}$ can be segmented and interleaved with search spaces with $R2_{MAX}$. An example is shown in Figure 9, where each PO is associated with one of two types of NB-PDCCH Common Search Space (CSS) with $R1_{MAX}$ and $R2_{MAX}$, respectively. CSS1 belongs to PO1, starts at time t_1 and has a max repetition of $R1_{MAX}$ where $R1_{MAX} > T_S$, (meaning that, if measures are not taken, then CSS1 will overlap with the adjacent PO (that is, PO2)). Using the method of an embodiment, CSS1 (belonging to the first version of PO1) is segmented into 3 segments, wherein the 1st segment starts at time t_1 and ends at time t_2. The 2nd segment occupies the time t_3 to t_4, which avoids overlapping CSS2 (belonging to the first version of PO2) between time t_2 and t_3. The 3rd segment occupies time t_5 to t_6, which avoids overlapping CSS3 (belonging to the second version of PO1) between time t_4 and t_5. The segments of CSS1 are therefore interleaved with CSS2 and CSS3. CSS3 and CSS4 belong to PO1 (the second and third versions of PO1, respectively) but with a smaller maximum repetition, that is, $R2_{MAX} < T_S$, and therefore do not overlap with any adjacent PO. CSS3 and CSS4 are thus not segmented. CSS5 belongs to PO2 (in particular, the second version of PO2), and since its max repetition is greater that T_S, it is segmented and interleaved in a similar manner as that for CSS1. The example in Figure 9 shows two types of CSS (that is, with two different max repetition values). However, it should be appreciated this method is also applicable for more than two different max repetition CSSs. Also, the segments of CSS1 can be interleaved using a different pattern, for example, interleaved with different CSSs such as CSS3 and CSS4 (as shown in Figure 10).

In an embodiment, different POs have different max CSS repetitions. For example, the CSS for PO1 may have repetition $R1_{MAX} > T_S$ whilst the CSS for PO2 may have max repetition $R2_{MAX} < T_S$. In this embodiment, the CSS for PO1 is segmented and interleaved with the un-segmented CSS for PO2.

In another embodiment, all CSSs have $R1_{MAX} > T_S$. Each CSS (with $R1_{MAX}$) is segmented and the segment occupies multiple POs. That is, the CSS is spread among multiple POs. An example is shown in Figure 11, where CSS1 (belonging to PO1) has $R1_{MAX} > T_S$ and is segmented into two segments. The first segment occupies time t_1 to t_2 and the 2nd segment occupies time t_4 to t_5. Similarly, CSS5 (belonging to PO2) has $R1_{MAX} > T_S$ and is segmented into two segments. The first segment occupies time t_2 to t_3 and the 2nd segment occupies time t_6 to t_7. It should be noted that the 2nd segment length of each of CSS1 and CSS2 is less than T_S in this example.

In another embodiment, the overlapping problem shown in Figure 8 can be overcome by ensuring the Paging Occasion period $T_{PO} >$ R1max. Note that this is easier to achieve than to ensure that $T_S > R1_{MAX}$,

since T_{PO} can be much larger than T_S (for example, up to 2560 subframes) and multiple different POs may fit within the T_{PO}.

In embodiments, the segments of the NB-PDCCH search space can be defined by a predetermined pattern, this pattern being configured by the network and, for example, transmitted to the UE 104 from the eNB 101 as system information (in the System Information Block (SIB), for example). In an embodiment, the pattern may vary depending on the number of repeats of the NB-PDCCH, an identifier of the CSS which is used, or any other parameter which the UE may discern from the CSS or NB-PDCCH. The relationship between the predetermined pattern and the CSS or NB-PDCCH may be determined and transmitted to the UE 104 by the eNB 101 and may be in the form of a lookup table of the like. In another embodiment, the pattern may be fixed for the set of paging occasions associated with the UE (again, information indicative of this fixed pattern may be determined and transmitted to the UE 104 by the eNB 101).

It will thus be appreciated that, in a first embodiment, the present technique provides a terminal device 104 for use with a wireless telecommunications network. The terminal device comprises a transceiver 401, 402 and a controller 403. The controller is operable to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device (for example, the plurality of periodic paging occasions PO1 or PO2), a scheduling signal (carried by the NB-PDCCH, for example) scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network. Each periodic paging occasion associated with the terminal device is associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network. The controller is operable to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, and, if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

In one example, the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal. All periodic paging occasions associated with the terminal device may be associated with the same identifier of the scheduling signal (thus, for example, each paging occasion in the plurality of paging occasions PO1 may have the same index, each paging occasion in the plurality of paging occasions PO2 may have the same index, and so on). Alternatively, each periodic paging occasion

associated with the terminal device may be associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device (thus, for example, each paging occasion in the plurality of paging occasions PO1 may have a version number which distinguishes it from the other paging occasions in the plurality PO1, each paging occasion in the plurality of paging occasions PO2 may have a version number which distinguishes it from the other paging occasions in the plurality PO1, and so on). Any suitable identifier may be used as the paging occasion identifier, including, for example, an identifier comprising one or more of a PO index, PO version number or P-RNTI number, as previously discussed.

In another example, the characteristic of the scheduling signal is a scrambling of the scheduling signal. All periodic paging occasions associated with the terminal device may be associated with the same scrambling of the scheduling signal (thus, for example, each paging occasion in the plurality of paging occasions PO1 may be associated with the same scrambling of the scheduling signal, each paging occasion in the plurality of paging occasions PO2 may be associated with the same scrambling of the scheduling signal, and so on). Alternatively, each periodic paging occasion associated with the terminal device may be associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device (thus, for example, each paging occasion in the plurality of paging occasions PO1 may be associated with a different scrambling of the scheduling signal to the scrambling of the scheduling signal associated with the other paging occasions in the plurality PO1, each paging occasion in the plurality of paging occasions PO2 may be associated with a different scrambling of the scheduling signal to the scrambling of the scheduling signal associated with the other paging occasions in the plurality PO2, and so on).

In another example, the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space. For example, the radio search space may be a CSS and the scheduling signal may be the repeatedly transmitted NB-PDCCH. In this case the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a radio search space

with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

In this first embodiment, the present technique also provides infrastructure equipment 101 for use with a wireless telecommunications network. The infrastructure equipment comprises a transceiver 411, 412 and a controller 413. The controller is operable to control the transceiver to begin transmitting, during the one of the plurality of periodic paging occasions associated with the terminal device 104, the scheduling signal scheduling the paging message for paging the terminal device in the way as described.

It will also be appreciated that, in a second embodiment, the present technique provides a terminal device 101for use with a wireless telecommunications network. The terminal device comprises a transceiver 401, 402 and a controller 403. The controller is operable to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device (for example, the plurality of periodic paging occasions PO1 or PO2), a scheduling signal (carried by the NB-PDCCH, for example) scheduling a paging message for paging the terminal device. The scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods (in other words, the periodic repeats of the scheduling signal are segmented, as shown in Figures 9 to 11, for example), each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal. The controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

In one example, the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated. Scheduling signals with a duration of that of CSS1 or CSS 5 (shown in Figures 9 to 11) are examples of such scheduling signals.

In one example, the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network. This is shown, for example, in Figures 9 to 11, in which paging occasions belonging to the plurality PO1 are interleaved with paging occasions belonging to the plurality PO2.

In one example, the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods. In this case, for example, information indicative of the predetermined plurality of separate time periods (in other words, the segmentation pattern of the repeatedly transmitted scheduling signal) is stored in the storage medium 422 of the infrastructure equipment 101 and is signalled to the terminal device 104 using the transceiver 411, 412. The transceiver 401, 402 of the terminal device then receives the signal and the information indicative of the predetermined plurality of separate time periods is stored in the storage medium 420.

In one example, the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device. In this case, for example, there are at least two terminal devices in the wireless telecommunications network, wherein one terminal device is associated with the plurality of periodic paging occasions PO1 and the other terminal device is associated with the plurality of periodic paging occasions PO2, as shown in Figures 9 to 11. In another example, there may be no other terminal devices associated with a plurality of different periodic paging occasions (in which case, the only paging occasions present are those associated with the terminal device 104). It is noted that the present technique will still work in this case, in that if the terminal device knows the predetermined plurality of separate time periods over which the scheduling signal is repeatedly transmitted, the terminal device will know which paging occasion a particular set of repeats of the scheduling signal belongs to (thus avoiding the confusion arising from the situation shown in Figure 8, for example).

In this second embodiment, the present technique also provides infrastructure equipment 101 for use with a wireless telecommunications network. The infrastructure equipment comprises a transceiver 411, 412 and a controller 413. The controller is operable to control the transceiver to begin transmitting, during the one of the plurality of periodic paging occasions associated with a terminal device 104, the scheduling signal scheduling the paging message for paging the terminal device in the way as described.

Figure 12 illustrates a flow chart schematically showing a method according to the first embodiment of the present technique. The method starts at step 1201. At step 1202, the terminal device 104 begins receiving a scheduling signal during one of a plurality of periodic paging occasions associated with the terminal device. At step 1204, it is determined whether a value of a predetermined characteristic associated with each of the received scheduling signal and the one of the plurality of paging occasions matches. In the case that there is no match, the method ends at step 1208. On the other hand, in the case

that there is a match, the method moves on to step 1206, in which the terminal device receives a paging message scheduled by the scheduling signal. The method then ends at step 1208.

Figure 13 illustrates a flow chart schematically showing a method according to the second embodiment of the present technique. The method starts at step 1301. At step 1302, the terminal device 104 begins receiving a scheduling signal during one of a plurality of periodic paging occasions associated with the terminal device. At step 1303, the terminal device receives a predetermined number of repeats of the scheduling signal over a predetermined plurality of separate time periods. At step 1304, the terminal device receives a paging message scheduled by the scheduling signal. The method then ends at step 1305.

Features of various embodiments of the present technique are described by the following numbered clauses:

1. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

2. A terminal device according to clause 1, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

3. A terminal device according to clause 2, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

4. A terminal device according to clause 2, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

5. A terminal device according to clause 1, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

6. A terminal device according to clause 5, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

7. A terminal device according to clause 5, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

8. A terminal device according to any preceding clause, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

9. A terminal device according to clause 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space, wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a

radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

10. A terminal device according to any preceding clause, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

11. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

12. Infrastructure equipment according to clause 11, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

13. Infrastructure equipment according to clause 12, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

14. Infrastructure equipment according to clause 12, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

15. Infrastructure equipment according to clause 11, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

16. Infrastructure equipment according to clause 15, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

17. Infrastructure equipment according to clause 15, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

18. Infrastructure equipment according to any one of clauses 11 to 17, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate.

19. Infrastructure equipment according to clause 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, , wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, the starting time of the radio search space matching the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

20. Infrastructure equipment according to any one of clauses 11 to 19, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

21. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, controlling the transceiver to receive the paging message scheduled by the received scheduling message.

22. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

23. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver element to receive the paging message scheduled by the received scheduling message.

24. Integrated circuitry for infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

25. A wireless telecommunications network comprising a terminal device according to clause 1 and infrastructure equipment according to clause 11.

26. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

27. A terminal device according to clause 26, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

28. A terminal device according to clause 26 or 27, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

29. A terminal device according to any one of clauses 26 to 28, wherein the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods.

30. A terminal device according to any one of clauses 26 to 29, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

31. A terminal device according to any one of clauses 26 to 30, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

32. A terminal device according to any one of clauses 26 to 31, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

33. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

34. Infrastructure equipment according to clause 33, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the transceiver is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

35. Infrastructure equipment according to clause 33 or 34, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

36. Infrastructure equipment according to any one of claims 33 to 35, wherein the controller is operable to control the transceiver to transmit a signal to the terminal device indicative of the predetermined plurality of separate time periods.

37. Infrastructure equipment according to any one of clauses 33 to 36, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

38. Infrastructure equipment according to any one of clauses 33 to 37, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate..

39. Infrastructure equipment according to any one of clauses 33 to 38, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

40. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

transceiver is controlled to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

41. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the transceiver is controlled to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

42. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin receiving the scheduling signal; and

the controller element is operable to control the transceiver element to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

43. Integrated circuitry for operating infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller element is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin transmitting the scheduling signal.

44. A wireless telecommunications network comprising a terminal device according to clause 26 and infrastructure equipment according to clause 33.

Numerous modifications and variations of the present disclosure are possible in light of the above teachings. It is therefore to be understood that within the scope of the appended claims, the disclosure may be practiced otherwise than as specifically described herein.

In so far as embodiments of the disclosure have been described as being implemented, at least in part, by software-controlled data processing apparatus, it will be appreciated that a non-transitory machine-readable medium carrying such software, such as an optical disk, a magnetic disk, semiconductor memory or the like, is also considered to represent an embodiment of the present disclosure.

It will be appreciated that the above description for clarity has described embodiments with reference to different functional units, circuitry and/or processors. However, it will be apparent that any suitable distribution of functionality between different functional units, circuitry and/or processors may be used without detracting from the embodiments.

Described embodiments may be implemented in any suitable form including hardware, software, firmware or any combination of these. Described embodiments may optionally be implemented at least partly as computer software running on one or more data processors and/or digital signal processors. The elements and components of any embodiment may be physically, functionally and logically implemented in any suitable way. Indeed the functionality may be implemented in a single unit, in a plurality of units or as part of other functional units. As such, the disclosed embodiments may be implemented in a single unit or may be physically and functionally distributed between different units, circuitry and/or processors.

Although the present disclosure has been described in connection with some embodiments, it is not intended to be limited to the specific form set forth herein. Additionally, although a feature may appear to be described in connection with particular embodiments, one skilled in the art would recognize that various features of the described embodiments may be combined in any manner suitable to implement the technique.

Annex 1:

The simplified structure of the downlink of an LTE wireless access interface presented in Figure 2, also includes an illustration of each subframe 201, which comprises a control region 205 for the transmission of control data, a data region 206 for the transmission of user data , reference signals 207 and synchronisation signals which are interspersed in the control and data regions in accordance with a predetermined pattern. The control region 204 may contain a number of physical channels for the transmission of control data, such as a physical downlink control channel PDCCH, a physical control format indicator channel PCFICH and a physical HARQ indicator channel PHICH. The data region may contain a number of physical channel for the transmission of data, such as a physical downlink shared channel PDSCH and a physical broadcast channels PBCH. Although these physical channels provide a wide range of functionality to LTE systems, in terms of resource allocation and the present disclosure PDCCH and PDSCH are most relevant. Further information on the structure and functioning of the physical channels of LTE systems can be found in [1].

Resources within the PDSCH may be allocated by an eNodeB to UEs being served by the eNodeB. For example, a number of resource blocks of the PDSCH may be allocated to a UE in order that it may receive data that it has previously requested or data which is being pushed to it by the eNodeB, such as radio resource control RRC signalling. In Figure 2, UE1 has been allocated resources 208 of the data region 206, UE2 resources 209 and UE resources 210. UEs in a an LTE system may be allocated a fraction of the available resources of the PDSCH and therefore UEs are required to be informed of the location of their allocated resources within the PDCSH so that only relevant data within the PDSCH is detected and estimated. In order to inform the UEs of the location of their allocated communications resources, resource control information specifying downlink resource allocations is conveyed across the PDCCH in a form termed downlink control information DCI, where resource allocations for a PDSCH are communicated in a preceding PDCCH instance in the same subframe. During a resource allocation procedure, UEs thus monitor the PDCCH for DCI addressed to them and once such a DCI is detected, receive the DCI and detect and estimate the data from the relevant part of the PDSCH.

Each uplink subframe may include a plurality of different channels, for example a physical uplink shared channel PUSCH 305, a physical uplink control channel PUCCH 306, and a physical random access channel PRACH. The physical Uplink Control Channel PUCCH may carry control information such as ACK/NACK to the eNodeB for downlink transmissions, scheduling request indicators SRI for UEs wishing to be scheduled uplink resources, and feedback of downlink channel state information CSI for example. The PUSCH may carry UE uplink data or some uplink control data. Resources of the PUSCH are granted via PDCCH, such a grant being typically triggered by communicating to the network the amount of data ready to be transmitted in a buffer at the UE. The PRACH may be scheduled in any of the

resources of an uplink frame in accordance with a one of a plurality of PRACH patterns that may be signalled to UE in downlink signalling such as system information blocks. As well as physical uplink channels, uplink subframes may also include reference signals. For example, demodulation reference signals DMRS 307 and sounding reference signals SRS 308 may be present in an uplink subframe where the DMRS occupy the fourth symbol of a slot in which PUSCH is transmitted and are used for decoding of PUCCH and PUSCH data, and where SRS are used for uplink channel estimation at the eNodeB. Further information on the structure and functioning of the physical channels of LTE systems can be found in [1].

In an analogous manner to the resources of the PDSCH, resources of the PUSCH are required to be scheduled or granted by the serving eNodeB and thus if data is to be transmitted by a UE, resources of the PUSCH are required to be granted to the UE by the eNodeB. At a UE, PUSCH resource allocation is achieved by the transmission of a scheduling request or a buffer status report to its serving eNodeB. The scheduling request may be made, when there is insufficient uplink resource for the UE to send a buffer status report, via the transmission of Uplink Control Information UCI on the PUCCH when there is no existing PUSCH allocation for the UE, or by transmission directly on the PUSCH when there is an existing PUSCH allocation for the UE. In response to a scheduling request, the eNodeB is configured to allocate a portion of the PUSCH resource to the requesting UE sufficient for transferring a buffer status report and then inform the UE of the buffer status report resource allocation via a DCI in the PDCCH. Once or if the UE has PUSCH resource adequate to send a buffer status report, the buffer status report is sent to the eNodeB and gives the eNodeB information regarding the amount of data in an uplink buffer or buffers at the UE. After receiving the buffer status report, the eNodeB can allocate a portion of the PUSCH resources to the sending UE in order to transmit some of its buffered uplink data and then inform the UE of the resource allocation via a DCI in the PDCCH. For example, presuming a UE has a connection with the eNodeB, the UE will first transmit a PUSCH resource request in the PUCCH in the form of a UCI. The UE will then monitor the PDCCH for an appropriate DCI, extract the details of the PUSCH resource allocation, and transmit uplink data , at first comprising a buffer status report, and/or later comprising a portion of the buffered data, in the allocated resources.

Although similar in structure to downlink subframes, uplink subframes have a different control structure to downlink subframes, in particular the upper 309 and lower 310 subcarriers/frequencies/resource blocks of an uplink subframe are reserved for control signalling rather than the initial symbols of a downlink subframe. Furthermore, although the resource allocation procedure for the downlink and uplink are relatively similar, the actual structure of the resources that may be allocated may vary due to the different characteristics of the OFDM and SC-FDM interfaces that are used in the downlink and uplink respectively. In OFDM each subcarrier is individually modulated and therefore it is not necessary that frequency/subcarrier allocation are contiguous however, in SC-FDM subcarriers are modulation in

combination and therefore if efficient use of the available resources are to be made contiguous frequency allocations for each UE are preferable.

As a result of the above described wireless interface structure and operation, one or more UEs may communicate data to one another via a coordinating eNodeB, thus forming a conventional cellular telecommunications system. Although cellular communications system such as those based on the previously released LTE standards have been commercially successful, a number of disadvantages are associated with such centralised systems. For example, if two UEs which are in close proximity wish to communicate with each other, uplink and downlink resources sufficient to convey the data are required. Consequently, two portions of the system's resources are being used to convey a single portion of data. A second disadvantage is that an eNodeB is required if UEs, even when in close proximity, wish to communicate with one another. These limitations may be problematic when the system is experiencing high load or eNodeB coverage is not available, for instance in remote areas or when eNodeBs are not functioning correctly. Overcoming these limitations may increase both the capacity and efficiency of LTE networks but also lead to the creations of new revenue possibilities for LTE network operators.

CLAIMS

1. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

2. A terminal device according to claim 1, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

3. A terminal device according to claim 2, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

4. A terminal device according to claim 2, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

5. A terminal device according to claim 1, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

6. A terminal device according to claim 5, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

7. A terminal device according to claim 5, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

8. A terminal device according to claim 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

9. A terminal device according to claim 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space, wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

10. A terminal device according to claim 1, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

11. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

12. Infrastructure equipment according to claim 11, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

13. Infrastructure equipment according to claim 12, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

14. Infrastructure equipment according to claim 12, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

15. Infrastructure equipment according to claim 11, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

16. Infrastructure equipment according to claim 15, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

17. Infrastructure equipment according to claim 15, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

18. Infrastructure equipment according to claim 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate.

19. Infrastructure equipment according to claim 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, , wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, the starting time of the radio search space matching the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

20. Infrastructure equipment according to claim 11, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

21. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, controlling the transceiver to receive the paging message scheduled by the received scheduling message.

22. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the

plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

23. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver element to receive the paging message scheduled by the received scheduling message.

24. Integrated circuitry for infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from

a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

25. A wireless telecommunications network comprising a terminal device according to claim 1 and infrastructure equipment according to claim 11.

26. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

27. A terminal device according to claim 26, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

28. A terminal device according to claim 26, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

29. A terminal device according to claim 26, wherein the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods.

30. A terminal device according to claim 26, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

31. A terminal device according to claim 26, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

32. A terminal device according to claim 26, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

33. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

34. Infrastructure equipment according to claim 33, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the transceiver is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

35. Infrastructure equipment according to claim 33, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

36. Infrastructure equipment according to claim 33, wherein the controller is operable to control the transceiver to transmit a signal to the terminal device indicative of the predetermined plurality of separate time periods.

37. Infrastructure equipment according to claim 33, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

38. Infrastructure equipment according to claim 33, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate..

39. Infrastructure equipment according to claim 33, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

40. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the

plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

transceiver is controlled to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

41. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the transceiver is controlled to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

42. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin receiving the scheduling signal; and

the controller element is operable to control the transceiver element to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

43. Integrated circuitry for operating infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller element is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin transmitting the scheduling signal.

44. A wireless telecommunications network comprising a terminal device according to claim 26 and infrastructure equipment according to claim 33.

INTERNATIONAL SEARCH REPORT

International application No
PCT/EP2017/057758

A. CLASSIFICATION OF SUBJECT MATTER
INV. H04W68/00
ADD. H04W4/00 H04W68/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
H04W

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
EPO-Internal, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 2 999 280 A2 (APPLE INC [US]) 23 March 2016 (2016-03-23) paragraphs [0100] - [0159] ----- -/--	1-25

[X] Further documents are listed in the continuation of Box C.

[X] See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.
PCT/EP2017/057758

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

☒ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-25

   Identification of paging/scheduling signal for a given mobile terminal

   ---

2. claims: 26-44

   Avoiding interference for paging where paging signals are transmitted multiple times (Coverage Enhancement)

(54) Title: METHOD AND USER EQUIPMENT FOR RECEIVING DOWNLINK CONTROL INFORMATION, AND METHOD AND BASE STATION FOR TRANSMITTING DOWNLINK CONTROL INFORMATION

(57) **Abstract:** A search space (hereinafter, CSS) for a control channel for scheduling a random access response may be configured by a system information block. A user equipment (UE) may attempt to receive a control channel for a random access response on the assumption that CSS is configured in accordance with a configuration based on the system information block. The UE may attempt to receive the control channel within a UE-specific search space (USS) by assuming that the USS is configured in accordance with the configuration of the CSS until a configuration for the USS is received.

WO 2017/052199 A1

Description

Title of Invention: METHOD AND USER EQUIPMENT FOR RECEIVING DOWNLINK CONTROL INFORMATION, AND METHOD AND BASE STATION FOR TRANSMITTING DOWNLINK CONTROL INFORMATION

Technical Field

[1] The present invention relates to a wireless communication system, and more particularly, to a method for transmitting or receiving downlink control information and a device therefor.

Background Art

[2] With appearance and spread of machine-to-machine (M2M) communication and a variety of devices such as smartphones and tablet PCs and technology demanding a large amount of data transmission, data throughput needed in a cellular network has rapidly increased. To satisfy such rapidly increasing data throughput, carrier aggregation technology, cognitive radio technology, etc. for efficiently employing more frequency bands and multiple input multiple output (MIMO) technology, multi-base station (BS) cooperation technology, etc. for raising data capacity transmitted on limited frequency resources have been developed.

[3] A general wireless communication system performs data transmission/reception through one downlink (DL) band and through one uplink (UL) band corresponding to the DL band (in case of a frequency division duplex (FDD) mode), or divides a prescribed radio frame into a UL time unit and a DL time unit in the time domain and then performs data transmission/reception through the UL/DL time unit (in case of a time division duplex (TDD) mode). A base station (BS) and a user equipment (UE) transmit and receive data and/or control information scheduled on a prescribed time unit basis, e.g. on a subframe basis. The data is transmitted and received through a data region configured in a UL/DL subframe and the control information is transmitted and received through a control region configured in the UL/DL subframe. To this end, various physical channels carrying radio signals are formed in the UL/DL subframe. In contrast, carrier aggregation technology serves to use a wider UL/DL bandwidth by aggregating a plurality of UL/DL frequency blocks in order to use a broader frequency band so that more signals relative to signals when a single carrier is used can be simultaneously processed.

[4] In addition, a communication environment has evolved into increasing density of nodes accessible by a user at the periphery of the nodes. A node refers to a fixed point

capable of transmitting/receiving a radio signal to/from the UE through one or more antennas. A communication system including high-density nodes may provide a better communication service to the UE through cooperation between the nodes.

Disclosure of Invention

Technical Problem

[5] Due to introduction of new radio communication technology, the number of user equipments (UEs) to which a BS should provide a service in a prescribed resource region increases and the amount of data and control information that the BS should transmit to the UEs increases. Since the amount of resources available to the BS for communication with the UE(s) is limited, a new method in which the BS efficiently receives/transmits uplink/downlink data and/or uplink/downlink control information using the limited radio resources is needed.

[6] The technical objects that can be achieved through the present invention are not limited to what has been particularly described hereinabove and other technical objects not described herein will be more clearly understood by persons skilled in the art from the following detailed description.

Solution to Problem

[7] A search space (hereinafter, CSS_RAR) for a control channel for scheduling a random access response may be configured by a system information block. A user equipment (UE) may attempt to receive a control channel for a random access response by assuming that CSS_RAR is configured in accordance with a configuration based on the system information block. If the UE receives the control channel for a random access response, the UE may receive the random access response to a random access preamble transmitted therefrom in accordance with control information carried by the control channel. The UE may attempt to receive a control channel within a UE-specific search space (hereinafter, USS) by assuming that the USS is configured in accordance with the configuration of the CSS until a configuration for the USS is received.

[8] In an aspect of the present invention, provided herein is a method for receiving, by a user equipment (UE), downlink control information (DCI) for the UE. The method comprises: receiving, by the UE, a common search space configuration for a common search space; receiving, by the UE, a first physical downlink control channel (PDCCH) scheduling a random access response; and receiving, by the UE, a second PDCCH carrying the DCI for the UE. The UE can monitor first PDCCH candidates of the common search space according to the common search space configuration in order to receive the first PDCCH. The UE can monitor second PDCCH candidates of a UE-specific search space in order to receive the second PDCCH. The UE can assume that configuration of the UE-specific search space is the same as that of the common search

space until the UE receives a UE-specific search space configuration.

[9] In another aspect of the present invention, provided herein is a method for transmitting, by a base station (BS), downlink control information (DCI) for a user equipment (UE). The method comprises: transmitting, by the BS, common search space configuration for a common search space; transmitting, by the BS to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response; and transmitting, by the BS to the UE, a second PDCCH carrying the DCI for the UE. The BS can transmit the first PDCCH by using one of first PDCCH candidates of the common search space according to the common search space configuration. The BS can transmit the second PDCCH by using one of second PDCCH candidates of a UE-specific search space. The BS can configure the UE-specific search space according to the same configuration as the common search space configuration until the BS transmits a UE-specific search space configuration to the UE.

[10] In still another aspect of the present invention, provided herein a user equipment (UE) for receiving downlink control information (DCI) for the UE. The UE comprises a radio frequency (RF) unit and a processor connected to the RF unit. The processor can be configured to control the RF unit to receive common search space configuration for a common search space; control the RF unit to receive a first physical downlink control channel (PDCCH) scheduling a random access response; and control the RF unit to receive a second PDCCH carrying the DCI for the UE. The processor can be configured to monitor first PDCCH candidates of the common search space according to the common search space configuration in order to detect the firs PDCCH. The processor can be configured to monitor second PDCCH candidates of a UE-specific search space in order to detect the second PDCCH. The processor can be configured to assume that configuration of the UE-specific search space is the same as that of the common search space until the UE receives a UE-specific search space configuration.

[11] In a further aspect of the present invention, provided herein a base station (BS) for transmitting downlink control information (DCI) for a user equipment (UE). The BS comprises a radio frequency (RF) unit and a processor connected to the RF unit. The processor can be configured to control the RF unit to transmit common search space configuration for a common search space; control the RF unit to transmit a first physical downlink control channel (PDCCH) scheduling a random access response; and control the RF unit to transmit a second PDCCH carrying the DCI for the UE. The processor can be configured to control the RF unit to transmit the first PDCCH using one of first PDCCH candidates of the common search space according to the common search space configuration. The processor can be configured to control the RF unit to transmit the second PDCCH using one of second PDCCH candidates of a UE-specific search space. The processor can configure the UE-specific search space according to

the same as that of the common search space until the BS transmits a UE-specific search space configuration.

[12] In each aspect of the present invention, the common search space configuration can include information on a narrowband for the common search space. The second PDCCH candidates of the UE-specific search space can be configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[13] In each aspect of the present invention, the common search space configuration can include information on a maximum number of repetitions for the first common search space. The second PDCCH candidates of the UE-specific search space can be configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.

[14] In each aspect of the present invention, the common search space configuration can include information on a first physical resource block (PRB) set for transmitting the first PDCCH. The same physical resource block set as the first PRB set can be used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE

[15] In each aspect of the present invention, the first PDCCH candidates of the common search space can be configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, whereas the second PDCCH candidates of the UE-specific search space can be configured according to the plurality of aggregation levels.

[16] In each aspect of the present invention, the UE can transmit a random access preamble using a physical random access channel (PRACH) resource. The UE can monitor the first PDCCH candidates in response to transmission of the random access preamble. The UE can receive the random access response according to control information carried by the first PDCCH. The BS can receive a random access preamble using a physical random access channel (PRACH) resource. The BS can transmit the first PDCCH in response to reception of the random access preamble. The BS can transmit the random access response according to control information carried by the first PDCCH.

[17] The above technical solutions are merely some parts of the embodiments of the present invention and various embodiments into which the technical features of the present invention are incorporated can be derived and understood by persons skilled in the art from the following detailed description of the present invention.

Advantageous Effects of Invention

[18] According to the present invention, uplink/downlink signals can be efficiently transmitted/received. Therefore, overall throughput of a radio communication system can be improved.

[19] According to one embodiment of the present invention, a low cost/complexity UE can perform communication with a BS at low cost while maintaining compatibility with a legacy system.

[20] According to one embodiment of the present invention, the UE can be implemented at low cost/complexity.

[21] According to one embodiment of the present invention, coverage can be enhanced.

[22] According to one embodiment of the present invention, the UE and the BS can perform communication with each other at a narrowband.

[23] It will be appreciated by persons skilled in the art that that the effects that can be achieved through the present invention are not limited to what has been particularly described hereinabove and other advantages of the present invention will be more clearly understood from the following detailed description.

Brief Description of Drawings

[24] The accompanying drawings, which are included to provide a further understanding of the invention, illustrate embodiments of the invention and together with the description serve to explain the principle of the invention.

[25] FIG. 1 illustrates the structure of a radio frame used in a wireless communication system.

[26] FIG. 2 illustrates the structure of a downlink (DL)/uplink (UL) slot in a wireless communication system.

[27] FIG. 3 illustrates a radio frame structure for transmission of a synchronization signal (SS).

[28] FIG. 4 illustrates the structure of a DL subframe used in a wireless communication system.

[29] FIG. 5 illustrates the structure of a UL subframe used in a wireless communication system.

[30] FIG. 6 illustrates an example of a signal band for MTC.

[31] FIG. 7 illustrates repeated transmission of a channel for coverage enhancement.

[32] FIG. 8 illustrates a configuration of a common search space (CSS) for paging according to the present invention.

[33] FIG. 9 illustrates a configuration of a common search space (CSS) for random access response (RAR) according to the present invention.

[34] FIG. 10 illustrates the example of the monitoring time region of USS and CSS.

[35] FIG. 11 illustrates a procedure of configuring a search space according to the present

invention.

[36] FIG. 12 illustrates a configuration of M-PDCCH repeated transmission according to the present invention.

[37] FIG. 13 is a block diagram illustrating elements of a transmitting device 10 and a receiving device 20 for implementing the present invention.

Mode for the Invention

[38] Reference will now be made in detail to the exemplary embodiments of the present invention, examples of which are illustrated in the accompanying drawings. The detailed description, which will be given below with reference to the accompanying drawings, is intended to explain exemplary embodiments of the present invention, rather than to show the only embodiments that can be implemented according to the invention. The following detailed description includes specific details in order to provide a thorough understanding of the present invention. However, it will be apparent to those skilled in the art that the present invention may be practiced without such specific details.

[39] In some instances, known structures and devices are omitted or are shown in block diagram form, focusing on important features of the structures and devices, so as not to obscure the concept of the present invention. The same reference numbers will be used throughout this specification to refer to the same or like parts.

[40] The following techniques, apparatuses, and systems may be applied to a variety of wireless multiple access systems. Examples of the multiple access systems include a code division multiple access (CDMA) system, a frequency division multiple access (FDMA) system, a time division multiple access (TDMA) system, an orthogonal frequency division multiple access (OFDMA) system, a single carrier frequency division multiple access (SC-FDMA) system, and a multicarrier frequency division multiple access (MC-FDMA) system. CDMA may be embodied through radio technology such as universal terrestrial radio access (UTRA) or CDMA2000. TDMA may be embodied through radio technology such as global system for mobile communications (GSM), general packet radio service (GPRS), or enhanced data rates for GSM evolution (EDGE). OFDMA may be embodied through radio technology such as institute of electrical and electronics engineers (IEEE) 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802.20, or evolved UTRA (E-UTRA). UTRA is a part of a universal mobile telecommunications system (UMTS). 3rd generation partnership project (3GPP) long term evolution (LTE) is a part of evolved UMTS (E-UMTS) using E-UTRA. 3GPP LTE employs OFDMA in DL and SC-FDMA in UL. LTE-advanced (LTE-A) is an evolved version of 3GPP LTE. For convenience of description, it is assumed that the present invention is applied to 3GPP LTE/LTE-A. However, the

technical features of the present invention are not limited thereto. For example, although the following detailed description is given based on a mobile communication system corresponding to a 3GPP LTE/LTE-A system, aspects of the present invention that are not specific to 3GPP LTE/LTE-A are applicable to other mobile communication systems.

[41] For example, the present invention is applicable to contention based communication such as Wi-Fi as well as non-contention based communication as in the 3GPP LTE/LTE-A system in which an eNB allocates a DL/UL time/frequency resource to a UE and the UE receives a DL signal and transmits a UL signal according to resource allocation of the eNB. In a non-contention based communication scheme, an access point (AP) or a control node for controlling the AP allocates a resource for communication between the UE and the AP, whereas, in a contention based communication scheme, a communication resource is occupied through contention between UEs which desire to access the AP. The contention based communication scheme will now be described in brief. One type of the contention based communication scheme is carrier sense multiple access (CSMA). CSMA refers to a probabilistic media access control (MAC) protocol for confirming, before a node or a communication device transmits traffic on a shared transmission medium (also called a shared channel) such as a frequency band, that there is no other traffic on the same shared transmission medium. In CSMA, a transmitting device determines whether another transmission is being performed before attempting to transmit traffic to a receiving device. In other words, the transmitting device attempts to detect presence of a carrier from another transmitting device before attempting to perform transmission. Upon sensing the carrier, the transmitting device waits for another transmission device which is performing transmission to finish transmission, before performing transmission thereof. Consequently, CSMA can be a communication scheme based on the principle of "sense before transmit" or "listen before talk". A scheme for avoiding collision between transmitting devices in the contention based communication system using CSMA includes carrier sense multiple access with collision detection (CSMA/CD) and/or carrier sense multiple access with collision avoidance (CSMA/CA). CSMA/CD is a collision detection scheme in a wired local area network (LAN) environment. In CSMA/CD, a personal computer (PC) or a server which desires to perform communication in an Ethernet environment first confirms whether communication occurs on a network and, if another device carries data on the network, the PC or the server waits and then transmits data. That is, when two or more users (e.g. PCs, UEs, etc.) simultaneously transmit data, collision occurs between simultaneous transmission and CSMA/CD is a scheme for flexibly transmitting data by monitoring collision. A transmitting device using CSMA/CD adjusts data transmission thereof by sensing data transmission performed by another

device using a specific rule. CSMA/CA is a MAC protocol specified in IEEE 802.11 standards. A wireless LAN (WLAN) system conforming to IEEE 802.11 standards does not use CSMA/CD which has been used in IEEE 802.3 standards and uses CA, i.e. a collision avoidance scheme. Transmission devices always sense carrier of a network and, if the network is empty, the transmission devices wait for determined time according to locations thereof registered in a list and then transmit data. Various methods are used to determine priority of the transmission devices in the list and to re-configure priority. In a system according to some versions of IEEE 802.11 standards, collision may occur and, in this case, a collision sensing procedure is performed. A transmission device using CSMA/CA avoids collision between data transmission thereof and data transmission of another transmission device using a specific rule.

[42] In the present invention, a user equipment (UE) may be a fixed or mobile device. Examples of the UE include various devices that transmit and receive user data and/or various kinds of control information to and from a base station (BS). The UE may be referred to as a terminal equipment (TE), a mobile station (MS), a mobile terminal (MT), a user terminal (UT), a subscriber station (SS), a wireless device, a personal digital assistant (PDA), a wireless modem, a handheld device, etc. In addition, in the present invention, a BS generally refers to a fixed station that performs communication with a UE and/or another BS, and exchanges various kinds of data and control information with the UE and another BS. The BS may be referred to as an advanced base station (ABS), a node-B (NB), an evolved node-B (eNB), a base transceiver system (BTS), an access point (AP), a processing server (PS), etc. In describing the present invention, a BS will be referred to as an eNB.

[43] In the present invention, a node refers to a fixed point capable of transmitting/ receiving a radio signal through communication with a UE. Various types of eNBs may be used as nodes irrespective of the terms thereof. For example, a BS, a node B (NB), an e-node B (eNB), a pico-cell eNB (PeNB), a home eNB (HeNB), a relay, a repeater, etc. may be a node. In addition, the node may not be an eNB. For example, the node may be a radio remote head (RRH) or a radio remote unit (RRU). The RRH or RRU generally has a lower power level than a power level of an eNB. Since the RRH or RRU (hereinafter, RRH/RRU) is generally connected to the eNB through a dedicated line such as an optical cable, cooperative communication between RRH/ RRU and the eNB can be smoothly performed in comparison with cooperative communication between eNBs connected by a radio line. At least one antenna is installed per node. The antenna may mean a physical antenna or mean an antenna port, a virtual antennIn the present invention, a cell refers to a prescribed geographical area to which one or more nodes provide a communication service. Accordingly, in the present invention, communicating with a specific cell may mean communicating with an eNB

or a node which provides a communication service to the specific cell. In addition, a DL/UL signal of a specific cell refers to a DL/UL signal from/to an eNB or a node which provides a communication service to the specific cell. A node providing UL/DL communication services to a UE is called a serving node and a cell to which UL/DL communication services are provided by the serving node is especially called a serving cell. Furthermore, channel status/quality of a specific cell refers to channel status/ quality of a channel or communication link formed between an eNB or node which provides a communication service to the specific cell and a UE. The UE may measure DL channel state received from a specific node using cell-specific reference signal(s) (CRS(s)) transmitted on a CRS resource and/or channel state information reference signal(s) (CSI-RS(s)) transmitted on a CSI-RS resource, allocated by antenna port(s) of the specific node to the specific node. Detailed CSI-RS configuration may be understood with reference to 3GPP TS 36.211 and 3GPP TS 36.331 documents.

[44] Meanwhile, a 3GPP LTE/LTE-A system uses the concept of a cell in order to manage radio resources and a cell associated with the radio resources is distinguished from a cell of a geographic region.

[45] A "cell" of a geographic region may be understood as coverage within which a node can provide service using a carrier and a "cell" of a radio resource is associated with bandwidth (BW) which is a frequency range configured by the carrier. Since DL coverage, which is a range within which the node is capable of transmitting a valid signal, and UL coverage, which is a range within which the node is capable of receiving the valid signal from the UE, depends upon a carrier carrying the signal, the coverage of the node may be associated with coverage of the "cell" of a radio resource used by the node. Accordingly, the term "cell" may be used to indicate service coverage of the node sometimes, a radio resource at other times, or a range that a signal using a radio resource can reach with valid strength at other times. The "cell" of the radio resource will be described later in more detail.

[46] 3GPP LTE/LTE-A standards define DL physical channels corresponding to resource elements carrying information derived from a higher layer and DL physical signals corresponding to resource elements which are used by a physical layer but which do not carry information derived from a higher layer. For example, a physical downlink shared channel (PDSCH), a physical broadcast channel (PBCH), a physical multicast channel (PMCH), a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), and a physical hybrid ARQ indicator channel (PHICH) are defined as the DL physical channels, and a reference signal and a synchronization signal are defined as the DL physical signals. A reference signal (RS), also called a pilot, refers to a special waveform of a predefined signal known to both a BS and a UE. For example, a cell-specific RS (CRS), a UE-specific RS (UE-RS), a po-

sitioning RS (PRS), and channel state information RS (CSI-RS) may be defined as DL RSs. Meanwhile, the 3GPP LTE/LTE-A standards define UL physical channels corresponding to resource elements carrying information derived from a higher layer and UL physical signals corresponding to resource elements which are used by a physical layer but which do not carry information derived from a higher layer. For example, a physical uplink shared channel (PUSCH), a physical uplink control channel (PUCCH), and a physical random access channel (PRACH) are defined as the UL physical channels, and a demodulation reference signal (DM RS) for a UL control/data signal and a sounding reference signal (SRS) used for UL channel measurement are defined as the UL physical signals.

[47] In the present invention, a physical downlink control channel (PDCCH), a physical control format indicator channel (PCFICH), a physical hybrid automatic retransmit request indicator channel (PHICH), and a physical downlink shared channel (PDSCH) refer to a set of time-frequency resources or resource elements (REs) carrying downlink control information (DCI), a set of time-frequency resources or REs carrying a control format indicator (CFI), a set of time-frequency resources or REs carrying downlink acknowledgement (ACK)/negative ACK (NACK), and a set of time-frequency resources or REs carrying downlink data, respectively. In addition, a physical uplink control channel (PUCCH), a physical uplink shared channel (PUSCH) and a physical random access channel (PRACH) refer to a set of time-frequency resources or REs carrying uplink control information (UCI), a set of time-frequency resources or REs carrying uplink data and a set of time-frequency resources or REs carrying random access signals, respectively. In the present invention, in particular, a time-frequency resource or RE that is assigned to or belongs to PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH is referred to as PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH RE or PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH time-frequency resource, respectively. Therefore, in the present invention, PUCCH/PUSCH/PRACH transmission of a UE is conceptually identical to UCI/uplink data/random access signal transmission on PUSCH/PUCCH/PRACH, respectively. In addition, PDCCH/PCFICH/PHICH/PDSCH transmission of an eNB is conceptually identical to downlink data/DCI transmission on PDCCH/PCFICH/PHICH/PDSCH, respectively.

[48] Hereinafter, OFDM symbol/subcarrier/RE to or for which CRS/DMRS/CSI-RS/SRS/UE-RS/TRS is assigned or configured will be referred to as CRS/DMRS/CSI-RS/SRS/UE-RS/TRS symbol/carrier/subcarrier/RE. For example, an OFDM symbol to or for which a tracking RS (TRS) is assigned or configured is referred to as a TRS symbol, a subcarrier to or for which the TRS is assigned or configured is referred to as a TRS subcarrier, and an RE to or for which the TRS is

assigned or configured is referred to as a TRS RE. In addition, a subframe configured for transmission of the TRS is referred to as a TRS subframe. Moreover, a subframe in which a broadcast signal is transmitted is referred to as a broadcast subframe or a PBCH subframe and a subframe in which a synchronization signal (e.g. PSS and/or SSS) is transmitted is referred to a synchronization signal subframe or a PSS/SSS subframe. OFDM symbol/subcarrier/RE to or for which PSS/SSS is assigned or configured is referred to as PSS/SSS symbol/subcarrier/RE, respectively.

[49] In the present invention, a CRS port, a UE-RS port, a CSI-RS port, and a TRS port refer to an antenna port configured to transmit a CRS, an antenna port configured to transmit a UE-RS, an antenna port configured to transmit a CSI-RS, and an antenna port configured to transmit a TRS, respectively. Antenna ports configured to transmit CRSs may be distinguished from each other by the locations of REs occupied by the CRSs according to CRS ports, antenna ports configured to transmit UE-RSs may be distinguished from each other by the locations of REs occupied by the UE-RSs according to UE-RS ports, and antenna ports configured to transmit CSI-RSs may be distinguished from each other by the locations of REs occupied by the CSI-RSs according to CSI-RS ports. Therefore, the term CRS/UE-RS/CSI-RS/TRS ports may also be used to indicate a pattern of REs occupied by CRSs/UE-RSs/CSI-RSs/TRSs in a predetermined resource region. In the present invention, both a DMRS and a UE-RS refer to RSs for demodulation and, therefore, the terms DMRS and UE-RS are used to refer to RSs for demodulation.

[50] FIG. 1 illustrates the structure of a radio frame used in a wireless communication system.

[51] Specifically, FIG. 1(a) illustrates an exemplary structure of a radio frame which can be used in frequency division multiplexing (FDD) in 3GPP LTE/LTE-A and FIG. 1(b) illustrates an exemplary structure of a radio frame which can be used in time division multiplexing (TDD) in 3GPP LTE/LTE-A.

[52] Referring to FIG. 1, a 3GPP LTE/LTE-A radio frame is 10ms ($307,200T_s$) in duration. The radio frame is divided into 10 subframes of equal size. Subframe numbers may be assigned to the 10 subframes within one radio frame, respectively. Here, T_s denotes sampling time where T_s=1/(2048*15kHz). Each subframe is 1ms long and is further divided into two slots. 20 slots are sequentially numbered from 0 to 19 in one radio frame. Duration of each slot is 0.5ms. A time interval in which one subframe is transmitted is defined as a transmission time interval (TTI). Time resources may be distinguished by a radio frame number (or radio frame index), a subframe number (or subframe index), a slot number (or slot index), and the like.

[53] A radio frame may have different configurations according to duplex modes. In FDD mode for example, since DL transmission and UL transmission are discriminated

according to frequency, a radio frame for a specific frequency band operating on a carrier frequency includes either DL subframes or UL subframes. In TDD mode, since DL transmission and UL transmission are discriminated according to time, a radio frame for a specific frequency band operating on a carrier frequency includes both DL subframes and UL subframes.

[54] Table 1 shows an exemplary UL-DL configuration within a radio frame in TDD mode.

[55] [Table 1]

DL-UL configuration	Downlink-to-Uplink Switch-point periodicity	Subframe number									
		0	1	2	3	4	5	6	7	8	9
0	5ms	D	S	U	U	U	D	S	U	U	U
1	5ms	D	S	U	U	D	D	S	U	U	D
2	5ms	D	S	U	D	D	D	S	U	D	D
3	10ms	D	S	U	U	U	D	D	D	D	D
4	10ms	D	S	U	U	D	D	D	D	D	D
5	10ms	D	S	U	D	D	D	D	D	D	D
6	5ms	D	S	U	U	U	D	S	U	U	D

[56] In Table 1, D denotes a DL subframe, U denotes a UL subframe, and S denotes a special subframe. The special subframe includes three fields, i.e. downlink pilot time slot (DwPTS), guard period (GP), and uplink pilot time slot (UpPTS). DwPTS is a time slot reserved for DL transmission and UpPTS is a time slot reserved for UL transmission. Table 2 shows an example of the special subframe configuration.

[57] [Table 2]

Special subframe configuration	Normal cyclic prefix in downlink			Extended cyclic prefix in downlink		
	DwPTS	UpPTS		DwPTS	UpPTS	
		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink

[58] FIG. 2 illustrates the structure of a DL/UL slot structure in a wireless communication system.

[59] Referring to FIG. 2, a slot includes a plurality of orthogonal frequency division multiplexing (OFDM) symbols in the time domain and includes a plurality of resource blocks (RBs) in the frequency domain. The OFDM symbol may refer to one symbol duration. Referring to FIG. 2, a signal transmitted in each slot may be expressed by a resource grid including $N^{DL/UL}_{RB} * N^{RB}_{sc}$ subcarriers and $N^{DL/UL}_{symb}$ OFDM symbols. N^{DL}_{RB} denotes the number of RBs in a DL slot and N^{UL}_{RB} denotes the number of RBs in a UL slot. N^{DL}_{RB} and N^{UL}_{RB} depend on a DL transmission bandwidth and a UL transmission bandwidth, respectively. N^{DL}_{symb} denotes the number of OFDM symbols in a DL slot, N^{UL}_{symb} denotes the number of OFDM symbols in a UL slot, and N^{RB}_{sc} denotes the number of subcarriers configuring one RB.

[60] An OFDM symbol may be referred to as an OFDM symbol, a single carrier frequency division multiplexing (SC-FDM) symbol, etc. according to multiple access schemes. The number of OFDM symbols included in one slot may be varied according to channel bandwidths and CP lengths. For example, in a normal cyclic prefix (CP) case, one slot includes 7 OFDM symbols. In an extended CP case, one slot includes 6

OFDM symbols. Although one slot of a subframe including 7 OFDM symbols is shown in FIG. 2 for convenience of description, embodiments of the present invention are similarly applicable to subframes having a different number of OFDM symbols. Referring to FIG. 2, each OFDM symbol includes $N^{DL/UL}_{RB} * N^{RB}_{sc}$ subcarriers in the frequency domain. The type of the subcarrier may be divided into a data subcarrier for data transmission, a reference signal (RS) subcarrier for RS transmission, and a null subcarrier for a guard band and a DC component. The null subcarrier for the DC component is unused and is mapped to a carrier frequency f_0 in a process of generating an OFDM signal or in a frequency up-conversion process. The carrier frequency is also called a center frequency f_c.

[61] One RB is defined as $N^{DL/UL}_{symb}$ (e.g. 7) consecutive OFDM symbols in the time domain and as N^{RB}_{sc} (e.g. 12) consecutive subcarriers in the frequency domain. For reference, a resource composed of one OFDM symbol and one subcarrier is referred to a resource element (RE) or tone. Accordingly, one RB includes $N^{DL/UL}_{symb} * N^{RB}_{sc}$ REs. Each RE within a resource grid may be uniquely defined by an index pair (k, l) within one slot. k is an index ranging from 0 to $N^{DL/UL}_{RB} * N^{RB}_{sc} - 1$ in the frequency domain, and l is an index ranging from 0 to $N^{DL/UL}_{symb} - 1$ in the time domain.

[62] Meanwhile, one RB is mapped to one physical resource block (PRB) and one virtual resource block (VRB). A PRB is defined as N^{DL}_{symb} (e.g. 7) consecutive OFDM or SC-FDM symbols in the time domain and N^{RB}_{sc} (e.g. 12) consecutive subcarriers in the frequency domain. Accordingly, one PRB is configured with $N^{DL/UL}_{symb} * N^{RB}_{sc}$ REs. In one subframe, two RBs each located in two slots of the subframe while occupying the same N^{RB}_{sc} consecutive subcarriers are referred to as a physical resource block (PRB) pair. Two RBs configuring a PRB pair have the same PRB number (or the same PRB index).

[63] FIG. 3 illustrates a radio frame structure for transmission of a synchronization signal (SS). Specifically, FIG. 3 illustrates a radio frame structure for transmission of an SS and a PBCH in frequency division duplex (FDD), wherein FIG. 3(a) illustrates transmission locations of an SS and a PBCH in a radio frame configured as a normal cyclic prefix (CP) and FIG. 3(b) illustrates transmission locations of an SS and a PBCH in a radio frame configured as an extended CP.

[64] If a UE is powered on or newly enters a cell, the UE performs an initial cell search procedure of acquiring time and frequency synchronization with the cell and detecting a physical cell identity N^{cell}_{ID} of the cell. To this end, the UE may establish synchronization with the eNB by receiving synchronization signals, e.g. a primary synchronization signal (PSS) and a secondary synchronization signal (SSS), from the eNB and obtain information such as a cell identity (ID).

[65] An SS will be described in more detail with reference to FIG. 3. An SS is categorized

into a PSS and an SSS. The PSS is used to acquire time-domain synchronization of OFDM symbol synchronization, slot synchronization, etc. and/or frequency-domain synchronization and the SSS is used to acquire frame synchronization, a cell group ID, and/or CP configuration of a cell (i.e. information as to whether a normal CP is used or an extended CP is used). Referring to FIG. 3, each of a PSS and an SSS is transmitted on two OFDM symbols of every radio frame. More specifically, SSs are transmitted in the first slot of subframe 0 and the first slot of subframe 5, in consideration of a global system for mobile communication (GSM) frame length of 4.6 ms for facilitation of inter-radio access technology (inter-RAT) measurement. Especially, a PSS is transmitted on the last OFDM symbol of the first slot of subframe 0 and on the last OFDM symbol of the first slot of subframe 5 and an SSS is transmitted on the second to last OFDM symbol of the first slot of subframe 0 and on the second to last OFDM symbol of the first slot of subframe 5. A boundary of a corresponding radio frame may be detected through the SSS. The PSS is transmitted on the last OFDM symbol of a corresponding slot and the SSS is transmitted on an OFDM symbol immediately before an OFDM symbol on which the PSS is transmitted. A transmit diversity scheme of an SS uses only a single antenna port and standards therefor are not separately defined. That is, a single antenna port transmission scheme or a transmission scheme transparent to a UE (e.g. precoding vector switching (PVS), time switched transmit diversity (TSTD), or cyclic delay diversity (CDD)) may be used for transmit diversity of an SS.

[66] Upon detecting a PSS, a UE may discern that a corresponding subframe is one of subframe 0 and subframe 5 because the PSS is transmitted every 5ms but the UE cannot discern whether the subframe is subframe 0 or subframe 5. Accordingly, the UE cannot recognize the boundary of a radio frame only by the PSS. That is, frame synchronization cannot be acquired only by the PSS. The UE detects the boundary of a radio frame by detecting an SSS which is transmitted twice in one radio frame with different sequences.

[67] The UE, which has determined time and frequency parameters necessary for demodulating a DL signal and transmitting a UL signal at an accurate time by performing a cell search procedure using PSS/SSS, can communicate with the eNB only after acquiring system information necessary for system configuration of the UE from the eNB.

[68] The system information is configured by a master information block (MIB) and system information blocks (SIBs). Each SIB includes a set of functionally associated parameters and is categorized into an MIB, SIB Type 1 (SIB 1), SIB Type 2 (SIB2), and SIB3 to SIB17 in accordance with the parameters.

[69] The MIB includes most frequently transmitted parameters which are essential for

initial access of the UE to a network of the eNB. The UE may receive the MIB through a broadcast channel (e.g. PBCH). The MIB includes a DL bandwidth (BW), PHICH configuration, and a system frame number (SFN). Accordingly, the UE may be explicitly aware of information about the DL BW, SFN, and PHICH configuration by receiving the MIB. Meanwhile, information which may be implicitly recognized by the UE through reception of the PBCH includes the number of transmit antenna ports of the eNB. Information about the number of transmit antennas of the eNB is implicitly signaled by masking (e.g. XOR operation) a sequence corresponding to the number of transmit antennas to a 16-bit cyclic redundancy check (CRC) used for error detection of the PBCH.

[70] The SIB1 includes parameters needed to determine if a specific cell is suitable for cell selection, as well as information about time-domain scheduling of the other SIBs. The SIB1 is received by the UE through broadcast signaling or dedicated signaling.

[71] DL carrier frequency and corresponding system bandwidth may be acquired by the MIB carried by the PBCH. UL carrier frequency and corresponding system bandwidth may be acquired by system information which is a DL signal. The UE which has received the MIB applies a DL BW value within the MIB to a UL-bandwidth (UL BW) until system information block type 2 (SystemInformationBlockType2, SIB2) is received if there is no valid system information stored in a corresponding cell. For example, the UE may identify a full UL system band, which may be used by itself for UL transmission, through UL-carrier frequency and UL-bandwidth information within the SIB2 by acquiring system information block type 2 (SystemInformationBlockType2, SIB2).

[72] In the frequency domain, a PSS/SSS and a PBCH are transmitted only in a total of 6 RBs, i.e. a total of 72 subcarriers, irrespective of actual system BW, wherein 3 RBs are in the left and the other 3 RBs are in the right centering on a DC subcarrier on corresponding OFDM symbols. Therefore, the UE is configured to detect or decode the SS and the PBCH irrespective of DL BW configured for the UE.

[73] After initial cell search, the UE may perform a random access procedure to complete access to the eNB. To this end, the UE may transmit a preamble through a physical random access channel (PRACH) and receive a response message to the preamble through a PDCCH and a PDSCH. In contention based random access, the UE may perform additional PRACH transmission and a contention resolution procedure of a PDCCH and a PDSCH corresponding to the PDCCH.

[74] After performing the aforementioned procedure, the UE may perform PDDCH/PDSCH reception and PUSCH/PUCCH transmission as general uplink/downlink transmission procedures.

[75] The random access procedure is also called RACH (random access channel)

procedure. The random access procedure is used for initial access, uplink synchronization adjustment, resource assignment, handover, etc. The random access procedure is classified into a contention-based process and a dedicated (i.e. non-contention-based) process. The contention-based random access procedure includes initial access and is normally used, whereas the dedicated random access procedure is limitedly used for handover. In the contention-based random access procedure, a UE randomly select a RACH preamble sequence. Accordingly, a plurality of UEs can simultaneously transmit the same RACH preamble sequence and thus a contention resolution procedure is not needed. In the dedicated random access procedure, a UE uses a RACH preamble sequence uniquely allocated thereto by an eNB. Accordingly, the UE can perform the random access procedure without colliding with other UEs.

[76] The contention-based random access procedure has the following four steps. Hereinafter, messages transmitted in steps 1 to 4 may be respectively referred to as Msg 1 to Msg 4.

[77] - Step 1: RACH preamble (via PRACH) (UE to eNB)

[78] - Step 2: Random access response (RAR) (via PDCCH and PDSCH) (eNB to UE)

[79] - Step 3: Layer 2/Layer 3 message (via PUSCH) (UE to eNB)

[80] - Step 4: Contention resolution message (eNB to UE)

[81] The dedicated random access procedure includes the following three steps. Hereinafter, uplink transmission (i.e. step 3) corresponding to a RAR may be performed as a part of the random access procedure. The dedicated random access procedure can be triggered using a PDCCH (hereinafter, referred to as PDCCH order) used for an eNB to command RACH preamble transmission.

[82] - Step 0: PACH preamble allocation through dedicated signaling (eNB to UE)

[83] - Step 1: RACH preamble (via PRACH) (UE to eNB)

[84] - Step 2: RAR (via PDCCH and PDSCH) (eNB to UE)

[85] After transmission of RACH preamble, the UE attempts to receive a random access response (RAR) within a predetermined time window. Specifically, the UE attempts to detect a PDCCH (hereinafter, referred to as RA-RNTI PDCCH) having an RA-RNTI (Random Access RNTI) (e.g., CRC is masked with RA-RNTI in the PDCCH) within the time window. The UE checks whether a RAR therefor is present in a PDSCH corresponding to the RA-RNTI PDCCH during RA-RNTI PDCCH detection. The RAR includes timing advance (TA) information indicating timing offset information for UL synchronization, UL resource allocation information (UL grant information), a temporary UE identifier (e.g., temporary cell-RNTI, TC-RNTI), etc. The UE can perform UL transmission (e.g., Msg3) in accordance with resource allocation information and TA value in the RAR. HARQ is applied to UL transmission corresponding to the RAR. Accordingly, the UE can receive acknowledgement information

(e.g., PHICH) corresponding to Msg 3 after transmission of Msg 3.

[86] The random access preamble, i.e., RACH preamble consists of a cyclic prefix of length T_{CP} and a sequence part of length T_{SEQ} in the physical layer. T_{CP} and T_{SEQ} depend on the frame structure and the random access configuration. The preamble format is controlled by higher layers. The following table shows examples of T_{CP} and T_{SEQ}.

[87] [Table 3]

Preamble format	T_{CP}	T_{SEQ}
0	$3168 \cdot T_s$	$24576 \cdot T_s$
1	$21024 \cdot T_s$	$24576 \cdot T_s$
2	$6240 \cdot T_s$	$2 \cdot 24576 \cdot T_s$
3	$21024 \cdot T_s$	$2 \cdot 24576 \cdot T_s$
4(see NOTE)	$448 \cdot T_s$	$4096 \cdot T_s$
NOTE: Frame structure type 2 and special subframe configuration with UpPTS lengths $4384 \cdot T_s$ and $5120 \cdot T_s$ only.		

[88] The random access preamble is transmitted in UL subframe(s). The transmission of a random access preamble is restricted to certain time and frequency resources. These resources are called PRACH resources. The PRACH resources, are enumerated in increasing order of the subframe number within the radio frame and the PRBs in the frequency domain such that index 0 correspond to the lowest numbered PRB and subframe within the radio frame. PRACH resources within the radio frame are indicated by a PRACH configuration index.

[89] For frame structure type 1 with preamble format 0-3, for each of the PRACH configurations there is at most one random access resource per subframe. The following table shows examples of the preamble formats and the subframes in which random access preamble transmission is allowed for a given configuration in frame structure type 1. The PRACH configuration index is given by a higher layer signal (transmitted by an eNB).

[90] [Table 4]

PRACH Configuration Index	Preamble Format	SFN	Subframe number	PRACH Configuration Index	Preamble Format	SFN	Subframe number
0	0	Even	1	32	2	Even	1
1	0	Even	4	33	2	Even	4

30	N/A	N/A	N/A	62	N/A	N/A	N/A
31	1	Even	9	63	3	Even	9

[91] In Table 4, SFN denotes a system frame number.

[92] The first PRB, n^{RA}_{PRB}, allocated to the PRACH opportunity considered for preamble formats 0, 1, 2 and 3 is defined by $n^{RA}_{PRB}=n^{RA}_{PRBoffset}$, where the PRACH frequency offset $n^{RA}_{PRBoffset}$ is a PRB configured by higher layers and satisfies $0\leq n^{RA}_{PRBoffset}\leq N^{UL}_{RB}-6$.

[93] In case of frame structure type 2 with preamble formats 0 to 4, a plurality of random access resources may exist within UL subframe (or UpPTS for preamble format 4) in accordance with UL/DL configuration. The random access resources for the frame structure type 2 are defined in accordance with PRACH configuration index (see 3GPP TS 36.211 standard document).

[94] FIG. 4 illustrates the structure of a DL subframe used in a wireless communication system.

[95] Referring to FIG. 4, A DL subframe is divided into a control region and a data region in the time domain. Referring to FIG. 4, a maximum of 3 (or 4) OFDM symbols located in a front part of a first slot of a subframe corresponds to the control region. Hereinafter, a resource region for PDCCH transmission in a DL subframe is referred to as a PDCCH region. OFDM symbols other than the OFDM symbol(s) used in the control region correspond to the data region to which a physical downlink shared channel (PDSCH) is allocated. Hereinafter, a resource region available for PDSCH transmission in the DL subframe is referred to as a PDSCH region.

[96] Examples of a DL control channel used in 3GPP LTE include a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), a physical hybrid ARQ indicator channel (PHICH), etc.

[97] The PCFICH is transmitted in the first OFDM symbol of a subframe and carries information about the number of OFDM symbols available for transmission of a control channel within a subframe. The PCFICH notifies the UE of the number of OFDM symbols used for the corresponding subframe every subframe. The PCFICH is located at the first OFDM symbol. The PCFICH is configured by four resource element groups (REGs), each of which is distributed within a control region on the basis of cell ID. One REG includes four REs.

[98] A set of OFDM symbols available for the PDCCH at a subframe is given by the following Table.

[99] [Table 5]

Subframe	Number of OFDM symbols for PDCCH when $N^{DL}_{RB}>10$	Number of OFDM symbols for PDCCH when $N^{DL}_{RB}\leq 10$
Subframe 1 and 6 for frame structure type 2	1, 2	2
MBSFN subframes on a carrier supporting PDSCH, configured with 1 or 2 cell-specific antenna ports	1, 2	2
MBSFN subframes on a carrier supporting PDSCH, configured with 4 cell-specific antenna ports	2	2
Subframes on a carrier not supporting PDSCH	0	0
Non-MBSFN subframes (except subframe 6 for frame structure type 2) configured with positioning reference signals	1, 2, 3	2, 3
All other cases	1, 2, 3	2, 3, 4

[100] A subset of downlink subframes within a radio frame on a carrier for supporting PDSCH transmission may be configured as MBSFN subframe(s) by a higher layer. Each MBSFN subframe is divided into a non-MBSFN region and an MBSFN region. The non-MBSFN region spans first one or two OFDM symbols, and its length is given by Table 5. The same CP as cyclic prefix (CP) used for subframe 0 is used for transmission within the non-MBSFN region of the MBSFN subframe. The MBSFN region within the MBSFN subframe is defined as OFDM symbols which are not used in the non-MBSFN region.

[101] The PCFICH carries a control format indicator (CFI), which indicates any one of values of 1 to 3. For a downlink system bandwidth $N^{DL}_{RB}>10$, the number 1, 2 or 3 of OFDM symbols which are spans of DCI carried by the PDCCH is given by the CFI. For a downlink system bandwidth $N^{DL}_{RB}\leq 10$, the number 2, 3 or 4 of OFDM symbols which are spans of DCI carried by the PDCCH is given by CFI+1. The CFI is coded in accordance with the following Table.

[102] [Table 6]

CFI	CFI code word<b_0, b_1, ..., b_{31}>
1	<0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1>
2	<1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0>
3	<1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1>
4(Reserved)	<0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0>

[103] The PHICH carries a HARQ (Hybrid Automatic Repeat Request) ACK/NACK (acknowledgment/negative-acknowledgment) signal as a response to UL transmission. The PHICH includes three REGs, and is scrambled cell-specifically. ACK/NACK is indicated by 1 bit, and the ACK/NACK of 1 bit is repeated three times. Each of the repeated ACK/NACK bits is spread with a spreading factor (SF) 4 or 2 and then mapped into a control region.

[104] The control information transmitted through the PDCCH will be referred to as downlink control information (DCI). The DCI includes resource allocation information for a UE or UE group and other control information. Transmit format and resource allocation information of a downlink shared channel (DL-SCH) are referred to as DL scheduling information or DL grant. Transmit format and resource allocation information of an uplink shared channel (UL-SCH) are referred to as UL scheduling information or UL grant. The size and usage of the DCI carried by one PDCCH are varied depending on DCI formats. The size of the DCI may be varied depending on a coding rate. In the current 3GPP LTE system, various formats are defined, wherein formats 0 and 4 are defined for a UL, and formats 1, 1A, 1B, 1C, 1D, 2, 2A, 2B, 2C, 3 and 3A are defined for a DL. Combination selected from control information such as a hopping flag, RB allocation, modulation coding scheme (MCS), redundancy version (RV), new data indicator (NDI), transmit power control (TPC), cyclic shift, cyclic shift demodulation reference signal (DM RS), UL index, channel quality information (CQI) request, DL assignment index, HARQ process number, transmitted precoding matrix indicator (TPMI), precoding matrix indicator (PMI) information is transmitted to the UE as the DCI. The following table shows examples of DCI formats.

[105] [Table 7]

DCI format	Description
0	Resource grants for the PUSCH transmissions (uplink)
1	Resource assignments for single codeword PDSCH transmissions
1A	Compact signaling of resource assignments for single codeword PDSCH
1B	Compact signaling of resource assignments for single codeword PDSCH
1C	Very compact resource assignments for PDSCH (e.g. paging/broadcast system information)
1D	Compact resource assignments for PDSCH using multi-user MIMO
2	Resource assignments for PDSCH for closed-loop MIMO operation
2A	Resource assignments for PDSCH for open-loop MIMO operation
2B	Resource assignments for PDSCH using up to 2 antenna ports with UE-specific reference signals
2C	Resource assignment for PDSCH using up to 8 antenna ports with UE-specific reference signals
3/3A	Power control commands for PUCCH and PUSCH with 2-bit/1-bit power adjustments
4	Scheduling of PUSCH in one UL Component Carrier with multi-antenna port transmission mode

[106] Other DCI formats in addition to the DCI formats defined in Table 7 may be defined.

[107] A plurality of PDCCHs may be transmitted within a control region. A UE may monitor the plurality of PDCCHs. An eNB determines a DCI format depending on the DCI to be transmitted to the UE, and attaches cyclic redundancy check (CRC) to the DCI. The CRC is masked (or scrambled) with an identifier (for example, a radio network temporary identifier (RNTI)) depending on usage of the PDCCH or owner of the PDCCH. For example, if the PDCCH is for a specific UE, the CRC may be masked with an identifier (for example, cell-RNTI (C-RNTI)) of the corresponding UE. If the PDCCH is for a paging message, the CRC may be masked with a paging identifier (for example, paging-RNTI (P-RNTI)). If the PDCCH is for system information (in more detail, system information block (SIB)), the CRC may be masked with system information RNTI (SI-RNTI). If the PDCCH is for a random access response, the CRC may be masked with a random access RNTI (RA-RNTI). For example, CRC masking

(or scrambling) includes XOR operation of CRC and RNTI at the bit level.

[108] Generally, a DCI format, which may be transmitted to the UE, is varied depending on a transmission mode configured for the UE. In other words, certain DCI format(s) corresponding to the specific transmission mode not all DCI formats may only be used for the UE configured to a specific transmission mode.

[109] For example, a transmission mode is semi-statically configured for the UE by a higher layer so that the UE may receive a PDSCH transmitted in accordance with one of a plurality of transmission modes which are previously defined. The UE attempts to decode a PDCCH using DCI formats only corresponding to its transmission mode. In other words, in order to maintain UE operation load according to blind decoding attempt, at a certain level or less, all DCI formats are not searched by the UE at the same time. Table 8 illustrates transmission modes for configuring multi-antenna technology and DCI formats for allowing a UE to perform blind decoding at the corresponding transmission mode. Particularly, Table 8 illustrates a relation between PDCCH and PDSCH configured by C-RNTI (Cell RNTI(Radio Network Temporary Identifier)).

[110] [Table 8]

Transmission mode	DCI format	Search Space	Transmission scheme of PDSCH corresponding to PDCCH
Mode 1	DCI format 1A	Common andUE specific by C-RNTI	Single-antenna port, port 0
	DCI format 1	UE specific by C-RNTI	Single-antenna port, port 0
Mode 2	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1	UE specific by C-RNTI	Transmit diversity
Mode 3	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 2A	UE specific by C-RNTI	Large delay CDD or Transmit diversity
Mode 4	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 2	UE specific by C-RNTI	Closed-loop spatial multiplexing or Transmit diversity
Mode 5	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1D	UE specific by C-RNTI	Multi-user MIMO
Mode 6	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1B	UE specific by C-RNTI	Closed-loop spatial multiplexing using a single transmission layer
Mode 7	DCI format	Common andUE	If the number of PBCH antenna ports

	1A	specific by C-RNTI	is one, Single-antenna port, port 0 is used, otherwise Transmit diversity
	DCI format 1	UE specific by C-RNTI	Single-antenna port, port 5
Mode 8	DCI format 1A	Common andUE specific by C-RNTI	If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity
	DCI format 2B	UE specific by C-RNTI	Dual layer transmission, port 7 and 8 or single-antenna port, port 7 or 8
Mode 9	DCI format 1A	Common andUE specific by C-RNTI	Non-MBSFN subframe: If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity.MBSFN subframe: Single-antenna port, port 7
	DCI format 2C	UE specific by C-RNTI	Up to 8 layer transmission, ports 7-14 or single-antenna port, port 7 or 8
Mode 10	DCI format 1A	Common andUE specific by C-RNTI	Non-MBSFN subframe: If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity.MBSFN subframe: Single-antenna port, port 7
	DCI format 2D	UE specific by C-RNTI	Up to 8 layer transmission, ports 7-14 or single antenna port, port 7 or 8

[111] Although transmission modes 1 to 10 are listed in Table 8, other transmission modes in addition to the transmission modes defined in Table 8 may be defined.

[112] Referring to Table 8, a UE configured to a transmission mode 9, for example, tries to decode PDCCH candidates of a UE-specific search space (USS) to a DCI format 1A, and tries to decode PDCCH candidates of a common search space (CSS) and the USS to a DCI format 2C. The UE may decode a PDSCH in accordance with DCI based on the DCI format successfully decoded. If DCI decoding from one of a plurality of PDCCH candidates to the DCI format 1A is successfully performed, the UE may decode the PDSCH by assuming that up to 8 layers from antenna ports 7 to 14 are transmitted thereto through the PDSCH, or may decode the PDSCH by assuming that a single layer from the antenna port 7 or 8 is transmitted thereto through the PDSCH.

[113] The PDCCH is allocated to first m number of OFDM symbol(s) within a subframe.

In this case, m is an integer equal to or greater than 1, and is indicated by the PCFICH.

[114] The PDCCH is transmitted on an aggregation of one or a plurality of continuous control channel elements (CCEs). The CCE is a logic allocation unit used to provide a coding rate based on the status of a radio channel to the PDCCH. The CCE corresponds to a plurality of resource element groups (REGs). For example, one CCE corresponds to nine resource element groups (REGs), and one REG corresponds to four REs. Four QPSK symbols are mapped to each REG. A resource element (RE) occupied by the reference signal (RS) is not included in the REG. Accordingly, the number of REGs within given OFDM symbols is varied depending on the presence of the RS. The REGs are also used for other downlink control channels (that is, PCFICH and PHICH).

[115] Assuming that the number of REGs not allocated to the PCFICH or the PHICH is N_{REG}, the number of available CCEs in a DL subframe for PDCCH(s) in a system is numbered from 0 to N_{CCE}—1, where $N_{CCE} = \text{floor}(N_{REG}/9)$.

[116] A PDCCH format and the number of DCI bits are determined in accordance with the number of CCEs. The CCEs are numbered and consecutively used. To simplify the decoding process, a PDCCH having a format including n CCEs may be initiated only on CCEs assigned numbers corresponding to multiples of n. The number of CCEs used for transmission of a specific PDCCH is determined by a network or the eNB in accordance with channel status. For example, one CCE may be required for a PDCCH for a UE (for example, adjacent to eNB) having a good downlink channel. However, in case of a PDCCH for a UE (for example, located near the cell edge) having a poor channel, eight CCEs may be required to obtain sufficient robustness. Additionally, a power level of the PDCCH may be adjusted to correspond to a channel status.

[117] In a 3GPP LTE/LTE-A system, a set of CCEs on which a PDCCH can be located for each UE is defined. A CCE set in which the UE can detect a PDCCH thereof is referred to as a PDCCH search space or simply as a search space (SS). An individual resource on which the PDCCH can be transmitted in the SS is called a PDCCH candidate. A set of PDCCH candidates that the UE is to monitor is defined in terms of SSs, where a search space $S^{(L)}_k$ at aggregation level $L \in \{1,2,4,8\}$ is defined by a set of PDCCH candidates. SSs for respective PDCCH formats may have different sizes and a dedicated SS and a common SS are defined. The dedicated SS is a UE-specific SS (USS) and is configured for each individual UE. The common SS (CSS) is configured for a plurality of UEs.

[118] The following table shows an example of aggregation levels for defining SS.

[119] [Table 9]

Search space $S^{(L)}_k$			Number of PDCCH candidates $M^{(L)}$
Type	Aggregation level L	Size [in CCEs]	
UE-specific	1	6	6
	2	12	6
	4	8	2
	8	16	2
Common	4	16	4
	8	16	2

[120] For each serving cell on which PDCCH is monitored, the CCEs corresponding to PDCCH candidates m of the search space $S^{(L)}_k$ are configured by "$L*\{Y_k+m'\}$ mod floor($N_{CCE,k}/L$}+i", where i=0,...,L—1. For the common search space $m'=m$. For the PDCCH UE specific search space, for the serving cell on which PDCCH is monitored, if the monitorng UE is configured with carrier indicator field then $m'=m+M^{(L)}*n_{CI}$ where n_{CI} is the carrier indicator field (CIF) value, else if the monitoring UE is not configured with carrier indicator field then $m'=m$, where m=0,1,...,$M^{(L)}$—1. $M^{(L)}$ is the number of PDCCH candidates to monitor at aggregation level L in the given search space. The carrier indication field value can be the same as a serving cell index (*ServCellIndex*). For the common search space, Y_k is set to 0 for the two aggregation levels L=4 and L=8. For the UE-specific search space $S^{(L)}_k$ at aggregation level D, the variable Y_k is defined by "$Y_k = (A\cdot Y_{k-1})$ mod D", where $Y_{-1}=n_{RNTI}\neq 0$, A=39827, D=65537 and k =floor($n_s/2$). n_s is the slot number within a radio frame.

[121] The eNB transmits an actual PDCCH (DCI) on a PDCCH candidate in a search space and the UE monitors the search space to detect the PDCCH (DCI). Here, monitoring implies attempting to decode each PDCCH in the corresponding SS according to all monitored DCI formats. The UE may detect a PDCCH thereof by monitoring a plurality of PDCCHs. Basically, the UE does not know the location at which a PDCCH thereof is transmitted. Therefore, the UE attempts to decode all PDCCHs of the corresponding DCI format for each subframe until a PDCCH having an ID thereof is detected and this process is referred to as blind detection (or blind decoding (BD)).

[122] For example, it is assumed that a specific PDCCH is CRC-masked with a radio network temporary identity (RNTI) 'A' and information about data transmitted using a radio resource 'B' (e.g. frequency location) and using transport format information 'C' (e.g. transmission block size, modulation scheme, coding information, etc.) is transmitted in a specific DL subframe. Then, the UE monitors the PDCCH using RNTI

information thereof. The UE having the RNTI 'A' receives the PDCCH and receives the PDSCH indicated by 'B' and 'C' through information of the received PDCCH.

[123] FIG. 5 illustrates the structure of a UL subframe used in a wireless communication system.

[124] Referring to FIG. 5, a UL subframe may be divided into a data region and a control region in the frequency domain. One or several PUCCHs may be allocated to the control region to deliver UCI. One or several PUSCHs may be allocated to the data region of the UE subframe to carry user data.

[125] In the UL subframe, subcarriers distant from a direct current (DC) subcarrier are used as the control region. In other words, subcarriers located at both ends of a UL transmission BW are allocated to transmit UCI. A DC subcarrier is a component unused for signal transmission and is mapped to a carrier frequency f_0 in a frequency up-conversion process. A PUCCH for one UE is allocated to an RB pair belonging to resources operating on one carrier frequency and RBs belonging to the RB pair occupy different subcarriers in two slots. The PUCCH allocated in this way is expressed by frequency hopping of the RB pair allocated to the PUCCH over a slot boundary. If frequency hopping is not applied, the RB pair occupies the same subcarriers.

[126] The PUCCH may be used to transmit the following control information.

[127] - Scheduling request (SR): SR is information used to request a UL-SCH resource and is transmitted using an on-off keying (OOK) scheme.

[128] - HARQ-ACK: HARQ-ACK is a response to a PDCCH and/or a response to a DL data packet (e.g. a codeword) on a PDSCH. HARQ-ACK indicates whether the PDCCH or PDSCH has been successfully received. 1-bit HARQ-ACK is transmitted in response to a single DL codeword and 2-bit HARQ-ACK is transmitted in response to two DL codewords. A HARQ-ACK response includes a positive ACK (simply, ACK), negative ACK (NACK), discontinuous transmission (DTX), or NACK/DRX. HARQ-ACK is used interchangeably with HARQ ACK/NACK and ACK/NACK.

[129] - Channel state information (CSI): CSI is feedback information for a DL channel. CSI may include channel quality information (CQI), a precoding matrix indicator (PMI), a precoding type indicator, and/or a rank indicator (RI). In the CSI, MIMO-related feedback information includes the RI and the PMI. The RI indicates the number of streams or the number of layers that the UE can receive through the same time-frequency resource. The PMI is a value reflecting a space characteristic of a channel, indicating an index of a preferred precoding matrix for DL signal transmission based on a metric such as an SINR. The CQI is a value of channel strength, indicating a received SINR that can be obtained by the UE generally when the eNB uses the PMI.

[130] A general wireless communication system performs data transmission/reception through one downlink (DL) band and through one uplink (UL) band corresponding to

the DL band (in case of a frequency division duplex (FDD) mode), or divides a prescribed radio frame into a UL time unit and a DL time unit in the time domain and then performs data transmission/reception through the UL/DL time unit (in case of a time division duplex (TDD) mode). Recently, to use a wider frequency band in recent wireless communication systems, introduction of carrier aggregation (or BW aggregation) technology that uses a wider UL/DL BW by aggregating a plurality of UL/DL frequency blocks has been discussed. A carrier aggregation (CA) is different from an orthogonal frequency division multiplexing (OFDM) system in that DL or UL communication is performed using a plurality of carrier frequencies, whereas the OFDM system carries a base frequency band divided into a plurality of orthogonal subcarriers on a single carrier frequency to perform DL or UL communication. Hereinbelow, each of carriers aggregated by carrier aggregation will be referred to as a component carrier (CC).

[131] For example, three 20MHz CCs may be aggregated on each of a UL and a DL to support a bandwidth of 60MHz. The respective CCs may be contiguous or non-contiguous in the frequency domain. For convenience, although it has been described that the bandwidth of UL CC and the bandwidth of DL CC are the same as each other and symmetric to each other, the bandwidth of each CC may be independently determined. Asymmetrical carrier aggregation in which the number of UL CCs is different from the number of DL CCs may be implemented. DL/UL CC limited to a specific UE may be referred to as a serving UL/DL CC configured for the specific UE.

[132] Meanwhile, the 3GPP LTE-A standard uses the concept of a cell to manage radio resources. The "cell" associated with the radio resources is defined by combination of downlink resources and uplink resources, that is, combination of DL CC and UL CC. The cell may be configured by downlink resources only, or may be configured by downlink resources and uplink resources. If carrier aggregation is supported, linkage between a carrier frequency of the downlink resources (or DL CC) and a carrier frequency of the uplink resources (or UL CC) may be indicated by system information. For example, combination of the DL resources and the UL resources may be indicated by linkage of system information block type 2 (SIB2). In this case, the carrier frequency means a center frequency of each cell or CC. A cell operating on a primary frequency may be referred to as a primary cell (Pcell) or PCC, and a cell operating on a secondary frequency may be referred to as a secondary cell (Scell) or SCC. The carrier corresponding to the Pcell on downlink will be referred to as a downlink primary CC (DL PCC), and the carrier corresponding to the Pcell on uplink will be referred to as an uplink primary CC (UL PCC). A Scell means a cell that may be configured after completion of radio resource control (RRC) connection establishment and used to provide additional radio resources. The Scell may form a set of serving cells for the UE

together with the Pcell in accordance with capabilities of the UE. The carrier corresponding to the Scell on the downlink will be referred to as downlink secondary CC (DL SCC), and the carrier corresponding to the Scell on the uplink will be referred to as uplink secondary CC (UL SCC). Although the UE is in RRC-CONNECTED state, if it is not configured by carrier aggregation or does not support carrier aggregation, a single serving cell configured by the Pcell only exists.

[133] The eNB may activate all or some of the serving cells configured in the UE or deactivate some of the serving cells for communication with the UE. The eNB may change the activated/deactivated cell, and may change the number of cells which is/are activated or deactivated. If the eNB allocates available cells to the UE cell-specifically or UE-specifically, at least one of the allocated cells is not deactivated unless cell allocation to the UE is fully reconfigured or unless the UE performs handover. Such a cell which is not deactivated unless CC allocation to the UE is fully reconfigured will be referred to as Pcell, and a cell which may be activated/deactivated freely by the eNB will be referred to as Scell. The Pcell and the Scell may be discriminated from each other on the basis of the control information. For example, specific control information may be set to be transmitted and received through a specific cell only. This specific cell may be referred to as the Pcell, and the other cell(s) may be referred to as Scell(s).

[134] A configured cell refers to a cell in which carrier aggregation is performed for a UE based on measurement report from another eNB or UE among cells of an eNB and is configured per UE. The cell configured for the UE may be a serving cell in terms of the UE. For the cell configured for the UE, i.e. the serving cell, resources for ACK/NACK transmission for PDSCH transmission are reserved in advance. An activated cell refers to a cell configured to be actually used for PDSCH/PUSCH transmission among cells configured for the UE and CSI reporting and SRS transmission for PDSCH/PUSCH transmission are performed in the activated cell. A deactivated cell refers to a cell configured not to be used for PDSCH/PUSCH transmission by the command of an eNB or the operation of a timer and, if a cell is deactivated, CSI reporting and SRS transmission are also stopped in the cell.

[135] For reference, a carrier indicator (CI) denotes a serving cell index (*ServCellIndex*), CI=0 is applied to Pcell. The serving cell index is a short ID used to identify a serving cell. For example, any one of integers from 0 to 'maximum number of carrier frequencies which can be configured for the UE at a time - 1' may be allocated to one serving cell as the serving cell index. That is, the serving cell index may be a logical index used to identify a specific serving cell among cells allocated to the UE rather than a physical index used to identify a specific carrier frequency among all carrier frequencies.

[136] Meanwhile, the 3GPP LTE-A standard uses the concept of a cell to manage radio

resources.

[137] The cell mentioned in the present invention means a cell of carrier aggregation which is combination of UL CC and DL CC unless specifically noted.

[138] Meanwhile, since one serving cell is only present in case of communication based on a single carrier, a PDCCH carrying UL/DL grant and corresponding PUSCH/PDSCH are transmitted on one cell. In other words, in case of FDD under a single carrier environment, a PDCCH for a DL grant for a PDSCH, which will be transmitted on a specific DL CC, is transmitted on the specific CC, and a PDCCH for a UL grant for a PUSCH, which will be transmitted on a specific UL CC, is transmitted on a DL CC linked to the specific UL CC. In case of TDD under a single carrier environment, a PDCCH for a DL grant for a PDSCH, which will be transmitted on a specific DL CC, is transmitted on the specific CC, and a PDCCH for a UL grant for a PUSCH, which will be transmitted on a specific UL CC, is transmitted on the specific CC.

[139] On the contrary, since a plurality of serving cells may be configured in a multi-carrier system, transmission of UL/DL grant through a serving cell having a good channel status may be allowed. In this way, if a cell carrying UL/DL grant which is scheduling information is different from a cell where UL/DL transmission corresponding to the UL/DL grant is performed, this will be referred to as cross-carrier scheduling.

[140] Hereinafter, the case where the cell is scheduled from itself and the case where the cell is scheduled from another cell will be referred to as self-CC scheduling and cross-CC scheduling, respectively.

[141] For data transmission rate enhancement and stable control signaling, the 3GPP LTE/LTE-A may support aggregation of a plurality of CCs and a cross carrier-scheduling operation based on the aggregation.

[142] If cross-carrier scheduling (or cross-CC scheduling) is applied, a PDCCH for downlink allocation for a DL CC B or DL CC C, that is, carrying a DL grant may be transmitted through a DL CC A, and a corresponding PDSCH may be transmitted through the DL CC B or DL CC C. For cross-CC scheduling, a carrier indicator field (CIF) may be introduced. The presence or absence of the CIF within the PDCCH may be semi-statically and UE-specifically (or UE-group-specifically) configured by higher layer signaling (e.g., RRC signaling).

[143] Meanwhile, if RRH technology, cross-carrier scheduling technology, etc. are introduced, the amount of PDCCH which should be transmitted by the eNB is gradually increased. However, since a size of a control region within which the PDCCH may be transmitted is the same as before, PDCCH transmission acts as a bottleneck of system throughput. Although channel quality may be improved by the introduction of the aforementioned multi-node system, application of various communication schemes, etc., the introduction of a new control channel is required to apply the legacy commu-

nication scheme and the carrier aggregation technology to a multi-node environment. Due to the need, a configuration of a new control channel in a data region (hereinafter, referred to as PDSCH region) not the legacy control region (hereinafter, referred to as PDCCH region) has been discussed. Hereinafter, the new control channel will be referred to as an enhanced PDCCH (hereinafter, referred to as EPDCCH).

[144] The EPDCCH may be configured within rear OFDM symbols starting from a configured OFDM symbol, instead of front OFDM symbols of a subframe. The EPDCCH may be configured using continuous frequency resources, or may be configured using discontinuous frequency resources for frequency diversity. By using the EPDCCH, control information per node may be transmitted to a UE, and a problem that a legacy PDCCH region may not be sufficient may be solved. For reference, the PDCCH may be transmitted through the same antenna port(s) as that(those) configured for transmission of a CRS, and a UE configured to decode the PDCCH may demodulate or decode the PDCCH by using the CRS. Unlike the PDCCH transmitted based on the CRS, the EPDCCH is transmitted based on the demodulation RS (hereinafter, DMRS). Accordingly, the UE decodes/demodulates the PDCCH based on the CRS and decodes/demodulates the EPDCCH based on the DMRS. The DMRS associated with EPDCCH is transmitted on the same antenna port $p \in \{107,108,109,110\}$ as the associated EPDCCH physical resource, is present for EPDCCH demodulation only if the EPDCCH transmission is associated with the corresponding antenna port, and is transmitted only on the PRB(s) upon which the corresponding EPDCCH is mapped. For example, the REs occupied by the UE-RS(s) of the antenna port 7 or 8 may be occupied by the DMRS(s) of the antenna port 107 or 108 on the PRB to which the EPDCCH is mapped, and the REs occupied by the UE-RS(s) of antenna port 9 or 10 may be occupied by the DMRS(s) of the antenna port 109 or 110 on the PRB to which the EPDCCH is mapped. In other words, a certain number of REs are used on each RB pair for transmission of the DMRS for demodulation of the EPDCCH regardless of the UE or cell if the type of EPDCCH and the number of layers are the same as in the case of the UE-RS for demodulation of the PDSCH.

[145] For each serving cell, higher layer signalling can configure a UE with one or two EPDCCH-PRB-sets for EPDCCH monitoring. The PRB-pairs corresponding to an EPDCCH-PRB-set are indicated by higher layers. Each EPDCCH-PRB-set consists of set of ECCEs numbered from 0 to $N_{ECCE,p,k}-1$, where $N_{ECCE,p,k}$ is the number of ECCEs in EPDCCH-PRB-set p of subframe k. Each EPDCCH-PRB-set can be configured for either localized EPDCCH transmission or distributed EPDCCH transmission.

[146] The UE shall monitor a set of EPDCCH candidates on one or more activated serving cells as configured by higher layer signaling for control information.

[147] The set of EPDCCH candidates to monitor are defined in terms of EPDCCH UE-

specific search spaces. For each serving cell, the subframes in which the UE monitors EPDCCH UE-specific search spaces are configured by higher layers.

[148] An EPDCCH UE-specific search space $ES^{(L)}_k$ at aggregation level $L\in\{1,2,4,8,16,32\}$ is defined by a set of EPDCCH candidates.

[149] For an EPDCCH-PRB-set p, the ECCEs corresponding to EPDCCH candidate m of the search space $ES^{(L)}_k$ are given by the following equation.

[150] [Math.1]

$$L\left\{(Y_{p,k}+\left\lfloor\frac{m\cdot N_{ECCE,p,k}}{L\cdot M_p^{(L)}}\right\rfloor+b)\bmod\left\lfloor N_{\mathrm{ECCE},p,k}/L\right\rfloor\right\}+i$$

[151] where $i=0,\ldots,L-1$. $b=n_{CI}$ if the UE is configured with a carrier indicator field for the serving cell on which EPDCCH is monitored, otherwise $b=0$. n_{CI} is the carrier indicator field (CIF) value, which is the same as a serving cell index (*ServCellIndex*). $m=0,1,\ldots,M^{(L)}_p-1$. $M^{(L)}_p$ is the number of EPDCCH candidates to monitor at aggregation level L in EPDDCH-PRB-set p. The variable $Y_{p,k}$ is defined by '$Y_{p,k}=(A_p\cdot Y_{p,k-1})\bmod D$', where $Y_{p,-1}=n_{RNTI}\neq 0$, $A_0=39827$, $A_1=39829$, $D=65537$ and $k=\mathrm{floor}(n_s/2)$. n_s is the slot number within a radio frame.

[152] A UE is not expected to monitor an EPDCCH candidate, if an ECCE corresponding to that EPDCCH candidate is mapped to a PRB pair that overlaps in frequency with a transmission of either PBCH or PSS/SSS in the same subframe.

[153] An EPDCCH is transmitted using an aggregation of one or several consecutive enhanced control channel elements (ECCEs). Each ECCE consists of multiple enhanced resource element groups (EREGs). EEREGs are used for defining the mapping of enhanced control channels to resource elements. There are 16 EREGs, numbered from 0 to 15, per physical resource block (PRB) pair. Number all resource elements (REs), except resource elements carrying DMRS (hereinafter EPDCCH DMRS) for demoduation of the EPDCCH, in a physical resource-block pair cyclically from 0 to 15 in an increasing order of first frequency, then time. Therefore all the REs, except REs carrying the EPDCCH DMRS, in the PRB pair has any one of numbers 0 to 15. All REs with number i in that PRB pair constitutes EREG number i.As described above, it is noted that EREGs are distributed on frequency and time axes within the PRB pair and an EPDCCH transmitted using aggregation of one or more ECCEs, each of which includes a plurality of EREGs, is also distributed on frequency and time axes within the PRB pair.

[154] The number of ECCEs used for one EPDCCH depends on the EPDCCH format as given by Table 10, the number of EREGs per ECCE is given by Table 11. Table 10 shows an example of supported EPDCCH formats, and Table 11 shows an example of

the number of EREGs per ECCE, N^{EREG}_{ECCE}. Both localized and distributed transmission is supported.

[155] [Table 10]

EPDCCH format	Number of ECCEs for one EPDCCH, N^{ECCE}_{EPDCCH}			
	Case A		Case B	
	Localized transmission	Distributed transmission	Localized transmission	Distributed transmission
0	2	2	1	1
1	4	4	2	2
2	8	8	4	4
3	16	16	8	8
4	-	32	-	16

[156] [Table 11]

Normal cyclic prefix			Extended cyclic prefix	
Normal subframe	Special subframe,configuration3, 4, 8	Special subframe,configuration1, 2, 6, 7, 9	Normal subframe	Special subframe,configuration1, 2, 3, 5, 6
4		8		

[157] An EPDCCH can use either localized or distributed transmission, differing in the mapping of ECCEs to EREGs and PRB pairs. One or two sets of PRB pairs which a UE shall monitor for EPDCCH transmissions can be configured. All EPDCCH candidates in EPDCCH set S_p (i.e., EPDCCH-PRB-set) use either only localized or only distributed transmission as configured by higher layers. Within EPDCCH set S_p in subframe k, the ECCEs available for transmission of EPDCCHs are numbered from 0 to $N_{ECCE,p,k}-1$. ECCE number n is corresponding to the following EREG(s):

[158] - EREGs numbered $(n \bmod N^{ECCE}_{RB})+jN^{ECCE}_{RB}$ in PRB index $\text{floor}(n/N^{ECCE}_{RB})$ for localized mapping, and

[159] - EREGs numbered $\text{floor}\ (n/N^{Sp}_{RB})+jN^{ECCE}_{RB}$ in PRB indices $(n+j\max(1,N^{Sp}_{RB}/N^{EREG}_{ECCE}))\bmod N^{Sp}_{RB}$ for distributed mapping.

[160] where $j=0,1,\ldots,N^{EREG}_{ECCE}-1$, N^{EREG}_{ECCE} is the number of EREGs per ECCE, and $N^{ECCE}_{RB}=16/N^{EREG}_{ECCE}$ is the number of ECCEs per RB pair. The PRB pairs constituting EPDCCH set S_p are assumed to be numbered in ascending order from 0 to $N^{Sp}_{RB}-1$.

[161] Case A in Table 10 applies when:

[162] - DCI formats 2, 2A, 2B, 2C or 2D is used and $N^{DL}_{RB}\geq 25$, or

[163] - any DCI format when n_{EPDCCH}<104 and normal cyclic prefix is used in normal subframes or special subframes with configuration 3, 4, 8.

[164] Otherwise case B is used. The quantity n_{EPDCCH} for a particular UE is defined as the number of downlink resource elements (k,l) in a PRB pair configured for possible EPDCCH transmission of EPDCCH set S_0 and and fulfilling all of the following criteria,

[165] - they are part of any one of the 16 EREGs in the physical resource-block pair,

[166] - they are assumed by the UE not to be used for CRSs or CSI-RSs,

[167] - the index l in a subframe fulfils $l \geq l_{EPDCCHStart}$.

[168] where $l_{EPDCCHStart}$ is given based on higher layer signaling '*epdcch*-StartSymbol-r11', higher layer signaling '*pdsch*-Start-r11', or CFI value carried by PCFICH.

[169] The mapping to resource elements (k,l) on antenna port p meeting the criteria above is in increasing order of first the index k and then the index l, starting with the first slot and ending with the second slot in a subframe.

[170] For localized transmission, the single antenna port p to use is given by Table 12 with $n' = n_{ECCE,low} \bmod N^{ECCE}_{RB} + n_{RNTI} \bmod \min(N^{ECCE}_{EPDCCH}, N^{ECCE}_{RB})$, where $n_{ECCE,low}$ is the lowest ECCE index used by this EPDCCH transmission in the EPDCCH set, n_{RNTI} corresponds to the RNTI associated with the EPDCCH transmission, and N^{ECCE}_{EPDCCH} is the number of ECCEs used for this EPDCCH.

[171] [Table 12]

n'	Normal cyclic prefix		Extended cyclic prefix
	Normal subframes,Special subframes,configurations3, 4, 8	Special subframes, configurations1, 2, 6, 7, 9	Any subframe
0	107	107	107
1	108	109	108
2	109	-	-
3	110	-	-

[172] For distributed transmission, each resource element in an EREG is associated with one out of two antenna ports in an alternating manner where $p \in \{107,109\}$ for normal cyclic prefix and $p \in \{107,108\}$ for extended cyclic prefix.

[173] Recently, machine type communication (MTC) has come to the fore as a significant communication standard issue. MTC refers to exchange of information between a machine and an eNB without involving persons or with minimal human intervention. For example, MTC may be used for data communication for measurement/

sensing/reporting such as meter reading, water level measurement, use of a surveillance camera, inventory reporting of a vending machine, etc. and may also be used for automatic application or firmware update processes for a plurality of UEs. In MTC, the amount of transmission data is small and UL/DL data transmission or reception (hereinafter, transmission/reception) occurs occasionally. In consideration of such properties of MTC, it would be better in terms of efficiency to reduce production cost and battery consumption of UEs for MTC (hereinafter, MTC UEs) according to data transmission rate. Since the MTC UE has low mobility, the channel environment thereof remains substantially the same. If an MTC UE is used for metering, reading of a meter, surveillance, and the like, the MTC UE is very likely to be located in a place such as a basement, a warehouse, and mountain regions which the coverage of a typical eNB does not reach. In consideration of the purposes of the MTC UE, it is better for a signal for the MTC UE to have wider coverage than the signal for the conventional UE (hereinafter, a legacy UE).

[174] When considering the usage of the MTC UE, there is a high probability that the MTC UE requires a signal of wide coverage compared with the legacy UE. Therefore, if the eNB transmits a PDCCH, a PDSCH, etc. to the MTC UE using the same scheme as a scheme of transmitting the PDCCH, the PDSCH, etc. to the legacy UE, the MTC UE has difficulty in receiving the PDCCH, the PDSCH, etc. Therefore, the present invention proposes that the eNB apply a coverage enhancement scheme such as subframe repetition (repetition of a subframe with a signal) or subframe bundling upon transmission of a signal to the MTC UE having a coverage issue so that the MTC UE can effectively receive a signal transmitted by the eNB. For example, the PDCCH and PDSCH may be transmitted to the MTC UE having the coverage issue in a plurality of subframes (e.g. about 100 subframes).

[175] FIG. 6 illustrates an example of signals band for MTC.

[176] As one method for reducing the cost of the MTC UE, an operation of the MTC UE may be performed at a reduced UE downlink and uplink bandwidth of 1.4 MHz, for example, regardless of an operating system bandwidth of a cell. At this time, a subband (narrowband) for operating the MTC UE may always be located at the center (e.g., 6 center PRBs) of a cell as shown in FIG. 6(a), or several subbands for MTC may be provided for one subframe to multiplex MTC UEs as shown in FIG. 6(b), whereby the UEs may use their respective subbands different from each other or the UEs use the same subband not the subband of 6 center PRBs.

[177] In this case, the MTC UE cannot receive a legacy PDCCH transmitted through a full system band normally, and transmission of PDCCH for the MTC UE from an OFDM symbol region within which the legacy PDCCH is transmitted may not be preferable due to multiplexing issue with a PDCCH transmitted to another UE. As one method for

solving this, it is required to introduce a control channel transmitted within a subband where MTC is operated for the MTC UE. As a downlink control channel for such a low-complexity MTC UE, the legacy EPDCCH may be used as it is. Or, M-PDCCH for the MTC UE which is a control channel of a modified type of the legacy PDCCH/ EPDCCH may be introduced. Hereinafter, in the present invention, the legacy EPDCCH or M-PDCCH for the low-complexity MTC UE or normal complexity MTC UE will be referred to as M-PDCCH. Also, MTC-EPDCCH is hereinafter used to refer to M-PDCCH.

[178] A data channel (e.g., PDSCH, PUSCH) and/or a control channel (e.g., M-PDCCH, PUCCH, PHICH) may be transmitted for coverage enhancement (CE) of the UE by using a repetition or TTI bundling scheme through multiple subframes. The control/ data channel may be transmitted by additionally using cross-subframe channel estimation and frequency (narrowband) hopping for CE. In this case, cross-subframe channel estimation means a channel estimation method means channel estimation using a reference signal within a subframe of a corresponding channel and a reference signal within neighboring subframe(s).

[179] The MTC UE may need CE of 15dB, for example. However, all MTC UEs do not exist in an environment that CE is needed. Also, the same requirements of QoS are not applied to all MTC UEs. For example, since devices such as sensor and meter have low mobility and are likely to be located in a shaded area even while having a small amount of data transmission and reception, the devices may need high CE. However, wearable devices such as smart watch may have mobility and are likely to be located in a place not a shaded area while having a relatively large amount of data transmission and reception. Therefore, all MTC UEs do not need CE of high level, and their requirement capability may be varied depending on their type.

[180] In the present invention, an operation for monitoring M-PDCCH by means of an MTC UE (which needs coverage enhancement (CE)) will be suggested. Hereinafter, M-PDCCH monitoring, search space monitoring, or M-PDCCH candidates monitoring may mean that reception or detection of M-PDCCH is attempted within a corresponding search space or from one of M-PDCCH candidates configuring the corresponding search space.

[181] In the following embodiments, the expression "assume" may mean that an entity for transmitting a channel transmits the channel to be suitable for the corresponding "assumption". An entity for receiving the channel may receive or decode the channel to be suitable for the corresponding "assumption" provided that the channel has been transmitted to be suitable for the corresponding "assumption".

[182] FIG. 7 illustrates repeated transmission of a channel for coverage enhancement.

[183] A search space for M-PDCCH may be configured over a plurality of downlink

subframes. For example, M-PDCCH search space having an aggregation level L and a repetition level R is defined by a set of M-PDCCH candidates. In this case, each M-PDCCH candidate may be repeated within a set of R number of consecutive downlink subframes. Referring to FIG. 7, in an example of maximum repetitions R_{max}=8 and a possible repetition level of $R \in \{1, 2, 4, 0\}$, a UE may attempt decoding of M-PDCCH by assuming that repetition of M-PDCCH (transmitted at an aggregation level L) exists in each of R number of consecutive downlink subframes. For example, the UE may attempt decoding of M-PDCCH by regarding signals received from each of 8 subframes as those of the same M-PDCCH in case of a repetition level $R = 8$ and attempt decoding of different M-PDCCHs in each of 8 subframes in case of a repetition level $R = 1$.

[184] In FIG. 7, repetition of a channel is performed over consecutive downlink subframes. However, a data channel and/or a control channel (hereinafter, data/control channel) transmitted to/from the MTC UE which needs CE may be transmitted by being repeated through non-consecutive subframes. For example, the control/data channel for a specific MTC UE may not be in all downlink subframes but may be restricted to some downlink subframes. Non-consecutive downlink subframes available at the MTC UE may be configured in such a manner that a downlink subframe group comprised of one or more consecutive downlink subframes is repeated with a periodicity greater than the number of subframes within the downlink subframe group. In other words, the data/control channel may be transmitted not in physically consecutive subframes, but transmitted in transmitted in each of physically non-consecutive subframes (excluding uplink subframes in case of downlink transmission, downlink subframes in case of uplink transmission, and/or subframes except subframe used for other purpose of use and cannot be used for data/control channel transmission). Use of non-consecutive (downlink or uplink) subframes for repeated transmission of the data/control channel of the MTC UE may increase transmission/reception latency. However, as time diversity effect is obtained in the time domain by use of non-consecutive subframes, the number of repetitions or the number of subframes used for channel transmission may be reduced as compared with transmission based on consecutive subframes. Therefore, overall system throughput may be increased. The embodiments of the present invention, which will be described later, suggest UE operation and transmission subframe during transmission/reception of a corresponding channel when a data/control channel transmitted from MTC UE is transmitted with repetition through consecutive subframes or non-consecutive subframes.

[185] In the following embodiments, each search space within an interval where a UE monitors M-PDCCH (CSS and/or USS) may be configured over one or more (consecutive or non-consecutive) downlink subframes. That is, a search space for

reception of the same M-PDCCH may be configured in each of one or more downlink subframes.

[186] For example, referring to FIG. 8, in case of no CE or CE having a repetition level = 1, each of CSSs of FIG. 8 may be CSS on which a respective M-PDCCH can be transmitted. At this time, a CSS starting subframe may mean a first subframe of paging occasions for allowing a UE to monitor M-PDCCH for a paging message. As another example, referring to FIG. 9, in case of no CE or CE having a repetition level = 1, each of CSSs of FIG. 9 may be CSS on which a respective M-PDCCH can be transmitted. At this time, a CSS starting subframe may mean a first subframe of a RAR window for allowing a UE to monitor M-PDCCH for scheduling RAR.

[187] In case of coverage enhancement (CE), M-PDCCH may be transmitted by being repeated once or multiple times. Therefore, a search space where M-PDCCH (hereinafter, paging M-PDCCH) will be monitored may be configured repeatedly over a plurality of downlink subframes, and a UE may attempt repeated reception of M-PDCCH within search spaces within the plurality of downlink subframes. If CE having a repetition level greater than 1 is applied, for example, each CSS shown in FIG. 8 may be a plurality of consecutive subframes that may have repetitions of M-PDCCH. If CE having a repetition level greater than 1 is applied, as another example, a plurality of CSSs within the same paging occasion shown in FIG. 8 may be CSSs for repetitions of the same M-PDCCH. If CE having a repetition level greater than 1 is applied, as still another example, a plurality of CSSs over a plurality of paging occasions shown in FIG. 8 may be CSSs for repetitions of the same M-PDCCH.

[188] ■ Section 1. M-PDCCH CSS for paging message scheduling

[189] In Section 1, details on M-PDCCH CSS for paging message scheduling are discussed.

[190] The paging message is used to notify UE(s) under RRC_IDLE and UE(s) under RRC_CONNECTED of system information modification.

[191] An eNB initiates a paging process by transmitting the paging message at a paging occasion of a UE. The eNB may address a plurality of UEs within the paging message by including a paging record (*PagingRecord*) per UE. The paging record may include information indicating NAS (non-access stratum) identifier of a UE which is paged and information indicating the origin of paging. One paging occasion means a subframe having P-RNTI transmitted on PDCCH/M-PDCCH addressing the paging message. A paging frame (PF) means one radio frame that includes one or a plurality of paging occasion(s).

[192] The UE may use discontinuous reception (DRX) in an idle mode to reduce power consumption. If DRX is used, the UE monitors only one paging occasion per DRX cycle.

[193] The paging message may be transmitted through a PDSCH, and the PDSCH carrying the paging message may be scheduled by PDCCH/M-PDCCH.

[194] For paging message scheduling, multiple narrowbands can be configured by eNB. Then, a narrowband location for a paging occasion monitoring of a UE is determined by at least UE ID at least for paging record(s). However, the narrowband location and paging occasion for common signal transmission (e.g., SI update, earthquake and tsunami warning system (ETWS), and/or commercial mobile alert system (CMAS)) is not determined yet. To reduce UE complexity, it would be beneficial to apply the same paging occasion and narrowband location for paging record(s) reception and other information reception such as SI update, ETWS, and CMAS. For example, the UE may attempt reception of M-PDCCH for scheduling the paging message on the same narrowband at the same paging occasion for SI update and reception of ETWS and CMAS instead of monitoring different paging occasions and/or different narrowbands for SI update and reception of ETWS and CMAS.

[195] FIG. 8 illustrates a configuration of a common search space (CSS) for paging according to the present invention.

[196] Under the assumption that a paging occasion is a time region for M-PDCCH monitoring for paging message scheduling, a UE can monitor a common search space (CSS) within a paging occasion to check paging message transmission. Depending on duration of paging occasion and period of CSS starting subframe, there can be multiple CSS monitoring opportunities within a paging occasion as shown in FIG. 8. The period and offset of CSS starting subframe location can be configured by eNB. In this case, offset k_{offset} of the CSS starting subframe may mean a difference from a reference subframe n (e.g., subframe 0) to a subframe $n+k_{offset}$ in which the CSS starting subframe is first applied.

[197] The composition of decoding candidates (i.e. M-PDCCH candidates) and a subset of $\{L, R\}$ for CSS for paging should be composed to supports all UEs with different CE levels. In this case, L indicates an aggregation level, and M-PDCCH of the aggregation level L is transmitted using aggregation of L number of M-CCEs. ECCE may be used as M-CCE, and CCE for MTC UE may newly be defined as M-CCE for MTC UE.

[198] To transmit paging message adapt to the target CE level, a subset of $\{L, R\}$ of CSS for paging needs to be composed to cover all range of CE levels or all range of repetition numbers. One simple configuration is $\{8, R1\}$, $\{16, R1\}$, $\{24, R1\}$, $\{24, R2\}$, $\{24, R3\}$, $\{24, R4\}$ where $R1 = 1$ and $R4$ is the maximum repetition level.

[199] In the present invention, a paging occasion may be defined as an interval where a UE monitors a paging M-PDCCH. For example, the UE may attempt reception of (same) paging M-PDCCH (or M-PDCCH scrambled by P-RNTI) within CSS(s) existing in the paging occasion or paging M-PDCCH search space(s) as shown in FIG. 8. Since the

paging M-PDCCH may be transmitted in any one of CSS(s) within the paging occasion, the UE continuously monitors the CSS(s) within the paging occasion. If the paging M-PDCCH (or M-PDCCH scrambled by P-RNTI) is received within the corresponding interval, the UE may receive a PDSCH carrying the corresponding paging message even though a paging message scheduled by the corresponding M-PDCCH, that is, a PDSCH carrying paging is transmitted outside a paging occasion interval.

[200] A duration of the paging occasion may be configured to be a multiple of the number of subframes configuring CSSs or search spaces on which the paging M-PDCCH is transmitted. For example, if the paging M-PDCCH search space is configured in each of R number of (consecutive or non-consecutive) downlink subframes, the paging occasion may be configured to have a duration of R*X number of subframes (where X is a positive integer).

[201] ■ Section 2. M-PDCCH CSS for RAR scheduling

[202] FIG. 9 illustrates a configuration of a common search space (CSS) for RAR according to the present invention.

[203] There would be multiple narrowbands for CSS for RAR scheduling, and the narrowband location of a UE for RAR monitoring is determined by PRACH resource set.

[204] After transmitting PRACH, a UE would try to receive RAR. Similar to paging occasion, there can be multiple CSS regions within a RAR window as depicted in Figure 9. So, the UE can monitor M-PDCCH scheduling RAR in CSS region(s) within the RAR window.

[205] A subset of $\{L, R\}$ and composition of decoding candidates of CSS for RAR can depend on CE level of corresponding PRACH resource set. For example, for each CE level, PRACH resource set(s) and available repetition level(s) may be configured. In this case, the UE may monitor a CSS, that is, M-PDCCH in accordance with a set of $\{L, R\}$ configured for a CE level associated with a PRACH resource used for a successful RACH procedure. Regardless of CSS and USS, same composition of decoding candidates and same subset of $\{L, R\}$ can be used for same CE level of the search space. For example, the UE may monitor a CSS and a USS in accordance with $\{L, R\}$ of the same set with respect to the same CE level.

[206] The present invention suggests that a RAR window interval should be defined as an interval where a UE monitor M-PDCCH (hereinafter, RAR M-PDCCH) for scheduling RAR. That is, as shown in FIG. 9, the UE may attempt reception of RAR M-PDCCH (e.g., M-PDCCH scheduled by RA-RNTI) on CSS(s) existing within a RAR window or a search space(s) (hereinafter, RAR M-PDCCH search space) on which RAR M-PDCCH is transmitted. If the UE receives RAR M-PDCCH within the corresponding interval, the UE may receive a PDSCH through which the corresponding RAR is

transmitted, even though RAR (e.g., PDSCH carrying RAR) scheduled by the corresponding M-PDCCH is transmitted outside the RAR window interval.

[207] A duration of the RAR window may be configured to become a multiple of the number of subframes configuring CSSs or RAR M-PDCCH search spaces. For example, if RAR M-PDCCH search space is configured in each of R number of (consecutive or non-consecutive) downlink subframes, the RAR window may be configured to have a duration of R*X number of subframes (in this case, X is a positive integer).

[208] ■ Section 3. M-PDCCH CSS for other purposes

[209] M-PDCCH CSS can be used to transmit DCIs for other purposes except paging message and RAR scheduling. For example, M-PDCCH CSS can be used for transmission of DCI for unicast data, DCI for TPC, DCI for enhanced interference management and traffic adaptation (eIMTA), and DCI for enhanced PHICH (EPHICH). If CSS is used to transmit these DCIs, the narrowband location, monitoring subframe location, and decoding candidates composition need to be specified. Hereinafter, the CSS will be referred to as CSS_regular or CSS_others.

[210] CSS for these purposes (i.e. CSS_regular) can be located in the same narrowband to USS. Then, a UE does not need to re-tune its operating frequency to monitor this CSS.

[211] To reconfigure CE level of a UE, the CSS needs to support the maximum CE level of the cell considering CE level reconfiguration message can be transmitted by this CSS. Therefore, CE level or a subset of $\{L, R\}$ composing the CSS should support all CE level of the cell.

[212] FIG. 10 illustrates the example of the monitoring time region of USS and CSS.

[213] Period of starting subframe for M-PDCCH USS monitoring and CSS monitoring can be configured independently. The period of CSS monitoring can be longer than the period of USS, since CE level of USS and CSS can be different and CSS can be occurred sparsely to reduce UE complexity.

[214] Referring to Math Figure 1 which is a hashing function, it is noted that $Y_{p,k}$ is varied depending on n_{RNTI} which is UE ID. In this way, CCE(s) or ECCE(s) configuring decoding candidates in the USS is(are) determined UE-specifically to be monitored by a specific UE. M-PDCCH CSS can be monitored by a group of MTC UEs. Therefore, for CSS, there should not be a hashing function to randomize the starting ECCE location composing a search space UE-specifically.

[215] ■ Section 4. Coverage enhancement level of CSS

[216] For transmission of a broadcast PDSCH (e.g., paging, RAR), CSSs for other purposes such as unicast data, TPC, eIMTA DCI and EPHICH may exist, and USS where a UE monitors unicast data may exist. Hereinafter, a coverage enhancement level of corresponding search spaces will be described.

[217] The present invention suggests that a plurality of SS types exist as follows in accordance with a coverage enhancement level supported by a search space or repetitions of M-PDCCH.

[218] - Method 1.

[219] In view of the UE, two types of search spaces (SSs) may exist as follows:

[220] * SS type 1: SS supporting all coverage enhancement levels or all repetitions of M-PDCCH, and

[221] * SS type 2: SS where the number of repetitions of M-PDCCH which is supported is varied depending on a coverage enhancement level of the UE.

[222] In this case, the UE may assume that CSS for paging and/or CSS_regular has SS type 1, and CSS and/or USS for RAR has SS type 2.

[223] Alternatively, as SS monitored by the UE, one SS having SS type 1 and one SS having SS type 2 may exist. CSS for paging and/or CSS_regular may be the same as SS having SS type 1, and CSS and/or USS for RAR may be the same as SS having SS type 2.

[224] - Method 2.

[225] When N number of coverage enhancement levels (or the number of repetitions of M-PDCCH) supported by a cell exist, in view of the cell, a plurality of SS types may exist as follows:

[226] * SS type 1: SS supporting coverage enhancement level 1 (or the number of repetitions R_1 of M-PDCCH),

[227] * SS type 2: SS supporting coverage enhancement level 2 (or the number of repetitions R_2 of M-PDCCH),

[228] ...

[229] * SS type N: SS supporting coverage enhancement level N (or the number of repetitions R_N of M-PDCCH),

[230] * SS type N+1: SS supporting all coverage enhancement levels (or all repetitions for M-PDCCH).

[231] In this case, SS supporting the coverage enhancement level n may mean SS supporting the coverage enhancement levels 1 to n or the maximum number of repetitions R_n of M-PDCCH.

[232] In this case, the UE may assume that the CSS for paging and CSS_regular has SS type N+1, and the CSS for RAR and/or USS has SS type k if the coverage enhancement level of the UE is k.

[233] ■ Section 5. Relationship between search spaces

[234] **CSS for paging (i.e., CSS_paging)**

[235] It is a CSS for paging monitoring in RRC_IDLE state. Since UEs in different CE levels monitor the same CSS for paging scheduling, it should be designed to cover all

the CE levels. CSS_paging are configured by SIB. In other words, the configuration of CSS_paging may be transmitted through SIB. The UE may identify the configuration of CSS_paging by reading SIB. The UE may monitor M-PDCCH candidates of CSS within subframe(s) and/or narrowband(s) according to the CSS_paging configuration.

[236] **CSS for** RAR corresponding to initial RACH procedure (i.e., CSS_RAR)

[237] Using CSS for RAR, a UE can monitor RAR, Msg3 (for retransmission), and Msg4. Though it can be considered to allow separate SS configurations for Msg3 re-transmission and Msg4 scheduling M-PDCCH from the SS configuration for RAR, given that those (i.e. RAR, Msg3 and Msg4) will be used only for initial access, the present invention proposes that the same configuration is used for initial RACH procedure. Required configurations for CSS_RAR can be configured by SIB per CE level. Then, in a UE perspective, configurations for CSS_RAR can be determined based on the CE level of PRACH resource set used for the latest PRACH transmission.

[238] **CSS for others (i.e., CSS_others or CSS_regular)**

[239] M-PDCCH CSS can be used to transmit DCIs for other purposes except paging message and initial RAR scheduling. For example, CSS is required to transmit TPC, unicast data for reconfiguration (such as CE level, transmission mode, USS reconfiguration), a DCI transmitting multiple HARQ-ACK corresponding to PUSCH to multiple UEs (if supported), transmit RAR corresponding to PRACH triggered by M-PDCCH order. CSS for these purposes can be located in the same narrowband to USS once a UE is connected to the network. Then, a UE does not need to re-tune its operating frequency to monitor this CSS. A UE can monitor CSS_others (i.e., CSS_regular) and USS simultaneously.

[240] If there is a complexity issue, TDM of CSS and USS monitoring can be considered. In other words, CSS and USS are time-division multiplexed, whereby the CSS and the USS may not be monitored at the same time.

[241] If CSS for other purposes are not defined, legacy PUCCH TPC via DCI format 3/3A cannot be supported. Then, if downlink traffic is occurred sparsely, it could be difficult to adopt PUCCH power since PUCCH TPC is accomplished by accumulated way. So, other way to handle this issue needs to be considered such as absolute PUCCH TPC via DL grant or unicast DCI for PUCCH TPC transmitted by USS. Thus, at least for CE mode A (for TCP and reconfiguration), CSS_others needs to be supported.

[242] **USS**

[243] USS is a search space for unicast data scheduling. Configurations for USS can be configured by SIB and Msg4. If necessary, reconfiguration can be utilized by radio resource control (RRC) layer (i.e. RRC signal). Configurations for USS also can be applied for CSS_others. In this case, individual configurations for CSS_others and USS may not be required.

[244] FIG. 11 illustrates a procedure of configuring a search space according to the present invention.

[245] Referring to FIG. 11, the UE may receive a list of search space (SS) configurations per CE level for RAR through SIB (S1101). The UE may transmit RACH preamble through PRACH by using a PRACH resource. PRACH resource(s) per CE level may be configured by SIB. The UE may monitor M-PDCCH for scheduling a response to the RACH preamble transmitted therefrom, that is, a response to transmission of the PRACH in a search space (S1103). The UE may assume that a search space for M-PDCCH scheduling the RAR depends on SS configuration (e.g., CSS_RAR configuration) received through the SIB. The UE which has received RAR M-PDCCH may receive RAR in accordance with DCI carried by the RAR M-PDCCH (S1105).

[246] Initial configuration for RAR, Msg3 and/or Msg4 may depend on SS configuration per CE level received (S1101) through SIB (S1121). The UE may monitor M-PDCCH for scheduling Msg4, which includes CSS configuration/reconfiguration and/or USS configuration/reconfiguration parameters, in the SS according to initial configuration through SIB (S1121). For example, the UE may monitor Msg4 M-PDCCH by assuming that the maximum number of repetitions, narrowband, PRB-set, etc. which are the same as those of CSS for RAR, are also applied to M-PDCCH (hereinafter, Msg4 M-PDCCH) for scheduling Msg4 (S1121). The UE which has received Msg4 M-PDCCH may receive Msg4 in accordance with DCI of the Msg4 M-PDCCH (S1123). The Msg4 may carry RRC message that includes UE-specific configuration for USS and/or CSS. In this case, the UE may monitor M-PDCCH by applying the UE-specific SS configuration instead of initial SS configuration (S1125).

[247] The UE may monitor M-PDCCH order within the CSS according to the UE-specific CSS configuration (S1141). The UE which has received the M-PDCCH order may receive RAR in accordance with scheduling information carried by the M-PDCCH order (S1143).

[248] The UE may monitor M-PDCCH for scheduling RRC message having UE-specific reconfiguration parameter(s) within the CSS according to the UE-specific CSS configuration (S1161). The UE-specific reconfiguration may include M-PDCCH configuration. The UE which has received the M-PDCCH may receive a PDSCH carrying the RRC message in accordance with scheduling information (that is, DCI) of the M-PDCCH (S1163). The UE may reconfigure M-PDCCH search space in accordance with the UE-specific reconfiguration.

[249] Table 13 illustrates parameters and configuration details required for search spaces. All or some of the parameters illustrated in Table 13 may be configured and/or re-configured in accordance with Table 13.

[250] [Table 13]

Parameters	Configuration details				Description
	CSS_paging	CSS_RAR	CSS_others	USS	
Subset of L	Fixed to {8, 16, 24}			{1, 2, 4, 8, 16, 24}	
R_{max}	Configurable by SIB.	Configured by SIB per CE level (configuration can be shared for CSS_RAR, CSS_others, USS).For CSS_others/USS, it can be reconfigured by RRC.			Subset of repetition numbers is determined based on R_{max}. Details are described in Subsection 5.1.
PRB-sets	Configured by SIB.	Configured by SIB per CE level specific and cell-specific.	Alt 1. Configured by Msg4 per UE.Alt 2. Configured by SIB per CE level (in this case, same configuration for CSS_RAR, CSS_others, USS).It can be reconfigured by RRC.		This configuration includes the number of PRB-sets, PRB size/ location of each PRB-set.
Transmission type	Configured by SIB per PRB-set.	Configured by SIB per PRB-set.	Alt 1. Configured by Msg4 per UE (the network ensures the same type is used beween CSS_others and USS in case both are monitored at the same time).Alt 2. Configured by SIB per CE level (in this case, same configuration for CSS_RAR, CSS_others, USS).It can be reconfigured by RRC.		
Narrowband	Determined	Based on	Default value can be		

	by UE ID among paging narrowbands configured by SIB.	PRACH resource set where RAR narrowband corresponding to each PRACH resource set is configured by SIB.	CSS_RAR's narrowband location. Configurable by Msg 4 per UEIt can be reconfigured by RRC.	
M-PDCCH monitoring starting	Alt 1. Configured by SIB per CE level.Alt 2. Configured by SIB regardless of CE level (one maximum value to reset monitoring starting subframe).			See FIG. 7 and Subsection 5.1.
M-PDCCH starting subframe	Determined by repetition number R per repetition number R.	Alt 1. Determined by R_{max} for CE Mode A, determined by repetition number R per repetition number R for CE Mode B.Alt 2. Determined by repetition number R per repetition number R.		See FIG. 7 and Subsection 5.1.

[251] In Table 13, a merged cell means that the configuration can be shared by corresponding search spaces, so individual configuration is not needed for each search space. For example, referring to Table 13, "Fixed to {8, 16, 24}" which is the description of a subset of an aggregation level L exists within a cell merged for CSS_paging, CSS_RAR and CSS_others (i.e., CSS_regular), and thus means that a corresponding parameter is not required to be configured individually for CSS_paging, CSS_RAR and CSS_others(i.e. CSS_reguar) and a common parameter is applied to CSS_paging, CSS_RAR and CSS_others. According to Table 13, the UE may attempt reception of M-PDCCH at an aggregation level $L\in\{8, 16, 24\}$ for CSS_paging, CSS_RAR and CSS_others, and may attempt reception of M-PDCCH at $L\in\{1, 2, 4, 8, 16, 24\}$ for the USS.

[252] Reconfigurable parameters in Table 13 mean that the same value as initial configuration or default configuration is applied until a corresponding parameter is reconfigured, whereby search space(s) is(are) configured.

[253] For example, referring to Table 13, the maximum number of repetitions R_{max} of M-PDCCH may be provided through SIB as a configuration for CSS_RAR. The UE may monitor CSS_RAR, CSS_others and/or USS by assuming that R_{max} included in the SIB is applied to CSS_RAR, CSS_others, and USS. That is, the UE may monitor rep-

etitions of M-PDCCH in SS within maximum R_{max} number of subframes. According to Table 13, since R_{max} for CSS_others and/or USS (hereinafter, CSS_others/USS) may be reconfigured, if R_{max} for CSS_others/USS is reconfigured by RRC signal, the UE may monitor CSS_others/USS in accordance with the reconfigured R_{max}. In other words, the UE may monitor CSS_others/USS in accordance with R_{max} for CSS_RAR until R_{max} for CSS_others/USS is received.

[254] For another example, referring to parameters of PRB-sets in Table 13, PRBs on which PRB-set(s) for CSS_RAR, that is, RAR M-PDCCH may be transmitted may be configured CE level-specifically and cell-specifically by SIB. Referring to Alt 2, these PRB-sets configured per CE level may be applied to CSS_others and USS by SIB. Since PRB-set parameter for CSS_others and USS may be reconfigured by RRC, the UE may monitor CSS_others/USS by applying PRB-set(s) for CSS_RAR until reconfiguration PRB-set parameter for CSS_others/USS is received, and may monitor CSS_others/USS by applying the reconfiguration PRB-set parameter if the reconfiguration PRB-set parameter for CSS_others/USS is received. For example, if PRB-set(s) of CSS_RAR are fixed to 6, the UE may monitor M-PDCCH USS by assuming all PRBs within a narrowband according to CSS_RAR configuration as PRB-set(s) for USS until configuration of separate PRB-set(s) for USS is received.

[255] For still another example, referring to a narrowband parameter of Table 13, a narrowband (hereinafter, RAR narrowband) having CSS_RAR may be determined based on a PRACH resource set. In this case, a corresponding RAR narrowband per PRACH resource set is configured by SIB. A default narrowband location of CSS_others and/or USS may be a narrowband location of CSS_RAR. A narrowband for CSS_others/USS may be configured per UE by Msg4, and may be reconfigured by RRC. Therefore, the UE may monitor CSS_others/USS on the same narrowband as that for CSS_RAR until a narrowband parameter for CSS_others/USS is received, and if Msg4 for CSS_others/USS or reconfiguration RRC message is received, may monitor CSS_others/USS on a narrowband according to the Msg4 or the RRC message.

[256] □ Subsection 5.1. Aggregation levels and repetition numbers

[257] Search space configuration parameters of Table 13 may be applied as follows in view of an aggregation level and the number of repetitions. For example, a subset (and/or starting subframe of M-PDCCH SS and/or starting subframe of M-PDCCH) of the number of repetitions R based on R_{max} may be determined in accordance with the following description.

[258] **CSS for paging (i.e., CSS_paging)**

[259] - Aggregation levels:

[260] Since data transmission scheduled by CSS is targeted to multicast/broadcast, similar

to PDCCH CSS, some high aggregation levels can be supported. Aggregation levels (ALs) {8, 16, 24} can be supported for normal CP and ALs {4, 8, 12} can be supported for extended CP.

[261] - Repetition numbers:

[262] A subset of R for CSS for paging monitoring depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB. To support wide range of repetition numbers, the subset of R monitored for CSS_paging can be {$R_{max}/64$, $R_{max}/16$, $R_{max}/4$, R_{max}}.

[263] **CSS for** RAR corresponding to initial RACH procedure (i.e., CSS_RAR)

[264] - Aggregation levels:

[265] Similar to CSS_paging, ALs $L\in\{8, 16, 24\}$ can be supported for normal CP and ALs $L\in\{4, 8, 12\}$ can be supported for extended CP.

[266] - Repetition numbers:

[267] For CSS scheduling RAR, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level. The subset of R monitored for CSS_RAR can be {$R_{max}/4$, $R_{max}/2$, R_{max}}.

[268] **CSS for others (i.e., CSS_others)**

[269] - Aggregation levels:

[270] Similar to CSS_paging, ALs $L\in\{8, 16, 24\}$ can be supported for normal CP and ALs $L\in\{4, 8, 12\}$ can be supported for extended CP.

[271] - Repetition numbers:

[272] For CSS_others, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level or Msg4. R_{max} can be reconfigured by RRC if necessary. The subset of R monitored for CSS_others can be {$R_{max}/4$, $R_{max}/2$, R_{max}}. Or, to reduce UE complexity, the subset of R monitored for CSS_others can be {$R_{max}/2$, R_{max}}.

[273] **USS**

[274] - Aggregation levels:

[275] For CE Mode A, ALs $L\in\{1, 2, 4, 8, 16, 24\}$ are supported for normal CP. ALs $L\in\{1, 2, 4, 8, 12\}$ are supported for extended CP. For CE Mode B, ALs $L\in\{8, 16, 24\}$ is supported for normal CP. ALs $L\in\{4, 8, 12\}$ are supported for extended CP.

[276] - Repetition numbers:

[277] For USS, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level or Msg4. R_{max} can be reconfigured by RRC if necessary. The subset of R monitored for USS can be {$R_{max}/4$, $R_{max}/2$, R_{max}}. Or, to support higher R to CSS_others for CE level reconfiguration reliably, subset of R monitored for USS can be {$R_{max}/8$, $R_{max}/4$, $R_{max}/2$}.

[278] ■ Section 6. Collision of M-PDCCH(s)

[279] If there are some subframes not available for downlink transmission, M-

PDCCH/PDSCH transmission or repetitions can be postponed till the next available subframe. It can be applied in case unavailable subframes are aligned between eNB and UE.

[280] FIG. 12 illustrates a configuration of M-PDCCH repeated transmission according to the present invention.

[281] If a small interval (e.g., cycle of starting subframe of M-PDCCH search space) of M-PDCCH search space is configured or a large number of invalid subframes, which cannot have M-PDCCH, are provided between M-PDCCH search space starting subframes, M-PDCCH2 transmission may not end until next starting subframe of the search space, in the same manner as M-PDCCH2 transmission of FIG. 12. That is, the subframes configuring two search spaces may be overlapped with each other. In this case, the UE may be in the status that the UE should perform monitoring for M-PDCCH transmitted in a previous search space and monitoring for M-PDCCH transmitted in a next search space. However, this operation may not be preferable due to buffer size and complexity issue of the UE. In this case, the UE may perform reception of M-PDCCH as follows.

[282] - Method 1. If a starting time (hereinafter, subframe #n) of next search space occurs before reception of M-PDCCH is ended, the UE may assume that the M-PDCCH is transmitted up to subframe #n-1 and is not transmitted in subframe #n. In this case, the UE may attempt reception of the M-PDCCH by using repetitions smaller than the number of expected repetitions of M-PDCCH.

[283] - Method 2. If a starting time (hereinafter, subframe #n) of next search space occurs before reception of M-PDCCH is ended, the UE may determine that the M-PDCCH that the UE is receiving is invalid, and may not perform reception of the corresponding M-PDCCH.

[284] - Method 3. If subframe(s) configuring two search spaces are overlapped with each other, the UE may determine that a search space existing at an earlier time is invalid, and may not perform reception of M-PDCCH for one of the two search space, which is first started in a time domain.

[285] FIG. 13 is a block diagram illustrating elements of a transmitting device 10 and a receiving device 20 for implementing the present invention.

[286] The transmitting device 10 and the receiving device 20 respectively include Radio Frequency (RF) units 13 and 23 capable of transmitting and receiving radio signals carrying information, data, signals, and/or messages, memories 12 and 22 for storing information related to communication in a wireless communication system, and processors 11 and 21 operationally connected to elements such as the RF units 13 and 23 and the memories 12 and 22 to control the elements and configured to control the memories 12 and 22 and/or the RF units 13 and 23 so that a corresponding device may

perform at least one of the above-described embodiments of the present invention.

[287] The memories 12 and 22 may store programs for processing and controlling the processors 11 and 21 and may temporarily store input/output information. The memories 12 and 22 may be used as buffers.

[288] The processors 11 and 21 generally control the overall operation of various modules in the transmitting device and the receiving device. Especially, the processors 11 and 21 may perform various control functions to implement the present invention. The processors 11 and 21 may be referred to as controllers, microcontrollers, microprocessors, or microcomputers. The processors 11 and 21 may be implemented by hardware, firmware, software, or a combination thereof. In a hardware configuration, application specific integrated circuits (ASICs), digital signal processors (DSPs), digital signal processing devices (DSPDs), programmable logic devices (PLDs), or field programmable gate arrays (FPGAs) may be included in the processors 11 and 21. Meanwhile, if the present invention is implemented using firmware or software, the firmware or software may be configured to include modules, procedures, functions, etc. performing the functions or operations of the present invention. Firmware or software configured to perform the present invention may be included in the processors 11 and 21 or stored in the memories 12 and 22 so as to be driven by the processors 11 and 21.

[289] The processor 11 of the transmitting device 10 performs predetermined coding and modulation for a signal and/or data scheduled to be transmitted to the outside by the processor 11 or a scheduler connected with the processor 11, and then transfers the coded and modulated data to the RF unit 13. For example, the processor 11 converts a data stream to be transmitted into K layers through demultiplexing, channel coding, scrambling, and modulation. The coded data stream is also referred to as a codeword and is equivalent to a transport block which is a data block provided by a MAC layer. One transport block (TB) is coded into one codeword and each codeword is transmitted to the receiving device in the form of one or more layers. For frequency up-conversion, the RF unit 13 may include N_t (where N_t is a positive integer) transmit antennas.

[290] A signal processing process of the receiving device 20 is the reverse of the signal processing process of the transmitting device 10. Under control of the processor 21, the RF unit 23 of the receiving device 20 receives radio signals transmitted by the transmitting device 10. The RF unit 23 may include N_r (where N_r is a positive integer) receive antennas and frequency down-converts each signal received through receive antennas into a baseband signal. The processor 21 decodes and demodulates the radio signals received through the receive antennas and restores data that the transmitting device 10 intended to transmit.

[291] The RF units 13 and 23 include one or more antennas. An antenna performs a function for transmitting signals processed by the RF units 13 and 23 to the exterior or receiving radio signals from the exterior to transfer the radio signals to the RF units 13 and 23. The antenna may also be called an antenna port. Each antenna may correspond to one physical antenna or may be configured by a combination of more than one physical antenna element. The signal transmitted from each antenna cannot be further deconstructed by the receiving device 20. An RS transmitted through a corresponding antenna defines an antenna from the view point of the receiving device 20 and enables the receiving device 20 to derive channel estimation for the antenna, irrespective of whether the channel represents a single radio channel from one physical antenna or a composite channel from a plurality of physical antenna elements including the antenna. That is, an antenna is defined such that a channel carrying a symbol of the antenna can be obtained from a channel carrying another symbol of the same antenna. An RF unit supporting a MIMO function of transmitting and receiving data using a plurality of antennas may be connected to two or more antennas.

[292] In the embodiments of the present invention, a UE operates as the transmitting device 10 in UL and as the receiving device 20 in DL. In the embodiments of the present invention, an eNB operates as the receiving device 20 in UL and as the transmitting device 10 in DL. Hereinafter, a processor, an RF unit, and a memory included in the UE will be referred to as a UE processor, a UE RF unit, and a UE memory, respectively, and a processor, an RF unit, and a memory included in the eNB will be referred to as an eNB processor, an eNB RF unit, and an eNB memory, respectively.

[293] The eNB processor of the present invention may configure or reconfigure CSS_paging in accordance with section 1, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_paging, to the UE in accordance with section 1, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for scheduling a paging message within CSS_paging according to CSS_paging configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_paging from the eNB in accordance with section 1, section 5 and/or section 6. The UE may attempt reception of paging M-PDCCH from CSS_paging according to the CSS_paging configuration.

[294] The eNB processor of the present invention may configure or reconfigure CSS_RAR in accordance with section 2, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_RAR, to the UE in accordance with section 2, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for

scheduling RAR, Msg3 and/or Msg4 within a CSS according to CSS_RAR configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_RAR from the eNB in accordance with section 2, section 5 and/or section 6. The UE may attempt reception of RAR M-MPDCCH, Msg3 M-PDCCH and/or Msg4 M-PDCCH from the CSS according to the CSS_RAR configuration.

[295] The eNB processor of the present invention may configure or reconfigure CSS_others in accordance with section 3, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_others, to the UE in accordance with section 3, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for other purpose within a CSS according to CSS_others configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_others from the eNB in accordance with section 3, section 5 and/or section 6. The UE may attempt reception of M-PDCCH for other purpose from the CSS according to the CSS_others configuration.

[296] The eNB processor of the present invention may transmit initial configuration for CSS through SIB in accordance with section 6. The eNB processor may configure CSS and/or USS in accordance with the initial configuration until the other configuration (e.g., UE-specific configuration/reconfiguration) for SS is transmitted. The initial configuration may include a configuration (e.g., narrowband, PRB-set(s), starting subframe and/or period, and the number of maximum repetitions of SS) of time-frequency resources of SS. The eNB processor may transmit M-PDCCH in accordance with the initial configuration until the other configuration for SS is transmitted. For example, the eNB processor may control the eNB RF unit to transmit M-PDCCH by applying the number of repetitions R based on maximum R_{max} according to the initial configuration within the PRB-set according to the initial configuration on a narrowband according to the initial configuration. If the other configuration for SS is transmitted, the eNB processor may control the eNB RF unit to transmit M-PDCCH on the SS configured in accordance with the other configuration. The UE processor may receive the initial configuration for CSS through SIB in accordance with section 6. The UE processor may assume that CSS and/or USS is configured in accordance with the initial configuration until the other configuration (e.g., UE-specific configuration/reconfiguration) for SS is received. The UE processor may monitor M-PDCCH in accordance with the initial configuration until the other configuration for SS is transmitted. For example, the UE processor may control the UE RF unit to receive or monitor M-PDCCH by applying the number of repetitions R based on maximum R_{max} according to the initial configuration within the PRB-set according to the initial con-

figuration on a narrowband according to the initial configuration. If the other configuration for SS is received, the UE processor may control the UE RF unit to receive or monitor M-PDCCH on the SS configured in accordance with the other configuration.

[297] As described above, the detailed description of the preferred embodiments of the present invention has been given to enable those skilled in the art to implement and practice the invention. Although the invention has been described with reference to exemplary embodiments, those skilled in the art will appreciate that various modifications and variations can be made in the present invention without departing from the spirit or scope of the invention described in the appended claims. Accordingly, the invention should not be limited to the specific embodiments described herein, but should be accorded the broadest scope consistent with the principles and novel features disclosed herein.

Industrial Applicability

[298] The embodiments of the present invention are applicable to a BS, a UE, or other devices in a wireless communication system.

Claims

[Claim 1] A method for receiving, by a user equipment (UE), downlink control information (DCI) for the UE, the method comprising:
receiving, by the UE, a common search space configuration for a common search space;
receiving, by the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by monitoring first PDCCH candidates of the common search space according to the common search space configuration; and
receiving, by the UE, a second PDCCH carrying the DCI for the UE by monitoring second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are monitored according to the same configuration as the common search space configuration until the UE receives a UE-specific search space configuration.

[Claim 2] The method according to claim 1,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored on the same narrowband as the narrowband for the common search space until the UE receives a UE-specific search space configuration.

[Claim 3] The method according to claim 1 or 2,
wherein the common search space configuration includes information on a maximum number of repetitions for the common common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored based on the same number as the maximum number of repetitions for the common search space until the UE receives a UE-specific search space configuration.

[Claim 4] The method according to any one of claims 1 to 3,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for monitoring the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for monitoring the second PDCCH candidates until the UE receives a UE-specific search space configuration.

[Claim 5] The method according to any one of claims 1 to 4,
wherein the first PDCCH candidates of the common search space are monitored according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are monitored according to the plurality of aggregation levels.

[Claim 6] A method for transmitting, by a base station (BS), downlink control information (DCI) for a user equipment (UE), the method comprising:
transmitting, by the BS, common search space configuration for a common search space;
transmitting, by the BS to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by using one of first PDCCH candidates of the common search space according to the common search space configuration; and
transmitting, by the BS to the UE, a second PDCCH carrying the DCI for the UE by using one of second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are configured according to the same configuration as the common search space configuration until a UE-specific search space configuration is transmitted to the UE.

[Claim 7] The method according to claim 6,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 8] The method according to claim 6 or 7,
wherein the common search space configuration includes information on a maximum number of repetitions for the first common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 9] The method according to any one of claims 6 to 8,
wherein the common search space configuration includes information

on a first physical resource block (PRB) set for transmitting the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE.

[Claim 10] The method according to any one of claims 6 to 9,
wherein the first PDCCH candidates of the common search space are configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are configured according to the plurality of aggregation levels.

[Claim 11] A user equipment (UE) for receiving downlink control information (DCI) for the UE, the UE comprising:
a radio frequency (RF) unit, and
a processor connected to the RF unit, the processor configured to:
control the RF unit to receive common search space configuration for a common search space;
control the RF unit to receive a first physical downlink control channel (PDCCH) scheduling a random access response by monitoring first PDCCH candidates of the common search space according to the common search space configuration; and
control the RF unit to receive a second PDCCH carrying the DCI for the UE by monitoring second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are monitored according to the same configuration as the common search space configuration until the UE receives a UE-specific search space configuration.

[Claim 12] The UE according to claim 11,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored on the same narrowband as the narrowband for the common search space until the UE receives a UE-specific search space configuration.

[Claim 13] The UE according to claim 11 or 12,
wherein the common search space configuration includes information on a maximum number of repetitions for the common common search

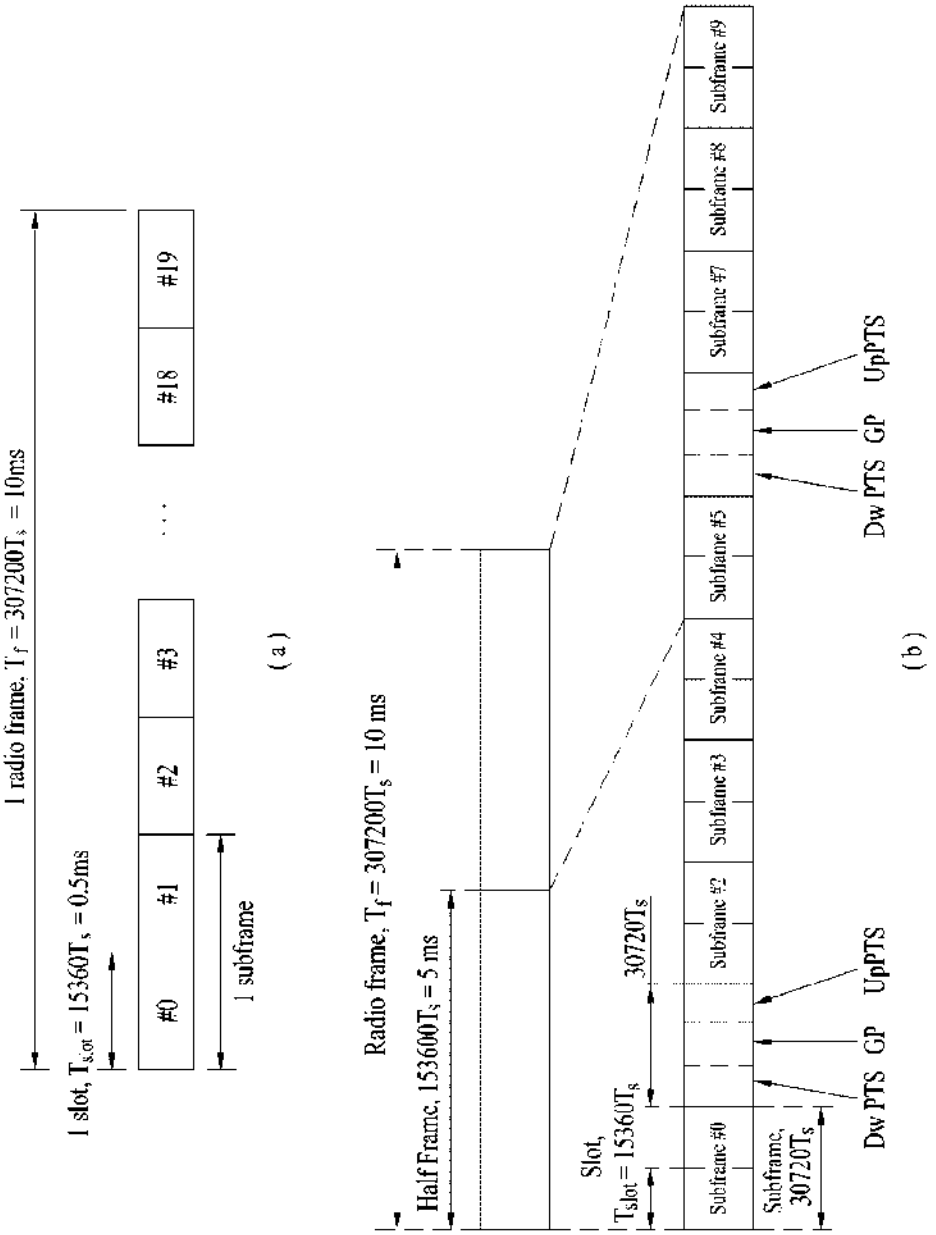
space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored based on the same number as the maximum number of repetitions for the common search space until the UE receives a UE-specific search space configuration.

[Claim 14] The UE according to any one of claims 11 to 13,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for monitoring the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for monitoring the second PDCCH candidates until the UE receives a UE-specific search space configuration.

[Claim 15] The UE according to any one of claims 11 to 14,
wherein the first PDCCH candidates of the common search space are monitored according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are monitored according to the plurality of aggregation levels.

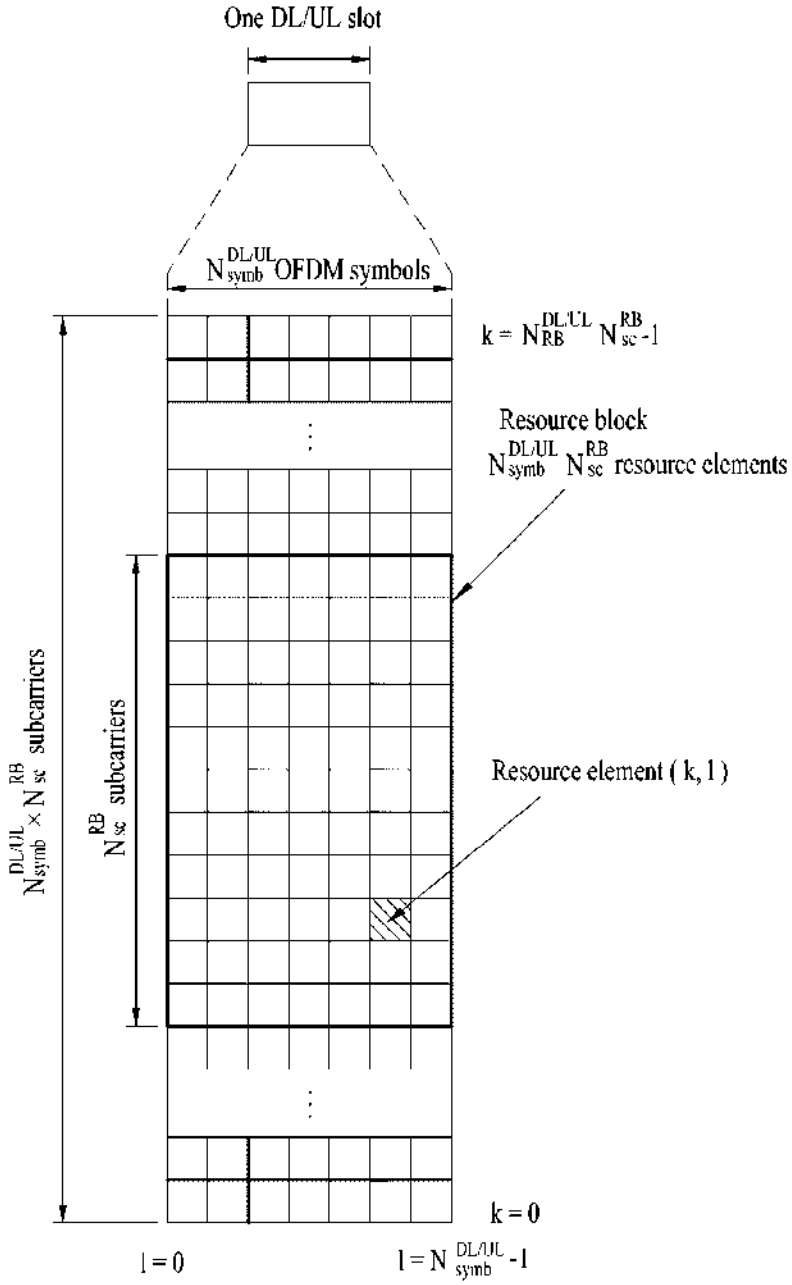
[Claim 16] A base station (BS) for transmitting downlink control information (DCI) to a user equipment (UE), the BS comprising:
a radio frequency (RF) unit, and
a processor connected to the RF unit, the processor configured to:
control the RF unit to transmit common search space configuration for a common search space;
control the RF unit to transmit, to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by using one of first PDCCH candidates of the common search space according to the common search space configuration; and
control the RF unit to transmit, to the UE, a second PDCCH carrying the DCI for the UE by using one of second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are configured according to the same configuration as the common search space configuration until a UE-specific search space configuration is transmitted to the UE.

[Claim 17] The BS according to claim 16,
wherein the common search space configuration includes information on a narrowband for the common search space, and



wherein the second PDCCH candidates of the UE-specific search space are configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 18] The BS according to claim 16 or 17,
wherein the common search space configuration includes information on a maximum number of repetitions for the first common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.



[Claim 19] The BS according to any one of claims 16 to 18,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for transmitting the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE.

[Claim 20] The BS according to any one of claims 16 to 19,
wherein the first PDCCH candidates of the common search space are configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are configured according to the plurality of aggregation levels.

(54) **Title**: DEVICE, SYSTEM AND METHOD EMPLOYING UNIFIED FLEXIBLE 5G AIR INTERFACE

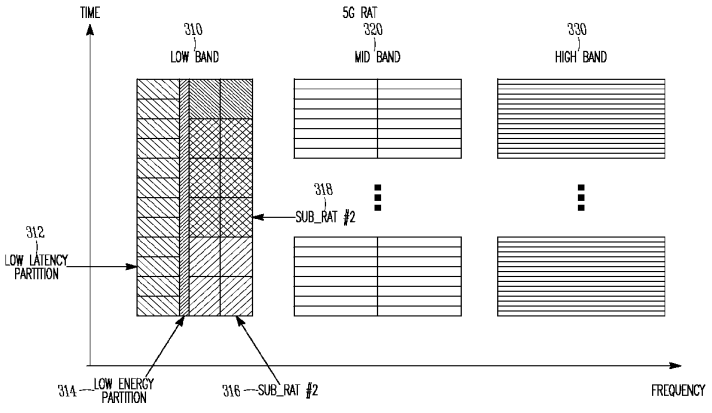

FIG. 3

(57) **Abstract**: An eNodeB (eNB), user equipment (UE) and method of providing a flexible Radio Access Technology (FRAT) are generally described. The information (resource allocation, partition information and numerology) of at least one of a plurality of RATs used by the eNB is provided to a UE. Each RAT has a flexible subcarrier spacing and symbol duration, which are integer multiples of a base subcarrier spacing and symbol duration, and is associated with at least one of different temporal and frequency resources. The symbol and/or frame structure of each RAT are independent. A Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration. The information of the RATs is provided either via a different RAT than the RAT used by the UE for communication or via a dedicated carrier in the RAT used by the UE for communication.

WO 2016/130175 A1

DEVICE, SYSTEM AND METHOD EMPLOYING UNIFIED FLEXIBLE 5G AIR INTERFACE

PRIORITY CLAIM

[0001] This application claims the benefit of priority to United States Provisional Patent Application Serial No. 62/114,733, filed February 11, 2015, and entitled "UNIFIED FLEXIBLE 5G NEW AIR INTERFACE DESIGN," which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

[0002] Embodiments pertain to radio access networks. Some embodiments relate to a unified communication framework using Radio Access Technologies (RAT) in 5th generation (5G) cellular networks.

BACKGROUND

[0003] The use of personal communication devices has increased astronomically over the last several decades. The penetration of mobile devices in modern society has continued to drive demand for a wide variety of networked devices in a number of disparate environments. The variety of available applications, especially video-related applications, has led to a concomitant increase in demand for increased bandwidth beyond that provided by Third Generation Partnership Project Long Term Evolution (3GPP LTE) and LTE advanced (LTE-A) systems.

[0004] The next generation wireless communication system, 5G, may provide access to information and sharing of data using a network that may be required to meet vastly different and sometimes conflicting performance dimensions and services driven by different services and use cases. It is therefore desirable that the next generation communication system be flexible and capable of providing high speed communications services for a wide ambit of devices under a multiplicity of circumstances.

BRIEF DESCRIPTION OF THE FIGURES

[0005] In the figures, which are not necessarily drawn to scale, like numerals may describe similar components in different views. Like numerals having different letter suffixes may represent different instances of similar components. The figures illustrate generally, by way of example, but not by way of limitation, various embodiments discussed in the present document.

[0006] FIG. 1 is a functional diagram of a 3GPP network in accordance with some embodiments.

[0007] FIG. 2 is a block diagram of a 3GPP device in accordance with some embodiments.

[0008] FIG. 3 illustrates one embodiment of a flexible Radio Access Technology (FRAT) of a 5G system in accordance with some embodiments.

[0009] FIG. 4 illustrates a unified frame structure in accordance with some embodiments.

[0010] FIG. 5 illustrates a Transmission Time Interval (TTI) boundary alignment in accordance with some embodiments.

[0011] FIG. 6 illustrates a symbol structure in accordance with some embodiments.

[0012] FIG. 7 illustrates frame structures within a TTI in accordance with some embodiments.

[0013] FIGS. 8A and 8B illustrate flowcharts of a uniform framework utilization method in accordance with some embodiments.

DETAILED DESCRIPTION OF THE INVENTION

[0014] The following description and the drawings sufficiently illustrate specific embodiments to enable those skilled in the art to practice them. Other embodiments may incorporate structural, logical, electrical, process, and other changes. Portions and features of some embodiments may be included in, or substituted for, those of other embodiments. Embodiments set forth in the claims encompass all available equivalents of those claims.

[0015] FIG. 1 is a functional diagram of a 3GPP network in accordance with some embodiments. The network may comprise a radio access network (RAN) (e.g., as depicted, the E-UTRAN or evolved universal terrestrial radio

access network) 100 and the core network 120 (e.g., shown as an evolved packet core (EPC)) coupled together through an S1 interface 115. For convenience and brevity sake, only a portion of the core network 120, as well as the RAN 100, is shown.

[0016] The core network 120 includes mobility management entity (MME) 122, serving gateway (serving GW) 124, and packet data network gateway (PDN GW) 126. The RAN 100 includes eNBs 104 (which may operate as base stations) for communicating with UE 102. The eNBs 104 may include macro eNBs and low power (LP) eNBs.

[0017] The MME is similar in function to the control plane of legacy Serving GPRS Support Nodes (SGSN). The MME manages mobility aspects in access such as gateway selection and tracking area list management. The serving GW 124 terminates the interface toward the RAN 100, and routes traffic packets (such as data packets or voice packets) between the RAN 100 and the core network 120. In addition, it may be a local mobility anchor point for inter-eNB handovers and also may provide an anchor for inter-3GPP mobility. Other responsibilities may include lawful intercept, charging, and some policy enforcement. The serving GW 124 and the MME 122 may be implemented in one physical node or separate physical nodes. The PDN GW 126 terminates a SGi interface toward the packet data network (PDN). The PDN GW 126 routes traffic packets between the EPC 120 and the external PDN, and may be a key node for policy enforcement and charging data collection. It may also provide an anchor point for mobility with non-LTE accesses. The external PDN can be any kind of IP network, as well as an IP Multimedia Subsystem (IMS) domain. The PDN GW 126 and the serving GW 124 may be implemented in one physical node or separated physical nodes.

[0018] The eNBs 104 (macro and micro) terminate the air interface protocol and may be the first point of contact for a UE 102. The eNBs 104 may communicate both with UEs 102 in a normal coverage mode and UEs 104 in one or more enhanced coverage modes. In some embodiments, an eNB 104 may fulfill various logical functions for the RAN 100 including but not limited to RNC (radio network controller functions) such as radio bearer management, uplink and downlink dynamic radio resource management and traffic packet

scheduling, and mobility management. In accordance with some embodiments, UEs 102 may be configured to communicate via orthogonal multiple access (OMA) communications such as Time Division Multiple Access (TDMA), Frequency Division Multiple Access (FDMA) Orthogonal FDMA (OFDMA), SC-FDMA or other communication signals with an eNB 104 over a multicarrier communication channel in accordance with the appropriate communication technique. The OFDM signals may comprise a plurality of orthogonal subcarriers. In accordance with some embodiments, UEs 102 may be configured to communicate via non-orthogonal multiple access (NOMA) signals.

[0019] The S1 interface 115 is the interface that separates the RAN 100 and the EPC 120. It is split into two parts: the S1-U, which carries traffic packets between the eNBs 104 and the serving GW 124, and the S1-MME, which is a signaling interface between the eNBs 104 and the MME 122.

[0020] With cellular networks, LP cells are typically used to extend coverage to indoor areas where outdoor signals do not reach well, or to add network capacity in areas with very dense phone usage, such as train stations. As used herein, the term low power (LP) eNB refers to any suitable relatively low power eNB for implementing a narrower cell (narrower than a macro cell) such as a femtocell, a picocell, or a micro cell. Femtocell eNBs are typically provided by a mobile network operator to its residential or enterprise customers. A femtocell is typically the size of a residential gateway or smaller and generally connects to the user's broadband line. Once plugged in, the femtocell connects to the mobile operator's mobile network and provides extra coverage in a range of typically 30 to 50 meters for residential femtocells. Thus, a LP eNB might be a femtocell eNB since it is coupled through the PDN GW 126. Similarly, a picocell is a wireless communication system typically covering a small area, such as in-building (offices, shopping malls, train stations, etc.), or more recently in-aircraft. A picocell eNB can generally connect through the X2 link to another eNB such as a macro eNB through its base station controller (BSC) functionality. Thus, LP eNB may be implemented with a picocell eNB since it is coupled to a macro eNB via an X2 interface. Picocell eNBs or other LP eNBs may incorporate some or all functionality of a macro eNB. In some cases, this may be referred to as an access point base station or enterprise femtocell.

[0021] As indicated in more detail below, communication over a 4G LTE network may be split up into 10ms frames, each of which may contain ten 1ms subframes. Each subframe of the frame, in turn, may contain two slots of 0.5ms. The eNB may schedule uplink and downlink transmissions over a variety of frequency bands. The allocation of resources in subframes used in one frequency band and may differ from those in another frequency band. Each slot of the subframe may contain 6-7 symbols, depending on the system used. In some embodiments, the subframe may contain 12 or 24 subcarriers. A resource grid may be used for downlink and uplink transmissions between an eNB and a UE. The resource grid may be a time-frequency grid, which is the physical resource in each slot. The smallest time-frequency unit in a resource grid may be denoted as a resource element (RE). Each column and each row of the resource grid may correspond to one OFDM symbol and one OFDM subcarrier, respectively. The resource grid may contain resource blocks (RBs) that describe the mapping of physical channels to resource elements and physical RBs (PRBs). A PRB may be the smallest unit of resources that can be allocated to a UE in the current 3GPP standard. A resource block may be 180 kHz wide in frequency and 1 slot long in time. In frequency, resource blocks may be either 12 x 15 kHz subcarriers or 24 x 7.5 kHz subcarriers wide. For most channels and signals, 12 subcarriers may be used per resource block, dependent on the system bandwidth. The duration of the resource grid in the time domain corresponds to one subframe or two resource blocks. Each resource grid may comprise 12 (subcarriers) *14 (symbols) =168 resource elements for normal cyclic prefix (CP) case. Several different physical channels may be conveyed using such resource blocks. As discussed in more detail below, in a 5G network, the sizes of the resource blocks, resource elements, and symbols, among others, may vary.

[0022] There may be several different physical downlink channels that are conveyed using such resource blocks, including the physical downlink control channel (PDCCH) and the physical downlink shared channel (PDSCH). Each subframe may contain a PDCCH, physical hybrid-ARQ indicator channel (PHICH), physical control format indicator channel (PCFICH) and the PDSCH. The PDCCH may normally occupy the first up to three symbols (four in the case

of narrow bandwidths of 1.4MHz) of each subframe and carry, among other things, information about the transport format and resource allocations related to the PDSCH channel and uplink scheduling grants for a physical uplink shared channel (PUSCH) transmission. The PHICH may be used to signal HARQ information in response to a PUSCH transmission. The PCFICH may inform the UE the control region size (e.g. one, two or three OFDM symbols) in each downlink subframe. The PDSCH may carry user data and higher layer signaling to a particular UE and occupy the remainder of the downlink subframe to avoid the resources in which downlink control channels (PDCCH/PHICH/PCFICH) are transmitted. Typically, downlink scheduling (assigning control and shared channel resource blocks to UEs within a cell) may be performed at the eNB based on channel quality information provided by the UEs, and then the downlink resource assignment information may be sent to a scheduled UE on the PDCCH used for (assigned to) PDSCH reception of the UE.

[0023] The PDCCH may contain downlink control information (DCI) in one of a number of formats that tell the UE where to find and how to decode the data, transmitted on PDSCH in the same subframe, from the resource grid. The DCI may provide details such as the number of resource blocks, resource allocation type, modulation scheme, transport block, redundancy version, coding rate etc. Each DCI format may have a cyclic redundancy code (CRC) and be scrambled with a Radio Network Temporary Identifier (RNTI) that identifies the target UE for which the PDSCH is intended. Use of the RNTI, which may be UE-specific, may limit decoding of the DCI information (and hence the corresponding PDSCH) to only the intended UE. The PDCCH may be located in any of a number of frequency/temporal regions, depending on whether the PDCCH is UE-Specific or common, as well as the aggregation level. The set of possible candidate locations for the PDCCH is defined in terms of search spaces. A search space is defined by a set of Control Channel Element (CCE) candidates with a number of aggregation level $L \in \{1,2,4,8\}$ where the UE may monitor to find its PDCCHs. A common search space may carry DCIs that are common for all UEs; for example, system information (using the SI-RNTI), paging (P-RNTI), PRACH responses (RA-RNTI), or UL TPC commands (TPC-PUCCH/PUSCH-RNTI). A UE-specific search space may carry DCIs for UE-

specific allocations using a Cell Radio-Network Temporary Identifier (C-RNTI) assigned to the UE, a semi-persistent scheduling (SPS C-RNTI), or an initial allocation (temporary C-RNTI). When configuring an SPS (either uplink or downlink), the SPS C-RNTI is provided by the eNB and the UE is configured by higher layers to decode a PDCCH with a CRC scrambled by the SPS C-RNTI. The UE may monitor the PDCCH having a CRC scrambled by the SPS C-RNTI in every subframe as the eNB can activate/re-activate/release the SPS at any time using a DCI format with a CRC scrambled by an SPS C-RNTI. The received DCI format with a CRC scrambled by the SPS C-RNTI can be a grant/assignment for a retransmission or for activation/re-activation/release of the SPS. 3GPP Technical Specification 36.213 has tabulated the validation procedure for activation/re-activation/release of SPS.

[0024] In addition to the PDCCH, an enhanced PDCCH (EPDCCH) may be used by the eNB and UE. The PDSCH may thus contain data in some of the resource blocks (RBs) and then EPDCCH contains the downlink control signals in others of the RBs of the bandwidth supported by the UE. Different UEs may have different EPDCCH configurations. The sets of RBs corresponding to EPDCCH may be configured, for example, by higher layer signaling such as Radio Resource Control (RRC) signaling for EPDCCH monitoring.

[0025] The Physical Uplink Control Channel (PUCCH) may be used by the UE to send Uplink Control Information (UCI) to the eNB. The PUCCH may be mapped to an UL control channel resource defined by an orthogonal cover code and two resource blocks (RBs), consecutive in time, with hopping potentially at the boundary between adjacent slots. The PUCCH may take several different formats, with the UCI containing information dependent on the format. Specifically, the PUCCH may contain a scheduling request (SR), acknowledgement responses/retransmission requests (ACK/NACK) or a Channel Quality Indication (CQI)/Channel State Information (CSI). The CQI/CSI may indicate to the eNB an estimate of the current downlink channel conditions as seen by the UE to aid channel-dependent scheduling and, if one MIMO transmission mode is configured to the UE, may include MIMO-related feedback (e.g. Precoder matrix indication, PMI).

[0026] FIG. 2 is a functional diagram of a 3GPP device in accordance with some embodiments. The device may be a UE or eNB, for example. In some embodiments, the eNB may be a stationary non-mobile device. The 3GPP device 200 may include physical layer circuitry 202 for transmitting and receiving signals using one or more antennas 201. The 3GPP device 200 may also include medium access control layer (MAC) circuitry 204 for controlling access to the wireless medium. The 3GPP device 200 may also include processing circuitry 206 and memory 208 arranged to perform the operations described herein.

[0027] In some embodiments, mobile devices or other devices described herein may be part of a portable wireless communication device, such as a personal digital assistant (PDA), a laptop or portable computer with wireless communication capability, a web tablet, a wireless telephone, a smartphone, a wireless headset, a pager, an instant messaging device, a digital camera, an access point, a television, a medical device (e.g., a heart rate monitor, a blood pressure monitor, etc.), or other device that may receive and/or transmit information wirelessly. In some embodiments, the mobile device or other device can be a UE 102 or eNB 104 configured to operate in accordance with 3GPP standards. In some embodiments, the mobile device or other device may be configured to operate according to other protocols or standards, including IEEE 802.11 or other IEEE standards. In some embodiments, the mobile device or other device may include one or more of a keyboard, a display, a non-volatile memory port, multiple antennas, a graphics processor, an application processor, speakers, and other mobile device elements. The display may be an LCD screen including a touch screen.

[0028] The antennas 201 may comprise one or more directional or omnidirectional antennas, including, for example, dipole antennas, monopole antennas, patch antennas, loop antennas, microstrip antennas or other types of antennas suitable for transmission of RF signals. In some multiple-input multiple-output (MIMO) embodiments, the antennas 201 may be effectively separated to take advantage of spatial diversity and the different channel characteristics that may result.

[0029] Although the 3GPP device 200 is illustrated as having several separate functional elements, one or more of the functional elements may be combined and may be implemented by combinations of software-configured elements, such as processing elements including digital signal processors (DSPs), and/or other hardware elements. For example, some elements may comprise one or more microprocessors, DSPs, field-programmable gate arrays (FPGAs), application specific integrated circuits (ASICs), radio-frequency integrated circuits (RFICs) and combinations of various hardware and logic circuitry for performing at least the functions described herein. In some embodiments, the functional elements may refer to one or more processes operating on one or more processing elements.

[0030] Embodiments may be implemented in one or a combination of hardware, firmware and software. Embodiments may also be implemented as instructions stored on a computer-readable storage device, which may be read and executed by at least one processor to perform the operations described herein. A computer-readable storage device may include any non-transitory mechanism for storing information in a form readable by a machine (e.g., a computer). For example, a computer-readable storage device may include read-only memory (ROM), random-access memory (RAM), magnetic disk storage media, optical storage media, flash-memory devices, and other storage devices and media. Some embodiments may include one or more processors and may be configured with instructions stored on a computer-readable storage device.

[0031] The term "machine readable medium" may include a single medium or multiple media (e.g., a centralized or distributed database, and/or associated caches and servers) configured to store one or more instructions. The term “machine readable medium” may include any medium that is capable of storing, encoding, or carrying instructions for execution by the 3GPP device 200 and that cause it to perform any one or more of the techniques of the present disclosure, or that is capable of storing, encoding or carrying data structures used by or associated with such instructions. The term “transmission medium” shall be taken to include any intangible medium that is capable of storing, encoding or carrying instructions for execution, and includes digital or analog

communications signals or other intangible medium to facilitate communication of such software.

[0032] As above, the upcoming 5G wireless communications technology systems may have a number of unique challenges, including carrying the inherent ability to provide different performances requirements for numerous different types of wireless devices. Higher data rates in particular may continue to drive network development and evolution for 5G system. It may be desirable for a 5G system to support a peak data rate of more than 10Gps and a minimum guaranteed user data rate of at least 100Mbps. In addition, it may be desirable for the 5G system to support the huge increase in variety and number of Internet of Things (IoT) and Machine-Type Communication (MTC)-type devices. MTC devices have been increasingly employed for different applications, using low operational power consumption and infrequent small burst transmissions. Moreover, it may be desirable for the 5G system to provide an extremely high level of reliable connectivity with guaranteed low latency, availability and reliability-of-service for mission critical MTC use cases.

[0033] In general, 5G systems may use a plurality of Radio Access Technologies (RATs), unlike previous 2G, 3G and 4G, systems. For example, an enormous amount of spectrum may be available through the use of higher frequency bands. In one example, the use of millimeter wave (mmWave) frequency bands ranging from 30 to 300GHz may provide the desired scalability, capacity and density for the 5G system. In this case, a new RAT may be defined for the mmWave band to achieve low latency and higher peak data rate. The RAT for mmWave band communications may differ from the RAT for one or more of the other frequency bands used to provide communication services. In some embodiments, the RATs may be used simultaneously by a single eNB for communications with different UEs.

[0034] In some embodiments, a 5G system may be provided that contains multiple RATs in a unified framework to support diverse applications, use cases and services and inter-networking in multiple frequency bands, including both licensed and unlicensed frequency bands. The RATs used in the licensed and unlicensed may be independent of each other. In some embodiments, flexible subcarrier spacing and symbol duration (i.e., configurable

numerology) may be provided across the frequency bands used in the 5G system. In addition, the 5G system may include mechanisms to multiplex multiple RATs, sub-RATs and other partitions in different or the same frequency resource or frequency bands.

[0035] The inter-networking in the unified frame structure may include, in some embodiments, a Transmission Time Interval (TTI) boundary alignment between multiple RATs may be provided to allow seamless scheduling, fallback and support of different RATs. In some embodiments, a TTI is the smallest unit of time in which the eNB is capable of scheduling any UE for uplink or downlink transmission. In some embodiments, the TTI boundary alignment may occur at a subframe or frame boundary. As used herein, a unified RAT with flexible air interface for the 5G system is referred to as a flexible Radio Access Technology (FRAT). A UE that communicates with an eNB operating using the FRAT may remain using a single air interface technology (i.e., RAT) or may switch between different RATs.

[0036] In some embodiments, a unified RAT with configurable numerologies may be used in the 5G system in which a base subcarrier spacing (Δf) and symbol duration (T) can be defined in the FRAT. In one example, to maintain the backward compatibility for existing LTE and LTE-Advanced systems, a base subcarrier spacing and symbol duration can be specified as Δf = 15KHz and T=66.7μs. Moreover, for convenience in some embodiments a single oscillator may be used, with the subcarrier spacing and symbol duration for different RATs specified as an integer number of the base subcarrier spacing and symbol duration, respectively.

[0037] Similarly, when a low latency use case and service is desired, a shortened symbol duration may be employed to reduce the latency by using larger subcarrier spacing. The subcarrier spacing and symbol duration may in this case be defined as $\Delta f_i = K*\Delta f$ and $T_i=(1/K)*T$. In one example, for frequency band between 6GHz and 30GHz, K can be chosen as 10, leading to a subcarrier spacing and symbol duration of 150KHz and 6.67μs, respectively. This may result in a 0.1ms TTI for low latency use case. In another example, for frequency bands below 6GHz, which includes the current LTE frequency range,

K can be selected by the network to be 2 or 4, and the corresponding subcarrier spacing and symbol duration changed proportional to the selected K value. Alternatively, the same subcarrier spacing and symbol duration can be defined for frequency bands below 6GHz (i.e., K =1), but a shorter TTI can be considered, e.g., with a fewer number of symbols, to support low latency use cases.

[0038] To efficiently support a massive number of MTC devices used in the 5G network, in other embodiments, the subcarrier spacing and symbol duration can be defined as $\Delta f_i = (1/K)*\Delta f$ and $T_i=K*T$. In such embodiments, K can be selected to be 10, and the subcarrier spacing and symbol duration 1.5KHz and 667μs, respectively. In this case, the subframe duration for MTC use cases can be defined to be 10ms, in the current generation LTE systems the length of a typical frame, rather than the typical 1ms. This may reduce the power consumption of MTC UEs by reducing the amount of time the MTC UE is active, thereby increasing the battery life of the MTC UEs.

[0039] A UE may be initially assigned the appropriate RAT by the eNB or other network device (such as the MME). In some embodiments, the UE may be configurable to communicate using any of the RATs, as indicated via the eNB, and can configure the subcarrier spacing and symbol duration accordingly. In some embodiments, the UE may be limited to communicating only using a subset of the RATs, and perhaps only a single RAT, e.g., when the UE is an MTC UE having a limited bandwidth and capabilities. The RAT may depend on the type of UE as well as the operating mode of the UE. For example, some UEs may change mode between a normal mode and an enhanced coverage mode in situations in which the link budget to the nearest serving eNB is worse than a typical link budget value in the network and additional link budget is to be obtained without increasing transmission power. Enhanced coverage mode may be employed by a variety of UEs, including a normal UE (e.g., a smartphone or the like), a machine-to-machine (M2M) UE or a stationary wireless UE (i.e., a UE that remains indefinitely in a single location) using MTC. The UE may determine whether additional link budget is desired, as well as how much additional link budget is desired, and enter an appropriate enhanced coverage mode (that provides the appropriate additional link budget). The different

enhanced coverage modes may correspond to different RATs. Some UEs, such as low cost, low complexity MTC UEs, further may be band limited and operate in a narrow bandwidth of e.g., to 1.4 MHz, for both control and data channels, leading to the ability to operate, e.g., in a single RAT unless the RAT is modified by the network.

[0040] FIG. 3 illustrates one embodiment of a FRAT of a 5G system in accordance with some embodiments. The FRAT 300 may contain one or more partitions in different frequency band regions 310, 320, 330. In one example, the low frequency band 310 may include frequencies used in 4G systems (up to 6 GHz), the mid-frequency band 320 may include higher frequencies (e.g., 6-30 GHz) and the high frequency band 330 may include the highest frequencies in the 5G system (e.g., mmWave, above 30 GHz). Although the RATs of only a low frequency band 310, a mid-frequency band 320, and a high frequency band 330 are shown, any number of RATs of different frequency bands may exist. The various RATs in frequency bands may each have a subcarrier spacing and symbol duration that is independent of the subcarrier spacing and symbol duration of another RAT in another frequency band (i.e., the RATs have configurable numerologies). Moreover, within each frequency band, one or more sub-RATs and partitions 312, 314, 316, 318 may be present with each sub-RAT or partition 312, 314, 316, 318 having a subcarrier spacing and symbol duration independent of the subcarrier spacing and symbol duration of another sub-RAT or partition 312, 314, 316, 318 and independent of the RAT in other frequency bands. As shown in FIG. 3, the sub_RATs 316, 318 in the low frequency band 310 may have the same subcarrier spacing and symbol duration and may be separated by frequency and/or time, while partitions 312, 314 may have different subcarrier spacings and symbol durations from each other and the sub_RATs 316, 318 and may be separated by frequency and/or time. Although the low frequency band 310 is shown as having multiple partitions 312, 314 and sub_RATs 316, 318, the mid frequency band 320 is shown as having two sub_RATs and the high frequency band 330 is shown as having no sub_RATs, the eNB may establish the number and type of RATs used within a particular frequency band differently.

[0041] In some embodiments, RATs and sub-RATs with same or different numerologies can be multiplexed. The multiplexing may be via Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), code-division multiplex (CDM), spatial division multiplex (SDM), other possible orthogonal or non-orthogonal multiplexing schemes, or any combination thereof. For example, multiple RATs, sub-RATs or partitions with same or different numerologies can be multiplexed in a TDM manner. Each RAT, sub-RAT and partition may have a numerology, access scheme and modulation scheme that is independent of the numerology, access scheme and modulation scheme of the other RATs, sub-RATs and partitions. The numerologies, resource allocation and partition information in the time domain can be predefined or configured by higher layer signaling, e.g. via a Master Information Block (MIB), System Information Block (SIB) or UE-specific dedicated RRC signaling. If a MIB is used to indicate the partition configuration for multiple RATs, sub-RATs or partitions, the resource for the transmission physical broadcast channel (PBCH) used to carry the MIB may be predefined and known at the UEs. In some embodiments, the PBCH may be transmitted in a predetermined RAT, independent of the UE or number of RATs, sub-RATs or partitions supported. Once the UE receives the configuration information via the PBCH on the predetermined RAT, the UE may use a different RAT for further control and data communications; that is, the predetermined RAT and the RAT used by the UE to communicate may be independent.

[0042] In some embodiments, multiple RATs, sub-RATs or partitions with same or different numerologies can be multiplexed in a FDM manner. To minimize the interference between multiple RATs, sub-RATs or partitions with different numerologies, guard bands may be inserted at the edge of frequency resources allocated for the RATs, sub-RATs or partitions. Similar to the above, the numerologies and/or resource partition for multiple RATs, sub-RATs or partitions may be predefined or configured by high layer signaling via a MIB, SIB or UE-specific dedicated RRC signaling.

[0043] In embodiments in which numerologies and/or resource partition for multiple RATs, sub-RATs or partitions is predefined or dedicated carriers are allocated for different RATs, a dedicated downlink synchronization signal and

PBCHs may be transmitted on each RAT, sub-RAT or partition. In embodiments in which the numerologies and/or resource partition for multiple RATs, sub-RATs or partitions is configured using a MIB or SIB, a single MIB or SIB may be transmitted on one of the RAT, sub-RAT or partition. After successfully decoding the MIB or SIB, the UEs may be able to derive the resource information or numerologies for other RATs, sub-RATs or partitions. Thus, information provided from the eNB to the UE via a single transmission in a particular RAT, sub-RAT or partition may enable communications using different RATs, sub-RATs or partitions.

[0044] Particular RATs/sub-RATs/partitions may be used for different types of communications, with each having independently sized resource blocks. For example, as shown, the resources in a first partition 312 may be used for low-latency communications while the resources in a second partition 314 may be used for low energy communications. The first and second partitions 312, 314 may be multiplexed, as shown, using FDM such that the first and second partitions 312, 314 occupy the same time but different frequency resources. The first partition 312 may be associated with low latency communications in which the UE operates in a low latency mode and may have a short symbol duration and TTI, while the second partition 314 may be associated with low energy communications in which the UE operates in a low energy mode and may have a long symbol duration and TTI.

[0045] Other sub-RATs 316, 318 may similarly be FDM multiplexed with the first and second partitions 312, 314 and TDM multiplexed with each other. The sub-RATs 316, 318 may have a symbol duration and TTI between those associated with the first and second partitions 312, 314.

[0046] The RATs 320, 330 for the mid- and high- frequency band may be supported simultaneously with each other and the RAT 310 for low frequency band, while maintaining TTI boundary alignment between the different RATs 310, 320, 330. The RATs 320, 330 may similarly be FDM multiplexed with the first and second partitions 312, 314 and sub-RATs 316, 318. The RATs 320, 330 may have a symbol duration and TTI smaller than those associated with the first partition 312. As shown in FIG. 3, in some embodiments, the amount of temporal and/or frequency resources associated with the different RATs, sub-

RATs and partitions may differ among the different types, and the same type may be associated either with different amounts of temporal and/or frequency resources (e.g., as partitions 312, 314) or the same amount of temporal and/or frequency resources (e.g., as sub-RATs 316, 318). A given frequency and temporal range may be associated with a particular frame and symbol structure (as well as subcarrier spacing and symbol duration), with the frame and symbol structures of the frequency and temporal range independent of the frame and symbol structures of other frequency and temporal ranges.

[0047] FIG. 4 illustrates a unified frame structure in accordance with some embodiments. The unified frame structure contains frames 400, subframes 410, slots 420 and symbols 430. More specifically, each frame 400 may contain L subframes of equal duration and have an overall duration of X ms. Each subframe 410 may similarly comprise N slots of equal duration and have an overall duration of Y ms. Each slot may, in turn, comprise M symbols of equal duration. The slot and symbol durations may be different between subframes of different RATs depending on specific use cases, frequency bands and deployment scenarios. The frame structure of each of RAT may be independent of the frame structure of the other RATs. Thus, a particular RAT may have one or more of different L, N and/or M values, as well as different X and/or Y values, as the other RATs. This may also apply to the sub-RATs and partitions shown in FIG. 3.

[0048] FIG. 5 illustrates a Transmission Time Interval (TTI) boundary alignment in accordance with some embodiments. In some embodiments of the unified frame structure, it may be beneficial from a simplified design standpoint to periodically align the TTI boundary 530 between different RATs 510, 520, e.g., at a particular subframe or frame boundary after a predetermined number of subframes or frames. Thus, in some embodiments an integral number of TTIs 540 of a RAT 510 having a smaller TTI duration (low latency RAT) may be disposed within a single TTI 550 of a RAT 520 having a larger TTI duration. In the example shown in FIG. 5, the smaller TTI duration RAT 510 may have a TTI 540 of 0.1ms while the larger TTI RAT 520 may have a TTI 550 of 1ms. By implementing a TTI of 1ms, a low latency RAT TTI may align with the existing LTE specification TTI boundary. Having a common TTI boundary may support

cross-carrier/RAT scheduling for high frequency band RATs from low frequency band RATs based an anchor booster architecture. This is to say that, in some embodiments for cross-carrier/RAT scheduling, as shown a common PDCCH may be used to schedule other RATs, with the UE switching to a particular RAT to obtain the scheduling and then switching to another RAT to communicate and perhaps to obtain further scheduling information using that RAT. In some embodiments, the other RAT may contain a PDCCH for additional scheduling, while in other embodiments the other RAT may not contain a PDCCH, in which case the UE may periodically switch to the scheduling RAT to obtain scheduling information for the other RAT. In some embodiments, a UE may obtain initial scheduling information (e.g., when it initially powers on or otherwise accesses the eNB) from the initial RAT (e.g., a conventional 4G system RAT) and from then on, after switching to its assigned RAT, obtains scheduling information using that RAT. In other embodiments, each RAT may contain a PDCCH and scheduling is performed for the UE operating on the RAT. A licensed low frequency band RAT may provide reliable coverage for control signaling as an anchor cell, using the PDCCH shown in FIG. 5, while a high frequency band RAT may provide opportunistic boosting in data rate when channel conditions are favorable as booster cell.

[0049] FIG. 6 illustrates a symbol structure in accordance with some embodiments. FIG. 6 shows an OFDM symbol 610 and a unique word (UW) OFDM symbol 620. Each OFDM symbol 610 may contain a cyclic prefix (CP) 612 that comprises a replication of the initial portion of the OFDM symbol 610. The CP 612 may range in size from 1/4 to 1/32 of the symbol period 614. The CP 612 may be disposed at the end of the symbol or outside the symbol, depending on specific waveform, thereby creating a guard between the symbol and the adjacent symbol. In some embodiments, when OFDM downlink and SC-FDMA uplink waveforms are selected for a 5G RAT, the CP 612 may be inserted outside the symbol 610. In embodiments in which a UW OFDM symbol 620 or UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM) symbol is used, the UW 622 may be inserted within one symbol duration 624. The symbol structure may be independent for each of the RATs, such that whether or not a particular RAT a

CP or UW and whether the CP or UW is outside or within a symbol is independent of the symbol structure of any other RAT.

[0050] As shown in FIG. 6, the UW-OFDM 620 may be used to support different UW lengths based on different channel delay spreads while maintaining the same symbol duration (or FFT size). This enables both shorter UW 622 and longer UW 626 to be used in the same size symbol 624 as the UW 622, 624 is inserted within the FFT instead of being adding after the FFT size. The ability to maintain the same symbol duration may provide a greater flexibility to support a unified RAT design. In one example, using an OFDM symbol for a low frequency band (below 6GHz), a subcarrier spacing of 60KHz (i.e., K = 4, Δf =60KHz) may be used to achieve a 0.1ms TTI. This translates to OFDM symbols of T=16.7μs (66.7μs/K). Thus, 5 OFDM symbols may be able to be accommodated within one subframe (83.5μs) with a CP length of approximately 3.3μs (0.1ms - 83.5μs =16.5μs/5 CPs).

[0051] FIG. 7 illustrates frame structures within a TTI in accordance with some embodiments. In FIG. 7, various TTIs 710, 720, 730, 740 are illustrated in which the TTIs 710, 720, 730, 740 comprise UW-OFDM waveforms. The first TTI 710 shown in FIG. 7 may comprise a UW 712 and symbol 714 of typical length. In this example, the subcarrier spacing may be 15KHz and the symbol duration 716 may be 66.7μs. A total of 3 OFDM symbols 716 may be present in a TTI 710 of 200μs.

[0052] The second TTI 720 shown in FIG. 7 may comprise a low latency TTI 720 with short symbol duration. Such a TTI 720 can be used for use cases such as mission critical MTC applications and Vehicle–to-Vehicle applications, among others. The UW 722 and symbol 724 may each be smaller than the first TTI 710. In this example, the subcarrier spacing may be 30KHz and the symbol duration 726 may be 33.3μs. For a TTI 720 of the same length as the first TTI (e.g., 200μs), a total of 6 short OFDM symbols 726 may be present.

[0053] The third TTI 730 shown in FIG. 7 may comprise another low latency TTI 730 similar to the low latency TTI 720. The UW 732 and symbol 734 may each be smaller than the first TTI 710, the subcarrier spacing may be 30KHz and the symbol duration 736 may be 33.3μs. However, in this example

the TTI 730 may only be half the length as the first TTI (i.e., 100μs), corresponding to a total of 3 short OFDM symbols 736.

[0054] The fourth TTI 740 shown in FIG. 7 may comprise a low energy TTI 740, e.g., for use by MTC UEs. The UW 742 and symbol 744 may each have a longer duration smaller than the first TTI 710. In one example, the subcarrier spacing may be 5KHz and the symbol duration 746 may be 200μs. In this example, the TTI 740 may be 1ms, corresponding to a total of 5 long OFDM symbols 746.

[0055] The above TTIs 710, 720, 730, 740 may be FDM or TDM multiplexed based on the FRAT design. One or more of the UW-OFDM waveforms may be replaced by other waveforms so long as the same symbol duration is maintained. Other examples of OFDM waveforms may include ZT-OFDM and UW-DFTs-OFDM, among others. When different waveforms are used in the same carrier, multi-RATs can be supported where each RAT may have different waveform design. In some embodiments, existing LTE waveforms may be reused, i.e., OFDM waveforms may be used for downlink and SC-FDMA waveforms may be used for uplink communications. In some embodiments, OFDM may be used both downlink and uplink communications. In some embodiments, UW-based waveforms may be used both downlink and uplink communications. For example, UW-OFDM waveforms may be used for downlink communications and UW-DFT-s-OFDM waveforms may be used for uplink communications or either UW-OFDM or UW-DFT-s-OFDM waveforms may be used for both downlink and uplink communications. In some embodiment, filtered OFDM and filter-bank multiple carrier (FBMC) may be used. FBMC waveforms are produced using a nonrectangular sub-channel pulse shape in the time domain during OFDM-offset quadrature amplitude modulation (OQAM) transmission (in which the real part of QAM symbols are mapped to ½ of the multi-carrier symbols and the imaginary parts are mapped to an interlaced 1/2 of the multi-carrier symbols) and may lack a CP.

[0056] Tables 1-3 below illustrate various examples of 5G numerology.

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform

<3GHz (low power or MTC)	1.5KHz	10ms	OFDM	SC-FDMA
<3GHz	15KHz	1ms	OFDM	SC-FDMA
[3-6]GHz	75KHz	0.2ms	UW-OFDM	UW-DFT-s-OFDM
[6-30]GHz	480KHz	0.1ms	UW-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	DFT-s-OFDM	DFT-s-OFDM

Table 1: First 5G numerology example

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform
<3GHz (low power or MTC)	1.5KHz	10ms	UW-OFDM	UW-OFDM
<3GHz	15KHz	1ms	UW-OFDM	UW-OFDM
[3-6]GHz	75KHz	0.2ms	UW-OFDM	UW-OFDM
[6-30]GHz	480KHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	OFDM	OFDM

Table 2: Second 5G numerology example

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform
<3GHz (low power or MTC)	1.5KHz	10ms	OFDM	OFDM
<3GHz	15KHz	1ms	OFDM	OFDM
[3,6]GHz	75KHz	0.2ms	OFDM	OFDM
[6,30]GHz	480KHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM

Table 3: Third 5G numerology example

[0057] FIGS. 8A and 8B illustrate flowcharts of a uniform framework utilization method in accordance with some embodiments. FIG. 8A in particular illustrates a flowchart of a uniform framework utilization method of an eNB such as the eNB shown in FIGS. 1 or 2 in accordance with some embodiments. As shown in FIG. 8A, the eNB may determine the unified framework at operation 802. The unified framework may include access scheme, modulation

scheme, frame structure, symbol structure, and configurable numerology including subcarrier spacing and symbol duration. The different frame and symbol structures may be associated with different temporal and/or frequency resources multiplexed respectively in a TDM or FDM manner.

[0058] At operation 804, the eNB may communicate specific unified framework configuration information of a particular RAT to one or more UEs serviced by the eNB. Different RAT information may be provided to different UEs attached to the eNB, in which different RATs may be associated with different frequency bands and/or time spans. The eNB may determine the configuration information to be provided to a particular UE based on the device type and/or data to be communicated between the UE and the eNB. The frequency bands may include both licensed and unlicensed frequency bands. The RAT information may include access and modulation scheme, frame and symbol structure, as well as numerology. The RAT information may also include resource allocation and partition information. The unified framework configuration information provided to each UE may be independent of the unified framework configuration information provided to any other UE. The RAT indicated by the eNB to the UE may be dependent on the type and/or operating mode of the UE.

[0059] The eNB may communicate with the UE at operation 806 using the RAT provided at operation 804. The information may include data and/or control information. For example, downlink communications from the eNB to the UE may include paging or control signals for channel estimation on the PDCCH and voice or video data from another UE on the PDSCH. The RAT information may be provided using a dedicated RAT that is different from the RAT used for communication with the UE or using a dedicated carrier on the RAT used for communication with the UE.

[0060] The eNB may, subsequent to communicating with the UE, receive an indication from the UE of a change of operating state of the UE at operation 808. The UE may, for example, be configured to operate in one or more of a normal mode, a low latency and low energy mode. The eNB may, at operation 804, assign the RAT to the UE based on the initial mode of the UE and

determine that an update of the operation mode of the UE has occurred at operation 808.

[0061] In response to determining at operation 808 that an update of the operation mode of the UE has occurred, the eNB may determine a new RAT and transmit the updated unified framework configuration information of the new RAT to the UE at operation 810. The new RAT may include a different frame and/or symbol structure and use a different frequency spectrum and/or time range. The eNB may then continue to communicate with the UE at operation 806.

[0062] FIG. 8B illustrates a uniform framework utilization method as performed by a UE in accordance with some embodiments. The UE may be the UE shown in FIGS. 1 or 2 and may attach to the eNB prior to communicating data. During the attachment, the UE may transmit the initial operation conditions to the eNB at operation 812. In particular, the UE may provide a UE type and/or operating mode during attachment. For example, the UE may be a MTC UE. The UE may moreover be configured to operate in a low latency and/or low energy mode. In some embodiments, a MTC UE may operate in an enhanced coverage, low energy mode.

[0063] In response to transmitting the operating conditions, unified framework configuration (RAT) information may be received by a particular UE at operation 814. The RAT information may be dependent on the type and/or operating mode of the UE. The RAT may be associated with a particular frequency band and/or time range. For example, when the UE operates in the low latency mode, a larger subcarrier spacing and shorter symbol duration may be indicated by the unified framework configuration information; while when the UE operates in the low energy mode, a smaller subcarrier spacing and longer symbol duration may be indicated by the unified framework configuration information.

[0064] Once the RAT received by the UE, the UE may then communicate using the RAT at operation 816. The UE may, for example, adjust FFT operating conditions and processing to meet the RAT information provided at operation 814. The UE may communicate with the eNB or may communicate directly with other UEs using device-to-device communication (D2D)

communication. The information may include uplink and downlink data and/or control information. For example, the information may include uplink communications of voice or video data for another UE or measurements of control signals for channel estimation.

[0065] The UE may, subsequent to communicating with the eNB, determine that a change of operating conditions is warranted at operation 818. For example, the UE may transition between the normal and enhanced coverage/low energy mode dependent on UE location, or between the normal and low latency mode dependent on the type of communication to transmit.

[0066] In response to determining that a change of operating conditions is warranted at operation 818, at operation 820 the UE may transmit an indication to the eNB indicating the change of operating state of the UE. The UE may instead determine that a change of operating conditions is desired at operation 820 and wait to change operating state until a new RAT is assigned to the UE.

[0067] In response to transmitting the indication at operation 820, the UE may return to operation 814 and receive a new RAT at operation 810. The new RAT may include a different frame and/or symbol structure and use a different frequency spectrum and/or time range. The eNB may then continue to communicate with the UE at operation 816.

[0068] Various examples of the disclosure are provided below. These examples are not intended to in any way limit the disclosure herein. In Example 1, user equipment (UE) may comprise processing circuitry configured to: configure a transceiver to receive a resource allocation from a network using a first Radio Access Technology (RAT), the first RAT selected from a plurality of RATs of a flexible RAT (FRAT) employed by the network, the plurality of RATs of the FRAT each comprising configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resources, the transceiver configurable to communicate using the plurality of RATs and configure the subcarrier spacing and symbol duration based on the numerology; and configure the transceiver to communicate using the first RAT.

[0069] In Example 2, the subject matter of Example 1 can optionally include that the processing circuitry is further configured to configure the transceiver to receive from an enhanced NodeB (eNB) higher layer signaling associated with the FRAT, the higher layer signaling indicating numerologies, resource allocation and partition information in at least one of a time and frequency domain.

[0070] In Example 3, the subject matter of one or any combination of Examples 1-2 can optionally include that the FRAT comprises a base subcarrier spacing and symbol duration, and at least one of the subcarrier spacing and symbol duration for different RATs of the FRAT is respectively specified as an integer number of the base subcarrier spacing or symbol duration.

[0071] In Example 4, the subject matter of one or any combination of Examples 1-3 can optionally include that the UE is a Machine-Type Communication (MTC) UE configured to operate in at least one of a low latency and low energy mode, and the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode.

[0072] In Example 5, the subject matter of one or any combination of Examples 1-4 can optionally include that at least one of the plurality of RATs of the FRAT comprises at least one of a plurality of sub-RATs and partitions, each of the at least one of the plurality of sub-RATs and partitions comprising an independent configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resource, and the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using at least one of a Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), Code-Division Multiplexing (CDM), and Spatial Division Multiplexing (SDM).

[0073] In Example 6, the subject matter of one or any combination of Examples 1-6 can optionally include that the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using TDM, and numerologies, resource allocation and partition information in a time domain are at least one of predefined or configured by higher-layer signaling via Master

Information Block (MIB), System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling, or the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using FDM, guard bands are inserted at an edge of frequency resources allocated for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions, and at least one of numerologies and resource partition for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are at least one of predefined or configured by the higher-layer signaling.

[0074] In Example 7, the subject matter of one or any combination of Examples 1-6 can optionally include that a Transmission Time Interval (TTI) boundary between different RATs of the plurality of RATs is common, and the plurality of RATs comprise a common reference TTI duration.

[0075] In Example 8, the subject matter of one or any combination of Examples 1-7 can optionally include that a symbol structure of each of the plurality of RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the plurality of RATs is independent of the symbol structure of the other RATs. ‘

[0076] In Example 9, the subject matter of one or any combination of Examples 1-8 can optionally include that the processing circuitry is further configured to configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

[0077] In Example 10, the subject matter of one or any combination of Examples 1-9 can optionally include that a frame structure in each of the plurality of RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and the frame structure of each of the plurality of RATs is independent of the frame structure of the other RATs.

[0078] In Example 11, the subject matter of one or any combination of Examples 1-10 can optionally include that the processing circuitry is further configured to configure the transceiver to receive numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[0079] In Example 12, the subject matter of one or any combination of Examples 1-11 can optionally include that the processing circuitry is configured to configure the transceiver to receive numerologies, resource allocation and partition information via a dedicated carrier in the first RAT, a dedicated carrier allocated for each of the plurality of RATs, and a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the plurality of RATs.

[0080] In Example 13, the subject matter of one or any combination of Examples 1-12 can optionally include an antenna configured to transmit and receive communications between the transceiver and the eNB.

[0081] Example 14 comprises an apparatus of an eNode B (eNB) comprising processing circuitry configured to: configure a transceiver to transmit resource allocations for different Radio Access Technologies (RATs) to a plurality of user equipment (UE), at least two of the UEs associated with a different RAT, each RAT comprising an independent subcarrier spacing, symbol duration, frame structure and symbol structure; and configure the transceiver to communicate with each UE using the RAT associated with the UE.

[0082] In Example 15, the subject matter of Example 14 can optionally include that the processing circuitry is configured to configure the transceiver to transmit higher layer signaling indicating numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a same RAT to each of the plurality of UEs.

[0083] In Example 16, the subject matter of one or any combination of Examples 14-15 can optionally include that the processing circuitry is

configured to configure the transceiver to transmit numerologies, resource allocation and partition information via a dedicated carrier allocated for each of the RATs, and a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the RATs.

[0084] In Example 17, the subject matter of one or any combination of Examples 14-16 can optionally include that at least one of the subcarrier spacing and symbol duration for each of the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration.

[0085] In Example 18, the subject matter of one or any combination of Examples 14-17 can optionally include that the RATs comprise a first RAT comprising a larger subcarrier spacing and shorter symbol duration configured for a UE operating in a low latency mode and a second RAT comprising a smaller subcarrier spacing and longer symbol duration configured for a UE operating in a low energy mode.

[0086] In Example 19, the subject matter of one or any combination of Examples 14-18 can optionally include that a Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration.

[0087] In Example 20, the subject matter of one or any combination of Examples 14-19 can optionally include that a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the RATs is independent of the symbol structure of the other RATs.

[0088] In Example 21, the subject matter of one or any combination of Examples 14-20 can optionally include that the processing circuitry is configured to at least one of: configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

[0089] In Example 22 a non-transitory computer-readable storage medium that stores instructions for execution by one or more processors of a user equipment (UE) to configure the UE to communicate with an enhanced Node B (eNB), the one or more processors to configure the UE to: receive resource allocation, partition information and numerology, including subcarrier spacing and symbol duration, for a first Radio Access Technology (RAT) of a plurality of RATs used by the eNB, the UE configurable to configure the subcarrier spacing and symbol duration based on the numerology and to communicate using the plurality of RATs; and communicate using the first RAT.

[0090] In Example 23, the subject matter of Example 22 can optionally include that at least one of: a) at least one of the subcarrier spacing and symbol duration for the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration, b) the UE is configured to operate in at least one of a low latency and low energy mode, and the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode, and c) a Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration.

[0091] In Example 24, the subject matter of one or any combination of Examples 22-23 can optionally include that at least one of: a) a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the RATs is independent of the symbol structure of the other RATs, and b) a frame structure in each of the RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and the frame structure of each of the RATs is independent of the frame structure of the other RATs.

[0092] In Example 25, the subject matter of one or any combination of Examples 22-24 can optionally include that the numerology, resource allocation and partition information is received via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[0093] Although an embodiment has been described with reference to specific example embodiments, it will be evident that various modifications and changes may be made to these embodiments without departing from the broader spirit and scope of the present disclosure. Accordingly, the specification and drawings are to be regarded in an illustrative rather than a restrictive sense. The accompanying drawings that form a part hereof show, by way of illustration, and not of limitation, specific embodiments in which the subject matter may be practiced. The embodiments illustrated are described in sufficient detail to enable those skilled in the art to practice the teachings disclosed herein. Other embodiments may be utilized and derived therefrom, such that structural and logical substitutions and changes may be made without departing from the scope of this disclosure. This Detailed Description, therefore, is not to be taken in a limiting sense, and the scope of various embodiments is defined only by the appended claims, along with the full range of equivalents to which such claims are entitled.

[0094] Such embodiments of the inventive subject matter may be referred to herein, individually and/or collectively, by the term “invention” merely for convenience and without intending to voluntarily limit the scope of this application to any single invention or inventive concept if more than one is in fact disclosed. Thus, although specific embodiments have been illustrated and described herein, it should be appreciated that any arrangement calculated to achieve the same purpose may be substituted for the specific embodiments shown. This disclosure is intended to cover any and all adaptations or variations of various embodiments. Combinations of the above embodiments, and other embodiments not specifically described herein, will be apparent to those of skill in the art upon reviewing the above description.

[0095] In this document, the terms "a" or "an" are used, as is common in patent documents, to include one or more than one, independent of any other instances or usages of "at least one" or "one or more." In this document, the term "or" is used to refer to a nonexclusive or, such that "A or B" includes "A but not B," "B but not A," and "A and B," unless otherwise indicated. In this document, the terms "including" and "in which" are used as the plain-English equivalents of the respective terms "comprising" and "wherein." Also, in the following claims, the

terms "including" and "comprising" are open-ended, that is, a system, UE, article, composition, formulation, or process that includes elements in addition to those listed after such a term in a claim are still deemed to fall within the scope of that claim. Moreover, in the following claims, the terms "first," "second," and "third," etc. are used merely as labels, and are not intended to impose numerical requirements on their objects.

[0096] The Abstract of the Disclosure is provided to comply with 37 C.F.R. §1.72(b), requiring an abstract that will allow the reader to quickly ascertain the nature of the technical disclosure. It is submitted with the understanding that it will not be used to interpret or limit the scope or meaning of the claims. In addition, in the foregoing Detailed Description, it can be seen that various features are grouped together in a single embodiment for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed embodiments require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter lies in less than all features of a single disclosed embodiment. Thus the following claims are hereby incorporated into the Detailed Description, with each claim standing on its own as a separate embodiment.

CLAIMS

What is claimed is:

1. User equipment (UE) comprising:

processing circuitry configured to:

configure a transceiver to receive a resource allocation from a network using a first Radio Access Technology (RAT), the first RAT selected from a plurality of RATs of a flexible RAT (FRAT) employed by the network, the plurality of RATs of the FRAT each comprising configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resources, the transceiver configurable to communicate using the plurality of RATs and configure the subcarrier spacing and symbol duration based on the numerology; and

configure the transceiver to communicate using the first RAT.

2. The UE of claim 1, wherein the processing circuitry is configured to:

configure the transceiver to receive from an enhanced NodeB (eNB) higher layer signaling associated with the FRAT, the higher layer signaling indicating numerologies, resource allocation and partition information in at least one of a time and frequency domain.

3. The UE of claim 1, wherein:

the FRAT comprises a base subcarrier spacing and symbol duration, and

at least one of the subcarrier spacing and symbol duration for different RATs of the FRAT is respectively specified as an integer number of the base subcarrier spacing or symbol duration.

4. The UE of claim 3, wherein:

the UE is a Machine-Type Communication (MTC) UE configured to operate in at least one of a low latency and low energy mode, and

the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller

subcarrier spacing and longer symbol duration when the UE operates in the low energy mode.

5. The UE of claim 1, wherein:

at least one of the plurality of RATs of the FRAT comprises at least one of a plurality of sub-RATs and partitions, each of the at least one of the plurality of sub-RATs and partitions comprising an independent configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resource, and

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using at least one of a Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), Code-Division Multiplexing (CDM), and Spatial Division Multiplexing (SDM).

6. The UE of claim 5, wherein one of:

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using TDM, and numerologies, resource allocation and partition information in a time domain are at least one of predefined or configured by higher-layer signaling via Master Information Block (MIB), System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling, or

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using FDM, guard bands are inserted at an edge of frequency resources allocated for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions, and at least one of numerologies and resource partition for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are at least one of predefined or configured by the higher -layer signaling.

7. The UE of claim 1, wherein:

a Transmission Time Interval (TTI) boundary between different RATs of the plurality of RATs is common, and

the plurality of RATs comprise a common reference TTI duration.

8. The UE of claim 1, wherein:

a symbol structure of each of the plurality of RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the plurality of RATs is independent of the symbol structure of the other RATs.

9. The UE of claim 1, wherein the processing circuitry is configured to at least one of:

configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and

configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

10. The UE of claim 1, wherein:

a frame structure in each of the plurality of RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and

the frame structure of each of the plurality of RATs is independent of the frame structure of the other RATs.

11. The UE of claim 1, wherein the processing circuitry is configured to:

configure the transceiver to receive numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

12. The UE of claim 1, wherein:

the processing circuitry is configured to configure the transceiver to receive numerologies, resource allocation and partition information via a dedicated carrier in the first RAT, a dedicated carrier allocated for each of the plurality of RATs, and

a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the plurality of RATs.

13. The UE of claim 1, further comprising an antenna configured to transmit and receive communications between the transceiver and the eNB.

14. An apparatus of an eNode B (eNB) comprising:

processing circuitry configured to:

configure a transceiver to transmit resource allocations for different Radio Access Technologies (RATs) to a plurality of user equipment (UE), at least two of the UEs associated with a different RAT, each RAT comprising an independent subcarrier spacing, symbol duration, frame structure and symbol structure; and

configure the transceiver to communicate with each UE using the RAT associated with the UE.

15. The apparatus of claim 14, wherein the processing circuitry is configured to:

configure the transceiver to transmit higher layer signaling indicating numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a same RAT to each of the plurality of UEs.

16. The apparatus of claim 14, wherein the processing circuitry is configured to:

configure the transceiver to transmit numerologies, resource allocation and partition information via a dedicated carrier allocated for each of the RATs, and

a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the RATs.

17. The apparatus of claim 14, wherein:

at least one of the subcarrier spacing and symbol duration for each of the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration.

18. The apparatus of claim 14, wherein:

the RATs comprise a first RAT comprising a larger subcarrier spacing and shorter symbol duration configured for a UE operating in a low latency mode and a second RAT comprising a smaller subcarrier spacing and longer symbol duration configured for a UE operating in a low energy mode.

19. The apparatus of claim 14, wherein:

a Transmission Time Interval (TTI) boundary between the RATs is common, and

the RATs comprise a common reference TTI duration.

20. The apparatus of claim 14, wherein:

a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the RATs is independent of the symbol structure of the other RATs.

21. The apparatus of claim 14, wherein the processing circuitry is configured to at least one of:

configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and

configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

22. A non-transitory computer-readable storage medium that stores instructions for execution by one or more processors of a user equipment (UE) to configure the UE to communicate with an enhanced Node B (eNB), the one or more processors to configure the UE to:

receive resource allocation, partition information and numerology, including subcarrier spacing and symbol duration, for a first Radio Access Technology (RAT) of a plurality of RATs used by the eNB, the UE configurable to configure the subcarrier spacing and symbol duration based on the numerology and to communicate using the plurality of RATs; and

communicate using the first RAT.

23. The medium of claim 22, wherein at least one of:

a) at least one of the subcarrier spacing and symbol duration for the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration,

b) the UE is configured to operate in at least one of a low latency and low energy mode, and

the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode, and

c) a Transmission Time Interval (TTI) boundary between the RATs is common, and

the RATs comprise a common reference TTI duration.

24. The medium of claim 22, wherein at least one of:

a) a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the RATs is independent of the symbol structure of the other RATs, and

b) a frame structure in each of the RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and

the frame structure of each of the RATs is independent of the frame structure of the other RATs.

25. The medium of claim 22, wherein:

the numerology, resource allocation and partition information is received via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

(54) Title: IDENTIFICATION OF DOWNLINK MESSAGES USING REPEATED TRANSMISSION

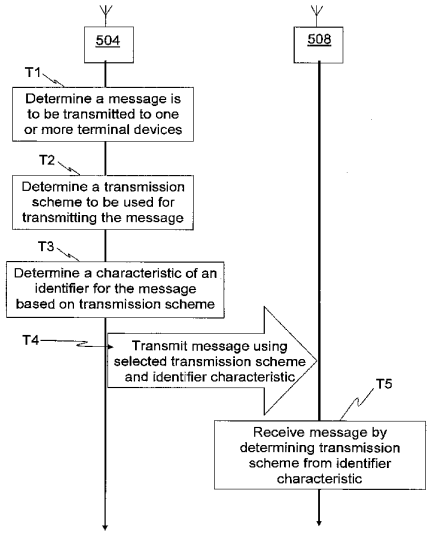

Fig. 9

(57) Abstract: A wireless telecommunication system comprises a base station arranged to communicate messages to one or more terminal devices over a radio interface. The radio interface has a radio frame structure comprising a plurality of subframes, wherein a message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes (e.g. one subframe) or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes (e.g. with repeat transmissions in a plurality of subframes). The message is transmitted in association with an identifier to indicate a terminal device to which the message is addressed. A characteristic for the identifier, for example a value or control region search space for the identifier, is dependent on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme. A terminal device to which the message is addressed determines the transmission scheme from the characteristic of the identifier and receives the message accordingly.

IDENTIFICATION OF DOWNLINK MESSAGES USING REPEATED TRANSMISSION

BACKGROUND

Field

The present disclosure relates to telecommunications apparatus and methods. In particular, certain embodiments relate to schemes for communicating allocations of transmission resources of a shared channel in a wireless telecommunications system.

Description of Related Art

The "background" description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description which may not otherwise qualify as prior art at the time of filing, are neither expressly or impliedly admitted as prior art against the present invention.

Mobile communication systems have evolved over the past ten years or so from the GSM System (Global System for Mobile communications) to the 3G system and now include packet data communications as well as circuit switched communications. The third generation partnership project (3GPP) is developing a fourth generation mobile communication system referred to as Long Term Evolution (LTE) in which a core network part has been evolved to form a more simplified architecture based on a merging of components of earlier mobile radio network architectures and a radio access interface which is based on Orthogonal Frequency Division Multiplexing (OFDM) on the downlink and Single Carrier Frequency Division Multiple Access (SC-FDMA) on the uplink.

Third and fourth generation mobile telecommunication systems, such as those based on the 3GPP defined UMTS and Long Term Evolution (LTE) architecture are becoming able to support more sophisticated services than simple voice and messaging services offered by previous generations of mobile telecommunication systems. For example, with the improved radio interface and enhanced data rates provided by LTE systems, a user is able to enjoy high data rate applications such as mobile video streaming and mobile video conferencing that would previously only have been available via a fixed line data connection. The demand to deploy third and fourth generation networks is therefore strong and there is a corresponding desire to extend the coverage available in such telecommunications systems (i.e. there is a desire to provide more reliable access to wireless telecommunications systems for terminal devices operating in coverage-limited locations).

A typical example of a coverage-limited terminal device might be a so-called machine type communication (MTC) device, such as a smart meter located in a customer's house and periodically transmitting information back to a central MTC server relating to the customer's consumption of a utility, such as gas, water, electricity and so on. Such a terminal device might operate in a coverage-limited location because, for example, it may be located in a basement or other location with relatively high penetration loss. Further information on characteristics of MTC-type devices can be found, for example, in the corresponding standards, such as ETSI TS 122 368 V10.530 (2011-07) / 3GPP TS 22.368 version 10.5.0 Release 10) [1]. Some typical characteristics of MTC type terminal devices / MTC type data might include, for example, characteristics such as low mobility, high delay tolerance, small data transmissions, infrequent transmission and group-based features, policing and addressing.

In some situations a terminal device in a coverage-limited situation in a particular communication cell served by a base station might be unable to receive communications from the base station unless specific provision is made for it to do so. One way to increase coverage in this situation would be for the base station to increase the power of its transmissions. However, a blanket increase in transmission power from a base station could be expected to give rise to increased interference in neighbouring communication cells. An alternative approach would be for the base station to in effect focus / concentrate its available transmission power budget into a subset of transmission resources (e.g. in terms of frequency) which are selected from within the base station's overall transmission resources and allocated for transmissions to coverage-limited terminal devices. However, this approach can again lead to increased interference in neighbouring cells and may in some cases require increased coordination among base stations to optimise performance.

Another approach for providing coverage extension is to rely on repeated transmissions of signalling in multiple subframes. A terminal device may then combine the signalling received for a plurality of repeated transmissions to increase the likelihood of successfully decoding the signalling, e.g. using chase combining / maximal ratio combining techniques. This repeated transmission approach may be applied for control signalling (e.g. sent on a physical downlink control channel such as PDCCH in LTE) and / or other signalling (e.g. sent on a physical downlink shared channel such as PDSCH in LTE).

One draw-back of a repeated transmission approach for providing coverage extension is a corresponding increase in the amount of transmission resources needed to communicate with terminal devices, particularly in the amount of transmission resources needed to provide control messages to the terminal devices, and the inventors have recognised how this issue can be especially significant for certain types of communications, as discussed further below. There is therefore a need for schemes which can allow for communications with terminal devices to be made over a number of subframes with a reduction in the overall amount of transmission resources needed to support this as compared to conventional techniques.

SUMMARY

According to a first aspect of the present disclosure, there is provided a method of operating a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises receiving a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and receiving a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a second aspect of the present disclosure, there is provided a terminal device for communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the

downlink data channel, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a third aspect of the present disclosure, there is provided circuitry for a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the terminal device to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message

According to a forth aspect of the present disclosure, there is provided a method of operating a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises transmitting a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and transmitting a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a fifth aspect of the present disclosure, there is provided a base station for communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the base station comprises a controller unit and a transceiver unit configured to operate together to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a sixth aspect of the present disclosure, there is provided circuitry for a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the

downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the base station to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a seventh aspect of the present disclosure, there is provided a method of operating a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein the method comprises selecting a characteristic for the identifier in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

According to an eighth aspect of the present disclosure, there is provided a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the base station comprises a controller unit and a transceiver unit configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

According to a ninth aspect of the present disclosure, there is provided circuitry for a base station communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the circuitry comprises a controller element and a transceiver element configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

According to a 10th aspect of the present disclosure, there is provided a method of operating a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission

resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the method comprises determining from an identifier associated with the message that the message is addressed to the terminal device, and further determining from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

According to an 11th aspect of the present disclosure, there is provided a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

According to a twelfth aspect of the present disclosure, there is provided circuitry for a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

Further respective aspects and features are defined by the appended claims.

The foregoing paragraphs have been provided by way of general introduction, and are not intended to limit the scope of the following claims. The described embodiments, together with further advantages, will be best understood by reference to the following detailed description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete appreciation of the disclosure and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings wherein like reference numerals designate identical or corresponding parts throughout the several views, and wherein:

Figure 1 provides a schematic diagram illustrating an example of a mobile telecommunication system;

Figure 2 provides a schematic diagram illustrating a LTE radio frame;

Figure 3 provides a schematic diagram illustrating an example of a LTE downlink radio subframe;

Figure 4 provides a schematic diagram illustrating a LTE "camp-on" procedure;

Figure 5 schematically represents a wireless telecommunications system according to an embodiment of the disclosure;

Figure 6 schematically represents a series of downlink subframes for communicating with a terminal device operating in the wireless telecommunications system of Figure 5;

Figure 7 schematically represents a series of downlink subframes for communicating with a terminal device operating in the wireless telecommunications system of Figure 5 in accordance with an embodiment of the disclosure;

Figure 8 is a signalling ladder diagram representing communications between a base station and a terminal device operating in accordance with an embodiment of the disclosure; and

Figure 9 is a signalling ladder diagram representing communications between a base station and a terminal device operating in accordance with another embodiment of the disclosure.

DETAILED DESCRIPTION OF THE EMBODIMENTS

Figure 1 provides a schematic diagram illustrating some basic functionality of a mobile telecommunications network / system 100 operating in accordance with LTE principles and which may be adapted to implement embodiments of the disclosure as described further below. Various elements of Figure 1 and their respective modes of operation are well-known and defined in the relevant standards administered by the 3GPP (RTM) body and also described in many books on the subject, for example, Holma H. and Toskala A [2]. It will be appreciated that operational aspects of the telecommunications network which are not specifically described below may be implemented in accordance with any known techniques, for example according to the relevant standards.

The network 100 includes a plurality of base stations 101 connected to a core network 102. Each base station provides a coverage area 103 (i.e. a cell) within which data can be communicated to and from terminal devices 104. Data is transmitted from base stations 101 to terminal devices 104 within their respective coverage areas 103 via a radio downlink. Data is transmitted from terminal devices 104 to the base stations 101 via a radio uplink. The core network 102 routes data to and from the terminal devices 104 via the respective base stations 101 and provides functions such as authentication, mobility management, charging and so on. Terminal devices may also be referred to as mobile stations, user equipment (UE), user terminal, mobile radio, and so forth. Base stations may also be referred to as transceiver stations / nodeBs / e-nodeBs, and so forth.

Mobile telecommunications systems such as those arranged in accordance with the 3GPP defined Long Term Evolution (LTE) architecture use an orthogonal frequency division modulation (OFDM) based interface for the radio downlink (so-called OFDMA) and a single carrier frequency division multiple access scheme (SC-FDMA) on the radio uplink. Figure 2 shows a schematic diagram illustrating an OFDM based LTE downlink radio frame 201. The LTE downlink radio frame is transmitted from a LTE base station

(known as an enhanced Node B) and lasts 10 ms. The downlink radio frame comprises ten subframes, each subframe lasting 1 ms. A primary synchronisation signal (PSS) and a secondary synchronisation signal (SSS) are transmitted in the first and sixth subframes of the LTE frame. A physical broadcast channel (PBCH) is transmitted in the first subframe of the LTE frame.

Figure 3 is a schematic diagram of a grid which illustrates the structure of an example conventional downlink LTE subframe. The subframe comprises a predetermined number of symbols which are transmitted over a 1ms period. Each symbol comprises a predetermined number of orthogonal subcarriers distributed across the bandwidth of the downlink radio carrier.

The example subframe shown in Figure 3 comprises 14 symbols and 1200 subcarriers spread across a 20MHz bandwidth and in this example is the first subframe in a frame (hence it contains PBCH). The smallest allocation of physical resource for transmission in LTE is a resource block comprising twelve subcarriers transmitted over one subframe. For clarity, in Figure 3, each individual resource element is not shown, instead each individual box in the subframe grid corresponds to twelve subcarriers transmitted on one symbol.

Figure 3 shows in hatching resource allocations for four LTE terminals 340, 341, 342, 343. For example, the resource allocation 342 for a first LTE terminal (UE 1) extends over five blocks of twelve subcarriers (i.e. 60 subcarriers), the resource allocation 343 for a second LTE terminal (UE2) extends over six blocks of twelve subcarriers (i.e. 72 subcarriers), and so on.

Control channel data can be transmitted in a control region 300 (indicated by dotted-shading in Figure 3) of the subframe comprising the first "n" symbols of the subframe where "n" can vary between one and three symbols for channel bandwidths of 3MHz or greater and where "n" can vary between two and four symbols for a channel bandwidth of 1.4MHz. For the sake of providing a concrete example, the following description relates to host carriers with a channel bandwidth of 3MHz or greater so the maximum value of "n" will be 3 (as in the example of Figure 3). The data transmitted in the control region 300 includes data transmitted on the physical downlink control channel (PDCCH), the physical control format indicator channel (PCFICH) and the physical HARQ indicator channel (PHICH). These channels transmit physical layer control information. Control channel data can also or alternatively be transmitted in a second region of the subframe comprising a number of subcarriers for a time substantially equivalent to the duration of the subframe, or substantially equivalent to the duration of the subframe remaining after the "n" symbols. The data transmitted in this second region is transmitted on the enhanced physical downlink control channel (EPDCCH). This channel transmits physical layer control information which may be in addition to that transmitted on other physical layer control channels.

PDCCH and EPDCCH contain control data indicating which subcarriers of the subframe have been allocated to specific terminals (or all terminals or subset of terminals). This may be referred to as physical-layer control signalling / data. Thus, the PDCCH and/or EPDCCH data transmitted in the control region 300 of the subframe shown in Figure 3 would indicate that UE1 has been allocated the block of resources identified by reference numeral 342, that UE2 has been allocated the block of resources identified by reference numeral 343, and so on.

PCFICH contains control data indicating the size of the control region (i.e. between one and three symbols for channel bandwidths of 3 MHz or greater and between two and four symbols for channel bandwidths of 1.4 MHz).

PHICH contains HARQ (Hybrid Automatic Request) data indicating whether or not previously transmitted uplink data has been successfully received by the network.

Symbols in a central band 310 of the time-frequency resource grid are used for the transmission of information including the primary synchronisation signal (PSS), the secondary synchronisation signal (SSS) and the physical broadcast channel (PBCH). This central band 310 is typically 72 subcarriers wide (corresponding to a transmission bandwidth of 1.08 MHz). The PSS and SSS are synchronisation signals that once detected allow a LTE terminal device to achieve frame synchronisation and determine the physical layer cell identity of the enhanced Node B transmitting the downlink signal. The PBCH carries information about the cell, comprising a master information block (MIB) that includes parameters that LTE terminals use to properly access the cell. Data transmitted to terminals on the physical downlink shared channel (PDSCH), which may also be referred to as a downlink data channel, can be transmitted in other resource elements of the subframe. In general PDSCH conveys a combination of user-plane data and non-physical layer control-plane data (such as Radio Resource Control (RRC) and Non Access Stratum (NAS) signalling). The user-plane data and non-physical layer control-plane data conveyed on PDSCH may be referred to as higher layer data (i.e. data associated with a layer higher than the physical layer).

Figure 3 also shows a region of PDSCH containing system information and extending over a bandwidth of R344. A conventional LTE subframe will also include reference signals which are discussed further below but not shown in Figure 3 in the interests of clarity.

The number of subcarriers in a LTE channel can vary depending on the configuration of the transmission network. Typically this variation is from 72 sub carriers contained within a 1.4MHz channel bandwidth to 1200 subcarriers contained within a 20MHz channel bandwidth (as schematically shown in Figure 3). As is known in the art, data transmitted on the PDCCH, PCFICH and PHICH is typically distributed on the subcarriers across the entire bandwidth of the subframe to provide for frequency diversity. Therefore a conventional LTE terminal must be able to receive the entire channel bandwidth in order to receive and decode the control region.

Figure 4 illustrates a LTE “camp-on” process, that is, the process followed by a terminal so that it can decode downlink transmissions which are sent by a base station via a downlink channel. Using this process, the terminal can identify the parts of the transmissions that include system information for the cell and thus decode configuration information for the cell.

As can be seen in Figure 4, in a conventional LTE camp-on procedure, the terminal first synchronizes with the base station (step 400) using the PSS and SSS in the centre band and then decodes the PBCH (step 401). Once the terminal has performed steps 400 and 401, it is synchronized with the base station.

For each subframe, the terminal then decodes the PCFICH which is distributed across the entire bandwidth of carrier 320 (step 402). As discussed above, a LTE downlink carrier can be up to 20 MHz wide (1200 subcarriers) and a standard LTE-compliant terminal therefore has to have the capability to receive and decode transmissions on a 20 MHz bandwidth in order to decode the PCFICH. Accordingly, at the PCFICH decoding stage, with a 20MHz carrier band, the terminal operates at a larger bandwidth

(bandwidth of R320) than during steps 400 and 401 (bandwidth of R310) relating to synchronization and PBCH decoding.

The terminal then ascertains the PHICH locations (step 403) and decodes the PDCCH (step 404), in particular for identifying system information transmissions and for identifying its dedicated allocation grants. The allocation grants are used by the terminal to locate system information and to locate its data in the PDSCH. Both system information and dedicated allocations are transmitted on PDSCH and scheduled within the carrier band 320. Steps 403 and 404 also require a standard LTE-compliant terminal to operate on the entire bandwidth R320 of the carrier band. Allocation grants may also or alternatively be decoded from EPDCCH.

At steps 402 to 404, the terminal decodes information contained in the control region 300 of a subframe. As explained above, in LTE, the three control channels mentioned above (PCFICH, PHICH and PDCCH) can be found across the control region 300 of the carrier where the control region extends over the range R320 and occupies the first one, two or three OFDM symbols of each subframe as discussed above. In a subframe, typically the control channels do not use all the resource elements within the control region 300, but they are scattered across the entire region, such that a LTE terminal has to be able to simultaneously receive the entire control region 300 for decoding each of the three control channels.

The terminal can then decode the PDSCH (step 405) which contains system information or data transmitted for this terminal.

As explained above, in a LTE subframe the PDSCH generally occupies groups of resource elements which follow the control region. The data in the blocks of resource elements 340, 341, 342, 343 allocated to the different mobile communication terminals (UEs) and the system information data in the block of resources 344 shown in Figure 3 have a smaller bandwidth than the bandwidth of the entire carrier. To decode these blocks a terminal first receives the PDCCH spread across the frequency range R320 and/or the EPDCCH to determine if the (E)PDCCH indicates there are PDSCH resources in the subframe that need to be decoded by the UE. The intended recipient(s) for (E)PDCCH signalling in LTE is established through the use of radio network temporary identifiers (RNTI). (E)PDCCH signalling is addressed to a particular RNTI by using the RNTI to scramble cyclic redundancy check (CRC) bits associated with the (E)PDCCH signalling. Each connected UE in a cell is associated with a Cell RNTI (C-RNTI) that may be used to address PDCCH signalling to that particular UE. In addition there are other RNTIs defined and these may be used to simultaneously address groups of terminal devices. For example, a System Information RNTI (SI-RNTI) is defined and PDSCH transmissions comprising SI are allocated by (E)PDCCH signalling addressed to SI-RNTI. Various other RNTIs are defined for various other types of signalling. Some examples include a random-access RNTI (RA-RNTI), a Paging RNTI (P-RNTI), a Transmit Power Control Physical Uplink Control Channel RNTI (TPC-PUCCH-RNTI) and a Transmit Power Control Physical Uplink Shared Channel-RNTI (TPC-PUSCH-RNTI).

Thus, once a UE has received a downlink subframe, the UE searches for (E)PDCCH signalling associated with any RNTI that apply for the UE in the subframe to identify any corresponding allocations of transmission resources on PDSCH. If there is an allocation message addressed to the UE on (E)PDCCH the UE will proceed to decode the PDSCH in the relevant frequency range (if any) indicated by the PDCCH. So for example, UE 1 discussed above decodes the whole control region 300 to

determine its resource allocation and then extracts the relevant data from the corresponding resource block 342.

Figure 5 schematically shows a telecommunications system 500 according to an embodiment of the disclosure. The telecommunications system 500 in this example is based broadly on a LTE-type architecture. As such many aspects of the operation of the telecommunications system 500 are standard and well understood and not described here in detail in the interest of brevity. Operational aspects of the telecommunications system 500 which are not specifically described herein may be implemented in accordance with any known techniques, for example according to the established LTE-standards and known variations thereof.

The telecommunications system 500 comprises a core network part (evolved packet core) 502 coupled to a radio network part. The radio network part comprises a base station (evolved-nodeB) 504, a first terminal device 506 and a second terminal device 508. It will of course be appreciated that in practice the radio network part may comprise a plurality of base stations serving a larger number of terminal devices across various communication cells. However, only a single base station and two terminal devices are shown in Figure 5 in the interests of simplicity.

As with a conventional mobile radio network, the terminal devices 506, 508 are arranged to communicate data to and from the base station (transceiver station) 504. The base station is in turn communicatively connected to a serving gateway, S-GW, (not shown) in the core network part which is arranged to perform routing and management of mobile communications services to the terminal devices in the telecommunications system 500 via the base station 504. In order to maintain mobility management and connectivity, the core network part 502 also includes a mobility management entity (not shown) which manages the enhanced packet service, EPS, connections with the terminal devices 506, 508 operating in the communications system based on subscriber information stored in a home subscriber server, HSS. Other network components in the core network (also not shown for simplicity) include a policy charging and resource function, PCRF, and a packet data network gateway, PDN-GW, which provides a connection from the core network part 502 to an external packet data network, for example the Internet. As noted above, the operation of the various elements of the communications system 500 shown in Figure 5 may be broadly conventional apart from where modified to provide functionality in accordance with embodiments of the disclosure as discussed herein.

In this example, it is assumed the first terminal device 506 is a conventional smart-phone type terminal device communicating with the base station 504. Thus, and as is conventional, this first terminal device 506 comprises a transceiver unit 506a for transmission and reception of wireless signals and a controller unit 506b configured to control the smart phone 506. The controller unit 506b may comprise a processor unit which is suitably configured / programmed to provide the desired functionality using conventional programming / configuration techniques for equipment in wireless telecommunications systems. The transceiver unit 506a and the controller unit 506b are schematically shown in Figure 5 as separate elements. However, it will be appreciated that the functionality of these units can be provided in various different ways, for example using a single suitably programmed general purpose computer, or suitably configured application-specific integrated circuit(s) / circuitry. As will be appreciated the conventional terminal device 506 will in general comprise various other elements associated with its operating functionality.

In this example, it is assumed the second terminal device 508 is a machine-type communication (MTC) terminal device according to an embodiment of the disclosure and located in an area of restricted coverage. As discussed above, MTC devices may be typically characterised as semi-autonomous or autonomous wireless communication devices communicating small amounts of data. Examples include so-called smart meters which, for example, may be located in a customer's house and periodically transmit information back to a central MTC server data relating to the customer's consumption of a utility such as gas, water, electricity and so on. MTC devices may in some respects be seen as devices which can be supported by relatively low bandwidth communication channels having relatively low quality of service (QoS), for example in terms of latency. It is assumed here the MTC terminal device 508 in Figure 5 is such a device. It will, however, the appreciated that embodiments of the disclosure may also be implemented for other types of terminal device.

As with the smart phone 506, the MTC device 508 comprises a transceiver unit 508a for transmission and reception of wireless signals and a controller unit 508b configured to control the MTC device 508. The controller unit 508b may comprise a processor unit which is suitably configured / programmed to provide the desired functionality described herein using conventional programming / configuration techniques for equipment in wireless telecommunications systems. The transceiver unit 508a and the controller unit 508b are schematically shown in Figure 5 as separate elements for ease of representation. However, it will be appreciated that the functionality of these units can be provided in various different ways, for example using a single suitably programmed general purpose computer, or suitably configured application-specific integrated circuit(s) / circuitry, or using a plurality of discrete circuitry / processing elements for providing different elements of the desired functionality. It will be appreciated the MTC device 508 will in general comprise various other elements associated with its operating functionality in accordance with established wireless telecommunications techniques (e.g. a power source, possibly a user interface, and so forth).

The base station 504 comprises a transceiver unit 504a for transmission and reception of wireless signals and a controller unit 504b configured to control the base station 504. The controller unit 504b may comprise a processor unit which is suitably configured / programmed to provide the desired functionality described herein using conventional programming / configuration techniques for equipment in wireless telecommunications systems. The transceiver unit 504a and the controller unit 504b are schematically shown in Figure 5 as separate elements for ease of representation. However, it will be appreciated that the functionality of these units can be provided in various different ways, for example using a single suitably programmed general purpose computer, or suitably configured application-specific integrated circuit(s) / circuitry or using a plurality of discrete circuitry / processing elements for providing different elements of the desired functionality. It will be appreciated the base station 504 will in general comprise various other elements associated with its operating functionality. For example, the base station 504 will in general comprise a scheduling entity responsible for scheduling communications. The functionality of the scheduling entity may, for example, be subsumed by the controller unit 504b.

Thus, the base station 504 is configured to communicate data with the smart phone 506 over a first radio communication link 510 and communicate data with the MTC device 508 over a second radio communication link 512. Both radio links may be supported within a single radio frame structure associated with the base station 504. It is assumed here the base station 504 is configured to communicate with the smart phone 506 over the first radio communication link 510 in accordance with the

established principles of LTE-based communications and to communicate with the MTC-device 506 over the second radio communication link 512 in accordance with embodiments of the disclosure as described herein. It will be appreciated the base station may readily obtain information indicating the different classes of terminal device which are attached to the base station in accordance with conventional techniques. That is to say, the base station will be aware that the smart phone is of a device class that includes conventional smartphones and the MTC device is of a device class that includes MTC devices. Furthermore, the base station may establish using conventional techniques that the MTC device 508 is a device operating in a coverage limited situation such that steps are needed to increase the likelihood of the MTC device being able to decode downlink transmissions.

As noted above, in a LTE-based wireless telecommunications system some of the fundamental information required for a terminal device to operate in a cell is transmitted on PBCH in the Master Information Block (MIB). Other information regarding the system configuration is divided among System Information Blocks (SIBs) referred to as SIB1, SIB2, SIB3,...etc. (there are 16 SIBs defined as of Release 11 LTE). The SIBs are transmitted in system information (SI) messages, which, apart from SIB1, may contain multiple SIBs (termed first SI, second SI, etc.). There may be one or several SI messages transmitted at different periodicities. Each SI message may convey multiple SIBs suitable for scheduling with the same periodicity. The timings for SIB1 message transmissions are fixed on an 80 ms period and they occur in the fifth subframe of radio frames when System Frame Number (SFN) is a multiple of 8 (i.e. SFN mod 8 = 0). There are retransmissions of SIB1 messages provided in every other radio frame within the 80 ms period. The timings for other SIB transmission messages are configured in SIB1. The transmission resource allocations for the SI messages on PDSCH within a subframe are provided to terminal devices using PDCCH allocation messages addressed to SI-RNTI (System Information Radio Network Temporary Identifier - currently 0xFFFF in LTE). At higher layers, SI is carried on the logical broadcast control channel (BCCH).

In LTE the SI messages are transmitted within periodically occurring time domain windows (referred to as SI-windows) using dynamic scheduling. Each SI message is associated with a SI-window and the SI-windows of different SI messages do not overlap. That is, within one SI-window only the corresponding SI message is transmitted. The length of the SI-window is common for all SI messages, and is configurable. Within the SI-window, the corresponding SI message can be transmitted a number of times in any subframe other than MBSFN (multicast-broadcast single frequency network) subframes, uplink subframes in TDD (time division duplex), and subframe #5 of radio frames for which SFN (system frame number) mod 2 = 0. Terminal devices acquire the detailed time-domain scheduling (and other information, e.g. frequency-domain scheduling, transport format) from decoding SI-RNTI on PDCCH. A single SI-RNTI is used to address SystemInformationBlockType1 as well as all SI messages. SystemInformationBlockType1 configures the SI-window length and the transmission periodicity for the SI messages.

The system information in a cell may be changed, although typically this happens rarely with system information perhaps remaining unchanged for hours, days, or even weeks.

For changes of system information other than those related to EAB (Extended Access Barring), ETWS (Earthquake Tsunami Warning System) and CMAS (Commercial Mobile Alert System), there is a BCCH modification period defined (which may be referred to as a “SI modification period”). SI modification period boundaries are defined on radio frames for which SFN mod q = 0, for a cell-specific value of q.

When there is a change in system information, the new system information is transmitted from the start of a new SI modification period.

The general process for implementing a change in system information in a LTE-based network is described, for example, in Section 5.2.1.3 of ETSI TS 136 331 V11.4.0 (2013-07) / 3GPP TS 36.331 version 11.4.0 Release 11 [3]. In summary, a base station indicates a change of system information as follows.

1. When the network changes system information it notifies terminal devices about the change by transmitting a PDCCH resource allocation message addressed to the paging RNTI (P-RNTI). This directs the terminal devices to decode PDSCH resources containing a Paging message with a SystemInfoModification flag set to true. This may be done, for example, throughout one SI modification period. Both RRC_IDLE and RRC_CONNECTED terminal devices check for paging messages periodically. It may be noted that EAB alterations, ETWS and CMAS notifications may be separately modified with separate flags in a paging message (but can also be modified along with other SIBs).

2. In a following SI modification period, the network transmits the modified system information, and may increment a SystemInfoValueTag in SIB1. This value tag can indicate changes in any SIB, but it might not be used for EAB, ETWS, CMAS and some regularly changing SI parameters such as CDMA2000 system time. Terminal devices can use SystemInfoValueTag to verify if currently stored system information is still valid, for example on return from being out of coverage when the UE may have missed a system information change notification in paging.

More details on system information and changes in system information in a LTE-based system can be found in ETSI TS 136 331 V11.4.0 (2013-07) / 3GPP TS 36.331 version 11.4.0 Release 11 [3].

As discussed above, it has been proposed to improve coverage for terminal devices in a wireless telecommunications system by introducing repetitions of a transmission which a terminal device may combine to provide an increased likelihood of successful decoding.

Figure 6 schematically represents an approach for providing coverage extension through repeated transmissions for an SI message in accordance with existing techniques. Figure 6 schematically shows a sequence of LTE downlink subframes (labelled as subframes "A", "B", "C", …, "L" to aid explanation) with shading to schematically indicate which regions in which subframes are used to convey system information. The subframes represented in Figure 6 comprise four groups of three contiguous subframes with spaces between the groups as schematically indicated by dotted lines and discussed further below. Although not shown in Figure 6, the gaps between the groups comprise a continuing sequence of subframes used for other communications that are not relevant to the system information messaging considered here. As discussed above, each subframe comprises a control region 600 and a PDSCH region 602. The control regions 600 for the respective subframes are labelled in Figure 6 with the identification letter for the relevant subframe, i.e. as 600A, 600B, 600C, etc. The PDSCH regions for the respective subframes are similarly labelled in Figure 6 as 602A, 602B, 602C, etc. Each subframe represented in Figure 6 is in essence a simplified version of what is represented in Figure 3. Thus, the control regions 600 support the PCFICH, PHICH and PDCCH channels as discussed above while the PDSCH regions 602 support user-plane data and system information (among other things) and the EPDCCD if implemented. The most significant aspect of the control region 600 in the context of

embodiments of the present disclosure relate to the PDCCH and so for simplicity the control regions 600 may sometimes be referred to herein as PDCCH regions 600.

Before explaining the repeated transmissions approach to providing coverage extension represented in Figure 6 it is considered helpful to clarify some aspects of the terminology to be used herein. The term "repeat transmission" (and related terms) will be used to refer to a transmission in an individual subframe which is part of a sequence of transmissions that are being repeated for the purposes of providing coverage extension for a message being conveyed between a base station and a terminal device (such as a PDCCH message or a PDSCH message). Thus in a coverage extension context, the transmission of a (E)PDCCH message comprises a plurality of "repeat transmissions" on (E)PDCCH and the transmission of a PDSCH message comprises a plurality of "repeat transmissions" on PDSCH. The term "re-transmission" (and related terms) will be used to refer to the transmission of a message that has already been sent at least once before. These terms should be interpreted accordingly unless the context demands otherwise.

For the example repeat transmission approach to coverage extension represented in Figure 6 it is assumed for ease of representation the approach relies on providing only three repeat transmissions for each PDCCH message and each PDSCH message. It will, however, be appreciated that in practice larger numbers of repeat transmissions will typically be involved, for example there may be tens or hundreds of repeats comprising each message to provide a correspondingly higher degree of coverage extension. Furthermore, it will be appreciated that PDCCH messages and PDSCH messages may comprise different numbers of repeat transmissions (for example because different coding schemes are adopted meaning that different numbers of repeat transmissions are needed for a given probability of successful reception).

Thus, referring to Figure 6, subframes A, B and C are used to signal a PDCCH message addressed to SI-RNTI by sending three repeat PDCCH transmissions in the respective PDCCH regions 600A, 600B, 600C. Each PDCCH repeat transmission addressed to SI-RNTI in the PDCCH regions 600A, 600B, 600C in effect comprises a duplication of the same downlink control information which a terminal device can combine to seek to establish the content of the PDCCH message. For this example repeat-transmission based coverage extension scheme it is assumed a particular type of message subject to repeat transmissions is addressed to the same RNTI (e.g. SI-RNTI for a system information related type of messages) as if the same type of message were subject to conventional single-subframe transmission. However, as discussed further below, in accordance with certain embodiments of the disclosure identifiers having different characteristics (e.g. values) may be used for a given type of message depending on whether the messages to be sent in accordance with a first transmission scheme (e.g. using a conventional single subframe based transmission approach) or a second transmission scheme (e.g. using a repeat-transmission scheme for coverage extension). Furthermore, it will be appreciated the approach of using identifiers associated with a particular type of message having different characteristics according to what transmission scheme is to be used to transmit the message can be used in accordance with embodiments of the disclosure with or without the use of validity periods as disclosed herein.

The PDCCH message comprising the three repeat transmissions in the PDCCH regions of subframes A, B and C indicates resource blocks to be used for a subsequent PDSCH message comprising the transmission of system information. This PDSCH message itself comprises a plurality of repeat transmissions, and, in this example, are represented by shading in the PDSCH regions 602D, 602E and 602F of subframes D, E and F. The transmission resources, for example in terms of specific resource

elements, used to convey the repeat transmissions of the system information message in the PDSCH regions 602D, 602E and 602F are indicated in the corresponding PDCCH message addressed to SI-RNTI and comprising the repeat transmissions in PDCCH regions 600A, 600B, 600C in accordance with conventional resource allocation techniques in the context of coverage extension using repeat transmissions. Whilst the shading in Figure 6 schematically represents the same frequency resources being used for each repeat transmission in the respective PDSCH regions 602D, 602E and 602F of the subframes D, E, F, in principle the repeat-transmission approach may be configured to include frequency hopping for the different repeat transmissions comprising the PDSCH message sent in subframes D, E, F. The nature of any such frequency hopping may be pre-defined, for example it may be pre-specified according to an operating standard for the wireless telecommunications system, or it may be established in previous RRC (radio resource control) signalling, or it may be indicated in the PDCCH message.

As schematically represented in Figure 6 there is a gap between subframes C and D. This follows the currently-proposed approaches for repeat-transmission coverage extension whereby the transmission of a PDSCH message comprising a plurality of repeat transmissions does not start until after all repeat transmissions of the corresponding PDCCH message have been sent. This is to help reduce the buffering requirements at the terminal device. Furthermore, current proposals indicate there should be no overlap between the end of the repeat transmissions comprising the PDCCH message and the start of the repeat transmissions comprising the PDSCH message. It will, however, be appreciated the specific implementation of such aspects of a repeat transmission approach for providing coverage extension are not significant to the principles underlying the present disclosure. That is to say, the principles described herein may equally be implemented in association with other repeat transmission approaches (e.g. with repeat transmissions of PDCCH and its corresponding PDSCH occurring in the same subframe).

In subframes following the transmission of the system information message as schematically indicated in subframes D, E and F in Figure 6, the wireless telecommunications system continues to operate in accordance with its normal operating techniques until subframe G represented. Subframe G represents the beginning of another system information message. As noted above, system information messages can be regularly retransmitted in accordance with LTE techniques, and in this regard the system information message beginning at subframe G is considered in this example to be a re-transmission of the system information message transmitted using subframes A to F as discussed above. The specific timing of the re-transmission of system information (i.e. the timing of subframe G relative to subframe A) may follow any conventional system information re-transmission schedule. The principles underlying the re-transmission of the system information message starting from subframe G follow those described above. Thus, a PDCCH message addressed to SI-RNTI is sent using the PDCCH regions 600G, 600H and 600I of subframes G, H and I to allocate resources for a PDSCH message comprising three repeat transmissions in the PDSCH regions 602J, 602K and 602L in subframes J, K and L as indicated by shading in Figure 6. It may be noted in this example the frequencies of the resource elements for the re-transmission of the system information message on PDSCH in subframes J, K, L is different from that used in subframes D, E, F for the previous transmission, but this is not of any particular significance. Furthermore, the transmissions of the PDSCH message in subframes D, E, F, J, K, L may comprise different so-called redundancy versions of the PDSCH message comprising different combinations of information bits and redundancy bits arising from a forward error correction coding process.

It will be appreciated the transmission resources represented in Figure 6 which are not involved in the SI message signalling discussed above can be used for other communications in the network in the usual manner. In particular, it will be appreciated that although the entirety of the PDCCH regions associated with repeat transmissions of the PDCCH for the system information messages are shown shaded in Figure 6, this is merely to highlight those subframes in which a PDCCH for the system information messages is transmitted compared to those where it is not, and in practice these regions will comprise multiple PDCCH messages addressing different terminal devices for allocating resources for various different types of communication on PDSCH.

System information signalling in LTE is sent on what is approaching a more or less continuous basis. This means there is a considerable amount of PDSCH traffic for broadcasting system information messages comprising the SIBs. There is a corresponding requirement for PDCCH signalling to schedule the PDSCH resources for system information messages. The inventors have recognised that this can become a significant issue in a coverage extension scenario where a number of repetitions are expected, as illustrated in Figure 6. This is because for each PDSCH message comprising a plurality of PDSCH repeat transmissions (i.e. the PDSCH message sent using resources in subframes D, E and F and the PDSCH message sent using resources in subframes J, K and L) there is a corresponding SI-RNTI PDCCH message comprising a plurality of PDCCH repeat transmissions (i.e. the PDCCH message sent using resources in subframes A, B and C and the PDCCH message sent using resources in subframes G, H and I). With the potential for perhaps a hundred or more repeat transmissions to provide coverage extension to the edge of a base station's corresponding cell for system information messages a large fraction of the available control region resources will be needed to support this function following the approach of Figure 6. There is of course a corresponding increase in the use of PDSCH resources with the approach represented in Figure 6, but it is to be expected that in many situations it will be PDCCH resources that are more at a premium owing to the limited resources available in the control channel region for PDCCH and the priority typically given to PDSCH over EPDCCH in the PDSCH region. This is especially likely in networks supporting large numbers of MTC devices since these are likely to have a higher ratio of control signalling to data signalling as compared to the traffic profiles typically associated with conventional terminal devices. The increased PDCCH and/or EPDCCH resources needed to support repeat transmissions of system information messages could ultimately make it difficult to schedule unicast PDSCH transmissions to terminal devices operating within the system because of a lack an availability of control region resources to indicate the allocation of PDSCH resources and/or a lack of PDSCH region resource to indicate the allocation of PDSCH resources.

To address this type of issue there have been proposals to stop using PDCCH and EPDCCH messages resource allocations for PDSCH messages comprising system information (i.e. for system information messages). One proposal (described in the 3GPP document R1-135422, "On the need of PDCCH for SIB and other Common Channel", Mediatek, RAN1#75, San Francisco, November 2013 [4]) is to avoid providing any scheduling information in respect of system information-carrying PDSCH transmissions. Instead, a terminal device will be expected to perform blind searching of the PDSCH region to identify if there are any relevant system information transmissions. A drawback with this approach is a significant increase in the processing load required for terminal devices. To reduce the processing load required at the terminal device to a more manageable level the system information messages could be confined to a restricted subset of transmission resources comprising the PDSCH region. However, this approach still requires additional processing tasks to be performed by the terminal device and introduces reduced

scheduling flexibility. Another proposal (described in the 3GPP document R1-134207, "Coverage enhancement techniques for PBCH", Alcatel-Lucent, Alcatel-Lucent Shanghai Bell, RAN1#74bis, Guangzhou, October 2013 [5]) is to avoid using PDCCH messages to provide scheduling information in respect of system information-carrying PDSCH messages. Instead it is proposed that some of the spare bits currently available in the Master Information Block (MIB) in LTE are used for providing scheduling indications for system information messages. However, there are a limited number of spare bits available for this and so the approach does not allow for any significant degree of flexibility in scheduling system information messages, and furthermore the approach further reduces the number of spare bits available for other uses.

In view of these issues, the inventors have developed an alternative approach for reducing the amount of control signalling required to support resource allocations for higher-layer transmissions in a wireless telecommunications system. In particular, but not exclusively, the inventors have developed an approach which may be applied for reducing the amount of control-channel signalling required to support resource allocations for downlink messages, such as system information messages, and in particular for messages which may be subject to re-transmissions on a defined schedule and which may, in some cases, be sent using a repeat transmission approach to provide a degree of coverage extension.

Figure 7 is similar to, and represents various aspects that will be understood from, Figure 6, but shows an approach in accordance with certain embodiments of the present disclosure. Figure 8 is a signalling ladder diagram schematically representing modes of operation for the terminal device 508 and the base station 504 schematically represented in Figure 5 in accordance with some embodiments of the present disclosure for implementing an approach of the kind represented in Figure 7. In broad summary, some embodiments of the disclosure introduce the concept of a validity period for a PDCCH message to thereby indicate transmission resources that may be used for a plurality of PDSCH messages within the validity period. That is to say the control message transmitted on the PDCCH is considered valid for a period that is longer than the period needed to transmit a single PDSCH message (whether in one subframe or with repeat transmissions in a plurality of subframes to provide coverage extension). This means multiple PDSCH messages can in effect be scheduled using the control-region resources of only a single PDCCH message. There are various different ways in which the validity period may be established/determined, as discussed further below.

For the example represented in Figure 7, and as with Figure 6, it is assumed system information is being transmitted from a base station to a terminal device with a repeat transmission approach to providing coverage extension. Again the example approach to coverage extension represented in Figure 7 is assumed for ease of representation to rely on providing only three repeat transmissions for each PDCCH and PDSCH message. However, as noted above, it will be appreciated that in practice larger numbers of repeat transmissions will typically be involved, for example there may be tens or hundreds of repeats comprising each message to provide a correspondingly higher degree of coverage extension. Furthermore, it will be appreciated that PDCCH messages and PDSCH messages need not necessarily comprise the same number of repeat transmissions (for example different coding schemes may be adopted meaning that different numbers of repeat transmissions are appropriate to provide a desired probability of successful reception for each message).

Thus Figure 7 schematically represents an approach for providing coverage extension through repeated transmissions for a plurality of SI messages with reduced control signalling overhead in accordance with

an embodiment of the disclosure. Figure 7 schematically shows a sequence of LTE downlink subframes (labelled as subframes "O", "P", "Q", …, "Z" to aid explanation) with shading to schematically indicate which regions in which subframes are used to convey messages associated with the system information. The subframes represented in Figure 7 comprise four groups of three contiguous subframes with spaces between the groups as schematically indicated by dotted lines. Although not shown in Figure 7, the gaps between the groups comprise a continuing sequence of subframes used for other communications that are not relevant to the system information messaging considered here. As discussed above, each subframe comprises a control region 700 and a PDSCH region 702. The control regions 700 for the respective subframes are labelled in Figure 7 with the identification letter for the relevant subframe, i.e. as 700O, 700P, 700Q, etc. The PDSCH regions for the respective subframes are similarly labelled in Figure 6 as 702O, 702P, 702Q, etc.

As already noted above, aspects of the operation of a wireless telecommunications system in accordance with embodiments of the disclosure, for example as shown in Figure 7 and 8, which are not specifically described herein may be implemented in accordance with any conventional techniques. In this regard, insofar as the operation of embodiments of the disclosure follow conventional techniques the respective subframes represented in Figure 7 may be similar to that is represented in Figure 3. Thus, the control regions 700 support PCFICH, PHICH and PDCCH channels as discussed above while the PDSCH regions 702 support user-plane data and system information (among other things) and EPDCCH if implemented. The most significant aspect of the control region 700 in the context of embodiments of the present disclosure relate to the PDCCH and so for simplicity the control regions 700 may sometimes be referred to herein as PDCCH regions 700.

Thus referring to Figure 7 subframes O, P and Q are used to signal a PDCCH message addressed to SI-RNTI by sending three repeat PDCCH transmissions in the respective PDCCH regions 700O, 700P, 700Q. Each PDCCH repeat transmission addressed to SI-RNTI in the PDCCH regions 700O, 700P, 700Q in effect comprises a duplication of the same downlink control information which a terminal device can combine to seek to establish the content of the PDCCH message addressed to SI-RNTI in accordance with conventional techniques for coverage extension through repeat transmissions. For this example implementation of a repeat-transmission based coverage extension scheme it is again assumed a particular type of message subject to repeat transmissions is addressed to the same RNTI (e.g. SI-RNTI for a system information related type of messages) as if the same type of message were subject to conventional single-subframe transmission. However, as discussed further below, in accordance with certain embodiments of the disclosure identifiers having different characteristics (e.g. in terms of their value or control region search space) may be used for a given type of message depending on whether the messages to be sent in accordance with a first transmission scheme (e.g. using a conventional single subframe based transmission approach) or a second transmission scheme (e.g. using a repeat-transmission scheme for coverage extension). Furthermore, it will be appreciated the approach of using identifiers associated with a particular type of message having different characteristics according to the transmission scheme is to be used in accordance with embodiments of the disclosure may or may not also implement an approach using validity periods as disclosed herein.

The PDCCH message sent in subframes O, P and Q in Figure 7 differs from a conventional PDCCH message, for example of the kind transmitted in subframes A, B and C of Figure 6, in that it is associated with a validity period that is sufficient to span the transmission of a plurality of PDSCH messages. This is

different from the conventional approach in which a PDCCH message is simply associated with a single PDSCH message. The validity period for the PDCCH message is known to both the base station and the terminal device. For example, the validity period may be based on a defined standard for operations in accordance with an embodiment of the disclosure, whereby the base station and the terminal device can each determine the validity period from the defined standard. In other embodiments the base station may have flexibility to select the validity period, for example according to current scheduling requirements, and to communicate an indication of the validity period to the terminal device(s) to which the PDCCH message is addressed. Some example implementation of this approach are discussed further below.

The PDCCH message comprising the three repeat transmissions in the PDCCH regions of subframes O, P and Q indicate transmission resource blocks to be used for a subsequent PDSCH message comprising the transmission of system information. This PDSCH message itself comprises a plurality of repeat transmissions, and, in this example, are represented by shading in the PDSCH regions 702R, 702S and 702T of subframes D, E and F. The manner in which the PDCCH message indicates the corresponding PDSCH resources in subframes R, S and T may be in accordance with conventional techniques/signalling protocols. That is to say, the transmission resources, for example in terms of specific resource elements, used to convey the repeat transmissions of the system information message in the PDSCH regions 702R, 702S and 702T may be indicated in the corresponding PDCCH message addressed to SI-RNTI and comprising the repeat transmissions in PDCCH regions 700O, 700P, 700Q in accordance with conventional resource allocation techniques in the context of coverage extension using repeat transmissions. Whilst the shading in Figure 7 schematically represents the same frequency resources being used for each repeat transmission in the respective PDSCH regions 702R, 702S and 702T of the subframes R, S and T, in principle the repeat-transmission approach may be configured to include frequency hopping for the different repeat transmissions comprising the PDSCH message sent in subframes R, S and T. The nature of any such frequency hopping may be pre-defined, for example it may be pre-specified according to an operating standard for the wireless telecommunications system, or it may be established in previous RRC (radio resource control) signalling, or it may be indicated in the PDCCH message.

As schematically represented in Figure 7 there is a gap between subframes C and D. This again follows the currently-proposed approaches for repeat-transmission coverage extension whereby the transmission of a PDSCH message comprising a plurality of repeat transmissions does not start until after all repeat transmissions of the corresponding PDCCH message have been sent. Furthermore, some proposals indicate there should be no overlap between the end of the repeat transmissions comprising the PDCCH message and the start of the repeat transmissions comprising the PDSCH message. It will, however, be appreciated the specific implementation of such aspects of a repeat transmission approach for providing coverage extension are not significant to the principles underlying the present disclosure. That is to say, the principles described herein may equally be implemented in association with other repeat transmission approaches (e.g. with repeat transmissions of PDCCH and an associated PDSCH occurring in the same subframe).

Thus, the communication of the PDCCH message in subframes O, P and Q and the corresponding communication of the PDSCH message conveying system information in subframes R, S and T as represented in Figure 7 may follow the same general principles as the approach represented in Figure 6. Similarly, in subframes following the repeat-transmission approach for transmitting the system information

message as schematically indicated in subframes R, S and T in Figure 7, the wireless telecommunications system may continue to operate in accordance with its normal operating techniques for conveying other messages.

As noted above, system information messages are regularly retransmitted in accordance with LTE techniques, and the approach of Figure 7 differs from the approach of Figure 6 in respect of how a subsequent transmission of system information is scheduled on PDSCH in subframes X, Y and Z. In particular, the approach of Figure 7 differs from the approach of Figure 6 if the subsequent retransmission of system information occurs within the validity period associated with the previously-received PDCCH message in subframes O, P and Q initially sent in association with the previously-received system information message on PDSCH in subframes R, S and T. In LTE the transmission of system information follows a defined timing schedule, for example based on the system information window defined for the relevant system information. Thus, a base station and a terminal device are able to independently determine in which subframe a system information message will be transmitted on PDSCH (or which plurality of subframes in the case of coverage extension through repeat-transmissions as in this example). Thus, in the example of Figure 7, a terminal device to which the system information is addressed can determine that a system information message is to be transmitted in subframes X, Y and Z.

Referring back to Figure 6, the terminal device receiving the system information on PDSCH in subframes J, K and L can similarly determine in accordance with conventional techniques that the transmission will occur in these subframes. However, to determine the specific resources (e.g. in terms of specific OFDM carriers / resource blocks) on which the transmissions will occur within the relevant subframe(s) the terminal device must first receive the corresponding PDCCH allocation message sent in subframes G, H and I.

However, in the approach of Figure 7 in accordance with an embodiment of the present disclosure the resource allocation used for the PDSCH transmissions of the system information message on subframes X, Y and Z is determined from the previous resource allocation message sent on PDCCH in subframes O, P and Q. For example, in accordance with one approach the specific PDSCH resources (e.g. in terms of frequency) to be used for transmitting the subsequent system information message in subframes X,Y and Z are assumed to be the same as the specific PDSCH resources (e.g. in terms of frequency) used for transmitting the system information message in subframes R, S and T and indicated in the PDCCH message sent in subframes O, P and Q. However, it will be appreciated that other mappings can be adopted. For example, the frequencies to be used can be configured to shift in accordance with a predefined pattern for each retransmission within the validity period for the PDCCH message.

Thus, in accordance with an embodiment of the disclosure, and in contrast to the approach in the corresponding subframes in Figure 6, there is no PDCCH message sent in subframes U, V and W to support the system information message sent on PDSCH in subframes X, Y and Z. Instead it is determined that a previous PDCCH message remains valid (because its associated validity period has yet to expire), and the resources used for conveying the system information message on PDSCH in subframes X, Y and Z are derived from the previous PDCCH.

This approach has an advantage of freeing up the control-channel resources, in particular in subframes U, V and W for the example subframes represented in Figure 7. The approach can also help reduce the

amount of processing required by the terminal device (since the terminal device does not need to decode a separate PDCCH message for each and every PDSCH message). Furthermore the approach can reduce latency in situations that require high repetition numbers because there is no need to wait to receive a series of PDCCH repetitions before receiving each series of PDSCH repetitions.

It will be appreciated the transmission resources represented in Figure 7 that are not involved in the SI message signalling discussed above can be used for other communications in the network in the usual manner. In particular, it will be appreciated that although the entirety of the PDCCH regions associated with repeat transmissions of the PDCCH for the system information messages are shown shaded in Figure 7, this is merely to highlight those subframes in which a PDCCH for the system information messages is transmitted compared to those where it is not, and in practice these regions will comprise multiple PDCCH messages addressing different terminal devices for allocating resources for various different types of communication on PDSCH.

Thus, to summarise an approach in accordance with an embodiment of the disclosure as represented in Figure 7, and with reference to Figure 8, a base station 504 is transmitting system information messages to terminal devices, including terminal device 508, according to a pre-defined timing schedule. The predefined timing schedule may follow conventional LTE techniques for transmitting system information. It is assumed the processing represented in Figure 8 starts just prior to subframe O at the beginning of the series of subframes represented in Figure 7 and while there is no currently valid PDCCH message for the relevant system information. Thus, in a first step S1 in Figure 8 the base station determines a validity period that is to apply for an upcoming control-plane message that is to be transmitted to allocate resources for system information messages on PDSCH. The duration of a validity period for a given PDCCH message may be fixed / predetermined according to a specific implementation, for example by a network operator, or may be selectable by a base station according to current conditions. The validity period might be relatively short, for example it might only comprise the time required to transmit two PDSCH messages to provide a potential saving of one PDCCH message transmission. On the other hand, the validity period might be significant number, for example hundreds, thousands, tens of thousands, or even more subframes. In general a longer validity period may be preferred to reduce the number of PDCCH message transmissions, while an overly-long validity period may be considered to overly restrict scheduling flexibility. An appropriate validity period in a given situation may depend on current traffic conditions within a cell supported by a base station. For example, if a base station is currently supporting a large number of terminal devices it may be more appropriate to select a relatively long validity period to provide a correspondingly large saving in PDCCH message transmissions. However, if a base station is currently supporting only a small number of terminal devices with low traffic requirements (i.e. such that PDCCH congestion is not an overly significant concern), it may be more appropriate to select a relatively short validity period to provide a corresponding increase in scheduling flexibility (example to take better account of fluctuations in radio propagation conditions or traffic changes). In one example a current proportion of non-MTC traffic may be used to help determine an appropriate validity period for a repeated PDCCH. Generally speaking, the higher this proportion, the higher the proportion of non-delay-tolerant non-small-message terminal devices in the cell whose performance may be disrupted by a heavy use of control channel resources due to repeated PDCCH transmission. Therefore, as the proportion of relatively higher priority terminal devices (e.g. non-MTC terminal devices) increases, the base station may opt for longer PDCCH validity times, especially for use in association with SI-messages.

In step S2 the base station transmits a control-plane message, which can also be referred to as a control message (using repeat transmissions for coverage extension in this example) to allocate the resources for subsequent system information messages on PDSCH. This control message is received and decoded by the terminal device 508. This aspect of the operation may be based generally on conventional techniques, for example using a PDCCH message addressed to an SI-RNTI in LTE. Furthermore, the specific resources selected by the base station for allocation to the system information messages may be selected in accordance with established scheduling techniques in wireless communication systems. Thus, step S2 correspond with the transmissions made in subframes O, P and Q of Figure 7.

In step S3 the terminal device determines the validity period for the control-plane message received in step S2. There are various ways in which the terminal device may determine the validity period for the control-plane resource allocation message in accordance with various embodiments of the disclosure, and some examples are discussed further below.

In step S4 the base station proceeds to transmit a system information message (using repeat transmissions for coverage extension in this example) in accordance with the resource allocation identified by the control-plane (PDCCH) message of step S2. This aspect of the operation may be made broadly in accordance with conventional techniques. The terminal device seeks to receive and decode this system information message (SI message #1) in accordance with conventional techniques.

In step S5 the base station determines it is time to transmit another system information message (SI message #2) according to the predefined timing for periodic system information transmissions in the wireless telecommunications system. The base station further determines the validity period for the control-plane message sent in step S2 has not yet expired. Accordingly, the base station does not send any new control-plane message to support the new system information message that is about to be transmitted (SI message#2). Instead the base station proceeds to transmit the system information message (using repeat transmissions for coverage extension in this example) in accordance with resource allocations derived from the previously-sent control-plane (PDCCH) message of step S2. For example, the base station may be configured to simply use the same frequency resources for transmitting SI message #2 in step S5 as were used for transmitting SI message #1 in step S2. The terminal device likewise determines the expected transmission timing for the new system information message (SI message #2) from the predefined timing for system information transmissions and also determines the validity period for the previous control-plane message received in step S2 has not expired. Accordingly, the terminal device need not seek to receive a new control-plane message to indicate the PDSCH resources for the new system information message that is to be next transmitted (SI message#2). Instead the terminal device simply assumes the transmission is to be made in the relevant subframes (determined according to the predefined timing) on frequency resources derived from the previously-sent control-plane (PDCCH) message of step S2. Once the terminal device has determined the specific resources on which to expect the system information message in step S5 (SI message #2) it may proceed to receive and decode the system information message in accordance with conventional PDSCH transmission techniques.

As noted above the timing s for specific SI messages in LTE are based on SI windows. Conventionally it is the transmission of an associated PDCCH message addressed to the relevant system information RNTI which determines the precise subframe(s) in which the system information message PDSCH is transmitted. However, in accordance with certain embodiments of the disclosure there can be PDSCH

messages conveying system information in an SI windows without there being a corresponding PDCCH message in that SI window. There are a number of different ways in which a terminal device can determine the relevant subframe for a further PDSDH message transmitted within the validity period of a previously-received PDCCH message in accordance with embodiments of the disclosure. In one case, the base station may be configured to send the PDSCH message in a predefined subframe of the SI window. In principle this could be permanently fixed for all PDSCH system information messages at the cost of reduced scheduling flexibility. In another case the subframe(s) could be based on the subframe(s) used in association with the initial PDCCH message. For example, if the initial PDCCH indicates a system information message is to be sent in subframe number n (or starting in subframe n for repeat transitions for coverage extension) within a particular SI window, subsequent PDSCH messages within the validity period of the PDCCH might also be sent in (or start in) subframe n of the relevant SI window. In another example, the base station may retain the flexibility to send (or start sending when using repeat transmissions) the subsequent system information message in any subframe within the SI window. In this case a terminal device may check for a newly addressed PDCCH message in the subframes in the SI window in the normal way, and if a new PDCCH message is not found, the terminal device may decode the PDSCH resources indicated in accordance with a previously-received still valid PDCCH message in the same subframe(s) relative to the SI window as for the previous transmission. In principle, with sufficient processing power, the terminal device could simply seek to decode the relevant resources in all subframes of an SI window to see if an SI message can be decoded.

The process of the base station sending further system information messages, and the terminal device receiving the further information messages, based on transmission resource allocation information indicated in the control-plane message of step S2 may continue (as schematically indicated in step S6 for transmitting SI message #n) until the validity period for the control-plane message received in step S2 has expired, as schematically indicated in step S7.

Following step S7 the processing in effect cycles back to where it started prior to step S1. The base station may thus determine a new validity period for a new control message to be sent in a further step corresponding with step S2 (the base station determines that a new PDCCH message is required because the previous one has expired). Processing may then continue from this point in the manner discussed above.

Thus, the various example schemes represented in Figures 7 and 8, and described above, provide an approach in which control-plane messages, and in particular SI-messages, are associated with a validity period that extends for more than one message transmission of the associated PDSCH. For example, for SIBs in SI-messages, one SI-RNTI addressed PDCCH message can provide the control information for multiple transmissions of SIBs, and in general over multiple SI-windows. Similar operation for other types of message, for example messages addressed to other common search-space RNTIs, may be adopted in accordance with other examples. This kind of approach can help reduce control resource requirements, which can be especially important in the context of coverage extension where according to conventional techniques PDCCH (comprising multiple repeat transmissions) messages would have to be transmitted every time an SI-message (comprising multiple repeat transmissions) needed to be sent.

As noted above, SIBs in system information messages can in some cases remain unchanged for extended period, for example a few hours. A terminal device may thus combine system information message transmissions from across multiple SI-windows if it does not successfully decode an SI-

message at first attempt and with a sufficiently long validity period this can be achieved in accordance with the approaches described herein with reduced control signalling requirements than current schemes.

As noted above, there are various different ways in which the validity period for a PDCCH message may be established. In one simple example the period may be defined according to an operating standard of the wireless telecommunications system. Both the base station and the terminal device can in effect be hardwired with the validity period (or multiple validity periods associated with different types of messages). In another example the base station may have flexibility for determining a suitable validity period according to the implementation and traffic conditions at hand. In this case there are various different ways in which the validity period could be conveyed to a terminal device.

In one example the base station may be configured to convey a selected validity period to terminal devices by selecting a particular transmission characteristic, for example timing, for the PDCCH message with which the validity period is associated. According to current proposals for repeat transmission coverage extension in LTE, the starting subframe of a PDCCH message being transmitted in multiple subframes should be confined to a subset of subframes. This is because in some circumstances the terminal device may be required to blindly search over the possible numbers of repetitions the PDCCH might comprise. If it were allowed for a PDCCH messages comprising an arbitrary number of repeat transmissions to start in an arbitrary subframe this could be expected to give rise to significant complexity in the processing required of the terminal device. To address this there has been proposed an approach in which, for example, a PDCCH message comprising N repeats can only begin in subframes having a subframe number that is a multiple of N (i.e. 0, N, 2N, 3N,...). This reduces the set of possible repetition numbers the UE needs to consider per subframe. Thus, a similar approach could be used to convey information on PDCCH validity. This can be done by linking the validity period to the starting subframe number of the associated PDCCH message. For example, a PDCCH message commencing in subframe M might be taken to indicate a validity period corresponding to M SI-windows for the relevant system information. Thus, a terminal device can readily establish the relevant validity period from the timing of the relevant control-claim message. It may be noted that in some circumstances it may be preferable to assign longer PDCCH validity periods to PDSCH messages that comprise high numbers of repetitions.

In another example the base station may be configured to convey a selected validity period to terminal devices through explicit signalling, for example in the downlink control information (DCI) of the relevant PDCCH message. Thus, the DCI may comprise an indication of a number of subframes / radio frames corresponding to the validity period or may comprise an indication of a specific subframe / radio frame in which the validity period is to expire. In the application to the transmission of system information messages it may be preferable to indicate timings in respect of a number of SI-windows of validity.

In yet another example the terminal devices may be configured to simply assume the validity period for a given PDCCH message addressed to a given RNTI (e.g. SI-RNTI) extends until a subsequent PDCCH message addressed to the relevant RNTI is received. That is to say, the PDCCH message may be considered to remain valid until it is replaced by another PDCCH message. In this respect, in terms of the processing schematically represented in Figure 8, this corresponds with the terminal device determining the validity period for the control message (corresponding to step S3) at the same time at which the validity period expires (responding to step S7), with this being triggered by a new PDCCH message being received by the terminal device. In this approach a terminal device may thus monitor for a new PDCCH message addressed to the relevant RNTI in each subframe of each SI-window in the normal way until a

new PDCCH message is received to in effect define the end the validity period for the previous PDCCH message addressed to that RNTI.

Thus, one principle of the approaches described above in accordance with some embodiments of the disclosure is to associate a PDCCH message with a time defining its validity, that time being extensible beyond the time taken to convey a corresponding PDSCH message. A terminal device may thus assume the PDSCH resource allocation, MCS (modulation and coding scheme), TBS (transport block size), etc. in the DCI of the PDCCH message is valid for receiving multiple PDSCH messages during the PDCCH validity time. No further PDCCHs for multiple PDSCH messages need be sent during the validity time. Thus, in the case of SIB transmissions, the transmission of all SI-messages (including all transmissions within a SI-window of a particular SI-message), may be scheduled with a single transmission of SI-RNTI PDCCH with an appropriately configured validity period.

One particular situation in which approaches in accordance with the embodiments described above might be expected to be useful is where the transmissions are used to provide coverage extension on both PDCCH and PDSCH. However, similar principles can be applied where coverage extension is not being used, for example in respect of messages sent within single subframes.

Whilst the above-described embodiments have focused on system information messages, it will be appreciated that similar principles can be applied for other types of messages in wireless telecommunications systems, and especially for messages which rely on resource allocations occurring with some degree of predictable timing. For example, similar principles can be used for control signalling addressed to other common search space RNTIs, such as RA-RNTI and P-RNTI.

Thus a random access RNTI addressed PDCCH message received by a terminal device during an initial cell access may be associated with a validity period such that the transmission resources identified in association with the random access RNTI PDCCH message are taken to apply for later random access procedures in accordance with the principles set out above. The specific subframe of a RAR (random access response) window in which a subsequent RAR arrives can be established in a manner similar to that described above for system information within a predefined series of subframes comprising an SI-window

Similarly, a paging RNTI addressed PDCCH message may be associated with an extended validity in accordance with the principles described above. Thus a PDSCH resource allocation associated with a PDCCH message addressed to a paging RNTI transmitted in one subframe may be taken to indicate a PDSCH resource allocation in a subsequent subframe within a validity period associated with the PDCCH message. This may be especially appropriate for paging when a terminal device is in idle mode since there is a higher degree of predictability as to when paging messages may be sent according to a currently configured DRX, discontinuous reception, cycle. That is to say, the concept of PDDCH validity timers as discussed herein may be applied to the most recent P-RNTI PDCCH used to decode a paging message by an RRC_IDLE UE. An RRC_IDLE UE is only expected to monitor specific subframes for P-RNTI and is in DRX for other subframes. If the relevant PDCCH validity timer expires before a subsequent paging message is to be sent, the base station may provide a new P-RNTI PDCCH message to schedule the next paging message as normal. Otherwise the IDLE UE may assume the most recent such PDCCH is still valid. For an RRC_CONNECTED UE, there is less predictability as regards whether a particular subframe should contain P-RNTI PDCCH or not. For a connected mode terminal device the

principles described herein for paging messages might, for example, be used for subframes in which the UE would check for P-RNTI if it were in fact in IDLE mode. In other subframes the base station may send conventional paging signalling using PDCCH to page the UE in connected mode.

In a wireless telecommunications using repeat-transmissions for coverage extension there may be terminal devices which are not in coverage-limited locations and able to successfully decode individual ones of the PDCCH (or EPDCCH) repeat transmissions in each subframe. For example, and referring to Figure 7, a non-coverage-limited terminal device may be able to successfully decode the individual PDCCH repeat transmission in the control region 700O of subframe O. If this terminal device is not aware of the use of repeat-transmissions for coverage extension (for example because it is a legacy / conventional terminal device) it might be expected to assume the PDCCH information derived from the control region 700O subframe O applies to a system information transmission on PDSCH in the same subframe (i.e. in PDSCH region 702O). However, the terminal device would fail to receive the system information transmission (because it is not sent in accordance with this particular repeat-transmission protocol). Potentially this terminal device could seek to do this for each and every repeat transmission and so waste a considerable amount of processing effort needlessly decoding individual PDCCH repeat transmissions and associated PDSCH resources in the expectation of receiving system information messages which are not in fact being sent in those subframes. This is an issue which applies generally for repeat transmission approaches for coverage extension and is not specific to approaches based on validity periods as discussed herein.

Thus in accordance with certain embodiments of the disclosure an identifier (RNTI) having different characteristics (e.g. in terms of value or associated control region search space) may be associated with SI messages sent using a repeat transmission approach as compared to SI messages sent without using a repeat transmission approach. More generally, in a wireless telecommunications system supporting different transmission schemes for a given type (classification / category) of message (e.g. a message comprising a given radio resource control, RRC, information element, such as a system information related message or a paging request related message), a characteristic of an identifier associated with the message (i.e. an identifier to indicate which terminal device(s) the message is for) may be selected according to the transmission scheme used for the message. This approach may be implemented in accordance with certain embodiments of the disclosure regardless of whether the wireless telecommunications system also implements an approach using validity periods as described herein (i.e. the approach may be implemented in association with the principles of the repeat transmission scheme represented in Figure 6 as well as that represented in Figure 7). That is to say, the concept of associating a validity period with a control message and the concept of using different identifier characteristics according to a transmission scheme being used may be used together in combination or separately from one another in accordance with different embodiments of the disclosure.

A terminal device having the ability to receive transmissions using the repeat transmission approach can identify the transmissions as such directly from the associated identifier characteristic and receive the message accordingly. The characteristic for the identifier can be selected so that a terminal device not having the ability to receive transmissions using a repeat transmission approach, for example a legacy terminal device, does not recognise the message as being addressed to the terminal device, and so in effect ignores it. Such a terminal device may in effect ignore the message because, for example, the identifier has a value which is not recognised as a value relevant to the terminal device or because a search space for a control message conveying the identifier is not searched by the terminal device.

Thus, if in a particular implementation it is assumed that a repeat transmission approach to coverage extension is intended primarily for MTC-type devices, an MTC-specific system information radio network temporary identifier (MTC-SI-RNTI) may be established. PDCCH messages associated with repeat transmissions for conveying system information messages may thus be addressed to MTC-SI-RNTI instead of an SI-RNTI used for conveying system information that is not sent using repeat transmissions. More generally some embodiments of the disclosure propose introducing other repetition specific RNTIs to address messages that rely on repetitions for coverage extension to complement corresponding RNTIs in existing systems. Thus, system information messages to be sent in accordance with a non-repeat transmission technique may be associated with a conventional system information identifier (e.g. SI-RNTI) while system information messages to be sent in accordance with a repeat-transmission technique may be associated with a modified system information identifier (e.g. REPEAT-SI-RNTI).

Similar issues can arises for other common RNTIs associated with other types of message that may be sent using a repeat transmission approach. Thus corresponding RNTIs having different characteristics may also be established for these. For example, for each of SI-RNTI, P-RNTI, RA-RNTI, TPC-PUCCH-RNTI, TPC-PUSCH-RNTI and M-RNTI to be used for addressing non-repeat transmission messages, there may be established a corresponding RNTI having a different value to be used for addressing repeat-transmission messages (e.g. what might be generally referred to as REPEAT-RNTIs, such as REPEAT-SI-RNTI, REPEAT-P-RNTI, REPEAT-RA-RNTI, REPEAT-TPC-PUCCH-RNTI, REPEAT-TPC-PUSCH-RNTI and REPEAT-M-RNTI). Thus an approach in accordance with an embodiment of the disclosure may be used in association with messages selected from the group comprising: (i) a message associated with transmitting system information; (ii) a message associated with transmitting a paging message; (iii) a message associated with transmitting a random access response message; (iv) a message associated with transmitting power control information for an uplink control channel; (v) a message associated with transmitting power control information for an uplink data channel; and (vi) a message associated with a broadcast and / or multicast service. A similar approach can be taken for types of message associated with other common RNTIs which may be introduced in future.

In some implementations in which a message to be transmitted using a repeat-transmission approach in association with an identifier having a characteristic selected to indicate this, a component part of the message (e.g. a repeat transmission) may also be transmitted in one, or more, subframes in association with an identifier having a characteristic that would be used if the message were being transmitted using a conventional single-transmission approach. This will allow legacy terminal devices who are able to receive the message from only a single repeat transmission to in effect receive the message based on one of the repeat transmissions.

One advantage of associating identifiers for a given type of message with different characteristics based on the transmission scheme is the potential for more complete use of the available transmission resources. For example, referring to Figure 7, the initial SI-RNTI addressed PDCCH repeat transmission in the control region 700O of subframe O is part of a repeat transmission comprising three repeat transmissions in the respective control regions of subframes O, P and Q. This PDCCH message identifies resources (and other parameters) associated with a PDSCH message to be subsequently transmitted starting from subframe R as discussed above. As previously noted, it is expected for repeat-transmission based coverage extension there will be no PDSCH signalling associated with the PDCCH message until after the repeat transmissions comprising the PDCCH message had been made. In principle the PDSCH

transmission resources in the PDSCH regions 702O, 702P and 702Q of subframes O, P and Q corresponding to the resources allocated by the PDCCH message for use in subframe starting from subframe R could be used to support other transmissions. For example, the respective control regions 700O, 700P, 700R could include conventional single-subframe PDCCH messages allocating the relevant PDSCH transmission resources for another purpose, for example unicast data. However, it would be confusing for a legacy terminal device to decode a unicast PDCCH message and a SI PDCCH message resource allocation identifying the same resources in the same subframe. Thus by preventing the legacy terminal device from decoding the SI PDCCH signalling (through use of an appropriate distinguishing characteristic for the identifier as discussed herein), the legacy terminal device is free to receive unicast data on the relevant PDSCH resources (in association with an appropriately addressed PDCCH transmission indicating these resources).

In implementations in which the distinguishing characteristic for the identifier is its value (i.e. with one value, such as SI-RNTI, indicating conventional single-subframe transmission, and another value, such as REPEAT-SI-RNTI, indicating repeat-transmission coverage extension), the "new" REPEAT-RNTIs may be defined in accordance with an operating standard for the wireless telecommunications network in parallel with the corresponding RNTIs. For example, as noted above, in LTE the SI-RNTI has a fixed value 0xFFFF. In accordance with an embodiment of the disclosure a fixed value for a REPEAT-SI-RNTI may be selected from one of the currently reserved RNTIs in LTE (from 0xFFF4 to 0xFFC). Thus, if, for example, a value 0xFFF5 is allocated as REPEAT-SI-RNTI (i.e. an identifier for a system information related message sent using repeat transmissions), a PDCCH addressed to 0xFFFF can be identified as corresponding to a system information message sent without repetition whereas a PDCCH addressed to 0xFFF5 can be identified as corresponding to a system information message sent using repetition. A terminal device that is unaware of repetition will in effect ignore the PDCCH addressed to 0xFFF5 as this will not be recognised as a valid RNTI for the terminal device. Corresponding principles apply where EPDCCH is used.

In the above-described example the value of the RNTI is the characteristic used to distinguish between the different transmission schemes. However, in accordance with other embodiments of the disclosure, other characteristics can be used to distinguish identifiers to indicate different transmission schemes. For example, in LTE there are currently eight "spare" values that could be used as new REPEAT-RNTIs. This is a sufficient number of values to provide a corresponding RNTI to be used in association with a transmission scheme comprising repeat transmissions for all currently-existing common RNTIs. However, it may be considered preferable in some cases to avoid using these "spare" values so they remain free for other uses, or there may be a need for more REPEAT-RNTIs (for example, to provide multiple extra RNTI for a given type of message, e.g. a system information message, to indicate another aspect of the transmission scheme, for example the number of repeats). Thus, in accordance with some embodiments a REPEAT-RNTI may in fact have a value that is the same as its corresponding "conventional" RNTI (e.g. 0xFFFF for SI-RNTI and REPEAT-SI-RNTI) but be associated with a different search space. As is well known a terminal device will typically search a defined subset of control region resources to seek to identify any control messages associated with an identifier (RNTI) common to a plurality of terminal devices. The subset of control region resources is known as a search space and comprises a plurality of candidate PDCCH for the terminal device to check. This search space approach is taken to reduce the amount of processing required by the terminal device to seek to identify any relevant control messages. Thus, PDCCH signalling associated with the existing common RNTIs are constrained to a particular set of

candidate PDCCH comprising the common search space. In accordance with some embodiments of the disclosure the characteristic of the identifier which is used to distinguish the different potential transmission schemes may be based on the specific PDCCH resources used.

For example, a PDCCH message to be transmitted in accordance with a conventional single-subframe approach may be associated with an identifier, such as SI-RNTI, in the common search space in the usual way. However, a PDCCH message to be transmitted in accordance with a repeat-transmission approach may instead be associated with the same value of identifier, such as SI-RNTI, but transmitted on PDCCH resources outside the common search space. Thus in accordance with some implementations the distinguishing characteristic for the identifier based on the transmission scheme may be a search space with which the identifier is associated. Thus a PDCCH message addressed to SI-RNTI within a particular search space (e.g. the common search space in LTE) can be identified as corresponding to a system information message sent without repetition whereas a PDCCH transmission addressed to SI-RNTI outside the particular search space (e.g. outside the common search space in LTE) can be identified as corresponding to a system information message sent using repetition. A terminal device that is unaware of repetition will in effect ignore the PDCCH addressed to SI-RNTI outside the common search space as the terminal device will not search for the SI-RNTI outside the common search. Corresponding principles apply where EPDCCH is used. Thus in effect, identifiers associated with repeat transmissions may be associated with a newly-defined search space which is outside the search space used for the corresponding identifiers for conventional single-subframe transmissions. In some examples the new search space may support only a single aggregation level, for example an aggregation level 8 (the high aggregation level being appropriate in view of the coverage extension context). The new search space may be smaller (i.e. comprise fewer candidate PDCCH) than the search space for existing common RNTIs. This can help reduce the blind search load associated with the repeat transmissions comprising a message transmitted using a repeat transmission for coverage extension.

It will appreciated the advantages of establishing a new search space comprising a reduced number of candidate PDCCHs with a single relatively high aggregation level to be used in association with identifiers for repeat transmission messages can be applied even in circumstances where different identifier values are associated with the different transmission schemes. In such cases the repeat-specific identifier values may be selected from among the values that are available for use as identifiers in the wireless telecommunications system. In one example, as referred to above, a repeat-specific identifier values may simply match its corresponding non-repeat specific identify value (e.g. SI-RNTI) with the different search space in which a control message associated with the identifier is transmitted providing the distinguishing characteristic for the identifier for the selected transmission scheme. However, in another implementation the repeat-specific identifier values may be selected from, for example, identifiers available for other uses, for example in LTE from identifiers available for cell-specific RNTIs (which may range from 0x001 to 0xFFF3). This approach can in principle provide a relatively large number of repeat-specific identifiers. For example, one or more of the values normally used for C-RNTI can be in effect reserved as one or more repeat-specific RNTIs, such as REPEAT-SI-RNTI in the terminology used above, and likewise for types / classes / classifications of messages other than system information related messages, such as paging messages and random access a response messages etc. Thus a base station could in effect reserve (re-allocate) in its cell a number of RNTI values for one purpose as actually being for use as repeat-specific RNTIs. If any of the re-allocated subset of RNTIs comprising the repeat-specific RNTI is detected by a terminal device as addressing a PDCCH in the newly-defined search space, the terminal

device may be configured to interpret this as a repeat-specific RNTI. This may be based on the base station conveying in previous signalling to terminal devices that support repeat-transmission communications an indication of the relevant RNTI(s). Alternatively, or in addition, the relevant RNTI(s) may be defined in accordance with an operating standard of the network for reallocation within the new search space. If the PDCCH candidates comprising the new search space do not overlap with those of the pre-existing common search space and UE-specific search space used by legacy devices, then the RNTIs allocated as repeat-specific RNTIs within the new search space could continue to be used in the other search space without giving rise to the potential for confusion for legacy terminal devices. If, on the other hand, the PDCCH candidates comprising the new search space do overlap with those of the pre-existing common search space or UE-specific search space, then the base station may be configured to avoid allocating any of a currently re-allocated RNTI to terminal devices in accordance with the usual function for the RNTI (i.e. a C-RNTI reallocated for use as a repeat-specific identifier should not be allotted to a terminal device for use as a C-RNTI). This can be remedied as a straightforward matter of RNTI scheduling (for example, the base station can in effect simply treat the re-allocated RNTIs as being already allotted for use).

If multiple RNTI are made available for use for a given type of message, the particular RNTI selected for use in association with a particular message may be used to indicate a further characteristic of the message, for example a number of repeats or a specific PDCCH validity period where implemented. This can provide the base station with a simple mechanism for modifying the specific repeat and all validity period parameters associated with a particular message, thereby improving overall flexibility.

Determining which identifiers a terminal device should search for to seek to identify messages to be sent to the terminal device using a repeat transmission scheme can be done in accordance with the usual principles by linking it to transmission mode (TM) configuration. In one implementation the repeat-specific RNTIs provided in accordance with embodiments of the disclosure might apply in all transmission modes as the principles governing their use will in many respects be similar to conventional, search space RNTIs. There could also be a link with the category/type of the terminal device. For example, a new terminal device category identifier could be introduced (e.g. category 0) to indicate the terminal device is a particular type of terminal device, for example an MTC-based terminal device. The repeat-specific identifiers may then be considered to apply to all transmission modes for terminal devices of category 0 (if the repeat-transmission based scheme is limited to category 0 terminal devices), as well as for additional terminal device categories if the use of the repeat-transmission based scheme is more widely supported.

Figure 9 is a signalling ladder diagram schematically representing modes of operation for the terminal device 508 and the base station 504 schematically represented in Figure 5 in accordance with some embodiments of the present disclosure.

Processing begins in step T1 when the base station determines that a message is to be transmitted to one or more terminal devices. The message may, for example, be a broadcast message or a multicast message. The determination that a message is to be transmitted may be made in accordance with conventional operating procedures for the wireless communications system. For example, if the message is a system information message, step T1 may arise in accordance with a conventional timing schedule for transmitting system information messages. If the message is a paging message, step T1 may arise because an event has arisen which requires a terminal device to be paged. In this example it is assumed the message which is to be transmitted is a system information message which is relevant for (i.e.

address to an identifier associated with) terminal device 508. Furthermore, it is assumed the message may be transmitted in accordance with either one of a first transmission scheme using transmission resources in a first number of radio subframes (e.g. using conventional single-subframe transmission) or a second transmission scheme using transmission resources in a plurality radio subframes (e.g. using repeat-transmission for coverage extension).

In step T2 the base station determines which of the first and second transmission schemes are to be used for transmitting the message. That is to say, in this example, the base station determines whether or not a conventional single subframe approach or a repeat-transmission approach for coverage extension will be used for the message. There are a number of factors that may govern this determination, either individually or in combination. For example, the terminal devices in the wireless telecommunication system may comprise a first set of terminal devices and a second set of terminal devices step and T2 may be based on whether the one or more terminal devices to which the message is to be sent comprises terminal devices in the first or second sets. For example, the first set of terminal devices may comprise terminal devices that do not require coverage extension techniques to receive messages (or simply do not support coverage extension), whereas the second set of terminal devices may comprise terminal devices that do require coverage extension techniques to receive messages (and support repeat-transmission based coverage extension). Whether or not a specific terminal device requires coverage extension may, for example, be based on a measured radio propagation metric associated with the terminal device, for example a path loss, block error rate, a bit error rate, a packet error rate, a frame error rate, a symbol error rate, or negative or positive acknowledgement signalling rate (ACK/NACK) associated with communications with the terminal device. In another implementation the decision may take account of a specific identity or category for the one or more terminal devices to which the messages to be sent.

In step T3 the base station determines a characteristic of an identifier for the message based on the transmission scheme determined in step T2. This characteristic may be selected in accordance with any of the principles discussed above (e.g. use of different values for the identifier or different search spaces to be used with the identifier).

In step T4 the message is transmitted in accordance with the transmission scheme determined in step T2 and in association with an identifier, e.g. RNTI, having the characteristic determined in step T3. For example, the message may be transmitted in accordance with a repeat-transmission scheme as described herein with an identifier selected to have a characteristic to identify this, for example in accordance with any of the principles discussed above. In this regard the message may comprise one or other or both of a control message transmitted on a downlink control channel, e.g. a PDCCH message and another message transmitted on a downlink data channel, e.g. PDSCH (i.e. such that the identifier is transmitted separately from the message).

In step T5 the terminal device receives the transmitted signalling from the base station and determines the transmission scheme being used from the characteristic of the identifier. The terminal device may then proceed to receive and decode the message in accordance with the transmission scheme being used.

Thus, the process represented in Figure 9 demonstrates a mechanism by which a base station can readily indicates to terminal devices the transmission scheme being used for a given message. Once the terminal device has determined the transmission scheme, subsequent operation, for example in terms of

receiving the message, they be performed in accordance with conventional principles for receiving such messages. Furthermore, these techniques may be modified to incorporate a validity period approach such as discussed above.

Thus there has been described a wireless telecommunication system that comprises a base station and a terminal device communicating over a radio interface. The radio interface supports a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel (e.g. a physical downlink shared channel) for conveying other messages from the base station to the terminal device. The control messages convey information on resource allocations for the other messages on the downlink data channel. The other messages may comprise user-plane messages or control-plane messages. The terminal device is configured to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel and determine a validity period for the control message. During the validity period for the control message the terminal device is configured to receive a plurality of the other messages from the base station on the downlink data channel using the allocated transmission resources.

There has also been described a wireless telecommunication system that comprises a base station arranged to communicate messages to one or more terminal devices over a radio interface. The radio interface has a radio frame structure comprising a plurality of subframes, wherein a message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes (e.g. one subframe) or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes (e.g. with repeat transmissions in a plurality of subframes). The message is transmitted in association with an identifier to indicate a terminal device to which the message is addressed. A characteristic for the identifier, for example a value or control region search space for the identifier, is dependent on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme. A terminal device to which the message is addressed determines the transmission scheme from the characteristic of the identifier and receives the message accordingly.

Further particular and preferred aspects of the present invention are set out in the accompanying independent and dependent claims. It will be appreciated that features of the dependent claims may be combined with features of the independent claims in combinations other than those explicitly set out in the claims.

Thus, the foregoing discussion discloses and describes merely exemplary embodiments of the present invention. As will be understood by those skilled in the art, the present invention may be embodied in other specific forms without departing from the spirit or essential characteristics thereof. Accordingly, the disclosure of the present invention is intended to be illustrative, but not limiting of the scope of the invention, as well as other claims. The disclosure, including any readily discernible variants of the teachings herein, define, in part, the scope of the foregoing claim terminology such that no inventive subject matter is dedicated to the public.

Respective features of the present disclosure are defined by the following two groups of numbered paragraphs:

Group 1 of numbered paragraphs:

Paragraph 1. A method of operating a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises receiving a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and receiving a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 2. The method of paragraph 1, wherein the other messages comprise system information messages.

Paragraph 3. The method of any preceding paragraph, wherein the system information messages comprise one or more system information blocks.

Paragraph 4. The method of any preceding paragraph, wherein the radio interface is based on a radio frame structure comprising a plurality of subframes, wherein each subframe comprises a control channel region for supporting the downlink control channel and a shared channel region for supporting the downlink data channel, and wherein respective ones of the control and / or the other messages comprise transmissions over a plurality of subframes.

Paragraph 5. The method of any preceding paragraph, wherein the validity period for the control message is determined in dependence on an identifier used in association with the control message.

Paragraph 6. The method of paragraph 5, wherein the identifier comprises an indication of one or more terminal devices to which the control message is addressed.

Paragraph 7. The method of any preceding paragraph, wherein the validity period for the control message is determined in dependence on a transmission characteristic of the control message.

Paragraph 8. The method of paragraph 7, wherein the transmission characteristic of the control message comprises a transmission time associated with the control message.

Paragraph 9. The method of any preceding paragraph, wherein the radio interface is based on a radio frame structure comprising a plurality of subframes, and wherein the timing of a subframe used to convey a first one of the plurality of other messages is used to determine the timing of a subframe used to convey a second one of the plurality of other messages within the validity period for the control message.

Paragraph 10. The method of any preceding paragraph, wherein the timing of a subframe used to convey the first one of the plurality of other messages relative to a first predefined range of subframes is used to determine the timing of a subframe used to convey the second one of the plurality of other messages relative to a second predefined range of subframes.

Paragraph 11. The method of any preceding paragraph, wherein the validity period is determined in dependence on a validity period indicator received in association with the control message.

Paragraph 12. The method of any preceding paragraph, wherein the validity period is determined in dependence on the time at which a subsequent control message is received.

Paragraph 13. The method of any preceding paragraph, wherein the other messages comprise random access response messages and / or paging messages..

Paragraph 14. A terminal device for communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 15. Circuitry for a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the terminal device to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message

Paragraph 16. A method of operating a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises transmitting a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and transmitting a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 17. A base station for communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the base station comprises a controller unit and a transceiver unit configured to operate together to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data

channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 18. Circuitry for a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the base station to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Group 2 of numbered paragraphs:

Paragraph 1. A method of operating a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein the method comprises selecting a characteristic for the identifier in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 2. The method of any preceding paragraph, wherein the first number of radio subframes comprises a single radio subframe and the second number of radio subframes comprises a plurality of radio subframes.

Paragraph 3. The method of any preceding paragraph, wherein terminal devices in the wireless telecommunications system comprise a first set of terminal devices and a second set of terminal devices, and wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on whether a terminal device to which the message is to be transmitted is a member of the first set of terminal devices or the second set of terminal devices.

Paragraph 4. The method of any preceding paragraph, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on a radio propagation parameter associated with radio communications between the base station and a terminal device to which the message is to be transmitted.

Paragraph 5. The method of paragraph 4, wherein the radio propagation parameter is selected from the group comprising: a path loss; an error rate; a positive acknowledgment, ACK, signalling rate; and a negative acknowledgment signalling, NACK, rate.

Paragraph 6. The method of any preceding paragraph, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on an identity and / or type of a terminal device to which the message is to be transmitted.

Paragraph 7. The method of any preceding paragraph, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises a control message transmitted on the downlink control channel.

Paragraph 8. The method of any preceding paragraph, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises one of the other messages transmitted on the downlink data channel.

Paragraph 9. The method of any preceding paragraph, wherein the identifier to indicate a terminal device to which the message is addressed is transmitted separately from the message.

1 Paragraph 0. The method of any preceding paragraph, wherein the identifier comprises a radio network temporary identifier, RNTI.

Paragraph 11. The method of any preceding paragraph, wherein the identifier is a common to a plurality of terminal devices.

Paragraph 12. The method of any preceding paragraph, wherein the message comprises a broadcast message.

Paragraph 13. The method of any preceding paragraph, wherein the message comprises a multicast message.

Paragraph 14. The method of any preceding paragraph, wherein for a given type of message the characteristic for the identifier is selected from a first predefined characteristic for the identifier associated with the given type of message and a second predefined characteristic for the identifier associated with the given type of message according to whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 15. The method of any preceding paragraph, wherein the message is selected from the group comprising: (i) a message associated with transmitting system information; (ii) a message associated with transmitting a paging message; (iii) a message associated with transmitting a random access response message; (iv) a message associated with transmitting power control information for an uplink control

channel; (v) a message associated with transmitting power control information for an uplink data channel; and (vi) a message associated with a broadcast and / or multicast service.

Paragraph 16. The method of any preceding paragraph, wherein for a message to be transmitted in accordance with the second transmission scheme, a component of the message transmitted in one of the second number of subframes is associated with a characteristic for the identifier corresponding to that which would be used if the message were to be transmitted in accordance with the first transmission scheme.

Paragraph 17. The method of any preceding paragraph, wherein the characteristic for the identifier comprises a value for the identifier.

Paragraph 18. The method of any preceding paragraph, wherein the characteristic for the identifier comprises a search space in which a terminal device searches using the identifier to determine if a message has been addressed to the terminal device.

Paragraph 19. The method of any preceding paragraph, wherein the method comprises selecting the characteristic for the identifier from a plurality of different characteristics associated with different types of message.

Paragraph 20. The method of any preceding paragraph, wherein the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme is defined in accordance with an operating standard for the wireless telecommunications system.

Paragraph 21. The method of any preceding paragraph, further comprising the base station pre-defining the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme.

Paragraph 22. The method of paragraph 21, wherein the pre-defining the characteristic for the identifier is a value for the identifier selected from among a plurality of values.

Paragraph 23. A base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the base station comprises a controller unit and a transceiver unit configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 24. Circuitry for a base station communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the circuitry comprises a controller element and a transceiver element configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of

radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 25. A method of operating a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the method comprises determining from an identifier associated with the message that the message is addressed to the terminal device, and further determining from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 26. A terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 27. Circuitry for a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

CLAIMS

What is claimed is:

1. A method of operating a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein the method comprises selecting a characteristic for the identifier in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

2. The method of claim 1, wherein the first number of radio subframes comprises a single radio subframe and the second number of radio subframes comprises a plurality of radio subframes.

3. The method of claim 1, wherein terminal devices in the wireless telecommunications system comprise a first set of terminal devices and a second set of terminal devices, and wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on whether a terminal device to which the message is to be transmitted is a member of the first set of terminal devices or the second set of terminal devices.

4. The method of claim 1, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on a radio propagation parameter associated with radio communications between the base station and a terminal device to which the message is to be transmitted.

5. The method of claim 4, wherein the radio propagation parameter is selected from the group comprising: a path loss; an error rate; a positive acknowledgment, ACK, signalling rate; and a negative acknowledgment signalling, NACK, rate.

6. The method of claim 1, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on an identity and / or type of a terminal device to which the message is to be transmitted.

7. The method of claim 1, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises a control message transmitted on the downlink control channel.

8. The method of claim 1, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises one of the other messages transmitted on the downlink data channel.

9. The method of claim 1, wherein the identifier to indicate a terminal device to which the message is addressed is transmitted separately from the message.

10. The method of claim 1, wherein the identifier comprises a radio network temporary identifier, RNTI.

11. The method of claim 1, wherein the identifier is a common to a plurality of terminal devices.

12. The method of claim 1, wherein the message comprises a broadcast message.

13. The method of claim 1, wherein the message comprises a multicast message.

14. The method of claim 1, wherein for a given type of message the characteristic for the identifier is selected from a first predefined characteristic for the identifier associated with the given type of message and a second predefined characteristic for the identifier associated with the given type of message according to whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

15. The method of claim 1, wherein the message is selected from the group comprising: (i) a message associated with transmitting system information; (ii) a message associated with transmitting a paging message; (iii) a message associated with transmitting a random access response message; (iv) a message associated with transmitting power control information for an uplink control channel; (v) a message associated with transmitting power control information for an uplink data channel; and (vi) a message associated with a broadcast and / or multicast service.

16. The method of claim 1, wherein for a message to be transmitted in accordance with the second transmission scheme, a component of the message transmitted in one of the second number of subframes is associated with a characteristic for the identifier corresponding to that which would be used if the message were to be transmitted in accordance with the first transmission scheme.

17. The method of claim 1, wherein the characteristic for the identifier comprises a value for the identifier.

18. The method of claim 1, wherein the characteristic for the identifier comprises a search space in which a terminal device searches using the identifier to determine if a message has been addressed to the terminal device.

19. The method of claim 1, wherein the method comprises selecting the characteristic for the identifier from a plurality of different characteristics associated with different types of message.

20. The method of claim 1, wherein the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme is defined in accordance with an operating standard for the wireless telecommunications system.

21. The method of claim 1, further comprising the base station pre-defining the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme.

22. The method of claim 21, wherein the pre-defining the characteristic for the identifier is a value for the identifier selected from among a plurality of values.

23. A base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the base station comprises a controller unit and a transceiver unit configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

24. Circuitry for a base station communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the circuitry comprises a controller element and a transceiver element configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

25. A method of operating a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the method comprises determining from an identifier associated with the message that the message is addressed to the terminal device, and further determining from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

26. A terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

27. Circuitry for a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

(54) **Title**: ENHANCED PHYSICAL SIGNAL STRUCTURE FOR LTE V2V COMMUNICATIONS

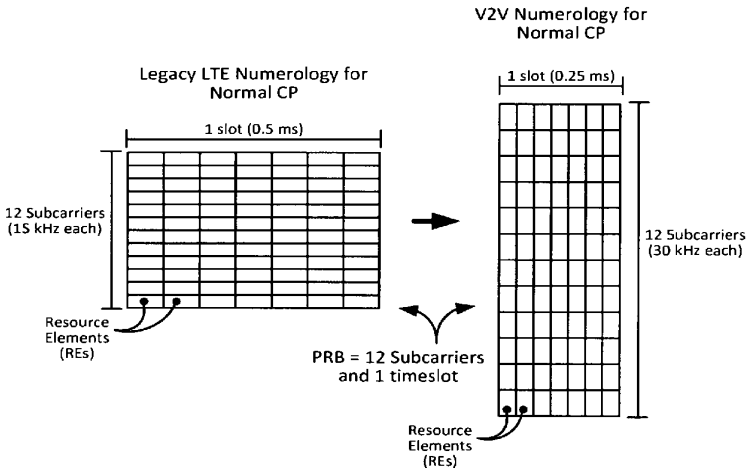

Fig. 4

(57) **Abstract**: A vehicle may wirelessly communicate with another vehicle via a physical channel (a vehicle-to-vehicle (V2V) channel) that is robust and reliable under high mobility propagation conditions. The physical channel may be created by modifying an existing long-term evolution (LTE) physical channel, such as an LTE sidelink (SL) channel. For instance, the V2V physical channel may be created by increasing, by a particular factor, the subcarrier spacing of legacy LTE channels (e.g., from 15 kilohertz (kHz) to 30 kHz). Additionally, a symbol duration and a fast Fourier transform (FFT) size for the V2V physical channel may each be reduced by the same factor. Doing so may enable the V2V physical channel to be implemented without significant modifications to other aspects of the LTE standard.

WO 2017/026983 A1

ENHANCED PHYSICAL SIGNAL STRUCTURE FOR LTE V2V COMMUNICATIONS

RELATED APPLICATIONS

The present application claims the benefit of U.S. Provisional Patent Application No. 62/203,301, which was filed on August 10, 2015, the contents of which are hereby incorporated by reference as though fully set forth herein.

BACKGROUND

The so-called "connected car concept" includes the idea that vehicles may be enabled to communicate wirelessly with one another. The 3GPP (3rd Generation Partnership Project) Long Term Evolution (LTE) communications standard has been proposed as the communication standard for implementing the connected car concept (also referred to as vehicle-to-vehicle (V2V) communications). V2V communications include one vehicle establishing a direct connection with one or multiple other vehicles.

Examples of such connections may include an LTE sidelink connection (also referred as direct connection, a proximity services (ProSe) connection, a device-to-device (D2D) connection, etc.). Once connected, vehicles may communicate a variety of information to each other, such as location information, velocity information, acceleration information, directional information, performance information, and more. Such information may be used to provide a variety of functionalities, such as preventing car accidents, determining driving conditions (e.g., traffic jams, icy roads, car accidents, etc.), determining optimal routes for driving from one location to another, etc.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments described herein will be readily understood by the following detailed description in conjunction with the accompanying drawings. To facilitate this description, like reference numerals may designate like structural elements. Embodiments are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings.

Fig. 1 is a diagram of an example environment in which systems and/or methods described herein may be implemented;

Fig. 2 is a diagram illustrating an example process for sending information to another vehicle;

Fig. 3 is a diagram illustrating an example process for receiving information from another vehicle;

Fig. 4 is a diagram of an example physical resource block (PRB) of a legacy long term evolution (LTE) numerology and an example PRB of a vehicle-to-vehicle (V2V) numerology, under normal cyclic prefix (CP) conditions;

Fig. 5 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under extended CP conditions;

Fig. 6 is a diagram of example PRB pairs of a legacy LTE numerology and example PRB pairs of a V2V numerology, under normal CP conditions;

Fig. 7 is a diagram of example PRB pairs of a legacy LTE numerology and PRB pairs of a V2V numerology, under extended CP conditions;

Figs. 8A-8D are diagrams of example PRBs according to one or more embodiments described herein;

Figs. 9A-9D are diagrams of example PRBs according to one or more embodiments described herein;

Fig. 10 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 30 kilohertz (kHz) subcarrier spacing;

Fig. 11 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 60 kHz subcarrier spacing;

Fig. 12 is a table representing an example of legacy LTE and V2V transmission multiplexing; and

Fig. 13 illustrates, for one embodiment, example components of an electronic device.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The following detailed description refers to the accompanying drawings. The same reference numbers in different drawings may identify the same or similar elements. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope of the present disclosure. Therefore, the following detailed description is not to be taken in a limiting sense, and the scope of embodiments defined by the appended claims and their equivalents.

As mentioned above, the 3GPP (3rd Generation Partnership Project) Long Term Evolution (LTE) communications standard has been proposed as the communication standard for vehicle-to-vehicle (V2V) communications. One reason behind the proposal is the reliability and high data rate capabilities of LTE technology. However, the current LTE standard includes

certain limitations when it comes to enabling vehicles to communicate with one another directly. For example, legacy LTE sidelink (SL) physical channels (also referred to as PC5 channels or device-to-device (D2D) channels) are considered to be used or enable V2V communications. At the same time, the legacy SL physical channels were designed with an assumption of substantially lower mobility conditions than the ones considered to be used for V2V communication (e.g., a scenario in which two vehicles are driving toward one another at 140 kilometers per hour (km/h) each). As a result, when subjected to wireless propagation in high mobility conditions (that may cause high Doppler fading and/or frequency shifts), legacy LTE physical channels may experience an unacceptably high block error rate (BLER) performance and/or use an unacceptably high signal-to-interference-noise ratio (SINR) to achieve reliable performance for V2V wireless communication.

Techniques described herein may be used to provide a physical channel (referred to herein as "V2V physical channel") of greater robustness and reliability when subjected to the high mobility conditions of V2V communications. For example, a V2V physical channel may have increased subcarrier spacing (e.g., 30 kilohertz (kHz) subcarriers) instead of the 15 kHz subcarrier spacing used in legacy LTE SL physical channels. The increased subcarrier spacing may improve physical channel robustness (particularly under high mobility wireless propagation effects) via a reduction of the impacts of frequency offset errors on the subcarriers orthogonality, reduced channel variations on the packet transmission duration, etc.

In some embodiments, the V2V physical channel may include additional alterations from current LTE SL physical channels. For example, the V2V physical channel may include a reduced symbol duration (e.g., a single-carrier frequency-division multiple access (SC-FDMA) symbol duration, etc.). The decrease in symbol duration may be proportional to the increased subcarrier spacing. For instance, if the subcarrier spacing of the V2V physical channel is twice as large as subcarrier spacing of a legacy LTE SL physical channel (e.g., 30 kHz instead of 15 kHz), the symbol duration for the V2V physical channel may be halved. Additionally, the decrease in symbol duration may be accompanied by a similar decrease (e.g., half) to a fast Fourier transform (FTT) size.

Additionally, since LTE air interfaces currently implement physical resource blocks (PRBs) as a fundamental unit of allocation for air interface resources, the techniques described herein may include one or more PRB formats for implementing the enhancements described above regarding modified subcarrier spacing and symbol duration of the V2V physical channels. For instance, a PRB of the V2V physical channel may

include time-domain changes, such as a change in the duration of each PRB and/or the number of slots per PRB. Similarly, a PRB of the V2V channel may include frequency-domain changes, such as the number of subcarriers per PRB, the PRB size in terms of frequency, etc. PRB formats may be discussed herein in terms of numerologies (e.g., legacy LTE numerologies and V2V numerologies), which may include a representation of subcarriers, slot durations, and resource elements (REs) of a PRB or PRB pair.

In some embodiments, the techniques described herein may be implemented within the context of cyclic prefixing (CP). For example, in the 3GPP LTE communication standard, CP may include copying a portion of one symbol (e.g., an end portion of the symbol) and adding the copied portion to a beginning portion of the symbol, such that the symbol begins and ends with the same portion. Doing so may, for example, reduce inter-symbol interference.

Fig. 1 is a diagram of an example environment 100 in which systems and/or methods described herein may be implemented. Environment 100 may include one or more vehicles with vehicle-to-X (V2X) devices 110, user equipment devices (UEs) 120, and network 130.

V2X device 110 may include a computing and communication device installed in a vehicle, such as a car, a truck, a sports utility vehicle (SUV), etc. V2X device 110 may be capable of gathering, processing, and communicating information regarding the vehicle in which V2X device 110 is installed. Examples of such information may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, etc. In some embodiments, V2X device 110 may be capable over gathering, processing, and communicating other types of information, such as information relating to a driver or passenger of the vehicle. V2X device 110 may be an example of user equipment device (UE) or another type of end terminal.

As shown, V2X device 110 may be capable of communicating with one or more networks or devices, such as UE 120, the V2X device of another vehicle, network 130, etc. In some embodiments, V2X device 110 may do so by establishing a connection that is based on a particular communications standard, such as the 3GPP LTE communication standard. For instance, V2X device 110 may establish a vehicle-to-pedestrian (V2P) connection with UE 120, which may include a D2D connection, an LTE SL connection, or other type of direct connection. V2X device 110 may also, or alternatively, establish a vehicle-to-infrastructure/network (V2I) connection with network 130. The V2I connection may include a standard connection with a base station (e.g., an evolved Node B (eNB)), a wireless access point (AP), or another device capable of enabling V2X device 110 to communicate with network 130.

As such, the "X" in "V2X device," may represent an ability of V2X device 110 to communicate with one or more types of devices (e.g., other V2X devices, UEs 120, a base station, a network access point (AP), etc.).

Additionally, or alternatively, V2X device 110 may establish a V2V connection with the V2X device of another vehicle. The V2V connection may include a D2D connection, an LTE SL connection, or other type of direct connection between UEs (e.g., a connection that does not, for example, include network 130). In some embodiments, V2X device 110 may be capable of communicating with other V2X devices using one or more of the techniques described herein. For example, V2X device 110 may be capable of using a V2V physical channel that ensure improved robustness and reliability when subjected to the high mobility conditions of V2V communications. The V2V physical channel may, for example, include greater subcarrier spacing and reduced symbol durations to, for example, improve demodulation performance including BLER reduction but still operating within the framework of an established communications standard (such as the 3GPP LTE communications standard).

UE 120 may include a portable computing and communication device, such as a personal digital assistant (PDA), a smart phone, a cellular phone, a laptop computer with connectivity to a cellular wireless network, a tablet computer, etc. UE 120 may also include non-portable computing devices, such as a desktop computer, a consumer or business appliance, or other devices that have the ability to connect to network 130. UE 120 may also include a computing and communication device that may be worn by a user (also referred to as wearable devices) as a watch, a fitness band, a necklace, glasses, an eyeglass, a ring, a belt, a headset, or another type of wearable device. As shown, UE 120 may establish a direct connection (e.g., a D2D connection) with V2X device 110. Additionally, UE 120 may communicate with V2X device 110 regarding the vehicle of V2X device 110, a driver or passenger of the vehicle, a user of UE 120, a location of the vehicle with respect to the user of UE 120, etc.

Network 130 may include one or more wired and/or wireless networks. For example, network 130 may include an LTE network. In some embodiments, network 130 may include one or more additional networks, such as a cellular network (e.g., a second generation (2G) network, a third generation (3G) network, a fourth generation (4G) network, a fifth generation (5G) network, a global system for mobile (GSM) network, a code division multiple access (CDMA) network, an evolution-data optimized (EVDO) network, or the like), a public land mobile network (PLMN), and/or another network. Additionally, or alternatively, network 150 may include a local area network (LAN), a wireless LAN (WLAN), a wide area network (WAN), a metropolitan network (MAN), the Public Switched Telephone Network (PSTN), an

ad hoc network, a managed IP network, a virtual private network (VPN), an intranet, the Internet, a fiber optic-based network, and/or a combination of these or other types of networks.

The quantity of devices and/or networks, illustrated in Fig. 1, is provided for explanatory purposes only. In practice, there may be additional devices and/or networks; fewer devices and/or networks; different devices and/or networks; or differently arranged devices and/or networks than illustrated in Fig. 1. Alternatively, or additionally, one or more of the devices of environment 100 may perform one or more functions described as being performed by another one or more of the devices of system 100. Furthermore, while "direct" connections are shown in Fig. 1, these connections should be interpreted as logical communication pathways, and in practice, one or more intervening devices (e.g., routers, gateways, modems, switches, hubs, etc.) may be present.

Additionally, while some of the techniques described herein may involve V2V communications as an example, the techniques described herein may be applied to various scenarios and/or other types of communications. For example, techniques described herein may be applicable to time division duplexing (TDD) or frequency division duplexing (FDD) communications. In some embodiments, techniques described herein may be applied to all of downlink (DL), uplink (UL), and sidelink (SL) communications, while other embodiments may only apply the techniques described herein to DL or UL or SL communications. Additionally, while the techniques described herein may be described within the context of the 3GPP LTE communications standard, the techniques may also be applied to other communication standards. Additionally, while examples provided herein may include enabling vehicles to communicate with one another more reliably, the techniques described herein may be applied to other scenarios as well (such as another system or device that may experience significant Doppler fading conditions when attempting to communicate wirelessly).

Fig. 2 is a diagram illustrating an example process 200 for sending information to another vehicle. Process 200 may be particularly appropriate for devices capable of wireless communications that may be subjected to high mobility propagation conditions (e.g., wireless propagation in high mobility conditions characterized by high Doppler fading and/or frequency shifts that may jeopardize the integrity or reliability of the wireless communications). Process 200 may be implemented by, for example, V2X device 110. Additionally, process 200 provides an example of how a V2V physical channel may be used; however, it should be noted that the V2V physical channel, as described herein, may

be used in additional and alternative ways, which may include fewer, additional, and/or alternative operations than the operations described below with reference to Fig. 2.

As shown, process 200 may include identifying a physical channel that is appropriate for communicating with another vehicle (block 210). For example, in some embodiments, V2X device 110 may be capable of using multiple physical channels for communicating with another vehicle. As described above, examples of such channels may include an LTE SL physical channel, a V2V physical channel (as described herein), etc. In some embodiments, V2X device 110 may identify the appropriate physical channel based on one or more factors.

Examples of such factors may include whether the physical channel will likely be subjected to high mobility propagation conditions. For instance, if the vehicle of the V2X device 110 and/or the other vehicle are traveling at a high speed, V2X device 110 may determine that communications between the vehicles are likely to be subjected to such conditions. As such, a V2V physical channel (as opposed to, for example, a legacy LTE SL channel) may be appropriate for communicating with the other vehicle.

Another example of a factor that may be considered by V2X device 110 may include the communication capabilities of the other vehicle. For example, V2X device 110 may determine the types of physical channels that the other vehicle is capable of using and select the most appropriate physical channel from on the physical channels that the other vehicle is capable of using. In some embodiments, determining the communication capabilities of the other vehicle may include determining what type of communications device is being implemented by the other vehicle (e.g., a V2X device or another type of communications device).

Additional examples of factors that may be used to identify an appropriate physical channel may include physical channel availability (e.g., whether V2X device is already using one or more physical channels), a measure of importance regarding the information (or type of information) that is to be sent to the other vehicle (e.g., less important information may be allocated with less reliable physical channels), a measure of importance of other information that is to communicated to a different vehicle, etc. In yet another example, V2X device may implement one or more rules for prioritizing which type of physical channel (e.g., an LTE SL channel, a V2V physical channel, etc.) should be implemented in light of one or more of the factors described above.

Process 200 may include generating information to communicate to the vehicle (block 220). For example, V2X device 110 may generate the information that is to be

transmitted to the other vehicle. Examples of such information may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, information relating to a driver or passenger of the vehicle, etc.

Process 200 may include processing the information based on the physical channel identified for communicating with the other vehicle (block 230). For example, V2X device 110 may arrange the information in accordance with a particular PRB format, which may be particular to the type of physical channel identified as the suitable for communicating with the other vehicle. For instance, if the identified physical channel corresponds to a currently available physical channel (such as an LTE LS physical channel), the information may be allocated to accommodate a format where a PRB includes 12 subcarriers (also referred to herein as frequency REs) with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. However, if the identified physical channel corresponds to a V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time. Additional examples of PRB formats are discussed below with reference to Figs. 4-9.

Process 200 may include using the physical channel to communicate information to vehicle (block 240). For example, V2X device 110 may use the physical channel identified as being appropriate for communicating with the vehicle to transmit the information to the vehicle. As described above, the physical channel may include a legacy channel (such as an LTE SL channel) or a V2V physical channel, and the information may be formatted in accordance with a format (e.g., a PRB format) that is particular to the physical channel used to transmit the information.

Fig. 3 is a diagram illustrating an example process 300 for receiving information from another vehicle. Process 300 may be particularly appropriate for devices capable of wireless communications that may be subjected to high mobility conditions (e.g., that may cause high Doppler fading and/or frequency shifts) during V2V communications. Process 300 may be implemented by, for example, V2X device 110.

As shown, process 300 may include receiving information from another vehicle via a physical channel (block 310). For example, V2X device 110 may be capable of using physical channels for communicating with another vehicle. As described above, examples

of such channels may include an LTE SL channel, a V2V physical channel, etc. The information sent and received between vehicles may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, information relating to a driver or passenger of the vehicle, etc.

Process 300 may include determining a physical channel type corresponding to the physical channel (block 320). For example, V2X device 110 may identify the type of physical channel (e.g., an LTE SL channel, a V2V channel, etc.) used to receive the information. In some embodiments, V2X device 110 may determine the manner in which the information is arranged in the physical channel based on the physical channel type may include. For example, if the physical channel corresponds to an LTE SL physical channel, the information may be formatted into PRBs that include 12 subcarriers with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. In another example, if the physical channel corresponds to a V2V physical channel, the information may be formatted into PRBs that include 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for a V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time. Additional examples of PRB formats are discussed below with reference to Figs. 4-9.

Process 300 may include interpreting the information based on the physical channel type of the physical channel (block 330). For example, V2X device 110 may interpret the information, received from another vehicle, based on a type of physical channel used to communicate the information. For instance, if the physical channel corresponds to an LTE LS physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. By contrast, if the physical channel corresponds to a V2V physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for V2V physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time.

Fig. 4 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under normal CP conditions. The legacy LTE numerology may correspond to a legacy LTE physical channel (e.g., an LTE SL channel), while the V2V

numerology may correspond to a V2V physical channel. A numerology, as discussed herein, may include parameters and characteristics of a physical channel (e.g., a legacy LTE SL channel or a V2V physical channel).

Such parameters and characteristics may include a bandwidth supported by the physical channel, a number of subcarriers per channel, a subcarrier spacing, a fast Fourier transform (FFT) size, a symbol duration, a slot duration, a subframe duration. Additional examples of numerological parameters and characteristics may include a direct, or indirect, description of a PRB and/or PRB pair of the physical channel, such as a number of subcarriers per PRB, a PRB duration (e.g., a number of slots per PRB), a number of resource elements (REs) per PRB, a number of symbols per PRB, etc.

Additionally, in the 3GPP LTE communication standard, CP may include copying a small portion of one symbol (e.g., an end portion of the symbol) and adding the copied portion to a beginning portion of the symbol, such that the symbol begins and ends with the same portion. Normal CP (as depicted in Figs. 4 and 6) may be implemented for wireless communications over shorter distances, while extended CP (as depicted in Figs. 5 and 7) may be implemented for wireless communications over longer distances. As such, normal CP may include a PRB of more symbols (or REs) per slot in time domain (e.g., 7), while extended CP may include a PRB of fewer symbols (or REs) per slot in time domain (e.g., 6).

As shown in Fig. 4, a PRB of the legacy LTE numerology for normal CP may include 12 subcarriers with 15 kHz subcarrier spacing, a slot of 0.5 ms in time domain comprising 7 consecutive symbols, and 84 REs in total. By contrast, the PRB of the V2V numerology for normal CP may include 12 subcarriers with 30 kHz subcarrier spacing, 1 slot of 0.25 ms in the time domain, comprising 7 consecutive symbols, and 84 REs in total. As such, each subcarrier of a V2V physical channel PRB may have twice as much subcarrier spacing as the subcarriers of the legacy LTE channel PRB; however, the duration of the slot of the V2V physical channel may be half the duration of the slot of the legacy LTE physical channel. As mentioned above, the decrease in slot duration may be accompanied by a similar decrease (e.g., a factor of 2, 4, etc.) to the FTT size associated with the V2V physical channel. Doing so may help ensure that the sampling time and/or sampling frequency of the V2V physical channel remains the same as the sampling time and sampling frequency of the legacy LTE channel.

For example, sampling time, as described herein, may include the basic time unit for the corresponding physical channel. For instance, in the 3GPP LTE communication standard, sampling time may be represented by "Ts" and may be equal to 1/(subcarrier spacing x FFT

size) (e.g., 1/(1500Hz x 2048)). By contrast, sampling frequency, as described herein, may include the basic frequency unit for a particular physical channel. For example, in the 3GPP LTE communication standard, sampling frequency may be represented by "Fs" and may be equal to subcarrier spacing (e.g., 15 kHz) multiplied by the number of FFT time samples (e.g., 2048).

As described above, a V2V channel may have increased subcarrier spacing (e.g., 30 kHz or 60 kHz instead of 15 kHz) but still be implemented within the LTE framework since decreasing symbol duration and FFT size proportionally may help ensure that sampling frequency and sampling time for the V2V channel are the same as the sampling frequency and sampling time of legacy LTE channels (e.g., an LTE SL channel). For example, since sampling time is equal to the inverse of subcarrier spacing multiplied by the corresponding FFT size, increasing the subcarrier spacing by a factor of two (e.g., from 15 kHz to 30 kHz) or four (e.g., from 15 kHz to 60 kHz) does not change the sampling time so long as the FFT size is reduced by the same factor (e.g., from 2048 to 1024 for factor of two or from 2048 to 512 for factor of four). The same can be said for sampling frequency since sampling frequency may be equal to subcarrier spacing multiplied by the corresponding FFT size. As such, the arrow depicted in Fig. 4 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels (which may be more robust and reliable in high mobility conditions (e.g., that may cause high Doppler fading and/or frequency shifts)) without affecting other aspects of the LTE communications standard.

For example, in some embodiments, the duration for a single subframe of a V2V channel may be set to 0.5 ms, such that the subframe may include 2 slots at 0.25 ms each. In such an implementation, relatively few (if any) modifications to the 3GPP LTE communication standard may implement the V2V channel since, for example, legacy LTE channels also include 2 slots per subframe. In other embodiments, the duration for a single subframe of the V2V channel may be set to 1.0 ms (for example), which may result in a subframe including 4 slots at 0.25 ms each. In such embodiments, certain modifications to the 3GPP LTE communications standard may be beneficial, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

Fig. 5 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under extended CP conditions. The legacy LTE numerology may correspond to a legacy LTE channel (e.g., an LTE SL channel), while the V2V numerology may correspond to a V2V channel. As shown, a PRB of the legacy LTE numerology for extended CP may include 12 subcarriers of 15 kHz each, a slot of 0.5 ms, and 72 REs (6 symbols or (REs)

per slot). By contrast, the PRB of the V2V numerology for normal CP may include 12 subcarriers of 30 kHz each, 1 slot of 0.25 ms, and 84 REs. As such, each subcarrier of a V2V channel PRB may include twice as much bandwidth as the subcarriers of the legacy LTE channel PRB; however, the slot of the V2V channel PRB may be half the duration of the slot of the legacy LTE channel PRB. As mentioned above, the decrease in slot duration may be accompanied by a similar decrease (e.g., a factor of 2, 4, etc.) to the FTT size associated with the V2V channel. The sampling frequency of the V2V channel may remain the same as the sampling frequency of the legacy LTE channel. As such, the arrow depicted in Fig. 5 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels (which may be more robust and reliable in high mobility conditions) without affecting other aspects of the LTE communications standard.

Fig. 6 is a diagram of example PRB pairs of a legacy LTE numerology and example PRB pairs of a V2V numerology, under normal CP conditions. As shown, the legacy LTE numerology and the V2V numerology may each include 4 PRBs, PRB 6.1 through PRB 6.4 and PRB 6.5 through 6.8, respectively. Each PRB of the legacy LTE numerology, and each PRB of the V2V numerology, may be similar to the corresponding PRBs discussed above with reference to Fig. 4. Additionally, the PRBs of Fig. 6 may corresponds to normal CP conditions since the PRB format includes 7 symbols (or REs) for each slot.

In the legacy LTE numerology, the PRB pairs may be differentiated from one another in the frequency domain, such that PRB 6.1 and PRB 6.2 include one pair (e.g., a 1st PRB pair) and PRB 6.3 and PRB 6.4 are another pair (e.g., a 2nd PRB pair). By contrast, in V2V numerology, the PRB pairs may be differentiated from one another in the time domain, such that PRB 6.5 and PRB 6.6 include one pair (e.g., a 1st PRB pair) and PRB 6.7 and PRB 6.8 are another pair (e.g., a 2nd PRB pair). Similar to the arrows in Fig. 4 and Fig. 5, the arrow depicted in Fig. 6 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels affecting other aspects of the LTE communications standard.

Fig. 7 is a diagram of example PRB pairs of a legacy LTE numerology and PRB pairs of a V2V numerology, under extended CP conditions. As shown, the legacy LTE numerology and the V2V numerology may each include 4 PRBs, PRB 7.1 through PRB 7.4 and PRB 7.5 through 7.8, respectively. Each PRB of the legacy LTE numerology, and each PRB of the V2V numerology, may be similar to the corresponding PRBs discussed above with reference to Fig. 5. Additionally, the PRBs of Fig. 7 may correspond to extended CP conditions since the PRB format includes 6 symbols (or REs) for each slot.

In the legacy LTE numerology, the PRB pairs may be differentiated from one another in the frequency domain, such that PRB 7.1 and PRB 7.2 include one pair (e.g., a 1st PRB pair) and PRB 6.3 and PRB 6.4 are another pair (e.g., a 2nd PRB pair). By contrast, in V2V numerology, the PRB pairs may be differentiated from one another in the time domain, such that PRB 7.5 and PRB 7.6 include one pair (e.g., a 1st PRB pair) and PRB 7.7 and PRB 7.8 are another pair (e.g., a 2nd PRB pair). Similar to the arrow in Fig. 6, the arrow depicted in Fig. 7 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels affecting other aspects of the LTE communications standard.

Figs. 8A-8D are diagrams of example PRBs according to one or more embodiments described herein. Additionally, the PRBs of Figs. 8A-8D may corresponds to normal CP conditions since each PRB includes 7 symbols per slot in time domain. The example PRB of Fig. 8A may correspond to the V2V channel PRB described above with reference to Fig. 4. The example PRBs of Fig. 8B may include a PRB pair (PRB 8.1 and PRB 8.2), similar to the V2V channel PRB pairs described above with reference to Fig. 5. Fig. 8C may include an example PRB that is similar to the PRB of Fig. 8A, except that the example PRB of Fig. 8C includes only 6 subcarriers (also, "REs in frequency" or "Frequency REs") of 30 kHz each. Similarly, Fig. 8D may include an example PRB pair (PRB 8.3 and PRB 8.4) that is similar to the PRB pair of Fig. 9B, except that the example PRBs of Fig. 8D include only 6 subcarriers with 30 kHz subcarrier spacing. In some embodiments, reducing the number of subcarriers per V2V channel may increase the number of transmission channels that may be used for V2V communications, which may in turn increase V2V system capacity (e.g., in a location with a high number of vehicles, such as a traffic jam on a freeway or major intersection).

Figs. 9A-9D are diagrams of example PRBs according to one or more embodiments described herein. Additionally, the PRBs of Figs. 9A-9D may correspond to extended CP conditions since each PRB includes 6 symbols per slot. The example PRB of Fig. 9A may correspond to the V2V channel PRB described above with reference to Fig. 5. The example PRBs of Fig. 9B may include a PRB pair (PRB 9.1 and PRB 9.2), similar to the V2V channel PRB pairs described above with reference to Fig. 5. Fig. 9C may include an example PRB that is similar to the PRB of Fig. 9A, except that the example PRB of Fig. 9C includes only 6 subcarriers (also, "REs in frequency" or "Frequency REs") of 30 kHz each. Similarly, Fig. 9D may include an example PRB pair (PRB 9.3 and PRB 9.4) that is similar to the PRB pair of Fig. 9B, except that the example PRBs of Fig. 9D include only 6 (instead of 12) subcarriers of 30 kHz each. As described above with reference to Figs. 8A-8D, in some embodiments, reducing

the number of subcarriers per V2V channel may increase the number of transmission channels that may be used for V2V communications, which may in turn increase the level of V2V system capacity (e.g., in a location with a high number of vehicles, such as a traffic jam on a freeway or major intersection).

Fig. 10 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 30 kHz subcarrier spacing. As shown, the table of Fig. 10 includes a Channel Characteristics column, a Legacy LTE Channel Numerology column, and a V2V Channel numerology column. Fig. 10 provides a non-limiting example of differences and similarities that may exists between a legacy LTE channel and a V2V channel.

For example, a legacy LTE channel may include a subcarrier spacing of 15 kHz, while a V2V channel may include a subcarrier spacing of 30 kHz. Both channels may support the same bandwidths; however, the channels may only support some of the same FTT sizes. For instance, only the legacy LTE channel may use FTT sizes of 1536 and 2048, and the V2V channel may use FTT sizes of 64 and 768. As such, the FFT size for the legacy LTE channel may include a lower limit of 128 for the 1.4 MHz bandwidth and an upper limit of 2048 for 20 MHz bandwidth, while the FFT size for the V2V channel (with 30 kHz subcarrier spacing), may include a lower limit of 64 for 1.4 MHz bandwidth and an upper limit of 1024 for the 20 MHz bandwidth. As described above, this is due to reducing the FTT sizes for the V2V channel by the same factor (e.g., "2") that was used to increase the subcarrier spacing of the V2V channel. The following table may represent a logical relationship between different BWs, legacy LTE FFT sizes, and V2V channel FFT sizes (when the subcarrier spacing for the V2V channel is 30 kHz).

Bandwidth (BW)	Nominal FFT Size	
	Legacy LTE Channel	V2V Channel with 30 kHz
1.4 MHz	128	64
3 MHz	256	128
5 MHz	512	256
10 MHz	1024	512
15 MHz	1536	768
20 MHz	2048	1024

Since the same factor was used to increase and decrease the subcarrier spacing and FFT size (respectively), both channels may have the same sampling time (Ts) of 32.55 nanoseconds

(ns) because sampling time may be calculated by taking the inverse of the product of the subcarrier spacing and the FFT size (e.g., Ts = 1/(subcarrier spacing x FFT size). In some embodiments, for similar reasons, both channels may also have the same sampling frequency (Fs) (e.g., Fs = subcarrier spacing x FFT size). As mentioned above, maintaining the same sampling time and sampling frequency as the legacy LTE channel may help ensure that the V2V channel can be implemented in an LTE environment without having to make significant adjustments to other aspects of the 3GPP LTE communication standard.

Similar to the change in FFT size, the symbol durations for the V2V channel may also be reduced by the same factor (e.g., "2") that was used to increase the subcarrier spacing of the V2V channel. As shown in Figs. 6-7, this may enable PRBs and PRB pairs to be formatted in a manner that enables the V2V channel to reduce the slot duration by half (e.g., from 0.5 ms to 0.25 ms) and output PRBs at the same rate as the legacy LTE channel, even though the subcarrier spacing for the V2V channel was doubled. Similar to maintaining the same sampling time and sampling frequency, maintaining a similar output rate as the legacy LTE channel, may help reduce the impact of the V2V channel on other aspects of the 3GPP LTE communication standard.

Additionally, the single subframe duration for the legacy LTE channel may be 1.0 ms, whereas the single subframe duration for the V2V channel may be 0.5 or 1.0 ms. A single subframe duration of 0.5 ms may enable the V2V channel to have two slots per subframe since the slot duration for the V2V channel was reduced to 0.25 ms. Additionally, since a PRB duration may be 0.25 ms (which corresponds to 1 slot), a 0.5 ms subframe may consist of one PRB pair (i.e., two 0.25 ms PRBs). In other words, the V2V channel may have a subframe-to-PRB-pair ratio of 1:1 when the subframe duration of the V2V channel is 0.5 ms, which may reduce the impact of the V2V channel on the 3GPP LTE communication standard since, for example, the legacy LTE channel also has a subframe-to-PRB-pair ratio of 1:1.

By contrast, a single subframe duration of 1.0 ms may enable the V2V channel to have four slots per subframe since the slot duration for the V2V channel was reduced to 0.25 ms. As such, the subframe may include four slots. In other words, a subframe duration of 1.0 ms, as opposed to the 0.5 ms subframe scenario above, may give rise to a relative increase in the amount of information that may be communicated in one subframe. As a result, implementing a 1.0 ms subframe may additional modifications to the 3GPP LTE communication standard, including changes to the design of physical channels, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

As shown in Fig. 10, whether the legacy LTE channel and the V2V channel have the same number of subcarriers per PRB may depend on the scenario or embodiment. For example, both channels may have 12 subcarriers for each PRB. Additionally, or alternatively, the V2V channel may have 6 subcarriers per PRB. In some embodiments, while allocating 6 subcarriers (instead of 12) to each PRB may decrease the rate at which a channel may transmit data, doing so may also increase the number of V2V channels that are available for V2X devices 110 to communicate with other V2X devices, UEs, etc. As such, allocating 6 subcarriers to each V2V channel may be beneficial in scenarios where V2V channels might not benefit from a high data rate connections and/or a vehicle with a V2X device is in a traffic jam, rush hour traffic, or in another situation involving a lot of V2X devices 110, UEs 110, etc., that within range of one another.

Fig. 11 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 60 kHz subcarrier spacing. As shown, the table of Fig. 11 includes a Channel Characteristics column, a Legacy LTE Channel Numerology column, and a V2V Channel numerology column. Fig. 11 provides a non-limiting example of differences and similarities that may exists between a legacy LTE channel and a V2V channel.

For example, a legacy LTE channel may include a subcarrier spacing of 15 kHz, while a V2V channel may include a subcarrier spacing of 60 kHz. Both channels may support the same bandwidths; however, the channels may only support some of the same FTT sizes. For instance, only the legacy LTE channel may support FTT sizes of 1024, 1536, and 2048, and only the V2V channel may support an FTT size of 32, 64, and 384. As such, the FFT size for the legacy LTE channel may include a lower limit of 128 and an upper limit of 2048, while the FFT size for the V2V channel (with 60 kHz subcarrier spacing), may include a lower limit of 32 kHz and an upper limit of 512 kHz. This may be due to reducing the FTT sizes for the V2V channel by the same factor (e.g., "4") that was used to increase the subcarrier spacing of the V2V channel. The following table may represent a logical relationship between different BWs, legacy LTE FFT sizes, and V2V channel FFT sizes (when the subcarrier spacing for the V2V channel is 30 kHz).

Bandwidth (BW)	Nominal FFT Size	
	Legacy LTE Channel	V2V Channel with 60 kHz
1.5 MHz	128	32
3 MHz	256	64
5 MHz	512	128
10 MHz	1024	256

15 MHz	1536	384
20 MHz	2048	512

Since the same factor was used to increase and decrease the subcarrier spacing and FFT size (respectively), both channels may have the same sampling time (Ts) of 32.55 nanoseconds (ns) because sampling time may be calculated by taking the inverse of the product of the subcarrier spacing and the FFT size (e.g., Ts = 1/(subcarrier spacing x FFT size). In some embodiments, for similar reasons, both channels may also have the same sampling frequency (Fs) (e.g., Fs = subcarrier spacing x FFT size). As mentioned above, maintaining the same sampling time and sampling frequency as the legacy LTE channel may help ensure that the V2V channel can be implemented in an LTE environment without having to make significant adjustments to other aspects of the 3GPP LTE communication standard.

Similar to the change in FFT size, the symbol durations for the V2V channel may also be reduced by the same factor (e.g., "4") that was used to increase the subcarrier spacing of the V2V channel. This may enable PRBs and PRB pairs to be formatted in a manner that enables the V2V channel to reduce the slot duration by one-fourth (e.g., from 1.0 ms to 0.125 ms) and output PRBs at the same rate as the legacy LTE channel, even though the subcarrier spacing for the V2V channel was quadrupled. Similar to maintaining the same sampling time and sampling frequency, maintaining a similar output rate as the legacy LTE channel, may help reduce the impact of the V2V channel on other aspects of the 3GPP LTE communication standard.

Additionally, the single subframe duration for the legacy LTE channel may be 1.0 ms, whereas the single subframe duration for the V2V channel may be 0.25 or 1.0 ms. A single subframe duration of 0.25 ms may enable the V2V channel to have two slots per subframe since the slot duration for the V2V channel was reduced to 0.125 ms. Additionally, since a PRB duration may be 0.125 ms (which corresponds to 1 slot), a 0.25 ms subframe may consist of one PRB pair (i.e., two 0.125 ms PRBs). In other words, the V2V channel may have a subframe-to-PRB-pair ratio of 1:1 when the subframe duration of the V2V channel is 0.25 ms, which may reduce the impact of the V2V channel on the 3GPP LTE communication standard since, for example, the legacy LTE channel also has a subframe-to-PRB-pair ratio of 1:1.

By contrast, a single subframe duration of 1.0 ms may enable the V2V channel to have eight slots per subframe since the slot duration for the V2V channel was reduced to 0.125 ms. As such, the subframe may include eight slots. In other words, a subframe duration of 1.0 ms, as opposed to the 0.25 ms subframe scenario above, may give rise to a relative increase in the amount of information that may be communicated in one subframe. As a result, implementing a

1.0 ms subframe may additional modifications to the 3GPP LTE communication standard, including changes to the design of physical channels, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

As shown in Fig. 11, whether the legacy LTE channel and the V2V channel have the same number of subcarriers per PRB may depend on the scenario or embodiment. For example, both channels may have 12 subcarriers for each PRB. Additionally, or alternatively, the V2V channel may have 3 or 6 subcarriers per PRB. In some embodiments, while allocating 3 or 6 subcarriers (instead of 12) to each PRB may decrease the rate at which a channel may transmit data, doing so may also increase the number of V2V channels that are available for V2X devices 110 to communicate with other V2X devices, UEs, etc. As such, allocating 3 or 6 subcarriers to each V2V channel may be beneficial in scenarios where V2V channels might not benefit from high data rate connections and/or a vehicle with a V2X device is in a traffic jam, rush hour traffic, or in another situation involving a lot of V2X devices 110, UEs 110, etc., that within range of one another.

Fig. 12 is a table representing an example of legacy LTE and V2V transmission multiplexing. As shown, Fig. 12 may include a vertical axis representing frequency and a horizontal axis representing time. V2V devices 110, UEs 110, etc., may support both legacy and V2V PHY numerologies (e.g. for cellular and V2V operation). Time domain multiplexing of legacy and V2V transmissions at one UE 110 may be used for these purposes. To facilitate efficient use of resources the minimum granularity for time domain multiplexing may be a multiple of legacy subframe granularity (e.g., 1.0 ms).

In one example, subframes for legacy LTE and V2V operation may be semi-statically, higher-layer configured, by an eNB (e.g., via radio resource control (RRC) protocol), on a per V2V device basis (or V2V device group basis). Semi-statically may include, for example, physical channels that are predefined by the eNB and assigned to a particular V2V device 210 or UE in a given scenario. In another example, subframes for legacy LTE and V2V operation may be dynamically assigned. In yet another example, subframes for legacy LTE and V2V operation may be specified by a communications standard (such as the 3GPP LTE communication standard).

A V2V transmissions (e.g., transmissions with a V2V numerology) may take place in either TDD or FDD modes. In the latter case, the transmissions may be configured in either a DL or a UL spectrum and can be configured independently (e.g., V2V transmissions on a UL spectrum may not impose use of V2V numerology in a DL spectrum in the same time resources).

In some embodiments, V2V device 110, UE 110, etc., may implement an autonomous selection capability for the numerology for the V2V transmissions (e.g., either a legacy LTE numerology or a V2V numerology) based on one or more instructions, conditions, or other criteria. As such, a V2V receiver (or another type of communication component) may either be informed on the type of the transmission in advance or may dynamically detect the transmission type. In embodiments where the transmission type is dynamically detected, a receiver (or another component of V2V device 110) may attempt to receive information under different hypothesis simultaneously (e.g., attempt to receive a signal under both a 15 kHz subcarrier spacing assumption and a 30 kHz subcarrier spacing assumptions)

As used herein, the term "circuitry" or "processing circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

Embodiments described herein may be implemented into a system using any suitably configured hardware and/or software. Fig. 13 illustrates, for one embodiment, example components of an electronic device 1300. In embodiments, the electronic device 1300 may be a UE, an eNB, a WLAN AP, or some other appropriate electronic device. In some embodiments, the electronic device 1300 may include application circuitry 1302, baseband circuitry 1304, Radio Frequency (RF) circuitry 1306, front-end module (FEM) circuitry 1308 and one or more antennas 1360, coupled together at least as shown.

The application circuitry 1302 may include one or more application processors. For example, the application circuitry 1302 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The processor(s) may include any combination of general-purpose processors and dedicated processors (e.g., graphics processors, application processors, etc.). The processors may be coupled with and/or may include memory/storage, such as storage medium 1303, and may be configured to execute instructions stored in the memory/storage to enable various applications and/or operating systems to run on the system. In some implementations, storage medium 1303 may include a non-transitory computer-readable medium. Application circuitry 1302 may, in some embodiments, connect to or include one or more sensors, such as environmental sensors, cameras, etc.

Baseband circuitry 1304 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry 1304 may include one or more baseband processors and/or control logic to process baseband signals received from a receive signal path of the RF circuitry 1306 and to generate baseband signals for a transmit signal path of the RF circuitry 1306. Baseband processing circuitry 1304 may interface with the application circuitry 1302 for generation and processing of the baseband signals and for controlling operations of the RF circuitry 1306. For example, in some embodiments, the baseband circuitry 1304 may include a second generation (2G) baseband processor 1304a, third generation (3G) baseband processor 1304b, fourth generation (4G) baseband processor 1304c, and/or other baseband processor(s) 1304d for other existing generations, generations in development or to be developed in the future (e.g., fifth generation (5G), 6G, etc.). The baseband circuitry 1304 (e.g., one or more of baseband processors 1304a-d) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry 1306. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some implementations, baseband circuitry 1304 may be associated with storage medium 1303 or with another storage medium.

In some embodiments, modulation/demodulation circuitry of the baseband circuitry 1304 may include FFT, precoding, and/or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry 1304 may include convolution, tail-biting convolution, turbo, Viterbi, and/or Low Density Parity Check (LDPC) encoder/decoder functionality. Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments. In some embodiments, the baseband circuitry 1304 may include elements of a protocol stack such as, for example, elements of an evolved universal terrestrial radio access network (E-UTRAN) protocol including, for example, physical (PHY), MAC, radio link control (RLC), packet data convergence protocol (PDCP), and/or radio resource control (RRC) elements. A central processing unit (CPU) 1304e of the baseband circuitry 1304 may be configured to run elements of the protocol stack for signaling of the PHY, MAC, RLC, PDCP and/or RRC layers. In some embodiments, the baseband circuitry may include one or more audio digital signal processor(s) (DSP) 1304f. The audio DSP(s) 1304f may be include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments.

The baseband circuitry 1304 may further include memory/storage 1304g. The memory/storage 1304g may be used to load and store data and/or instructions for operations

performed by the processors of the baseband circuitry 1304. Memory/storage for one embodiment may include any combination of suitable volatile memory and/or non-volatile memory. The memory/storage 1304g may include any combination of various levels of memory/storage including, but not limited to, read-only memory (ROM) having embedded software instructions (e.g., firmware), random access memory (e.g., dynamic random access memory (DRAM)), cache, buffers, etc. The memory/storage 1304g may be shared among the various processors or dedicated to particular processors.

Components of the baseband circuitry may be suitably combined in a single chip, a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry 1304 and the application circuitry 1302 may be implemented together such as, for example, on a system on a chip (SOC).

In some embodiments, the baseband circuitry 1304 may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry 1304 may support communication with an E-UTRAN and/or other wireless metropolitan area networks (WMAN), a WLAN, a wireless personal area network (WPAN). Embodiments in which the baseband circuitry 1304 is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

RF circuitry 1306 may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry 1306 may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry 1306 may include a receive signal path which may include circuitry to down-convert RF signals received from the FEM circuitry 1308 and provide baseband signals to the baseband circuitry 1304. RF circuitry 1306 may also include a transmit signal path which may include circuitry to up-convert baseband signals provided by the baseband circuitry 1304 and provide RF output signals to the FEM circuitry 1308 for transmission.

In some embodiments, the RF circuitry 1306 may include a receive signal path and a transmit signal path. The receive signal path of the RF circuitry 1306 may include mixer circuitry 1306a, amplifier circuitry 1306b and filter circuitry 1306c. The transmit signal path of the RF circuitry 1306 may include filter circuitry 1306c and mixer circuitry 1306a. RF circuitry 1306 may also include synthesizer circuitry 1306d for synthesizing a frequency for use by the mixer circuitry 1306a of the receive signal path and the transmit signal path. In some

embodiments, the mixer circuitry 1306a of the receive signal path may be configured to down-convert RF signals received from the FEM circuitry 1308 based on the synthesized frequency provided by synthesizer circuitry 1306d. The amplifier circuitry 1306b may be configured to amplify the down-converted signals and the filter circuitry 1306c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals.

Output baseband signals may be provided to the baseband circuitry 1304 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals. In some embodiments, mixer circuitry 1306a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 1306a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 1306d to generate RF output signals for the FEM circuitry 1308. The baseband signals may be provided by the baseband circuitry 1304 and may be filtered by filter circuitry 1306c. The filter circuitry 1306c may include a low-pass filter (LPF), although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may include two or more mixers and may be arranged for quadrature downconversion and/or upconversion respectively. In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a may be arranged for direct downconversion and/or direct upconversion, respectively. In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may be configured for super-heterodyne operation.

In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 1306 may include analog-to-digital converter (ADC) and digital-to-analog converter (DAC) circuitry and the baseband circuitry 1304 may include a digital baseband interface to communicate with the RF circuitry 1306.

In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

In some embodiments, the synthesizer circuitry 1306d may be a fractional-N synthesizer or a fractional N/N+6 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 1306d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

The synthesizer circuitry 1306d may be configured to synthesize an output frequency for use by the mixer circuitry 1306a of the RF circuitry 1306 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 1306d may be a fractional N/N+6 synthesizer.

In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO. Divider control input may be provided by either the baseband circuitry 1304 or the applications processor 1302 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the applications processor 1302.

Synthesizer circuitry 1306d of the RF circuitry 1306 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or N+6 (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into Nd equal packets of phase, where Nd is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

In some embodiments, synthesizer circuitry 1306d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 1306 may include an IQ/polar converter.

FEM circuitry 1308 may include a receive signal path which may include circuitry configured to operate on RF signals received from one or more antennas 1360, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 1306 for further processing. FEM circuitry 1308 may also include a transmit signal path which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 1306 for transmission by one or more of the one or more antennas 1360.

In some embodiments, the FEM circuitry 1308 may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry may include a low-noise amplifier (LNA) to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry 1306). The transmit signal path of the FEM circuitry 1308 may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry 1306), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas 1360.

In some embodiments, the electronic device 1300 may include additional elements such as, for example, memory/storage, display, camera, sensors, and/or input/output (I/O) interface. In some embodiments, the electronic device of Fig. 13 may be configured to perform one or more methods, processes, and/or techniques such as those described herein.

A number of examples, relating to embodiments of the techniques described above, will next be given.

In a first example, a communication device may comprise: a radio frequency (RF) circuitry to communicate with other communication devices via a physical channel; and baseband circuitry to cause the RF circuitry to communicate with another communication device via the physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 2, the subject matter of example 1, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 3, the subject matter of example 1, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6

subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 4, the subject matter of example 1, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In example 5, the subject matter of example 1, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: a vehicle-to-vehicle (V2V) communication, a vehicular-to-infrastructure (V2I) communication, or a vehicular-to-pedestrian (V2P) communication.

In example 6, the subject matter of example 1, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an long-term evolution (LTE) sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In a seventh example, an apparatus for a wireless communication device may comprise: a radio (RF) circuitry to communicate with other communication devices via a physical channel; and a baseband circuitry to: use a physical channel, from a plurality of physical channel types, that is appropriate for communicating with the other wireless communication devices, the plurality of physical channel types including: a long-term evolution (LTE) physical channel, and a V2V physical channel that includes: a bandwidth that is at least as large as a bandwidth of the LTE physical channel; a subcarrier spacing that is greater, by a preselected factor, than a subcarrier spacing corresponding to the LTE physical channel, a fast Fourier transform (FFT) size that is less, by the preselected factor, than an FFT size corresponding to the LTE physical channel, a symbol duration that is less, by the preselected factor, than a symbol duration corresponding to the LTE physical channel, and a sampling frequency that is equal to a sampling frequency of the LTE physical channel, and a sampling time that is equal to a sampling time of the LTE physical channel; and communicate with the other wireless communication devices via the V2V physical channel.

In example 8, the subject matter of example 7, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an LTE sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In example 9, the subject matter of example 7, or any of the examples herein, may further include wherein the V2V physical channel includes physical resource blocks (PRBs) that

each include a number of subcarriers that is less than, or equal to, a number of subcarriers of the PRBs of the LTE physical channel.

In example 10, the subject matter of example 7, or any of the examples herein, may further include wherein: the subcarrier spacing for the V2V physical channel is 30 or 60 kilohertz (kHz); and the subcarrier spacing for the LTE physical channel is 15 kHz.

In example 11, the subject matter of example 7, or any of the examples herein, may further include wherein, for normal cyclic prefix (CP) conditions and extended CP conditions, a number of resource elements (REs) and a number of single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols per a physical resource block (PRB) of the V2V physical channel is equal to the number of REs and a number of SC-FDMA or OFDM symbols per PRB of the LTE physical channel.

In example 12, the subject matter of example 7, or any of the examples herein, may further include wherein application circuitry is to: communicate with a user equipment device (UE) of a vehicle via a vehicle-to-vehicle (V2V) connection, communicate with a UE of a user via a vehicle-to-pedestrian (V2P) connection, or communicate with a wireless telecommunications network via a vehicle-to-infrastructure (V2I) connection.

In example 13, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry uses the type of physical channel that is appropriate for communicating with the other wireless communication device based on at least one of: a likelihood of communications, between the wireless communication device and the other wireless communication device being subjected to high mobility conditions, whether the other wireless communication device is capable of communicating via the LTE physical channel or the V2V physical channel, an availability, of the LTE physical channel or the V2V physical channel, for communicating with the other wireless communication device, a measure of importance regarding information that will be communicated to the other wireless communication device, or a preselected priority for communicating via the LTE physical channel or the V2V physical channel.

In example 14, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry is configured, by via an eNB, to use the V2V physical channel or the LTE physical channel.

In example 15, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry uses time-division multiplexing of the V2V physical channel and the LTE physical channel to communicate in different subframes.

In example 16, the subject matter of example 7, or any of the examples herein, may further include wherein subframes for the V2V physical channel and the LTE physical channel are semi-statically configured by an eNB.

In a seventeenth example, a wireless communication device as in the first or seventh examples, wherein a physical resource block (PRB), corresponding to the vehicle-to-vehicle (V2V) physical channel, includes: 7 consecutive single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols in time domain under normal cyclic prefix (CP) conditions, and 6 consecutive SC-FDMA or OFDM symbols in time domain under extended CP conditions.

In example 18, the subject matter of example 17, or any of the examples herein, may further include a subframe, corresponding to the V2V physical channel, includes two slots, a physical resource block (PRB), corresponding to the V2V physical channel, contains one slot; and a subframe duration, corresponding to the V2V physical channel, is equal to at least one of: 0.5 milliseconds (ms) and a slot duration is 0.25 ms when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz); or 0.25 milliseconds (ms) and a slot duration is 0.125 ms when subcarrier spacing for the V2V physical channel is 60 kilohertz (kHz).

In example 19, the subject matter of example 17, or any of the examples herein, may further include a subframe duration, corresponding to the vehicle-to-vehicle (V2V) physical channel, is equal to 1.0 ms, and the subframe, corresponding to the V2V physical channel, includes four slots with 0.25 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains two slots when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz), or the subframe, corresponding to the V2V physical channel, includes eight slots with 0.125 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains four slots when subcarrier spacing for the V2V physical channel is 60 kHz.

In a twentieth example, a computer readable medium may contain program instructions for causing one or more processors to: communicate with other communication devices via a physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 21, the subject matter of example 20, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 22, the subject matter of example 20, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 23, the subject matter of example 20, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: a vehicle-to-vehicle (V2V) communication, a vehicular-to-infrastructure (V2I) communication, or a vehicular-to-pedestrian (V2P) communication.

In example 24, the subject matter of example 20, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an LTE sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In example 25, the subject matter of example 20, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In a twenty-sixth example, a communication device may comprise: a means for communicating with other communication devices via a physical channel; and a means for causing the means for communicating to communicate with another communication device via the physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 27, the subject matter of example 26, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 28, the subject matter of example 26, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6

subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 29, the subject matter of example 26, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In the preceding specification, various embodiments have been described with reference to the accompanying drawings. It will, however, be evident that various modifications and changes may be made thereto, and additional embodiments may be implemented, without departing from the broader scope as set forth in the claims that follow. The specification and drawings are accordingly to be regarded in an illustrative rather than restrictive sense.

For example, while series of signals and/or operations have been described with regard to Figs. 3-4, the order of the signals and/or operations may be modified in other embodiments. Further, non-dependent signals may be performed in parallel.

It will be apparent that example aspects, as described above, may be implemented in many different forms of software, firmware, and hardware in the embodiments illustrated in the figures. The actual software code or specialized control hardware used to implement these aspects should not be construed as limiting. Thus, the operation and behavior of the aspects were described without reference to the specific software code--it being understood that software and control hardware could be designed to implement the aspects based on the description herein.

Further, certain portions may be implemented as "logic" that performs one or more functions. This logic may include hardware, such as an application-specific integrated circuit ("ASIC") or a field programmable gate array ("FPGA"), or a combination of hardware and software.

Even though particular combinations of features are recited in the claims and/or disclosed in the specification, these combinations are not intended to be limiting. In fact, many of these features may be combined in ways not specifically recited in the claims and/or disclosed in the specification.

No element, act, or instruction used in the present application should be construed as critical or essential unless explicitly described as such. An instance of the use of the term "and," as used herein, does not necessarily preclude the interpretation that the phrase "and/or" was intended in that instance. Similarly, an instance of the use of the term "or," as used herein, does not necessarily preclude the interpretation that the phrase "and/or" was intended in that instance. Also, as used herein, the article "a" is intended to include one or more items, and may be used

interchangeably with the phrase "one or more." Where only one item is intended, the terms "one," "single," "only," or similar language is used.

Samsung Exhibit 1026, Page 31 of 53

WHAT IS CLAIMED IS:

1. A communication device, comprising:

a radio frequency (RF) circuitry to communicate with other communication devices via a physical channel; and

baseband circuitry to cause the RF circuitry to communicate with another communication device via the physical channel, the physical channel including:

a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform,

a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and

a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

2. The communication device of claim 1, wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

3. The communication device of claim 1, wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

4. The communication device of claim 1, wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

5. The communication device of claim 1, wherein the physical channel corresponds to at least one of:

a vehicle-to-vehicle (V2V) communication,

a vehicular-to-infrastructure (V2I) communication, or

a vehicular-to-pedestrian (V2P) communication.

6. The communication device of claim 1, wherein the physical channel corresponds to at least one of:

an long-term evolution (LTE) sidelink (SL) physical channel,

an LTE downlink (DL) physical channel, or

an LTE uplink (UL) physical channel.

7. An apparatus for a wireless communication device, comprising:

a radio (RF) circuitry to communicate with other communication devices via a physical channel; and

a baseband circuitry to:

use a physical channel, from a plurality of physical channel types, that is appropriate for communicating with the other wireless communication devices, the plurality of physical channel types including:

a long-term evolution (LTE) physical channel, and

a V2V physical channel that includes:

a bandwidth that is at least as large as a bandwidth of the LTE physical channel;

a subcarrier spacing that is greater, by a preselected factor, than a subcarrier spacing corresponding to the LTE physical channel,

a fast Fourier transform (FFT) size that is less, by the preselected factor, than an FFT size corresponding to the LTE physical channel,

a symbol duration that is less, by the preselected factor, than a symbol duration corresponding to the LTE physical channel, and

a sampling frequency that is equal to a sampling frequency of the LTE physical channel, and

a sampling time that is equal to a sampling time of the LTE physical channel; and

communicate with the other wireless communication devices via the V2V physical channel.

8. The apparatus of claim 7, wherein the LTE physical channel and the V2V physical channel correspond to at least one of:

long-term evolution (LTE) sidelink (SL) physical channels,

LTE downlink (DL) physical channels, or

LTE uplink (UL) physical channels.

9. The apparatus of claim 7, wherein the V2V physical channel includes physical resource blocks (PRBs) that each include a number of subcarriers that is less than, or equal to, a number of subcarriers of the PRBs of the LTE physical channel.

10. The apparatus of claim 7, wherein:
the subcarrier spacing for the V2V physical channel is 30 or 60 kilohertz (kHz); and
the subcarrier spacing for the LTE physical channel is 15 kHz.

11. The apparatus of claim 7, wherein, for normal cyclic prefix (CP) conditions and extended CP conditions, a number of resource elements (REs) and a number of single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols per a physical resource block (PRB) of the V2V physical channel is equal to the number of REs and a number of SC-FDMA or OFDM symbols per PRB of the LTE physical channel.

12. The apparatus of claim 7, wherein application circuitry is to:
communicate with a user equipment device (UE) of a vehicle via a vehicle-to-vehicle (V2V) connection,
communicate with a UE of a user via a vehicle-to-pedestrian (V2P) connection, or
communicate with a wireless telecommunications network via a vehicle-to-infrastructure (V2I) connection.

13. The apparatus of claim 7, wherein the baseband circuitry uses the type of physical channel that is appropriate for communicating with the other wireless communication device based on at least one of:
a likelihood of communications, between the wireless communication device and the other wireless communication device being subjected to high mobility conditions,
whether the other wireless communication device is capable of communicating via the LTE physical channel or the V2V physical channel,
an availability, of the LTE physical channel or the V2V physical channel, for communicating with the other wireless communication device,
a measure of importance regarding information that will be communicated to the other wireless communication device, or

a preselected priority for communicating via the LTE physical channel or the V2V physical channel.

14. The apparatus of claim 7, wherein the baseband circuitry is configured, by via an eNB, to use the V2V physical channel or the LTE physical channel.

15. The apparatus of claim 7, wherein the baseband circuitry uses time-division multiplexing of the V2V physical channel and the LTE physical channel to communicate in different subframes.

16. The apparatus of either of claims 15, wherein subframes for the V2V physical channel and the LTE physical channel are semi-statically configured by an eNB.

17. A wireless communication device as in claims 1 or 7, wherein a physical resource block (PRB), corresponding to the vehicle-to-vehicle (V2V) physical channel, includes:

7 consecutive single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols in time domain under normal cyclic prefix (CP) conditions, and

6 consecutive SC-FDMA or OFDM symbols in time domain under extended CP conditions.

18. The wireless communication device of claim 17, wherein:

a subframe, corresponding to the V2V physical channel, includes two slots,

a physical resource block (PRB), corresponding to the V2V physical channel, contains one slot; and

a subframe duration, corresponding to the V2V physical channel, is equal to at least one of:

0.5 milliseconds (ms) and a slot duration is 0.25 ms when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz); or

0.25 milliseconds (ms) and a slot duration is 0.125 ms when subcarrier spacing for the V2V physical channel is 60 kilohertz (kHz).

19. The wireless communication device of claim 17, wherein:

a subframe duration, corresponding to the vehicle-to-vehicle (V2V) physical

channel, is equal to 1.0 ms, and

the subframe, corresponding to the V2V physical channel, includes four slots with 0.25 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains two slots when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz), or

the subframe, corresponding to the V2V physical channel, includes eight slots with 0.125 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains four slots when subcarrier spacing for the V2V physical channel is 60 kHz.

20. A computer readable medium containing program instructions for causing one or more processors to:

communicate with other communication devices via a physical channel, the physical channel including:

a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform,

a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and

a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

21. The computer readable medium of claim 20, wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

22. The computer readable medium of claim 20, wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

23. The computer readable medium of claim 20, wherein the physical channel corresponds to at least one of:

a vehicle-to-vehicle (V2V) communication,

a vehicular-to-infrastructure (V2I) communication, or

a vehicular-to-pedestrian (V2P) communication.

24. The computer readable medium of claim 20, wherein the physical channel corresponds to at least one of:

an long-term evolution (LTE) sidelink (SL) physical channel,

an LTE downlink (DL) physical channel, or

an LTE uplink (UL) physical channel.

25. The computer readable medium of claim 20, wherein a PRB pair, of the physical channel, corresponds to two consecutive PRBs in a time-domain.

Method for paging in user equipment, method for paging in base station, user equipment for paging and base station equipment for paging

Abstract

The invention discloses a method for paging in user equipment, a method for paging in a base station, the user equipment for paging and base station equipment for paging. The user equipment first monitors first signaling in X time intervals respectively, and then receives a first radio signal. The X is a positive integer. The first signaling is used for determining scheduling information for the first radio signal. The scheduling information comprises at least one of {an occupied time-frequency resource, an employed MCS (Modulation Coding Scheme), and subcarrier spacing of subcarriers in an occupied frequency domain resource}. The first radio signal carries a paging message. The frequency domain resource for transmitting the first signaling belongs to a first subband. The first subband comprises a positive integer number of consecutive subcarriers in a frequency domain. At least one of {a location of the first subband in the frequency domain, and subcarrier spacing of the subcarriers included in the first subband} is used for determining the X time intervals. According to the methods, the user equipment and the base station equipment, paging capacity is kept, and moreover, power consumption of the user equipment is reduced.

(54) 发明名称

一种被用于寻呼的用户设备、基站中的方法和装置

(57) 摘要

本发明公开了一种被用于寻呼的用户设备、基站中的方法和装置。用户设备首先在X个时间间隔中分别监测第一信令，接着接收第一无线信号。其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被用于确定所述X个时间间隔。本发明可以在保持寻呼容量的同时降低用户设备功率消耗。

CN 108923896 B

1.一种用于寻呼的用户设备中的方法，其特征在于，包括如下步骤：

-步骤A.在X个时间间隔中分别监测第一信令；

-步骤B.接收第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

2.根据权利要求1所述的方法，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

3.根据权利要求2所述的方法，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

4.根据权利要求1至3中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A0.接收第二无线信号；

其中，所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

5.根据权利要求1至3中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A1.接收第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

6.根据权利要求4所述的方法，其特征在于，所述步骤A还包括如下步骤：

步骤A1.接收第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

7.一种用于寻呼的基站中的方法，其特征在于，包括如下步骤：

-步骤A.在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

-步骤B.发送第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正

整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

8.根据权利要求7所述的方法，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

9.根据权利要求8所述的方法，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

10.根据权利要求7至9中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A0.发送第二无线信号；

其中，所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

11.根据权利要求7至9中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A1.发送第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

12.根据权利要求10所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A1.发送第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

13.一种用于寻呼的用户设备，其特征在于，包括如下模块：

-第一接收模块：用于在X个时间间隔中分别监测第一信令；

-第二接收模块：用于接收第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

14.根据权利要求13所述的用户设备，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令

的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

15.根据权利要求14所述的用户设备，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

16.根据权利要求13至15中任一权利要求所述的用户设备，其特征在于，所述第一接收模块还被用于接收第二无线信号；所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

17.根据权利要求13至15中任一权利要求所述的用户设备，其特征在于，所述第一接收模块还被用于接收第二信令所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

18.根据权利要求16所述的用户设备，其特征在于，所述第一接收模块还被用于接收第二信令所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

19.一种用于寻呼的基站设备，其特征在于，包括如下模块：

-第一发送模块：用于在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

第二发送模块：用于发送第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

20.根据权利要求19所述的基站设备，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

21.根据权利要求20所述的基站设备，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

22.根据权利要求19至21中任一权利要求所述的基站设备，其特征在于，所述第一发送模块还被用于发送第二无线信号；所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

23.根据权利要求19至21中任一权利要求所述的基站设备，其特征在于，所述第一发送模块还被用于发送第二信令；所述第二信令被用于确定Q个子频带，所述第一子频带属于所

述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

24.根据权利要求22所述的基站设备，其特征在于，所述第一发送模块还被用于发送第二信令；所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

一种被用于寻呼的用户设备、基站中的方法和装置

技术领域

[0001] 本申请涉及无线通信系统中的传输方案，特别是涉及支持多种数理结构(Numerology)的通信系统中的寻呼传输的方法和装置。

背景技术

[0002] 未来无线通信系统的应用场景越来越多元化，不同的应用场景对系统提出了不同的性能要求。为了满足多种应用场景的不同的性能需求，在3GPP(3rd Generation Partner Project，第三代合作伙伴项目)RAN(Radio Access Network，无线接入网)#72次全会上决定对新空口技术(NR，New Radio)进行研究。在3GPP RAN#75次全会上通过了5G新空口技术(NR)的工作项目(WI，Working Item)的立项，开始对5G新空口技术进行标准化。

[0003] 为了能够灵活适应多种不同的应用场景，未来的无线通信系统，特别是5G NR将可以支持多种数理结构(Numerology)，多种数理结构是指多种子载波间隔，多种符号时间长度，多种CP(Cyclic Prefix，循环前缀)长度等。为了能够简化系统的设计与用户设备实现的复杂度，针对不同的数理结构，整个系统物理层设计最好能够采用一种统一结构。

发明内容

[0004] 在现有LTE系统中，寻呼的传输时机统一通过PF(Paging Frame，寻呼帧)和PO(Paging Occasion，寻呼机会)来定义，其中PF为有可能传输寻呼消息的无线帧，而PO用来确定在PF的帧中有可能传输寻呼消息的子帧。LTE中的无线帧的时间长度为固定的10毫秒，子帧的时间长度为固定的1毫秒。由于一个LTE网络一般采用单一的数理结构(Numerology)或者数理结构在一个网络中基本长时间不变，采用固定时长的PF和PO来定义寻呼的可能时间可以在保证寻呼容量和不增加用户设备(UE，User Equipment)功率消耗的前提下，简化系统设计。在5G NR下，由于支持不同的数理结构，在一个给定的时长内，比如1毫秒，可能包含了多个基本的调度单元(比如时隙，Slot)，如果沿用现有的寻呼时机的设计，在这个1毫秒内用户设备针对不同的数理结构要对寻呼消息进行不同次数的检测，因而导致在某些数理结构下的功率消耗的大大增加。同时也会导致寻呼容量因为不同的数理结构的采用而相差巨大。

[0005] 为了解决上述在5G NR中当采用多种数理结构(Numerology)时的寻呼的设计问题，本申请提供了解决方案。该方案依据寻呼所采用的数理结构来确定寻呼的传输时机，从而保证在不同的数理结构下用户设备监测寻呼消息的复杂度和功耗相差不大，同时寻呼的容量也保持基本不变。需要说明的是，在不冲突的情况下，本申请的UE(User Equipment，用户设备)中的实施例和实施例中的特征可以应用到基站中，反之亦然。进一步的，在不冲突的情况下，本申请的实施例和实施例中的特征可以任意相互组合。

[0006] 本申请公开了一种用于寻呼的用户设备中的方法，其中，包括如下步骤：

[0007] -步骤A.在X个时间间隔中分别监测第一信令；

[0008] -步骤B.接收第一无线信号。

[0009] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0010] 作为一个实施例，采用所述方法，所述用于设备可以依据传输寻呼所采用的子载波间隔来确定监测传输寻呼的时间间隔，节省功耗。

[0011] 作为一个实施例，所述方法设计了基于不同的子载波间隔的一致的寻呼时机的计算方式，同时当采用不同的子载波间隔传输寻呼消息时，保持寻呼容量不变。

[0012] 作为一个实施例，所述寻呼消息包括被寻呼的用户设备的特征ID。

[0013] 作为一个实施例，在所述X个时间间隔中的每一个时间间隔中针对所述第一信令最多执行P次检测，所述P是正整数。

[0014] 作为一个实施例，所述X个时间间隔中的任意两个时间间隔的时间长度相等。

[0015] 作为一个实施例，所述X个时间间隔中存在两个时间间隔的时间长度不等。

[0016] 作为一个实施例，所述X个时间间隔中的任意一个时间间隔为一个时隙(Slot)。

[0017] 作为一个实施例，所述X个时间间隔中的任意两个时间间隔的时间长度相等，所述X个时间间隔中的每个时间间隔的时间长度和所述第一频带中所包括的子载波的子载波间隔有关。

[0018] 作为一个实施例，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于14的正整数。

[0019] 作为一个实施例，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于7的正整数。

[0020] 作为一个实施例，所述X个时间间隔中的任意两个时间间隔在时域正交，所述正交是指不存在一个时间单元同时属于所述X个时间间隔中的任意两个时间间隔。

[0021] 作为一个实施例，所述X个时间间隔中存在两个时间间隔在时域是离散的。

[0022] 作为一个实施例，所述第一信令是物理层信令。

[0023] 作为一个实施例，所述第一信令是DCI(Downlink Control Information，下行控制信息)。

[0024] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输。

[0025] 作为一个实施例，所述第一信令通过NR-PDCCH(New Radio Physical Downl ink Control Channel，新空口物理下行控制信道)传输。

[0026] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输，所述PDCCH在CSS(Common Search Space，公共搜索空间)中传输。

[0027] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control

Channel，物理下行控制信道)传输，所述PDCCH在USS(UE-Specific Search Space，UE特定搜索空间)中传输。

[0028] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输，所述PDCCH的CRC(Cyclic Redundancy Check，循环冗余校验)经过P-RNTI(Paging Radio Network Temporary Identity，寻呼无线网络临时标识)加扰。

[0029] 作为一个实施例，所述MCS(Modulation Coding Scheme，调制编码方式)包括的调制方式为{QPSK，16QAM，64QAM，256QAM，1024QAM}中之一。

[0030] 作为一个实施例，所述子载波间隔等于15kHz乘以2的K次幂，所述K为整数。

[0031] 作为一个实施例，所述第一子频带(Subband)包括12的正整数倍个子载波。

[0032] 作为一个实施例，所述第一子频带中包括的所有子载波的子载波间隔都相等。

[0033] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的位置。

[0034] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)在频域的位置。

[0035] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的子频带索引。

[0036] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的频带(Band)所对应的频率资源中的位置。

[0037] 作为一个实施例，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被所述用户设备用于确定所述X个时间间隔。

[0038] 作为一个实施例，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被所述用户设备基于给定映射规则确定所述X个时间间隔。

[0039] 作为一个实施例，所述第一无线信号通过DL-SCH(Downlink Shared Channel，下行共享信道)传输。

[0040] 作为一个实施例，所述第一无线信号通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输。

[0041] 作为一个实施例，第一比特块依次经过调制映射器(Modulation Mapper)，层映射器(Layer Mapper)，预编码(Precoding)，资源粒子映射器(Resource Element Mapper)，OFDM信号发生(Generation)之后得到所述第一无线信号。所述第一比特块包括一个码块经过信道编码之后的输出。作为一个子实施例，所述码块是TB(Transport Block，传输块)。作为一个子实施例，所述码块是TB(Transport Block，传输块)中的一部分。

[0042] 具体的，根据本申请的一个方面，上述方法的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0043] 作为一个实施例，所述第一时间窗的时间长度是固定不变的。

[0044] 作为一个实施例，所述第一时间窗中包括正整数个时域连续的多载波符号。作为

一个子实施例，所述多载波符号包括数据符号和CP(Cyclic Prefix，循环前缀)。

[0045] 作为一个实施例，所述所述第一时间窗的时间长度为1毫秒。

[0046] 作为一个实施例，所述所述第一时间窗的时间长度为10毫秒。

[0047] 作为一个实施例，所述第一时间窗为一个子帧(Subframe)。

[0048] 作为一个实施例，所述第一时间窗为一个无线帧(Radio Frame)。

[0049] 作为一个实施例，所述Y个时间间隔中的任意两个时间间隔的时间长度相等。

[0050] 作为一个实施例，所述Y个时间间隔中存在两个时间间隔的时间长度不等。

[0051] 作为一个实施例，所述Y大于所述X。

[0052] 作为一个实施例，所述Y与所述所述第一频带中所包括的子载波的子载波间隔成正比。

[0053] 作为一个实施例，所述所述第一频带中所包括的子载波的子载波间隔被所述用户设备用于确定所述Y。

[0054] 作为一个实施例，所述所述第一频带中所包括的子载波的子载波间隔被所述用户设备基于给定的映射关系确定所述Y。

[0055] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备用于在所述Y个时间间隔中确定所述X个时间间隔。

[0056] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备基于给定的映射关系在所述Y个时间间隔中确定所述X个时间间隔。

[0057] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)。

[0058] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对1024的余数。

[0059] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对4096的余数。

[0060] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对16384的余数。

[0061] 作为一个实施例，所述特征ID是指C-RNTI(Cell Radio Network Temporary Identity，小区无线网络临时标识)。

[0062] 作为一个实施例，所述第一信令的发送小区的物理小区ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0063] 具体的，根据本申请的一个方面，上述方法的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0064] 作为一个实施例，所述Z等于10。

[0065] 作为一个实施例，所述Z个时间窗中的任意两个时间窗在时域正交。

[0066] 作为一个实施例，所述Z个时间窗中的任意一个时间窗为一个子帧，所述Z等于10.

[0067] 作为一个实施例，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述Z等于非连续接收周期(DRX(Discontinuous Reception)cycle)所包含的无线帧的数量。

[0068] 作为一个实施例，所述步骤A还包括如下步骤：

[0069] -步骤A2.接收第三信令。

[0070] 其中，所述第三信令被用于配置所述Z。

[0071] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备用于在所述Z个时间窗中确定所述第一时间窗。

[0072] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备基于给定的映射关系在所述Z个时间窗中确定所述第一时间窗。

[0073] 作为一个实施例，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述第一时间窗由下式得到：

[0074] SFN mod Z=(Z div N)*(UE_ID mod N)

[0075] 其中，SFN为所述第一时间窗对应的无线帧的帧号，N=min(Z,nB)，nB等于{4Z,2Z,Z,Z/2,Z/4,Z/8,Z/16,Z/32,Z/64,Z/128,Z/256,Z/512,Z/1024}中之一。

[0076] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0077] -步骤A0.接收第二无线信号。

[0078] 其中，所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0079] 作为一个实施例，所述第二无线信号包括主同步信号(PSS，Primary Synchronization Signal)。

[0080] 作为一个实施例，所述第二无线信号包括辅同步信号(SSS，Secondary Synchronization Signal)。

[0081] 作为一个实施例，所述第二无线信号通过BCH(Broadcast Channel，广播信道)传输。

[0082] 作为一个实施例，所述第二无线信号通过PBCH(Physical Broadcast Channel，物理广播信道)传输。

[0083] 作为一个实施例，所述第二无线信号通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输。

[0084] 作为一个实施例，所述第二无线信号携带MIB(Master Information Block，主信息块)信息。

[0085] 作为一个实施例，所述第二无线信号携带SIB(System Information Block，系统信息块)信息。

[0086] 作为一个实施例，所述第二无线信号所携带的信息是被周期性传输的。

[0087] 作为一个实施例，所述第二无线所携带的信息是按需(On-Demand)传输的。

[0088] 作为一个实施例，所述第二无线信号携带第一信息，所述第一信息被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0089] 作为一个实施例，所述第二无线信号携带第一信息，所述第一信息指示{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0090] 作为一个实施例，所述第二无线信号被所述用户设备用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0091] 作为一个实施例，所述第二无线信号指示{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0092] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0093] -步骤A1.接收第二信令。

[0094] 其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0095] 作为一个实施例，所述Q个子频带中的任意一个子频带所包括的子载波的子载波间隔都相等。

[0096] 作为一个实施例，所述Q个子频带中任意两个子频带中的子载波的子载波间隔不同。

[0097] 作为一个实施例，所述Q个子频带中存在两个子频带中的子载波的子载波间隔相同。

[0098] 作为一个实施例，所述Q个子频带中任意两个子频带的频域带宽相同。

[0099] 作为一个实施例，所述Q个子频带中存在两个子频带的频域带宽不相等。

[0100] 作为一个实施例，所述Q个子频带都属于同一个载波(Carrier)。

[0101] 作为一个实施例，所述Q个子频带中存在两个子频带属于不同的载波(Carrier)。

[0102] 作为一个实施例，所述第二信令是高层信令。

[0103] 作为一个实施例，所述第二信令是物理层信令。

[0104] 作为一个实施例，所述第二信令是通过BCH(Broadcast Channel，广播信道)传输的。

[0105] 作为一个实施例，所述第二信令是通过PBCH(Physical Broadcast Channel，物理广播信道)传输的。

[0106] 作为一个实施例，所述第二信令是通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输的。

[0107] 作为一个实施例，所述第二信令是RRC(Radio Resource Control，无线资源控制)信令。

[0108] 作为一个实施例，所述第二信令是SIB(System Information Block，系统信息块)。

[0109] 作为一个实施例，所述第二信令是通过DCI传输的。

[0110] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备用于在所述Q个子频带中确定所述第一子频带。

[0111] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备基于给定的映射关系在所述Q个子频带中确定所述第一子频带。

[0112] 本申请公开了一种用于寻呼的基站中的方法，其中，包括如下步骤：

[0113] -步骤A.在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

[0114] -步骤B.发送第一无线信号。

[0115] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0116] 具体的，根据本申请的一个方面，上述方法的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0117] 具体的，根据本申请的一个方面，上述方法的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0118] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0119] -步骤A0.发送第二无线信号。

[0120] 其中，所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0121] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0122] -步骤A1.发送第二信令。

[0123] 其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0124] 本申请公开了一种用于寻呼的用户设备，其中，包括如下模块：

[0125] -第一接收模块：用于在X个时间间隔中分别监测第一信令；

[0126] -第二接收模块：用于接收第一无线信号。

[0127] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0128] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y

是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0129] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0130] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述第一接收模块还被用于接收第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0131] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述第一接收模块还被用于接收第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0132] 本申请公开了一种用于寻呼的基站设备，其中，包括如下模块：

[0133] -第一发送模块：用于在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

[0134] -第二发送模块：用于发送第一无线信号。

[0135] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0136] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0137] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0138] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述第一发送模块还被用于发送第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0139] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述第一发送模块还被用于发送第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述

第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

附图说明

[0140] 通过阅读参照以下附图所作的对非限制性实施例所作的详细描述，本申请的其它特征、目的和优点将会变得更加明显：

[0141] 图1示出了根据本申请的一个实施例的无线信号传输流程图；

[0142] 图2示出了根据本申请的一个实施例的Z个时间窗和Q个子频带的关系的示意图；

[0143] 图3示出了根据本申请的一个实施例的第一时间窗与X个时间间隔的关系的示意图；

[0144] 图4示出了根据本申请的一个实施例的第一信令，第一无线信号和第二无线信号之间的关系的示意图；

[0145] 图5示出了根据本申请的一个实施例的用户设备(UE)中的处理装置的结构框图；

[0146] 图6示出了根据本申请的一个实施例的基站中的处理装置的结构框图；

具体实施方式

[0147] 下文将结合附图对本申请的技术方案作进一步详细说明，需要说明的是，在不冲突的情况下，本申请的实施例和实施例中的特征可以任意相互组合。

[0148] 实施例1

[0149] 实施例1示例了根据本申请的一个实施例的无线信号传输流程图，如附图1所示。附图1中，基站N1是UE U2的服务小区的维持基站，虚线框F1中标识的步骤是可选的。

[0150] 对于基站N1，在步骤S11中发送第二无线信号，在步骤S12中发送第二信令，在步骤S13中在X个时间间隔中的正整数个时间间隔中分别发送第一信令，在步骤S14中发送第一无线信号。

[0151] 对于UE U2，在步骤S21中接收第二无线信号，在步骤S22中接收第二信令，在步骤S23中在X个时间间隔中分别监测第一信令，在步骤S24中接收第一无线信号。

[0152] 在实施例1中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息，传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0153] 在实施例1的子实施例1中，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第

一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0154] 在实施例1的子实施例2中，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0155] 在实施例1的子实施例3中，所述寻呼消息包括被寻呼的用户设备的特征ID。

[0156] 在实施例1的子实施例4中，所述MCS(Modulation Coding Scheme，调制编码方式)包括的调制方式为{QPSK，16QAM，64QAM，256QAM，1024QAM}中之一。

[0157] 在实施例1的子实施例5中，所述子载波间隔等于15kHz乘以2的K次幂，所述K为整数。

[0158] 在实施例1的子实施例6中，所述第一子频带(Subband)包括12的正整数倍个子载波。

[0159] 在实施例1的子实施例7中，所述第一子频带中包括的所有子载波的子载波间隔都相等。

[0160] 在实施例1的子实施例8中，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的位置。

[0161] 在实施例1的子实施例9中，所述所述第一子频带在频域的位置是指所述第一子频带所处的载波(Carrier)在频域的位置。

[0162] 在实施例1的子实施例10中，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的子频带索引。

[0163] 在实施例1的子实施例11中，所述所述第一子频带在频域的位置是指所述第一子频带在所处的频带(Band)所对应的频率资源中的位置。

[0164] 在实施例1的子实施例12中，所述第二信令是高层信令。

[0165] 在实施例1的子实施例13中，所述第二信令是物理层信令。

[0166] 在实施例1的子实施例14中，所述第二信令是通过BCH(Broadcast Channel，广播信道)传输的。

[0167] 在实施例1的子实施例15中，所述第二信令是通过PBCH(Physical Broadcast Channel，物理广播信道)传输的。

[0168] 在实施例1的子实施例16中，所述第二信令是通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输的。

[0169] 在实施例1的子实施例17中，所述第二信令是RRC(Radio Resource Control，无线资源控制)信令。

[0170] 在实施例1的子实施例18中，所述第二信令是SIB(System Information Block，系统信息块)。

[0171] 在实施例1的子实施例19中，所述第二信令是通过DCI传输的。

[0172] 实施例2

[0173] 实施例2示例了根据本申请的一个实施例的Z个时间窗和Q个子频带的关系的示意图，如附图2所示。附图2中，横轴代表时间，纵轴代表频率，每个矩形代表一个时间间隔，斜

线填充的矩形代表UE#1在时间窗#a中所监测的X1个时间间隔，十字线填充的矩形代表UE#2在时间窗#b中所监测的X2个时间间隔，斜线交叉线填充的矩形代表UE#3在时间窗#c中所监测的X3个时间间隔。

[0174] 在实施例2中，对于UE#1，在X1个时间间隔中分别监测第一信令，传输所述第一信令所使用的频域资源属于子频带#1，所述子频带#1在频域包括正整数个连续的子载波，所述子频带#1在频域的位置，所述子频带#1所包括的子载波的子载波间隔1中至少之一被用于确定所述X1个时间间隔。所述X1个时间间隔中的任意一个时间间隔在时域都属于时间窗#a，所述时间窗#a的时间长度是预定义的，所述时间窗#a被分成Y1个时间间隔，所述X1个时间间隔是所述Y1个时间间隔中的X1个，所述Y1是不小于X1的正整数，所述所述子频带#1中所包括的子载波的子载波间隔被用于确定所述Y1，所述UE#1的特征ID被用于在所述Y1个时间间隔中确定所述X1个时间间隔。所述时间窗#a属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述UE#1的特征ID被用于在所述Z个时间窗中确定所述时间窗#a。所述子频带#1属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述UE#1的特征ID被用于在所述Q个子频带中确定所述子频带#1，所述Q是正整数。

[0175] 在实施例2的子实施例1中，所述Z等于10。

[0176] 在实施例2的子实施例2中，所述Z个时间窗中的任意两个时间窗在时域正交。

[0177] 在实施例2的子实施例3中，所述Z个时间窗中的任意一个时间窗为一个子帧，所述Z等于10。

[0178] 在实施例2的子实施例4中，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述Z等于非连续接收周期(DRX(Discontinuous Reception)cycle)所包含的无线帧的数量。

[0179] 在实施例2的子实施例5中，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述时间窗#a由下式得到：

[0180] SFN mod Z=(Z div N)*(UE_ID mod N)

[0181] 其中，SFN为所述时间窗#a对应的无线帧的帧号，N=min(Z,nB)，nB等于{4Z,2Z,Z,Z/2,Z/4,Z/8,Z/16,Z/32,Z/64,Z/128,Z/256,Z/512,Z/1024}中之一。

[0182] 在实施例2的子实施例6中，所述Q个子频带中的任意一个子频带所包括的子载波的子载波间隔都相等。

[0183] 在实施例2的子实施例7中，所述Q个子频带中任意两个子频带中的子载波的子载波间隔不同。

[0184] 在实施例2的子实施例8中，所述Q个子频带中存在两个子频带中的子载波的子载波间隔相同。

[0185] 在实施例2的子实施例9中，所述Q个子频带中任意两个子频带的频域带宽相同。

[0186] 在实施例2的子实施例10中，所述Q个子频带中存在两个子频带的频域带宽不相等。

[0187] 在实施例2的子实施例11中，所述Q个子频带都属于同一个载波(Carrier)。

[0188] 在实施例2的子实施例12中，所述Q个子频带中存在两个子频带属于不同的载波(Carrier)。

[0189] 实施例3

[0190] 实施例3示例了根据本申请的一个实施例的第一时间窗与X个时间间隔的关系的示意图，如附图3所示。在附图3中，列出了依据不同的Y值和不同的UE的特征ID，X=1个时间间隔在第一时间窗中的索引。

[0191] 在实施例3中，UE在X个时间间隔中分别监测第一信令，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述UE的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0192] 在实施例3的子实施例1中，在所述X个时间间隔中的每一个时间间隔中针对所述第一信令最多执行P次检测，所述P是正整数。

[0193] 在实施例3的子实施例2中，所述X个时间间隔中的任意两个时间间隔的时间长度相等。

[0194] 在实施例3的子实施例3中，所述X个时间间隔中存在两个时间间隔的时间长度不等。

[0195] 在实施例3的子实施例4中，所述X个时间间隔中的任意一个时间间隔为一个时隙(Slot)。

[0196] 在实施例3的子实施例5中，所述X个时间间隔中的任意两个时间间隔的时间长度相等，所述X个时间间隔中的每个时间间隔的时间长度和所述第一频带中所包括的子载波的子载波间隔有关。

[0197] 在实施例3的子实施例6中，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于14的正整数。

[0198] 在实施例3的子实施例7中，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于7的正整数。

[0199] 在实施例3的子实施例8中，所述X个时间间隔中的任意两个时间间隔在时域正交，所述正交是指不存在一个时间单元同时属于所述X个时间间隔中的任意两个时间间隔。

[0200] 在实施例3的子实施例9中，所述X个时间间隔中存在两个时间间隔在时域是离散的。

[0201] 在实施例3的子实施例10中，所述第一时间窗的时间长度是固定不变的。

[0202] 在实施例3的子实施例11中，所述第一时间窗中包括正整数个时域连续的多载波符号。作为一个子实施例，所述多载波符号包括数据符号和CP(Cyclic Prefix，循环前缀)。

[0203] 在实施例3的子实施例12中，所述所述第一时间窗的时间长度为1毫秒。

[0204] 在实施例3的子实施例13中，所述所述第一时间窗的时间长度为10毫秒。

[0205] 在实施例3的子实施例14中，所述第一时间窗为一个子帧(Subframe)。

[0206] 在实施例3的子实施例15中，所述第一时间窗为一个无线帧(Radio Frame)。

[0207] 在实施例3的子实施例16中，所述Y个时间间隔中的任意两个时间间隔的时间长度相等。

[0208] 在实施例3的子实施例17中，所述Y与所述所述第一频带中所包括的子载波的子载波间隔成正比。

[0209] 在实施例3的子实施例18中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)。

[0210] 在实施例3的子实施例19中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对1024的余数。

[0211] 在实施例3的子实施例20中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对4096的余数。

[0212] 在实施例3的子实施例21中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对16384的余数。

[0213] 在实施例3的子实施例22中，所述特征ID是指C-RNTI(Cell Radio Network Temporary Identity，小区无线网络临时标识)。

[0214] 实施例4

[0215] 实施例4示例了根据本申请的一个实施例的第一信令，第一无线信号和第二无线信号之间的关系的示意图，如附图4所示。附图4中，横轴代表时间，纵轴代表频率，斜线填充的矩形代表传输第二无线信号所占用的时频资源，十字线填充的矩形代表传输第一信令所占用的时频资源，斜线交叉线填充的矩形代表传输第一无线信号所占用的时频资源，虚线箭头代表了特定的使用关系。

[0216] 在实施例4中，第一信令被用于确定第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波。第二无线信号被用于确定{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0217] 在实施例4的子实施例1中，所述第一信令是物理层信令。

[0218] 在实施例4的子实施例2中，所述第一信令是DCI(Downlink Control Information，下行控制信息)。

[0219] 在实施例4的子实施例3中，所述第一信令通过NR-PDCCH(New Radio Physical Downlink Control Channel，新空口物理下行控制信道)传输。

[0220] 在实施例4的子实施例4中，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输，所述PDCCH的CRC(Cyclic Redundancy Check，循环冗余校验)经过P-RNTI(Paging Radio Network Temporary Identity，寻呼无线网络临时标识)加扰。

[0221] 在实施例4的子实施例5中，所述第一无线信号通过DL-SCH(Downlink Shared Channel，下行共享信道)传输。

[0222] 在实施例4的子实施例6中，所述第一无线信号通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输。

[0223] 在实施例4的子实施例7中，第一比特块依次经过调制映射器(Modulation Mapper)，层映射器(Layer Mapper)，预编码(Precoding)，资源粒子映射器(Resource Element Mapper)，OFDM信号发生(Generation)之后得到所述第一无线信号。所述第一比特

块包括一个码块经过信道编码之后的输出。作为一个子实施例，所述码块是TB(Transport Block，传输块)。作为一个子实施例，所述码块是TB(Transport Block，传输块)中的一部分。

[0224] 在实施例4的子实施例8中，所述第一无线信号包括主同步信号(PSS，Primary Synchronization Signal)。

[0225] 在实施例4的子实施例9中，所述第一无线信号包括辅同步信号(SSS，Secondary Synchronization Signal)。

[0226] 在实施例4的子实施例10中，所述第二无线信号通过BCH(Broadcast Channel，广播信道)传输。

[0227] 在实施例4的子实施例11中，所述第二无线信号通过PBCH(Physical Broadcast Channel，物理广播信道)传输。

[0228] 在实施例4的子实施例12中，所述第二无线信号携带MIB(Master Information Block，主信息块)信息。

[0229] 在实施例4的子实施例13中，所述第二无线信号携带SIB(System Information Block，系统信息块)信息。

[0230] 在实施例4的子实施例14中，所述第二无线信号所携带的信息是被周期性传输的。

[0231] 在实施例4的子实施例15中，所述第二无线所携带的信息是按需(On-Demand)传输的。

[0232] 在实施例4的子实施例16中，所述第二无线信号携带第一信息，所述第一信息被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0233] 在实施例4的子实施例17中，所述第二无线信号携带第一信息，所述第一信息指示{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0234] 实施例5

[0235] 实施例5示例了一个用户设备中的处理装置的结构框图，如附图5所示。附图5中，用户设备处理装置100主要由第一接收模块101和第二接收模块102组成。

[0236] 在实施例5中，第一接收模块101被用于在X个时间间隔中分别监测第一信令，第二接收模块102被用于接收第一无线信号。其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0237] 在实施例5的子实施例1中，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0238] 在实施例5的子实施例2中，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0239] 在实施例5的子实施例3中，第一接收模块101还被用于接收第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0240] 在实施例5的子实施例4中，第一接收模块101还被用于接收第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0241] 实施例6

[0242] 实施例6示例了一个基站设备中的处理装置的结构框图，如附图6所示。在附图6中，基站处理装置200主要由第一发送模块201和第二发送模块202组成。

[0243] 在实施例6中，第一发送模块201被用于在X个时间间隔中的正整数个时间间隔中分别发送第一信令，第二发送模块202被用于发送第一无线信号。其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0244] 在实施例6的子实施例1中，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0245] 在实施例6的子实施例2中，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0246] 在实施例6的子实施例3中，第一发送模块201还被用于发送第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0247] 在实施例6的子实施例4中，第一发送模块201还被用于发送第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0248] 本领域普通技术人员可以理解上述方法中的全部或部分步骤可以通过程序来指令相关硬件完成，所述程序可以存储于计算机可读存储介质中，如只读存储器，硬盘或者光

盘等。可选的，上述实施例的全部或部分步骤也可以使用一个或者多个集成电路来实现。相应的，上述实施例中的各模块单元，可以采用硬件形式实现，也可以由软件功能模块的形式实现，本申请不限于任何特定形式的软件和硬件的结合。本申请中的UE或者终端包括但不限于手机，平板电脑，笔记本，上网卡，低功耗设备，eMTC设备，NB-IoT设备，无人机，遥控飞机，车载通信设备等无线通信设备。本申请中的基站或者网络侧设备包括但不限于宏蜂窝基站，微蜂窝基站，家庭基站，中继基站，eNB，gNB，传输接收节点TRP等无线通信设备。

[0249] 以上所述，仅为本申请的较佳实施例而已，并非用于限定本申请的保护范围。凡在本申请的精神和原则之内，所做的任何修改，等同替换，改进等，均应包含在本申请的保护范围之内。

Method for paging in user equipment, method for paging in base station, user equipment for paging and base station equipment for paging

Abstract

The invention discloses a method for paging in user equipment, a method for paging in a base station, the user equipment for paging and base station equipment for paging. The user equipment first monitors first signaling in X time intervals respectively, and then receives a first radio signal. The X is a positive integer. The first signaling is used for determining scheduling information for the first radio signal. The scheduling information comprises at least one of {an occupied time-frequency resource, an employed MCS (Modulation Coding Scheme), and subcarrier spacing of subcarriers in an occupied frequency domain resource}. The first radio signal carries a paging message. The frequency domain resource for transmitting the first signaling belongs to a first subband. The first subband comprises a positive integer number of consecutive subcarriers in a frequency domain. At least one of {a location of the first subband in the frequency domain, and subcarrier spacing of the subcarriers included in the first subband} is used for determining the X time intervals. According to the methods, the user equipment and the base station equipment, paging capacity is kept, and moreover, power consumption of the user equipment is reduced.

(54) 发明名称

一种被用于寻呼的用户设备、基站中的方法和装置

(57) 摘要

本发明公开了一种被用于寻呼的用户设备、基站中的方法和装置。用户设备首先在X个时间间隔中分别监测第一信令，接着接收第一无线信号。其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被用于确定所述X个时间间隔。本发明可以在保持寻呼容量的同时降低用户设备功率消耗。

CN 108923896 B

1.一种用于寻呼的用户设备中的方法，其特征在于，包括如下步骤：

-步骤A.在X个时间间隔中分别监测第一信令；

-步骤B.接收第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

2.根据权利要求1所述的方法，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

3.根据权利要求2所述的方法，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

4.根据权利要求1至3中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A0.接收第二无线信号；

其中，所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

5.根据权利要求1至3中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A1.接收第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

6.根据权利要求4所述的方法，其特征在于，所述步骤A还包括如下步骤：

步骤A1.接收第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

7.一种用于寻呼的基站中的方法，其特征在于，包括如下步骤：

-步骤A.在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

-步骤B.发送第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正

整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

8.根据权利要求7所述的方法，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

9.根据权利要求8所述的方法，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

10.根据权利要求7至9中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A0.发送第二无线信号；

其中，所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

11.根据权利要求7至9中任一权利要求所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A1.发送第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

12.根据权利要求10所述的方法，其特征在于，所述步骤A还包括如下步骤：

-步骤A1.发送第二信令；

其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

13.一种用于寻呼的用户设备，其特征在于，包括如下模块：

-第一接收模块：用于在X个时间间隔中分别监测第一信令；

-第二接收模块：用于接收第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

14.根据权利要求13所述的用户设备，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令

的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

15.根据权利要求14所述的用户设备，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

16.根据权利要求13至15中任一权利要求所述的用户设备，其特征在于，所述第一接收模块还被用于接收第二无线信号；所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

17.根据权利要求13至15中任一权利要求所述的用户设备，其特征在于，所述第一接收模块还被用于接收第二信令所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

18.根据权利要求16所述的用户设备，其特征在于，所述第一接收模块还被用于接收第二信令所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

19.一种用于寻呼的基站设备，其特征在于，包括如下模块：

-第一发送模块：用于在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

第二发送模块：用于发送第一无线信号；

其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源、所采用的MCS中至少之一，所述第一无线信号携带寻呼消息；传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置和所述第一子频带中所包括的子载波的子载波间隔被用于确定所述X个时间间隔。

20.根据权利要求19所述的基站设备，其特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

21.根据权利要求20所述的基站设备，其特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数；所述Z是预定义的；或者所述Z是可配置的；所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

22.根据权利要求19至21中任一权利要求所述的基站设备，其特征在于，所述第一发送模块还被用于发送第二无线信号；所述第二无线信号被用于确定所述第一子频带在频域的位置、所述第一子频带中所包括的子载波的子载波间隔中至少之一。

23.根据权利要求19至21中任一权利要求所述的基站设备，其特征在于，所述第一发送模块还被用于发送第二信令；所述第二信令被用于确定Q个子频带，所述第一子频带属于所

述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

24.根据权利要求22所述的基站设备，其特征在于，所述第一发送模块还被用于发送第二信令；所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

一种被用于寻呼的用户设备、基站中的方法和装置

技术领域

[0001] 本申请涉及无线通信系统中的传输方案，特别是涉及支持多种数理结构(Numerology)的通信系统中的寻呼传输的方法和装置。

背景技术

[0002] 未来无线通信系统的应用场景越来越多元化，不同的应用场景对系统提出了不同的性能要求。为了满足多种应用场景的不同的性能需求，在3GPP(3rd Generation Partner Project，第三代合作伙伴项目)RAN(Radio Access Network，无线接入网)#72次全会上决定对新空口技术(NR，New Radio)进行研究。在3GPP RAN#75次全会上通过了5G新空口技术(NR)的工作项目(WI，Working Item)的立项，开始对5G新空口技术进行标准化。

[0003] 为了能够灵活适应多种不同的应用场景，未来的无线通信系统，特别是5G NR将可以支持多种数理结构(Numerology)，多种数理结构是指多种子载波间隔，多种符号时间长度，多种CP(Cyclic Prefix，循环前缀)长度等。为了能够简化系统的设计与用户设备实现的复杂度，针对不同的数理结构，整个系统物理层设计最好能够采用一种统一结构。

发明内容

[0004] 在现有LTE系统中，寻呼的传输时机统一通过PF(Paging Frame，寻呼帧)和PO(Paging Occasion，寻呼机会)来定义，其中PF为有可能传输寻呼消息的无线帧，而PO用来确定在PF的帧中有可能传输寻呼消息的子帧。LTE中的无线帧的时间长度为固定的10毫秒，子帧的时间长度为固定的1毫秒。由于一个LTE网络一般采用单一的数理结构(Numerology)或者数理结构在一个网络中基本长时间不变，采用固定时长的PF和PO来定义寻呼的可能时间可以在保证寻呼容量和不增加用户设备(UE，User Equipment)功率消耗的前提下，简化系统设计。在5G NR下，由于支持不同的数理结构，在一个给定的时长内，比如1毫秒，可能包含了多个基本的调度单元(比如时隙，Slot)，如果沿用现有的寻呼时机的设计，在这个1毫秒内用户设备针对不同的数理结构要对寻呼消息进行不同次数的检测，因而导致在某些数理结构下的功率消耗的大大增加。同时也会导致寻呼容量因为不同的数理结构的采用而相差巨大。

[0005] 为了解决上述在5G NR中当采用多种数理结构(Numerology)时的寻呼的设计问题，本申请提供了解决方案。该方案依据寻呼所采用的数理结构来确定寻呼的传输时机，从而保证在不同的数理结构下用户设备监测寻呼消息的复杂度和功耗相差不大，同时寻呼的容量也保持基本不变。需要说明的是，在不冲突的情况下，本申请的UE(User Equipment，用户设备)中的实施例和实施例中的特征可以应用到基站中，反之亦然。进一步的，在不冲突的情况下，本申请的实施例和实施例中的特征可以任意相互组合。

[0006] 本申请公开了一种用于寻呼的用户设备中的方法，其中，包括如下步骤：

[0007] -步骤A.在X个时间间隔中分别监测第一信令；

[0008] -步骤B.接收第一无线信号。

[0009] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0010] 作为一个实施例，采用所述方法，所述用于设备可以依据传输寻呼所采用的子载波间隔来确定监测传输寻呼的时间间隔，节省功耗。

[0011] 作为一个实施例，所述方法设计了基于不同的子载波间隔的一致的寻呼时机的计算方式，同时当采用不同的子载波间隔传输寻呼消息时，保持寻呼容量不变。

[0012] 作为一个实施例，所述寻呼消息包括被寻呼的用户设备的特征ID。

[0013] 作为一个实施例，在所述X个时间间隔中的每一个时间间隔中针对所述第一信令最多执行P次检测，所述P是正整数。

[0014] 作为一个实施例，所述X个时间间隔中的任意两个时间间隔的时间长度相等。

[0015] 作为一个实施例，所述X个时间间隔中存在两个时间间隔的时间长度不等。

[0016] 作为一个实施例，所述X个时间间隔中的任意一个时间间隔为一个时隙(Slot)。

[0017] 作为一个实施例，所述X个时间间隔中的任意两个时间间隔的时间长度相等，所述X个时间间隔中的每个时间间隔的时间长度和所述第一频带中所包括的子载波的子载波间隔有关。

[0018] 作为一个实施例，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于14的正整数。

[0019] 作为一个实施例，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于7的正整数。

[0020] 作为一个实施例，所述X个时间间隔中的任意两个时间间隔在时域正交，所述正交是指不存在一个时间单元同时属于所述X个时间间隔中的任意两个时间间隔。

[0021] 作为一个实施例，所述X个时间间隔中存在两个时间间隔在时域是离散的。

[0022] 作为一个实施例，所述第一信令是物理层信令。

[0023] 作为一个实施例，所述第一信令是DCI(Downlink Control Information，下行控制信息)。

[0024] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输。

[0025] 作为一个实施例，所述第一信令通过NR-PDCCH(New Radio Physical Downl ink Control Channel，新空口物理下行控制信道)传输。

[0026] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输，所述PDCCH在CSS(Common Search Space，公共搜索空间)中传输。

[0027] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control

Channel，物理下行控制信道)传输，所述PDCCH在USS(UE-Specific Search Space，UE特定搜索空间)中传输。

[0028] 作为一个实施例，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输，所述PDCCH的CRC(Cyclic Redundancy Check，循环冗余校验)经过P-RNTI(Paging Radio Network Temporary Identity，寻呼无线网络临时标识)加扰。

[0029] 作为一个实施例，所述MCS(Modulation Coding Scheme，调制编码方式)包括的调制方式为{QPSK，16QAM，64QAM，256QAM，1024QAM}中之一。

[0030] 作为一个实施例，所述子载波间隔等于15kHz乘以2的K次幂，所述K为整数。

[0031] 作为一个实施例，所述第一子频带(Subband)包括12的正整数倍个子载波。

[0032] 作为一个实施例，所述第一子频带中包括的所有子载波的子载波间隔都相等。

[0033] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的位置。

[0034] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)在频域的位置。

[0035] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的子频带索引。

[0036] 作为一个实施例，所述所述第一子频带在频域的位置是指所述第一子频带在所处的频带(Band)所对应的频率资源中的位置。

[0037] 作为一个实施例，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被所述用户设备用于确定所述X个时间间隔。

[0038] 作为一个实施例，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被所述用户设备基于给定映射规则确定所述X个时间间隔。

[0039] 作为一个实施例，所述第一无线信号通过DL-SCH(Downlink Shared Channel，下行共享信道)传输。

[0040] 作为一个实施例，所述第一无线信号通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输。

[0041] 作为一个实施例，第一比特块依次经过调制映射器(Modulation Mapper)，层映射器(Layer Mapper)，预编码(Precoding)，资源粒子映射器(Resource Element Mapper)，OFDM信号发生(Generation)之后得到所述第一无线信号。所述第一比特块包括一个码块经过信道编码之后的输出。作为一个子实施例，所述码块是TB(Transport Block，传输块)。作为一个子实施例，所述码块是TB(Transport Block，传输块)中的一部分。

[0042] 具体的，根据本申请的一个方面，上述方法的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0043] 作为一个实施例，所述第一时间窗的时间长度是固定不变的。

[0044] 作为一个实施例，所述第一时间窗中包括正整数个时域连续的多载波符号。作为

一个子实施例，所述多载波符号包括数据符号和CP(Cyclic Prefix，循环前缀)。

[0045] 作为一个实施例，所述所述第一时间窗的时间长度为1毫秒。

[0046] 作为一个实施例，所述所述第一时间窗的时间长度为10毫秒。

[0047] 作为一个实施例，所述第一时间窗为一个子帧(Subframe)。

[0048] 作为一个实施例，所述第一时间窗为一个无线帧(Radio Frame)。

[0049] 作为一个实施例，所述Y个时间间隔中的任意两个时间间隔的时间长度相等。

[0050] 作为一个实施例，所述Y个时间间隔中存在两个时间间隔的时间长度不等。

[0051] 作为一个实施例，所述Y大于所述X。

[0052] 作为一个实施例，所述Y与所述所述第一频带中所包括的子载波的子载波间隔成正比。

[0053] 作为一个实施例，所述所述第一频带中所包括的子载波的子载波间隔被所述用户设备用于确定所述Y。

[0054] 作为一个实施例，所述所述第一频带中所包括的子载波的子载波间隔被所述用户设备基于给定的映射关系确定所述Y。

[0055] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备用于在所述Y个时间间隔中确定所述X个时间间隔。

[0056] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备基于给定的映射关系在所述Y个时间间隔中确定所述X个时间间隔。

[0057] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)。

[0058] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对1024的余数。

[0059] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对4096的余数。

[0060] 作为一个实施例，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对16384的余数。

[0061] 作为一个实施例，所述特征ID是指C-RNTI(Cell Radio Network Temporary Identity，小区无线网络临时标识)。

[0062] 作为一个实施例，所述第一信令的发送小区的物理小区ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0063] 具体的，根据本申请的一个方面，上述方法的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0064] 作为一个实施例，所述Z等于10。

[0065] 作为一个实施例，所述Z个时间窗中的任意两个时间窗在时域正交。

[0066] 作为一个实施例，所述Z个时间窗中的任意一个时间窗为一个子帧，所述Z等于10.

[0067] 作为一个实施例，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述Z等于非连续接收周期(DRX(Discontinuous Reception)cycle)所包含的无线帧的数量。

[0068] 作为一个实施例，所述步骤A还包括如下步骤：

[0069] 步骤A2.接收第三信令。

[0070] 其中，所述第三信令被用于配置所述Z。

[0071] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备用于在所述Z个时间窗中确定所述第一时间窗。

[0072] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备基于给定的映射关系在所述Z个时间窗中确定所述第一时间窗。

[0073] 作为一个实施例，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述第一时间窗由下式得到：

[0074] SFN mod Z=(Z div N)*(UE_ID mod N)

[0075] 其中，SFN为所述第一时间窗对应的无线帧的帧号，N=min(Z,nB)，nB等于{4Z,2Z,Z,Z/2,Z/4,Z/8,Z/16,Z/32,Z/64,Z/128,Z/256,Z/512,Z/1024}中之一。

[0076] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0077] 步骤A0.接收第二无线信号。

[0078] 其中，所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0079] 作为一个实施例，所述第二无线信号包括主同步信号(PSS，Primary Synchronization Signal)。

[0080] 作为一个实施例，所述第二无线信号包括辅同步信号(SSS，Secondary Synchronization Signal)。

[0081] 作为一个实施例，所述第二无线信号通过BCH(Broadcast Channel，广播信道)传输。

[0082] 作为一个实施例，所述第二无线信号通过PBCH(Physical Broadcast Channel，物理广播信道)传输。

[0083] 作为一个实施例，所述第二无线信号通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输。

[0084] 作为一个实施例，所述第二无线信号携带MIB(Master Information Block，主信息块)信息。

[0085] 作为一个实施例，所述第二无线信号携带SIB(System Information Block，系统信息块)信息。

[0086] 作为一个实施例，所述第二无线信号所携带的信息是被周期性传输的。

[0087] 作为一个实施例，所述第二无线所携带的信息是按需(On-Demand)传输的。

[0088] 作为一个实施例，所述第二无线信号携带第一信息，所述第一信息被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0089] 作为一个实施例，所述第二无线信号携带第一信息，所述第一信息指示{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0090] 作为一个实施例，所述第二无线信号被所述用户设备用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0091] 作为一个实施例，所述第二无线信号指示{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0092] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0093] -步骤A1.接收第二信令。

[0094] 其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0095] 作为一个实施例，所述Q个子频带中的任意一个子频带所包括的子载波的子载波间隔都相等。

[0096] 作为一个实施例，所述Q个子频带中任意两个子频带中的子载波的子载波间隔不同。

[0097] 作为一个实施例，所述Q个子频带中存在两个子频带中的子载波的子载波间隔相同。

[0098] 作为一个实施例，所述Q个子频带中任意两个子频带的频域带宽相同。

[0099] 作为一个实施例，所述Q个子频带中存在两个子频带的频域带宽不相等。

[0100] 作为一个实施例，所述Q个子频带都属于同一个载波(Carrier)。

[0101] 作为一个实施例，所述Q个子频带中存在两个子频带属于不同的载波(Carrier)。

[0102] 作为一个实施例，所述第二信令是高层信令。

[0103] 作为一个实施例，所述第二信令是物理层信令。

[0104] 作为一个实施例，所述第二信令是通过BCH(Broadcast Channel，广播信道)传输的。

[0105] 作为一个实施例，所述第二信令是通过PBCH(Physical Broadcast Channel，物理广播信道)传输的。

[0106] 作为一个实施例，所述第二信令是通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输的。

[0107] 作为一个实施例，所述第二信令是RRC(Radio Resource Control，无线资源控制)信令。

[0108] 作为一个实施例，所述第二信令是SIB(System Information Block，系统信息块)。

[0109] 作为一个实施例，所述第二信令是通过DCI传输的。

[0110] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备用于在所述Q个子频带中确定所述第一子频带。

[0111] 作为一个实施例，所述所述第一信令的监测者的特征ID被所述用户设备基于给定的映射关系在所述Q个子频带中确定所述第一子频带。

[0112] 本申请公开了一种用于寻呼的基站中的方法，其中，包括如下步骤：

[0113] -步骤A.在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

[0114] -步骤B.发送第一无线信号。

[0115] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被用于确定所述X个时间间隔。

[0116] 具体的，根据本申请的一个方面，上述方法的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0117] 具体的，根据本申请的一个方面，上述方法的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0118] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0119] -步骤A0.发送第二无线信号。

[0120] 其中，所述第二无线信号被用于确定所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔中至少之一。

[0121] 具体的，根据本申请的一个方面，上述方法的特征在于，所述步骤A还包括如下步骤：

[0122] -步骤A1.发送第二信令。

[0123] 其中，所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0124] 本申请公开了一种用于寻呼的用户设备，其中，包括如下模块：

[0125] -第一接收模块：用于在X个时间间隔中分别监测第一信令；

[0126] -第二接收模块：用于接收第一无线信号。

[0127] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔中至少之一被用于确定所述X个时间间隔。

[0128] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y

是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0129] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0130] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述第一接收模块还被用于接收第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0131] 具体的，根据本申请的一个方面，上述用户设备的特征在于，所述第一接收模块还被用于接收第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0132] 本申请公开了一种用于寻呼的基站设备，其中，包括如下模块：

[0133] -第一发送模块：用于在X个时间间隔中的正整数个时间间隔中分别发送第一信令；

[0134] -第二发送模块：用于发送第一无线信号。

[0135] 其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0136] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0137] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0138] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述第一发送模块还被用于发送第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0139] 具体的，根据本申请的一个方面，上述基站设备的特征在于，所述第一发送模块还被用于发送第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述

第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

附图说明

[0140] 通过阅读参照以下附图所作的对非限制性实施例所作的详细描述，本申请的其它特征、目的和优点将会变得更加明显：

[0141] 图1示出了根据本申请的一个实施例的无线信号传输流程图；

[0142] 图2示出了根据本申请的一个实施例的Z个时间窗和Q个子频带的关系的示意图；

[0143] 图3示出了根据本申请的一个实施例的第一时间窗与X个时间间隔的关系的示意图；

[0144] 图4示出了根据本申请的一个实施例的第一信令，第一无线信号和第二无线信号之间的关系的示意图；

[0145] 图5示出了根据本申请的一个实施例的用户设备(UE)中的处理装置的结构框图；

[0146] 图6示出了根据本申请的一个实施例的基站中的处理装置的结构框图；

具体实施方式

[0147] 下文将结合附图对本申请的技术方案作进一步详细说明，需要说明的是，在不冲突的情况下，本申请的实施例和实施例中的特征可以任意相互组合。

[0148] 实施例1

[0149] 实施例1示例了根据本申请的一个实施例的无线信号传输流程图，如附图1所示。附图1中，基站N1是UE U2的服务小区的维持基站，虚线框F1中标识的步骤是可选的。

[0150] 对于基站N1，在步骤S11中发送第二无线信号，在步骤S12中发送第二信令，在步骤S13中在X个时间间隔中的正整数个时间间隔中分别发送第一信令，在步骤S14中发送第一无线信号。

[0151] 对于UE U2，在步骤S21中接收第二无线信号，在步骤S22中接收第二信令，在步骤S23中在X个时间间隔中分别监测第一信令，在步骤S24中接收第一无线信号。

[0152] 在实施例1中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息，传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0153] 在实施例1的子实施例1中，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第

子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0154] 在实施例1的子实施例2中，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0155] 在实施例1的子实施例3中，所述寻呼消息包括被寻呼的用户设备的特征ID。

[0156] 在实施例1的子实施例4中，所述MCS(Modulation Coding Scheme，调制编码方式)包括的调制方式为{QPSK，16QAM，64QAM，256QAM，1024QAM}中之一。

[0157] 在实施例1的子实施例5中，所述子载波间隔等于15kHz乘以2的K次幂，所述K为整数。

[0158] 在实施例1的子实施例6中，所述第一子频带(Subband)包括12的正整数倍个子载波。

[0159] 在实施例1的子实施例7中，所述第一子频带中包括的所有子载波的子载波间隔都相等。

[0160] 在实施例1的子实施例8中，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的位置。

[0161] 在实施例1的子实施例9中，所述所述第一子频带在频域的位置是指所述第一子频带所处的载波(Carrier)在频域的位置。

[0162] 在实施例1的子实施例10中，所述所述第一子频带在频域的位置是指所述第一子频带在所处的载波(Carrier)中的子频带索引。

[0163] 在实施例1的子实施例11中，所述所述第一子频带在频域的位置是指所述第一子频带在所处的频带(Band)所对应的频率资源中的位置。

[0164] 在实施例1的子实施例12中，所述第二信令是高层信令。

[0165] 在实施例1的子实施例13中，所述第二信令是物理层信令。

[0166] 在实施例1的子实施例14中，所述第二信令是通过BCH(Broadcast Channel，广播信道)传输的。

[0167] 在实施例1的子实施例15中，所述第二信令是通过PBCH(Physical Broadcast Channel，物理广播信道)传输的。

[0168] 在实施例1的子实施例16中，所述第二信令是通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输的。

[0169] 在实施例1的子实施例17中，所述第二信令是RRC(Radio Resource Control，无线资源控制)信令。

[0170] 在实施例1的子实施例18中，所述第二信令是SIB(System Information Block，系统信息块)。

[0171] 在实施例1的子实施例19中，所述第二信令是通过DCI传输的。

[0172] 实施例2

[0173] 实施例2示例了根据本申请的一个实施例的Z个时间窗和Q个子频带的关系的示意图，如附图2所示。附图2中，横轴代表时间，纵轴代表频率，每个矩形代表一个时间间隔，斜

线填充的矩形代表UE#1在时间窗#a中所监测的X1个时间间隔，十字线填充的矩形代表UE#2在时间窗#b中所监测的X2个时间间隔，斜线交叉线填充的矩形代表UE#3在时间窗#c中所监测的X3个时间间隔。

[0174] 在实施例2中，对于UE#1，在X1个时间间隔中分别监测第一信令，传输所述第一信令所使用的频域资源属于子频带#1，所述子频带#1在频域包括正整数个连续的子载波，所述子频带#1在频域的位置，所述子频带#1所包括的子载波的子载波间隔1中至少之一被用于确定所述X1个时间间隔。所述X1个时间间隔中的任意一个时间间隔在时域都属于时间窗#a，所述时间窗#a的时间长度是预定义的，所述时间窗#a被分成Y1个时间间隔，所述X1个时间间隔是所述Y1个时间间隔中的X1个，所述Y1是不小于X1的正整数，所述所述子频带#1中所包括的子载波的子载波间隔被用于确定所述Y1，所述UE#1的特征ID被用于在所述Y1个时间间隔中确定所述X1个时间间隔。所述时间窗#a属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述UE#1的特征ID被用于在所述Z个时间窗中确定所述时间窗#a。所述子频带#1属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述UE#1的特征ID被用于在所述Q个子频带中确定所述子频带#1，所述Q是正整数。

[0175] 在实施例2的子实施例1中，所述Z等于10。

[0176] 在实施例2的子实施例2中，所述Z个时间窗中的任意两个时间窗在时域正交。

[0177] 在实施例2的子实施例3中，所述Z个时间窗中的任意一个时间窗为一个子帧，所述Z等于10。

[0178] 在实施例2的子实施例4中，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述Z等于非连续接收周期(DRX(Discontinuous Reception)cycle)所包含的无线帧的数量。

[0179] 在实施例2的子实施例5中，所述Z个时间窗中的任意一个时间窗为一个无线帧，所述时间窗#a由下式得到：

[0180] SFN mod Z=(Z div N)*(UE_ID mod N)

[0181] 其中，SFN为所述时间窗#a对应的无线帧的帧号，N=min(Z,nB)，nB等于{4Z,2Z,Z,Z/2,Z/4,Z/8,Z/16,Z/32,Z/64,Z/128,Z/256,Z/512,Z/1024}中之一。

[0182] 在实施例2的子实施例6中，所述Q个子频带中的任意一个子频带所包括的子载波的子载波间隔都相等。

[0183] 在实施例2的子实施例7中，所述Q个子频带中任意两个子频带中的子载波的子载波间隔不同。

[0184] 在实施例2的子实施例8中，所述Q个子频带中存在两个子频带中的子载波的子载波间隔相同。

[0185] 在实施例2的子实施例9中，所述Q个子频带中任意两个子频带的频域带宽相同。

[0186] 在实施例2的子实施例10中，所述Q个子频带中存在两个子频带的频域带宽不相等。

[0187] 在实施例2的子实施例11中，所述Q个子频带都属于同一个载波(Carrier)。

[0188] 在实施例2的子实施例12中，所述Q个子频带中存在两个子频带属于不同的载波(Carrier)。

[0189] 实施例3

[0190] 实施例3示例了根据本申请的一个实施例的第一时间窗与X个时间间隔的关系的示意图，如附图3所示。在附图3中，列出了依据不同的Y值和不同的UE的特征ID，X=1个时间间隔在第一时间窗中的索引。

[0191] 在实施例3中，UE在X个时间间隔中分别监测第一信令，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述UE的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0192] 在实施例3的子实施例1中，在所述X个时间间隔中的每一个时间间隔中针对所述第一信令最多执行P次检测，所述P是正整数。

[0193] 在实施例3的子实施例2中，所述X个时间间隔中的任意两个时间间隔的时间长度相等。

[0194] 在实施例3的子实施例3中，所述X个时间间隔中存在两个时间间隔的时间长度不等。

[0195] 在实施例3的子实施例4中，所述X个时间间隔中的任意一个时间间隔为一个时隙(Slot)。

[0196] 在实施例3的子实施例5中，所述X个时间间隔中的任意两个时间间隔的时间长度相等，所述X个时间间隔中的每个时间间隔的时间长度和所述第一频带中所包括的子载波的子载波间隔有关。

[0197] 在实施例3的子实施例6中，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于14的正整数。

[0198] 在实施例3的子实施例7中，所述X个时间间隔中的任意一个时间间隔为M个OFDM(Orthogonal Frequency Division Multiplexing，正交频分复用)符号，所述M为小于7的正整数。

[0199] 在实施例3的子实施例8中，所述X个时间间隔中的任意两个时间间隔在时域正交，所述正交是指不存在一个时间单元同时属于所述X个时间间隔中的任意两个时间间隔。

[0200] 在实施例3的子实施例9中，所述X个时间间隔中存在两个时间间隔在时域是离散的。

[0201] 在实施例3的子实施例10中，所述第一时间窗的时间长度是固定不变的。

[0202] 在实施例3的子实施例11中，所述第一时间窗中包括正整数个时域连续的多载波符号。作为一个子实施例，所述多载波符号包括数据符号和CP(Cyclic Prefix，循环前缀)。

[0203] 在实施例3的子实施例12中，所述所述第一时间窗的时间长度为1毫秒。

[0204] 在实施例3的子实施例13中，所述所述第一时间窗的时间长度为10毫秒。

[0205] 在实施例3的子实施例14中，所述第一时间窗为一个子帧(Subframe)。

[0206] 在实施例3的子实施例15中，所述第一时间窗为一个无线帧(Radio Frame)。

[0207] 在实施例3的子实施例16中，所述Y个时间间隔中的任意两个时间间隔的时间长度相等。

[0208] 在实施例3的子实施例17中，所述Y与所述所述第一频带中所包括的子载波的子载波间隔成正比。

[0209] 在实施例3的子实施例18中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)。

[0210] 在实施例3的子实施例19中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对1024的余数。

[0211] 在实施例3的子实施例20中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对4096的余数。

[0212] 在实施例3的子实施例21中，所述特征ID指IMSI(International Mobile Subscriber Identification Number国际移动用户识别码)对16384的余数。

[0213] 在实施例3的子实施例22中，所述特征ID是指C-RNTI(Cell Radio Network Temporary Identity，小区无线网络临时标识)。

[0214] 实施例4

[0215] 实施例4示例了根据本申请的一个实施例的第一信令，第一无线信号和第二无线信号之间的关系的示意图，如附图4所示。附图4中，横轴代表时间，纵轴代表频率，斜线填充的矩形代表传输第二无线信号所占用的时频资源，十字线填充的矩形代表传输第一信令所占用的时频资源，斜线交叉线填充的矩形代表传输第一无线信号所占用的时频资源，虚线箭头代表了特定的使用关系。

[0216] 在实施例4中，第一信令被用于确定第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波。第二无线信号被用于确定{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0217] 在实施例4的子实施例1中，所述第一信令是物理层信令。

[0218] 在实施例4的子实施例2中，所述第一信令是DCI(Downlink Control Information，下行控制信息)。

[0219] 在实施例4的子实施例3中，所述第一信令通过NR-PDCCH(New Radio Physical Downlink Control Channel，新空口物理下行控制信道)传输。

[0220] 在实施例4的子实施例4中，所述第一信令通过PDCCH(Physical Downlink Control Channel，物理下行控制信道)传输，所述PDCCH的CRC(Cyclic Redundancy Check，循环冗余校验)经过P-RNTI(Paging Radio Network Temporary Identity，寻呼无线网络临时标识)加扰。

[0221] 在实施例4的子实施例5中，所述第一无线信号通过DL-SCH(Downlink Shared Channel，下行共享信道)传输。

[0222] 在实施例4的子实施例6中，所述第一无线信号通过PDSCH(Physical Downlink Shared Channel，物理下行共享信道)传输。

[0223] 在实施例4的子实施例7中，第一比特块依次经过调制映射器(Modulation Mapper)，层映射器(Layer Mapper)，预编码(Precoding)，资源粒子映射器(Resource Element Mapper)，OFDM信号发生(Generation)之后得到所述第一无线信号。所述第一比特

块包括一个码块经过信道编码之后的输出。作为一个子实施例，所述码块是TB(Transport Block，传输块)。作为一个子实施例，所述码块是TB(Transport Block，传输块)中的一部分。

[0224] 在实施例4的子实施例8中，所述第一无线信号包括主同步信号(PSS，Primary Synchronization Signal)。

[0225] 在实施例4的子实施例9中，所述第一无线信号包括辅同步信号(SSS，Secondary Synchronization Signal)。

[0226] 在实施例4的子实施例10中，所述第二无线信号通过BCH(Broadcast Channel，广播信道)传输。

[0227] 在实施例4的子实施例11中，所述第二无线信号通过PBCH(Physical Broadcast Channel，物理广播信道)传输。

[0228] 在实施例4的子实施例12中，所述第二无线信号携带MIB(Master Information Block，主信息块)信息。

[0229] 在实施例4的子实施例13中，所述第二无线信号携带SIB(System Information Block，系统信息块)信息。

[0230] 在实施例4的子实施例14中，所述第二无线信号所携带的信息是被周期性传输的。

[0231] 在实施例4的子实施例15中，所述第二无线所携带的信息是按需(On-Demand)传输的。

[0232] 在实施例4的子实施例16中，所述第二无线信号携带第一信息，所述第一信息被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0233] 在实施例4的子实施例17中，所述第二无线信号携带第一信息，所述第一信息指示{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0234] 实施例5

[0235] 实施例5示例了一个用户设备中的处理装置的结构框图，如附图5所示。附图5中，用户设备处理装置100主要由第一接收模块101和第二接收模块102组成。

[0236] 在实施例5中，第一接收模块101被用于在X个时间间隔中分别监测第一信令，第二接收模块102被用于接收第一无线信号。其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0237] 在实施例5的子实施例1中，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0238] 在实施例5的子实施例2中，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0239] 在实施例5的子实施例3中，第一接收模块101还被用于接收第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0240] 在实施例5的子实施例4中，第一接收模块101还被用于接收第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0241] 实施例6

[0242] 实施例6示例了一个基站设备中的处理装置的结构框图，如附图6所示。在附图6中，基站处理装置200主要由第一发送模块201和第二发送模块202组成。

[0243] 在实施例6中，第一发送模块201被用于在X个时间间隔中的正整数个时间间隔中分别发送第一信令，第二发送模块202被用于发送第一无线信号。其中，所述X是正整数，所述第一信令被用于确定所述第一无线信号的调度信息，所述调度信息包括{所占用的时频资源，所采用的MCS，所占用的频域资源中的子载波的子载波间隔}中至少之一，所述第一无线信号携带寻呼消息。传输所述第一信令所使用的频域资源属于第一子频带，所述第一子频带在频域包括正整数个连续的子载波，{所述第一子频带在频域的位置，所述第一子频带中所包括的子载波的子载波间隔}中至少之一被用于确定所述X个时间间隔。

[0244] 在实施例6的子实施例1中，所述X个时间间隔中的任意一个时间间隔在时域都属于第一时间窗，所述第一时间窗的时间长度是预定义的，所述第一时间窗被分成Y个时间间隔，所述X个时间间隔是所述Y个时间间隔中的X个，所述Y是不小于X的正整数，所述所述第一子频带中所包括的子载波的子载波间隔被用于确定所述Y，所述第一信令的监测者的特征ID被用于在所述Y个时间间隔中确定所述X个时间间隔。

[0245] 在实施例6的子实施例2中，所述第一时间窗属于Z个时间窗中之一，所述Z是大于1的整数。所述Z是预定义的；或者所述Z是可配置的。所述Z个时间窗中的任意两个时间窗的时间长度是相等的，所述所述第一信令的监测者的特征ID被用于在所述Z个时间窗中确定所述第一时间窗。

[0246] 在实施例6的子实施例3中，第一发送模块201还被用于发送第二无线信号。所述第二无线信号被用于确定{所述所述第一子频带在频域的位置，所述所述第一子频带中所包括的子载波的子载波间隔}中至少之一。

[0247] 在实施例6的子实施例4中，第一发送模块201还被用于发送第二信令。所述第二信令被用于确定Q个子频带，所述第一子频带属于所述Q个子频带中之一，所述Q个子频带中的任意一个子频带包括正整数个连续的子载波，所述所述第一信令的监测者的特征ID被用于在所述Q个子频带中确定所述第一子频带，所述Q是正整数。

[0248] 本领域普通技术人员可以理解上述方法中的全部或部分步骤可以通过程序来指令相关硬件完成，所述程序可以存储于计算机可读存储介质中，如只读存储器，硬盘或者光

盘等。可选的，上述实施例的全部或部分步骤也可以使用一个或者多个集成电路来实现。相应的，上述实施例中的各模块单元，可以采用硬件形式实现，也可以由软件功能模块的形式实现，本申请不限于任何特定形式的软件和硬件的结合。本申请中的UE或者终端包括但不限于手机，平板电脑，笔记本，上网卡，低功耗设备，eMTC设备，NB-IoT设备，无人机，遥控飞机，车载通信设备等无线通信设备。本申请中的基站或者网络侧设备包括但不限于宏蜂窝基站，微蜂窝基站，家庭基站，中继基站，eNB，gNB，传输接收节点TRP等无线通信设备。

[0249] 以上所述，仅为本申请的较佳实施例而已，并非用于限定本申请的保护范围。凡在本申请的精神和原则之内，所做的任何修改，等同替换，改进等，均应包含在本申请的保护范围之内。

(54) Title: METHOD AND APPARATUS FOR CONFIGURING FRAME STRUCTURE FOR NEW RADIO ACCESS TECHNOLOGY IN WIRELESS COMMUNICATION SYSTEM

(57) Abstract: A frame structure for a new radio access technology (RAT) is configured by a network node. The network node configures a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and communicates with a user equipment (UE) by using at least one of the first frame and the second frame. The UE may be a one of a massive machine-type communication (mMTC) UE, an ultra-reliable and low latency communication (URLLC) UE or an enhanced vehicle-to-everything (eV2X) UE.

WO 2017/171398 A1

Description

Title of Invention: METHOD AND APPARATUS FOR CONFIGURING FRAME STRUCTURE FOR NEW RADIO ACCESS TECHNOLOGY IN WIRELESS COMMUNICATION SYSTEM

Technical Field

[1] The present invention relates to wireless communications, and more particularly, to a method and apparatus for configuring a frame structure for a new ratio access technology (RAT) in a wireless communication system.

Background Art

[2] 3rd generation partnership project (3GPP) long-term evolution (LTE) is a technology for enabling high-speed packet communications. Many schemes have been proposed for the LTE objective including those that aim to reduce user and provider costs, improve service quality, and expand and improve coverage and system capacity. The 3GPP LTE requires reduced cost per bit, increased service availability, flexible use of a frequency band, a simple structure, an open interface, and adequate power consumption of a terminal as an upper-level requirement.

[3] As more and more communication devices require more communication capacity, there is a need for improved mobile broadband communication over existing radio access technology. Also, massive machine type communications (MTC), which provides various services by connecting many devices and objects, is one of the major issues to be considered in the next generation communication. In addition, communication system design considering reliability/latency sensitive service/UE is being discussed. The introduction of next generation radio access technology considering enhanced mobile broadband communication, massive MTC, ultra-reliable and low latency communication (URLLC) is discussed. This new technology may be called new radio access technology (RAT) for convenience.

[4] In the new RAT, analog beamforming may be introduced. In case of millimeter wave (mmW), the wavelength is shortened so that a plurality of antennas can be installed in the same area. For example, in the 30 GHz band, a total of 100 antenna elements can be installed in a 2-dimension array of 0.5 lambda (wavelength) intervals on a panel of 5 by 5 cm with a wavelength of 1 cm. Therefore, in mmW, multiple antenna elements can be used to increase the beamforming gain to increase the coverage or increase the throughput.

[5] In this case, if a transceiver unit (TXRU) is provided so that transmission power and phase can be adjusted for each antenna element, independent beamforming is possible for each frequency resource. However, installing a TXRU on all 100 antenna elements

has a problem in terms of cost effectiveness. Therefore, a method of mapping a plurality of antenna elements to one TXRU and adjusting the direction of a beam using an analog phase shifter is considered. This analog beamforming method has a disadvantage that it cannot perform frequency selective beaming because it can make only one beam direction in all bands.

[6] A hybrid beamforming with B TXRUs, which is an intermediate form of digital beamforming and analog beamforming, and fewer than Q antenna elements, can be considered. In this case, although there is a difference depending on the connection method of the B TXRU and Q antenna elements, the direction of the beam that can be simultaneously transmitted is limited to B or less.

[7] For operating new RAT efficiently, various schemes have been discussed. Specifically, in perspective of using frequency/spectrum, some new features may need to be required. Further, new frame structure may also need to be required.

Disclosure of Invention

Technical Problem

[8] The present provides a method and apparatus for configuring a frame structure for a new ratio access technology (RAT) in a wireless communication system. The present invention discusses initial access procedure which can allow different use cases supported in the same spectrum, e.g. massive machine-type communication (mMTC) and enhanced mobile broadband (eMBB), for both below and above 6 GHz. The present invention discusses how to support multi/variable transmission time interval (TTI) operation for each channel including hybrid automatic repeat request acknowledgement (HARQ-ACK) operation.

Solution to Problem

[9] In an aspect, a method for configuring a frame structure for a new radio access technology (RAT) by a network node in a wireless communication system is provided. The method includes configuring a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and communicating with a user equipment (UE) by using at least one of the first frame and the second frame.

[10] In another aspect, a network node for a new radio access technology (RAT) in a wireless communication system is provided. The network node includes a memory, a transceiver, and a processor, coupled to the memory and the transceiver, that configures a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and controls the transceiver to communicate with a user equipment (UE) by using at least one of the first frame and the second frame.

Advantageous Effects of Invention

[11] New frame structure can be configured for new RAT.

Brief Description of Drawings

[12] FIG. 1 shows a wireless communication system.

[13] FIG. 2 shows structure of a radio frame of 3GPP LTE.

[14] FIG. 3 shows a resource grid for one downlink slot.

[15] FIG. 4 shows an example of subframe type for new RAT.

[16] FIG. 5 shows an example of a frame structure for a new RAT according to an embodiment of the present invention.

[17] FIG. 6 shows another example of a frame structure for a new RAT according to an embodiment of the present invention.

[18] FIG. 7 shows an example of nested frame structure for a new RAT according to an embodiment of the present invention.

[19] FIG. 8 shows an example of scheduling of multiple and different TTI via different TTI levels.

[32] FIG. 21 shows a wireless communication system to implement an embodiment of the present invention.

Mode for the Invention

[33] Techniques, apparatus and systems described herein may be used in various wireless access technologies such as code division multiple access (CDMA), frequency division multiple access (FDMA), time division multiple access (TDMA), orthogonal frequency division multiple access (OFDMA), single carrier frequency division multiple access (SC-FDMA), etc. The CDMA may be implemented with a radio technology such as universal terrestrial radio access (UTRA) or CDMA2000. The TDMA may be implemented with a radio technology such as global system for mobile communications (GSM)/general packet radio service (GPRS)/enhanced data rates for GSM evolution (EDGE). The OFDMA may be implemented with a radio technology such as institute of electrical and electronics engineers (IEEE) 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802-20, evolved-UTRA (E-UTRA) etc. The UTRA is a part of a universal mobile telecommunication system (UMTS). 3rd generation partnership project (3GPP) long term evolution (LTE) is a part of an evolved-UMTS (E-UMTS) using the E-UTRA. The 3GPP LTE employs the OFDMA in downlink (DL) and employs the SC-FDMA in uplink (UL). LTE-advance (LTE-A) is an evolution of the 3GPP LTE. For clarity, this application focuses on the 3GPP LTE/LTE-A. However, technical features of the present invention are not limited thereto.

[34] FIG. 1 shows a wireless communication system. The wireless communication system 10 includes at least one evolved NodeB (eNB) 11. Respective eNBs 11 provide a communication service to particular geographical areas 15a, 15b, and 15c (which are generally called cells). Each cell may be divided into a plurality of areas (which are called sectors). A user equipment (UE) 12 may be fixed or mobile and may be referred to by other names such as mobile station (MS), mobile terminal (MT), user terminal (UT), subscriber station (SS), wireless device, personal digital assistant (PDA), wireless modem, handheld device. The eNB 11 generally refers to a fixed station that communicates with the UE 12 and may be called by other names such as base station (BS), base transceiver system (BTS), access point (AP), etc.

[35] In general, a UE belongs to one cell, and the cell to which a UE belongs is called a serving cell. An eNB providing a communication service to the serving cell is called a serving eNB. The wireless communication system is a cellular system, so a different cell adjacent to the serving cell exists. The different cell adjacent to the serving cell is called a neighbor cell. An eNB providing a communication service to the neighbor cell

is called a neighbor eNB. The serving cell and the neighbor cell are relatively determined based on a UE.

[36] This technique can be used for DL or UL. In general, DL refers to communication from the eNB 11 to the UE 12, and UL refers to communication from the UE 12 to the eNB 11. In DL, a transmitter may be part of the eNB 11 and a receiver may be part of the UE 12. In UL, a transmitter may be part of the UE 12 and a receiver may be part of the eNB 11.

[37] The wireless communication system may be any one of a multiple-input multiple-output (MIMO) system, a multiple-input single-output (MISO) system, a single-input single-output (SISO) system, and a single-input multiple-output (SIMO) system. The MIMO system uses a plurality of transmission antennas and a plurality of reception antennas. The MISO system uses a plurality of transmission antennas and a single reception antenna. The SISO system uses a single transmission antenna and a single reception antenna. The SIMO system uses a single transmission antenna and a plurality of reception antennas. Hereinafter, a transmission antenna refers to a physical or logical antenna used for transmitting a signal or a stream, and a reception antenna refers to a physical or logical antenna used for receiving a signal or a stream.

[38] FIG. 2 shows structure of a radio frame of 3GPP LTE. Referring to FIG. 2, a radio frame includes 10 subframes. A subframe includes two slots in time domain. A time for transmitting one transport block by higher layer to physical layer (generally over one subframe) is defined as a transmission time interval (TTI). For example, one subframe may have a length of 1ms, and one slot may have a length of 0.5ms. One slot includes a plurality of orthogonal frequency division multiplexing (OFDM) symbols in time domain. Since the 3GPP LTE uses the OFDMA in the DL, the OFDM symbol is for representing one symbol period. The OFDM symbols may be called by other names depending on a multiple-access scheme. For example, when SC-FDMA is in use as a UL multi-access scheme, the OFDM symbols may be called SC-FDMA symbols. A resource block (RB) is a resource allocation unit, and includes a plurality of contiguous subcarriers in one slot. The structure of the radio frame is shown for exemplary purposes only. Thus, the number of subframes included in the radio frame or the number of slots included in the subframe or the number of OFDM symbols included in the slot may be modified in various manners.

[39] The wireless communication system may be divided into a frequency division duplex (FDD) scheme and a time division duplex (TDD) scheme. According to the FDD scheme, UL transmission and DL transmission are made at different frequency bands. According to the TDD scheme, UL transmission and DL transmission are made during different periods of time at the same frequency band. A channel response of the TDD scheme is substantially reciprocal. This means that a DL channel response and a UL

channel response are almost the same in a given frequency band. Thus, the TDD-based wireless communication system is advantageous in that the DL channel response can be obtained from the UL channel response. In the TDD scheme, the entire frequency band is time-divided for UL and DL transmissions, so a DL transmission by the eNB and a UL transmission by the UE cannot be simultaneously performed. In a TDD system in which a UL transmission and a DL transmission are discriminated in units of subframes, the UL transmission and the DL transmission are performed in different subframes. In a TDD system, to allow fast switching between DL and UL, UL and DL transmission may be performed within a same subframe/slot in time division multiplexing (TDM)/frequency division multiplexing (FDM) manner.

[40] FIG. 3 shows a resource grid for one downlink slot. Referring to FIG. 3, a DL slot includes a plurality of OFDM symbols in time domain. It is described herein that one DL slot includes 7 OFDM symbols, and one RB includes 12 subcarriers in frequency domain as an example. However, the present invention is not limited thereto. Each element on the resource grid is referred to as a resource element (RE). One RB includes 12×7 or 12×14 resource elements. The number NDL of RBs included in the DL slot depends on a DL transmit bandwidth. The structure of a UL slot may be same as that of the DL slot. The number of OFDM symbols and the number of subcarriers may vary depending on the length of a CP, frequency spacing, etc. For example, in case of a normal cyclic prefix (CP), the number of OFDM symbols is 7 or 14, and in case of an extended CP, the number of OFDM symbols is 6 or 12. One of 128, 256, 512, 1024, 1536, and 2048 may be selectively used as the number of subcarriers in one OFDM symbol.

[41] 5th generation mobile networks or 5th generation wireless systems, abbreviated 5G, are the proposed next telecommunications standards beyond the current 4G LTE/ international mobile telecommunications (IMT)-dvanced standards. 5G planning aims at higher capacity than current 4G LTE, allowing a higher density of mobile broadband users, and supporting device-to-device, ultra-reliable, and massive machine communications. 5G research and development also aims at lower latency than 4G equipment and lower battery consumption, for better implementation of the Internet of things. Hereinafter, 5G technology may be referred to as new radio access technology (RAT).

[42] In new RAT, utilizing a subframe in which downlink and uplink are contained may be considered. This scheme may be applied for paired spectrum and unpaired spectrum. The paired spectrum means that one carrier consists of two carriers. For example, in the paired spectrum, the one carrier may include a DL carrier and an UL carrier, which are paired with each other. In the paired spectrum, communication, such as DL, UL, device-to-device communication, and/or relay communication, may be

performed by utilizing the paired spectrum. The unpaired spectrum means that that one carrier consists of only one carrier, like the current 4G LTE. In the unpaired spectrum, communication, such as DL, UL, device-to-device communication, and/or relay communication, may be performed in the unpaired spectrum.

[43] Further in new RAT, the following subframe types may be considered to support the paired spectrum and the unpaired spectrum mentioned above.

[44] (1) Subframes including DL control and DL data

[45] (2) Subframes including DL control, DL data, and UL control

[46] (3) Subframes including DL control and UL data

[47] (4) Subframes including DL control, UL data, and UL control

[48] (5) Subframes including access signals or random access signals or other purposes.

[49] (6) Subframes including both DL/UL and all UL signals.

[50] However, the subframe types listed above are only exemplary, and other subframe types may also be considered.

[51] FIG. 4 shows an example of subframe type for new RAT. The subframe shown in FIG. 4 may be used in TDD system of new RAT, in order to minimize latency of data transmission. Referring to FIG. 4, the subframe contains 14 symbols in one TTI, like the current subframe. However, the subframe includes DL control channel in the first symbol, and UL control channel in the last symbol. The remaining symbols may be used for DL data transmission or for UL data transmission. According to this subframe structure, DL transmission and UL transmission may sequentially proceed in one subframe. Accordingly, DL data may be transmitted in the subframe, and UL acknowledgement/non-acknowledgement (ACK/NACK) may also be received in the subframe. In this manner, the subframe shown in FIG. 4 may be referred to as self-contained subframe. As a result, it may take less time to retransmit data when a data transmission error occurs, thereby minimizing the latency of final data transmission. In the self-contained subframe structure, a time gap may be required for the transition process from the transmission mode to the reception mode or from the reception mode to the transmission mode. For this purpose, some OFDM symbols at the time of switching from DL to UL in the subframe structure may be set to the guard period (GP).

[52] Hereinafter, the present invention discusses transmission mechanism and resources used for synchronization signals, physical broadcast channel (PBCH), system information block (SIB) and physical random access channel (PRACH) related procedure for the new RAT, particularly considering forward compatibility in which different UEs are supported with different requirements in terms of radio frequency (RF)/baseband processing capability, latency requirements, power requirements, etc. For example, enhanced mobile broadband (eMBB) high data rate UEs with massive internet-of-things (IoT_ devices with relatively lower data rate and extremely limited

RF/baseband capability may be supported, compared to regular UEs or eMBB high data UEs. However, the present invention which will be described below may be applied to LTE technology wherever applicable.

[53] To allow coexistence of different use cases, at least one of the following aspects may be considered.

[54] - Different RF/baseband bandwidth capability: For example, an IoT device may support only very limited bandwidth such as M MHz of bandwidth or P*one subcarrier spacing. For another example, an IoT device may support 12*one subcarrier spacing (e.g. 12 * 7.5 kHz = 90 kHz).

[55] - Different processing capability in terms of encoding/decoding: For example, an IoT device may not support high processing decoding, such as turbo decoder or low-density parity-check (LDPC). If any common channel is shared among different UEs, this may be taken into account. For this manner, separate SIB may be transmitted per each UE. Alternatively, one main SIB or PBCH may be shared and different branch from the common channel may be allowed.

[56] - Different number of possible concurrent UEs attempting to access the cell: For example, though IoT device may not access the cell frequently, there may be many IoT devices attempting accessing the cell given a time duration. Handling massive UEs may require separate PRACH resource configuration or handling of RACH procedure differently.

[57] - Different synchronization requirement: For example, an IoT device may be supported by joint transmission from multiple cells to improve coverage. This may require larger CP overhead compared to other high data rate UEs.

[58] - Different subcarrier spacing: Due to different synchronization requirement or multiplexing capacity requirements, different subcarrier spacing may be used.

[59] - Different coverage requirement: Depending on use case, coverage and the required repetition numbers may be different.

[60]

[61] 1. Synchronization signal for the new RAT according to an embodiment of the present invention is described.

[62] For example, due to different subcarrier spacing and/or different RF/baseband requirement, synchronization signals, such as primary synchronization signal (PSS)/secondary synchronization signal (SSS), for eMBB and massive machine-type communication (mMTC) UEs may be different from the legacy synchronization signal. For example, synchronization signals for eMBB UEs may be transmitted over larger than M MHz of the lowest bandwidth supported UEs sharing the same spectrum. In this case, at least one of following approaches may be considered.

[63] (1) The common synchronization signals over the minimum system bandwidth (e.g.

M MHz) may be transmitted, and the same density of PSS/SSS may also be transmitted. The density may be determined by the coverage that the network intends to support.

[64] (2) Base sequence of synchronization signal may be transmitted in the minimum system bandwidth with the minimum density required for general UEs. For general UEs, repetition in frequency domain may be considered. And for high coverage requiring UEs, repetition in time domain may be considered. For example, minimum system bandwidth may be 180 kHz with 15 kHz subcarrier spacing with 12 subcarriers, and the bandwidth used for general UEs may be 1.4 MHz which may be repeated 6 times in frequency domain. On the other hand, for high coverage requiring UEs, repetition over multiple subframes may be considered. When repetition occurs in frequency domain, different root sequence may be used (which may affect overall peak-to-average power (PAPR)) or orthogonal cover code (OCC) may be applied over repetitions in frequency domain. Similar mechanism may be applied to repetition in time domain as well. From a UE perspective, if the network supports its UE type, appropriate repetition in either frequency domain or time (or both) domain may be used. In terms of repetition in frequency domain, the repetition may be done consecutively or discontinuously over the frequency.

[65] (3) Base sequence of synchronization signal may be based on synchronization signal system bandwidth designed for general UEs (e.g. 72 subcarriers * subcarrier spacing). For example, if the system bandwidth is K*M MHz, the base sequence may be mapped over k OFDM symbols for UE with lower bandwidth capability. In terms of mapping, M1, M2...Mk may be mapped over K OFDM symbols. Assuming a center frequency of a carrier where synchronization signal is transmitted, center frequency of the system bandwidth/carrier may be the same as the center frequency of synchronization signal for general UEs. Thus, if the channel raster is the same between different UEs, it means that center frequency of synchronization signals for low bandwidth UEs may be offset from the center of general UEs' synchronization signal. This offset may be prefixed. Alternatively, center frequency of system bandwidth/carrier may be the same as the center frequency of synchronization signal for low bandwidth UEs.

[66] (4) Separate synchronization signal may be configured between two types of UEs: In this case, to allow synchronization signal transmissions from different UEs, it is necessary to reserve some frequency regions for different types of UEs. This means that some signals/channels such as beam reference signal (RS) or PBCH or SIB may not be mapped to those reserved regions. At least a few potential regions may be reserved for future use of different system deployment or supporting different types of UEs.

[67] For the reserved regions, the following approaches may be considered. Within the

reserved time resource, any cell-common and/or group-common channels/RS/signals may not be transmitted.

[68] - Frequency resource(s) is reserved: For example, to allow different subcarrier spacing, frequency resource may be reserved. For the reserved frequency resources, the resources aligned with channel raster of low bandwidth UEs or future UEs may be considered. Generally, the same channel raster assumption may be used regardless of UE type. Thus, some frequency location which are aligned with channel raster may be reserved for future uses or supporting some different types of UEs.

[69] - Time resource(s) is reserved: For example, similar to legacy multicast-broadcast single-frequency network (MBSFN) subframe configuration, different types of future use subframes may be considered. In such subframes, one or a few symbols may be still used for control (DL and/or UL) transmissions. Within the reserved time resource, any cell-common and/or group-common channels/RS/signals may not be transmitted.

[70] - Time/frequency resource(s) is reserved: Both time and frequency domain may be considered for the reserved resources.

[71] - Beam direction(s) is reserved: Certain resources associated with a certain beam may be reserved. This implies that subcarrier spacing and/or CP length may be different per beam direction. In case below 6 GHz, this may be associated with a certain channel state information (CSI) RS and its associated virtual cell.

[72] If different subcarrier spacing is used, it may be necessary to fix synchronization signal (if they are common across UEs with different applications/subcarrier spacing values)

[73]

[74] 2. Empty frequency/time resources

[75] It is expected that some resources should be reserved for potential new services in future. The reason of reserving some frequency/time resource is to allow potentially different numerology (such as subcarrier spacing/CP length) and/or potentially different frame structure. In this sense, it is important to not allocate any available resources in frequency and time domain to one specific application. For example, the system bandwidth may not be entirely used for transmission of cell-specific signals, such as reference signals and channels. Also, it may be desirable to reserve some resources over the entire frequency domain rather than reserving some resources at the edge of system bandwidth. In this sense, it may be generally desirable to transmit any cell-specific RS and/or channel in rather discontinuous frequency resources. For example, PBCH may be transmitted in PRBs which are rather distributed over the system bandwidth, assuming minimum bandwidth. For example, if the minimum bandwidth is 20 MHz, and the number of PRBs are 20 with 75 kHz subcarrier spacing and PBCH uses 6 PRBs in one TTI, instead of placing PBCH in a contiguous 6 PRBs,

PBCH may be transmitted over 1 PRB in every 3 PRBs (or 2 PRBs excluding some PRBs used for synchronization signals). By this way, at least one or a few PRBs between PBCH PRBs may be reserved for some other future uses. Since additional RS and/or channels (cell-specific) may be transmitted in one TTI or one OFDM symbol, it may be also desirable to have discontinuous transmission of such RS/channels as well. Overall, the idea is to reserve at least one or a few subcarriers/RBs between two consecutive cell-specific RS/channels for future uses. The location of cell specific RS/channels may be determined based on cell ID and/or subframe and/or radio frame and/or frame index.

[76] Alternatively, signal system bandwidth may be signaled in synchronization signal where different frequency region can be used for different applications. For example, transmission of cell-specific RS may be different based on system bandwidth.

[77]

[78] 3. Frame structure

[79] It is expected that different frame structure may be necessary for the new RAT. Particularly, different frame structure in which UL and DL may be present in every subframe or may change very frequently in the same carrier may be necessary for the new RAT. Different application may require different minimum size of DL or UL portions to support different latency and coverage requirements. For example, mMTC for high coverage case may require relatively long DL and UL portion so that one transmission can be successfully transmitted. Furthermore, due to different requirement on synchronization and tracking accuracy requirements, different subcarrier spacing and/or different CP length may be considered. In this sense, it is necessary to consider mechanisms to allow different frame structures coexisting in the same carrier and be operated by the same cell/eNB.

[80] For the convenience, it is assumed in the description below that a frame structure type 1 (FS1) and a frame structure type 2 (FS2) are configured and coexist in the same carrier. The FS1 may be a baseline frame structure used for such as for eMBB use cases or typical use cases. The FS2 may be used for some other applications such as mMTC, ultra-reliable and low latency communication (URLLC), an enhanced vehicle-to-everything (eV2X) communication. The network or a cell may support one or multiple frame structures at the same time. For the convenience, the present invention may discuss relationship between two frame structures. However, more than two frame structures may be supported simultaneously.

[81]

[82] A. FS2 for mMTC/URLLC in FDD case

[83] In this case, one TTI of FS2 may consist of a few (e.g. 'm') TTIs of FS1. For example, if one TTI of FS1 is X ms, one TTI of FS2 may be 'm'*X ms. For de-

termining 'm', at least one of the following approaches may be considered.

[84] - 'm' may be predetermined. 'm' may be different per frequency or frequency range or frequency bands. To support variable coverage level or repetition level, it may be desirable to have different 'm' per repetition level. 'm' may be 2^N , where N=0,...P.

[85] - 'm' may be determined based on subcarrier spacing used for mMTC. For example, if 15*K1 kHz subcarrier spacing is used for FS1, and 15 kHz subcarrier spacing is used for FS2, 'm' may be same as K1 or multiple of K1.

[86] - Combination of the above two approaches may also be considered.

[87] FIG. 5 shows an example of a frame structure for a new RAT according to an embodiment of the present invention. Referring to FIG. 5, it is shown that FS1 is the same as the conventional frame structure, as one TTI includes 14 symbols. That is, one TTI of FS1 is 1 ms. On the other hand, one TTI of FS2 is 'm' ms. 'm' may be predetermined. Or, 'm' may be determined based on subcarrier spacing used for mMTC.

[88] If different subcarrier spacing is used, it may be necessary to have a gap between two different subcarrier regions. Also, for transmission of synchronization signals, collision between FS1 OFDM symbol carrying PSS and/or SSS and FS2 OFDM symbol carrying PSS and/or SSS should be avoided. For this, FS1 and FS2 may be configured by TDM manner. For this, in terms of system information or master information block (MIB) signaling, a set of subframes not usable may be configured. In other words, the set of available subframes for each FS may be signaled by each system information carried in each FS respectively. However, a set of available TTIs/subframes may not reflect the case where one or a few OFDM symbols within one TTI should not be used. For example, one OFDM symbol of FS2 colliding with synchronization signal(s) of FS1 may be excluded/punctured/rate matched. One or a few patterns of available OFDM symbols per TTI may be configured and signaled per each FS or to FS2. For example, patterns may be {all OFDM symbols available}, {the first symbol is not available}, {the first symbol in each slot is not available}, etc.

[89] Alternatively, CP length of FS2 may be configured smaller than m*CP length of FS1. The remaining portion may be used for gap or blank region between FS1 and FS2.

[90] FIG. 6 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. Referring to FIG. 6, like FIG. 5, one TTI of FS1 is 1 ms, and one TTI of FS2 is 'm' ms. However, CP length of FS2 is configured smaller than m*CP length of FS1, so gap occurs at the end of FS2. PSS/SSS of FS1 may be transmitted in gap of FS2, in order to avoid collision.

[91] Alternatively, when FS2 is constructed, additional gap may be considered, regardless of CP length, such that PSS/SSS (and also necessary system bandwidth wide signals such as CSI-RS, extended synchronization signal (ESS)) can be transmitted. In other

words, one or a few OFDM symbols may be reserved for some other purposes in FS2. For reservation, different CP may be configured so that the number of OFDM symbols within one TTI can be totally smaller than the size of one TTI (e.g. OFDM symbol size of 80 us*12 = 960 us in 1ms TTI leaves 40 us gap). Or, some OFDM symbols may be reserved for further uses. The future use or some other uses may include CSI-RS transmission, UL control transmission, DL control transmission, etc. Depending on reason of reservation, the gap may be formed in the beginning of each TTI (or multiple TTIs) or end of each TTI (or multiple TTIs). To support this, system bandwidth side signals of FS1, such as CSI-RS, ESS, PBCH, etc., may be transmitted in the beginning of TTI or ending of the TTI such that reservation on FS2 may be placed in the beginning or ending of TTI of FS2.

[92] Meanwhile, in order to reduce latency, short TTI which may be shorter than current TTI (i.e. 1ms) has been considered. For example, length of short TTI may be one of 1/2/3/4/7 symbols. When a short TTI is introduced for latency reduction in LTE, E-UTRAN may be configured with both normal TTI with 1ms and short TTI with a value less than 1ms, such as 1 symbol or 0.5ms. With keeping the current LTE frame structure, OFDM symbol length, subcarrier spacing, etc., reduction of TTI generally means smaller transport block size (TBS) contained in one TTI, and relatively larger control overhead if DCI size is kept as the same.

[93] When short TTI is adopted, and as a result, the number of OFDM symbols in reduced in one TTI (e.g. from 14 to 2) or subcarrier spacing increases (e.g. from 15 kHz to 60 kHz), a RB size may be different from the current RB size. For example, with subcarrier spacing of 60 kHz, one RB may include 12×8 resource elements, instead of 12×14 resource elements. For another example, when TTI length is 2 OFDM symbol length, one RB may include 12×2 resource elements. If short TTI is used, particularly with smaller number of OFDM symbols, larger RB size in frequency domain may be considered (e.g. one RB includes 48×2 resource elements).

[94] It is generally desirable to use short TTI for control. However, it may increase control overhead and thus decrease the overall performance benefit with short TTI operation. Thus, it may be desirable to support different TTI length per different application/packet.

[95] Hereinafter, as a proposal for FS2, a nested frame structure using short TTIs according to an embodiment of the present invention is described. It is assumed that "K" different levels (or lengths) of short TTIs is supported in the network. For example, level 1 may correspond to the legacy TTI length (e.g. 14 OFDM symbols with normal CP), which means 1 TTI in the network. Level 2 may correspond to 7 OFDM symbols, which means 2 TTIs in the network, and so on.

[96] FIG. 7 shows an example of nested frame structure for a new RAT according to an

embodiment of the present invention. Different TTI length may be used between FS1 and FS2. FIG. 7-(a) corresponds to level 1, in which one TTI includes 14 OFDM symbols. Level 1 may be called FS1. FIG. 7-(b) corresponds to level 2, in which one short TTI includes 7 OFDM symbols. That is, one TTI of FS1 includes two short TTIs of FS2. FIG. 7-(c) corresponds to level 3, in which one short TTI includes 3/4 OFDM symbols. That is, one TTI of FS1 includes 4 short TTIs of FS2. FIG. 7-(d) corresponds to level 4, in which one short TTI includes 1/2 OFDM symbols. That is, one TTI of FS1 includes eight short TTIs of FS2.

[97] Accordingly, depending on the needed number of short TTIs within one TTI (from 1 to 8, and 14), short TTIs may be placed. However, in FIG. 7-(c), instead of 4/3/4/3 OFDM symbols for short TTIs, 3/4/3/4 OFDM symbols or 3/4/4/3 OFDM symbols or 3/3/4/4 OFDM symbols or 4/4/3/3 OFDM symbols may be used. Similar rotation for 1/2 OFDM symbol may also be applied to FIG. 7-(d). In case of 1 OFDM symbol case, total of 14 short TTIs may be placed. Similar mechanisms may be applied to different OFDM symbols per TTI (e.g. 12 or 10). The proposed frame structure described above may allow that short TTI may be nested to the next level short TTI. In other words, one short TTI of one level may be divided to 2 short TTIs of the next level (except from 8 short TTIs to 14 short TTIs).

[98] In the proposed frame structure, the first one or two OFDM symbols of DL may be used for legacy control region, and the last OFDM symbol of UL may be reserved for sounding reference signal (SRS) transmission (or to minimize the impact by legacy SRS). In terms of SRS transmission for a short TTI supporting UE, the following two approaches may be considered.

[99] (1) If additional SRS configuration is given to short TTIs, a UE may transmit additional SRS according to short TTI configuration. If additional SRS transmission is considered, SRS may be transmitted in the last OFDM symbol of the configured short TTI for level 2 TTI structure. For level 3 and 4, the first OFDM symbol may be used for SRS except for the last short TTI in the legacy TTI. This additional SRS configuration may be cell-specific and may be configured per each TTI configuration. Thus, potentially multiple SRS configuration may be given. A UE configured with one level may perform rate matching or puncture in cell-specific SRS configuration of higher levels (i.e. shorter TTIs) to protect SRS. For example, if a UE is configured with level 2, and the cell also configures SRS for level 3, the UE may puncture or performing rate matching around SRS symbols of level 3.

[100] (2) Only legacy SRS configuration may be used, and additional SRS transmission in short TTI may not be used.

[101] More specifically, in FDD, option (2) above may be used. In TDD, option (1) may also be considered.

[102] With the nested frame structure, a UE supporting short TTI may be configured with multiple short TTI levels for control channel monitoring. For example, if level 4 is configured, the UE may monitor control channel in OFDM symbol 0 (possibly for legacy PDCCH), OFDM symbols 2, 4, 6, 7, 9, 11, and 14. In each short TTI, the multiple TTIs or variable TTI may schedule up to the maximum number of total short TTIs in the legacy TTI or multiple of the maximum short TTI numbers (e.g. 8 or 8*k in this example). For example, if a UE is scheduled with 4*sTTI in 2nd short TTI with level 2, PDSCH may be scheduled in 2nd, 3rd, 4th, 5th short TTIs, which in total of 7 OFDM symbols in length. The level may be determined by short TTI length used for control channel monitoring. More specifically, if the first short TTI schedules PDSCH, and the legacy PDCCH length is equal or larger than the size of short TTI, data may not be mapped to the fully overlapped short TTI. However, it may be counted for multiple TTIs scheduling. In other words, data may be rate matched, though it has been scheduled.

[103] It may be good to restrict the size of data channel only for a few cases (e.g. 1 symbol, 2 symbols, 4 symbols, 7 symbols and 12 symbols). It may be required by the network to schedule data properly not to vary the size of PDSCH in terms of OFDM symbols. For this, similar to ACK/NACK transmission, the timing from control channel to data channel may be considered. The timing from control channel to data channel may be signaled via number of short TTIs where short TTI length can be determined by sPDCCH TTI length (e.g. level 4). Alternatively, the basic short TTI length for ACK/NACK may also be determined by higher layer separately. In other words, a basic short TTI length or the level of short TTI used in DL and UL may be configured, respectively. Based on the basic short TTI length, multi/variable TTI scheduling which allows scheduling longer than the configured TTI length may be considered. If the first symbol is reserved for control channel in every short TTI, PDSCH may be rate matched in such OFDM symbols. Otherwise, data may be transmitted in the first control region of every short TTI as well, and data may be rate matched around its own scheduling DCI. Multi/variable TTI scheduling may be expanded to the next longer short TTI or level 1 TTI. If level 4 is used, data may not be scheduled in the same short TTI if the short TTI length is 1 OFDM symbol. For example, only 2 bits of 1, 2, 4, 8 multiple short TTIs may be scheduled in level 4 which allows PDSCH transmission ends aligned with the next higher level short TTI.

[104] FIG. 8 shows an example of scheduling of multiple and different TTI via different TTI levels. Referring to FIG. 8, legacy PDCCH may schedule PDSCH of level 1, 2, 3 and 4. PDCCH of each level may schedule PDSCH of each level. That is, PDCCH of level 2 may schedule PDSCH of level 2, PDCCH of level 3 may schedule PDSCH of level 3, and PDCCH of level 4 may schedule PDSCH of level 4.

[105] One drawback of the nested frame structure described above is that it leads different TTI lengths among short TTIs in the same level. To overcome this problem, partial overlap between two short TTIs may be considered.

[106] FIG. 9 shows an example of overlapped short TTI in a nested frame structure for a new RAT according to an embodiment of the present invention. That is, in the nested frame structure, short TTIs may be overlapped/shared to allow 2^N symbols per TTI. FIG. 9-(a) shows level 5 in which 16 short TTIs, instead of 14 short TTIs, are configured. In order to configure 16 short TTIs, fourth OFDM symbol are shared between TTI #3 and TTI #4, and eleventh OFDM symbol are shared between TTI #11 and TTI #12. FIG. 9-(b) shows level 4 in which 8 short TTIs are configured. In order to configure 8 short TTIs which has the same length, fourth OFDM symbol are shared between TTI #1 and TTI #2, and eleventh OFDM symbol are shared between TTI #5 and TTI #6. FIG. 9-(c) shows level 3 in which 4 short TTIs are configured. In order to configure 4 short TTIs which has the same length, fourth OFDM symbol are shared between TTI #0 and TTI #1, and eleventh OFDM symbol are shared between TTI #2 and TTI #3. 9-(d) shows level 2 in which 2 short TTIs are configured. In order to configure 2 short TTIs which has the length of 8 OFDM symbols, seventh and eighth OFDM symbols are shared between TTI #0 and TTI #1. The embodiment shown in FIG. 9 is only exemplary, and actual OFDM symbol which is shared between different short TTI may be changed. The idea is to allow some OFDM symbols overlapped among different short TTIs to align short TTI lengths.

[107] The drawback of the above approach is that control/data between two different short TTIs may be overlapped in the overlapped OFDM symbols, which may affect the overall FDM performance of control/data channels. However, if data and control is multiplexed by FDM, this overlap between control and data may be manageable if TDM between control and data is assumed. Alternatively, as the issue becomes more significant in level 2, overlap may not be considered in level 2.

[108] FIG. 10 shows another example of overlapped short TTI in a nested frame structure for a new RAT according to an embodiment of the present invention. Referring to FIG. 10, short TTI length may be configured as 7 actual OFDM symbols and fourth OFDM symbol may be mapped to #3 and #4 in each slot, respectively.

[109] The above approach may be applied to other levels as well. This may be explained that virtually there are 16 OFDM symbols which are mapped to physically 14 OFDM symbols. In this way, the design working for 16 OFDM symbols may be incorporated to 14 OFDM symbols cases (and vice versa). More specifically, in case from 16 OFDM symbols to 14 OFDM symbols, one OFDM symbol may be dropped between #3 and #4. In case from 14 OFDM symbols to 16 OFDM symbols, OFDM symbol #3 may be repeated. In terms of sharing OFDM symbol, at least in TDD, it is desirable to

use OFDM symbol #3 (in normal CP) in each slot may be preferable considering DM-RS position.

[110] When OFDM sharing is used, the number of OFDM symbols of multi/variable TTI scheduling may consider actual number of OFDM symbols in which multiple TTIs are spanning. In this sense, the total number of scheduled length may be smaller than multiple of short TTI length. This approach may allow that the number of OFDM symbols in each short TTI is 2^N, where N is 0, 1, 2...K depending on the necessity of latency and UE processing power requirement. In the overlapped short TTI with level 5 (e.g. TTI #3 and #4), it may be necessary to indicate which TTI is used for control and/or data channel, which may be differentiated via scrambling of control/data (some other means may also be considered). This may be particularly important when HARQ-ACK timing is determined based on 2^N number of OFDM symbols or the number of short TTIs in one the largest TTI size. For example, if TTI #3 schedules with gap of 2 TTI for sPDSCH, this may imply that PDSCH will be scheduled in TTI #5 (which is next OFDM symbol to TTI #3), thus, the gap may be in fact one short TTI. This may simplify the operation if system may require operating in multiple different levels of short TTI lengths. The similar concept may be used for UL as well. In UL, collision in the same resource between two short TTIs with level 5 may be considered as collision and transmission on one channel may be dropped per rule (if the network schedules collisions). For example, the rule may be configured based on uplink control channel information (UCI) priority or based on timing.

[111] For one example of the nested frame structure, if FS1 consists of 30 subframes, one subframe may be overlapped between two TTIs for FS2. If mMTC UE is scheduled in those overlapped TTIs, it may be counted only one as valid. Alternatively, instead of overlap of two TTIs, different TTI lengths may be configured. For example, level 2 of FS2 may have l TTIs with 2/2/2/2/1/2/2/2 in 1.5 ms range. Alternatively, reserve some resources may be reserved not used by mMTC devices. Those reserved resource blocks may be placed in any subframes consecutively or discontinuously. Alternatively, different levels may be defined by multiple of previous level's TTI length.

[112]

[113] B. Frame structure for mMTC in TDD case

[114] The above frame structure may be applied to a frame structure for mMTC in TDD. Additionally, in TDD, two different frame structures may be considered. One is a frame structure in which DL/UL switching may occur in a multiple TTI unit similar to current LTE TDD DL/UL configuration. The other is a frame structure that DL/UL switching may occur in every TTI to allow efficient DL and UL transmission and ACK/NACK transmission. For the latter case, DL control region and UL control region may need to be used for DL and UL, respectively, unless the network supports

full duplex capability. If the network does not support full duplex capability, thus, it may be necessary to align DL portions between FS1 and FS2. For this, the following two approaches may be considered.

[115] (1) FS1 configuration of DL/UL may be given to UEs of FS2, and UEs of FS2 may construct DL portion and UL portion according to DL/UL configuration of FS1. For example, if subcarrier spacing of FS2 is 2 times that of FS1, and the configuration of DL/UL configuration is DDDDDUUUUU (where D indicates subframes in which PDSCH may be transmitted, and U indicates subframes in which PUSCH may be transmitted), then DL and UL portion of FS2 may be constructed as DDSUU, where D indicates DL control and PDSCH portions can be used for DL and U indicates PUSCH portion and UL control portion can be used for UL.

[116] (2) FS2 configuration of DL/UL may be given to UEs of FS1, and UEs of FS1 may assume that subframe type (either PDSCH or PUSCH) may be determined by FS2 configuration, unless it's dynamically changed via scheduling or dynamic indication per each TTI. For example, assuming that the subcarrier spacing of FS2 is two times of that of FS1, FS2 may indicate DDDDDUUUUU. It may imply that default DL/UL configuration of FS1 is DDDDDDDDDDUUUUUUUUUU. More generally, a default DL/UL configuration of FS1 may be configured, and it may be overwritten by dynamic indication of subframe type change and/or via scheduling (e.g. DL grant or UL grant). Higher layer reconfiguration may also be considered.

[117] In terms of configuration of FS1 default DL/UL configuration type, a subset of TTIs/subframes with fixed D or U may be configured. Those fixed subframes may not change the subframe type either via dynamic singling or dynamic scheduling. For FS2, those fixed subframes may be at least used. For other subframes, additional configuration of subframe type and/or DL/UL configuration and/or availability for FS2 UEs' usage may be configured.

[118] Alternatively, In terms of configuration of FS1 default DL/UL configuration type, different types of subframe to FS1 UEs and FS2 UEs may be configured and FS1 UEs and FS2 UEs are multiplexed by FDM between DL and UL. FS1 UEs may be further classified between FS1 UEs with eMBB use cases and FS1 UEs with eV2X use cases. In other words, a subset of subframes with "D" type subframes may be fixed such that measurement signals and/or cell system bandwidth wide and/or cell specific signals/channels can be transmitted. For other subframes, the subframe type may be indicated as "U" from FS1 UE perspective such that sidelink resources can be configured/used in those resources, whereas the subframe type can be indicated as "D" from FS2 UE perspective. From the network perspective, the resource may be shared among FS1 and FS2 UEs and the network may transmit DL signals towards FS2 UEs. This may be applied to the same FS UEs depending on its communication/discovery types as well.

In other words, partial resources may be allocated for sidelink resources which can be multiplexed by FDM with DL resources in the same TTI. However, from a UE perspective, it may either perform DL or SL transmission.

[119]

[120] C. Frame structure for URLLC in TDD case

[121] The above frame structure with different subcarrier spacing may be applied to a frame structure for URLLC in TDD. If short TTI needs to be used for FS2, more DL/UL switching points within one TTI or different subframe type may be used. Or, if shorter OFDM symbol lengths are used for URLLC UEs for FS2, in one TTI of FS1, there may be different OFDM symbols used for DL and UL between FS1 and FS2.

[122] If the network does not support full duplex capability, it seems to be difficult to support different DL and UL in the same OFDM symbol duration. To minimize the impact, partial DL or UL transmission may be used in FS1. In partial DL or UL transmission, a UE may be scheduled with only one slot PDSCH or PUSCH transmission (if subcarrier spacing of FS2 is twice of FS1). In this case, the network may transmit data and then switch to UL and process URLCC uplink data. More generally, if FDM between FS1 and FS2 with different subcarrier spacing is used with potentially different UL/DL direction between FS1 and FS2, length of PDSCH or PUSCH scheduling and/or starting OFDM symbol index of PDSCH/PUSCH may be configured. Supporting partial PDSCH/PUSCH may be enabled by higher layer or dynamically indicated via common signaling or DCI or some signaling. Furthermore, FS2 needs to ensure DL control portion and UL control portion of FS1. Thus, first a few OFDM symbols may be used for DL control portion and last few OFDM symbols may be used for UL control portion. To minimize the DCI overhead, partial subframe length may be higher layer configured, and only starting position may be signaled. 0 or 1 may be used between partial and full TTI scheduling. Alternatively, it may also be combined with multiple TTI scheduling as well. Accordingly, partial TTI scheduling may be one of multi-TTI scheduling option.

[123] FIG. 11 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. FIG. 11 shows examples of frame structures when short TTIs are used in TDD. This may be treated similar to the above case with FDD, assuming that the last short TTI or first short TTI may not be used and gap symbol may be punctured or rate matched. FIG. 11-(a) corresponds to level 1, i.e. FS1. FIG. 11-(b) corresponds to level 2 of FS2, in which one short TTI consists of 6 OFDM symbols. 2 short TTIs are configured in one TTI of FS1. FIG. 11-(c) corresponds to level 3 of FS2, in which one short TTI consists of 3 OFDM symbols. 4 short TTIs are configured in one TTI of FS1. FIG. 11-(d) corresponds to level 4 of FS2, in which one short TTI consists of 1/2 OFDM symbols. For DL, short TTIs having 2/1/2/1/2/1/2/1

OFDM symbols are configured, and for UL, short TTIs having 1/2/1/2/1/2/1/2 OFDM symbols are configured. 8 short TTIs are configured in one TTI of FS1. FIG. 11-(e) corresponds to level 4 of FS2, in which one short TTI consists of 2 OFDM symbols. 6 short TTIs are configured in one TTI of FS1.

[124] Meanwhile, similar to FDD case, different layout may also be possible. For example, if guard period or switching from DL to UL takes more than one OFDM symbol, portioning of short TTIs may be changed. Depending on the network capability, short TTI of FS2 may have different direction from FS1.

[125] For both FDD and TDD, in terms of scheduling, FS1 UE may also be scheduled with FS2, and where only data portion may be mapped over multiple TTIs of FS2. In terms of resource mapping, UEs of FS1 may be configured with the size of FS2 (if any), and the bitmap may indicate the data mapping to a set of short TTIs of FS2. For example, if a case of FIG. 11-(e) is used, bitmap of 6 bits may be used to indicate to which short TTIs FS1 UE PDSCH can be mapped. For example, [1 1 1 1 0 0] may indicate that PDSCH is mapped to first four short TTIs, is not mapped to the last two short TTIs. Depending on the latency requirement, different level of short TTIs may be used for each packet. In terms of scheduling, a UE supporting short TTI may monitor DL control region in the lowest level that the network supports (which may be signaled by SIB or higher layer), or the level may be configured per UE or per session or per application. It is also possible that short TTI transmission may start in the middle of longer TTI transmission. In this case, preemption of longer TTI transmission may also be possible. To minimize the impact from this preemption, the network may send a common signal in short TTI control region which indicates whether there is any short TTI transmission or not. Alternatively, a longer TTI UE may perform blind search on data. Alternatively, in the next longer TTI control, the network may indicate whether there was interrupt in the previous transmission or not, and if so, the network may further indicate which short TTIs have been used.

[126] In summary, the proposed frame structure may allow that shorter TTIs can be nested to the next level of short TTI. In other words, one TTI of one level may be divided to 2 short TTIs of the next level (except from 4 short TTIs to 6 short TTIs and 6 short TTIs to 12 short TTIs if nested frame structure for 8 short TTIs is not used, and if the nested frame structure is used, only exception from 8 short TTIs to 12 short TTIs). Similar to FDD case, the order between 1/2 in 8 short TTIs case may be changed. This nested frame structure may allow multi-TTI scheduling a bit easier. For example, the shortest TTI may be configured to allow potentially many control possibilities with multi-TTI scheduling to [1...N], where N is the level of the configured short TTI level.

[127] FIG. 12 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. If DL and UL portion is equal within one TTI,

potentially limited number of levels may be supported for short TTIs. Referring to FIG. 12, only level 1, level 2, and level 3 are supported. FIG. 12-(a) corresponds to level 1, i.e. FS1. FIG. 12-(b) corresponds to level 2 of FS2, in which one short TTI consists of 6 OFDM symbols. 2 short TTIs are configured in one TTI of FS1. FIG. 12-(c) corresponds to level 3 of FS2. For level 3, short TTI size of 2 OFDM symbols may be considered (in total of 3 short TTIs per DL/UL) or 1/2/1/2 (or 2/1/2/1) short TTI lengths may be considered to support 4 short TTIs.

[128] UL switching symbol may be placed in any OFDM symbol in subframe with DL transmission. In other words, gap for DL to UL switching may be placed in any OFDM symbol which will be used by UE for switching. From DL perspective, the gap and UL symbols may be rate matched or punctured. From UL perspective, the gap and DL symbols may be rate matched or punctured.

[129]

[130] D. Frame structure for eV2X in FDD

[131] In this case, sharing among UEs transmitting towards the network needs to share UEs transmitting sidelink. The resource allocation mechanism or frame structure of eV2X UEs may be similar to other FS1 UEs. From a V2X UE perspective, if the same RF/ baseband capability of DL is used for both reception from the network and reception from other UEs, it may be necessary to separate DL resources between two transmission types.

[132] Similar mechanisms used in TDD case may be applied to FDD case as well, where sidelink resources may be configured in either DL or UL spectrum. The TTI length of sidelink may also be reduced to allow DL control reception and/or gap creation. Similar approach to place SL DL/UL control may be considered. In this case, if sidelink is only configured in UL spectrum, DL control may not be considered. If sidelink is configured in DL spectrum, UL control may not be considered. Alternatively, UL and DL spectrum may be used in a pair among different cells for different UEs. For example, a set of subframes may be fixed as DL or UL in each DL and UL spectrum. These configured subframes may not be configured as sidelink resources in either DL or UL spectrum. Other subframes in either DL or UL may be used for sidelink operation, like multi-carrier sidelink operation. Each UE may determine reception frequency and transmission frequency between DL and UL spectrum. Once it determines its direction, the UE will continue receiving or transmitting in one frequency and do opposite in the other frequency. In other words, other than fixed subframes, flexible subframes in either DL or UL may be used, like one carrier from a sidelink perspective similar to TDD case. More generally, TDD case may be applied in those flexible subframes, and DL carrier may include DL control in each TTI depending on configurations and UL carrier may include UL control in each TTI

depending on configuration.

[133]

[134] E. Frame structure for eV2X in TDD

[135] If TDD is used for eV2X, FS1 may be configured. Depending on its subframe type configuration of FS1, subset of UL portions may be used for sidelink operation (possibly except for UL control regions). Alternatively, a subset of subframes may be configured with subframe type, and the other subframes may be determined based on higher layer signaling and/or dynamic signaling. For example, non-DL subframe may be potentially allowed as sidelink capable subframes, then which subframes are usable for sidelink operation may be dynamically indicated by scheduling assignment (SA) transmission. In this case, to avoid any ambiguity, the SA may be transmitted in fixed UL subframe configured in MIB and/or SIB.

[136] IF DL control is potentially used in flexible subframes (i.e. flexible subframe is a subframe without configured subframe type via MIB and/or SIB), it may be desirable to avoid use of potential DL control portion in sidelink operation to minimize interference to other UEs, and potentially allow listening on DL control by eV2X UEs. In this case, DL control and potentially a gap to switch from DL to UL may be assigned in every flexible subframe. Alternatively, a subset of subframes with DL control may also be preconfigured, and a UE may assume that the first one or a few OFDM symbols may not be used for sidelink transmission in such subframes. To align resources among different cells, cells may be coordinated including DL control portions. Or, simply one or a few first OFDM symbols may always not be used for sidelink transmission in every TTI.

[137] Alternatively, subframe type for FS1 may be ignored and only sidelink resource information may be considered. For example, the network may perform FDM approaches between DL and UL between FS1 UEs receiving the data from the network and sidelink UEs.

[138] Whether to reserve DL control and UL control may be determined by at least one of the following approaches.

[139] - The network may configure the length of sidelink resource used in one TTI or the necessity of DL control and/or UL control region reservation. This may also allow flexible configuration of DL and UL control resource from network perspective. Only DL control portion may be reserved.

[140] - The UE may determine whether to reserve DL control and UL control depending on communication/discovery type. If the network controlled communication/discovery is used, DL control may be reserved. Otherwise, full TTI may be used for sidelink transmission. The gap may be used between DL and UL direction to minimize interference.

[141] - The resource may also include TTI size per each TTI in resource configuration.

[142] - It may be prefixed or follow a rule to determine the size.

[143] When each cell uses dynamic subframe type, different interference may be expected depending on subframe type on sidelink resources. In this sense, a subset of default UL subframes may be configured, and at least control channels of sidelink (such as SA) may be transmitted in those UL subframes. Those fixed UL subframes may be aligned among neighbor cells to minimize the interference among cells (similar concept may also be applied to DL as well).

[144] Also, ACK/NACK and control information for sidelink operations may be supported. Thus, sidelink DL control (configuration of sidelink resources, collision handling, etc., where all UEs except for the controlling UEs are supposed to listen) and ACK/NACK or feedback resource of sidelink (called sidelink UL control) should be placed somewhere. For this, at least one of the following options may be considered.

[145] - Option 1: Sidelink SL control may be multiplexed with DL/UL control by FDM (same direction): Or, the same OFDM symbol for DL control may be used for sidelink DL control and the same OFDM symbol for UL control may be used for sidelink UL control. It may follow the network configuration and the same configuration may be indicated to other UEs. This may be beneficial for relay nodes or UEs without network controlled operation. If this option is used, proper gap or interference mitigation between DL control and sidelink DL control may be assumed.

[146] - Option 2: Sidelink control FDM may be multiplexed with DL/UL control by FDM (opposite direction): Or, sidelink DL control may be placed in UL control region and sidelink UL control may be placed in SL DL control region to minimize the interference, assuming that interference from a UE to the network may be less significant to interference between UEs.

[147] - Option 3: Nested self-contained subframe

[148] FIG. 13 shows an example of a nested self-contained subframe according to an embodiment of the present invention. Referring to FIG. 13, sidelink DL control and/or sidelink UL control may be placed only in resources configured for sidelink operation. Depending on UE capability, gap from sidelink DL control to sidelink-transmit may be necessary. Depending on UE timing advance (TA) and other UL timing, gap between sidelink DL-receive to sidelink UL control may also be necessary. To allow a gap, it may be generally desirable not to use the last OFDM symbol for sidelink. In this case, either sidelink UL control or sidelink DL control may be placed in the second next to the last OFDM symbol.

[149] If the last OFDM symbol is used for UCI transmission toward to the network, it may not be used for the gap. To handle this case, a UE may create a gap by not receiving the next OFDM symbol if the next subframe is also used for sidelink. In this case,

sidelink UL control may be omitted and a UE may not receive sidelink DL control. To avoid such a case, if there is possibility of UCI transmission in the last OFDM symbol, it may be desirable to add one additional gap in the first OFDM symbol of the TTI.

[150] Overall, the followings may be considered for sidelink frame structure. TTI length of a sidelink may be at least 2 * gap OFDM symbols smaller than TTI length of host frame structure (e.g. if the gap size is 1 OFDM symbol, 2 OFDM symbols smaller than the FS1). Further, sidelink DL control and sidelink UL control may be placed in next to DL control and UL control (after and before) in the same TTI. If the gap is necessary to switch from sidelink DL/UL control to DL/UL control, the following order of priorities, UL control, sidelink DL/UL control, and DL control, may be used. If there is no sufficient gap is created by dropping lower priority, the next lower priority channel may be dropped.

[151]

[152] 4. Additional frame structure design for URLLC considering U-plane latency

[153] In the new RAT, scalable numerology may be considered. Some candidates of subcarrier spacing include 15 kHz, 30 kHz, 60 kHz, 120 kHz, etc. Among those, at least 15, 30, 60 kHz subcarrier spacing may be applied for under 6 GHz frequency band. Considering that the requirement of URLLC is 0.5ms for U-plane latency, some consideration on frame structure may be necessary. To minimize the overall U-plane latency, UL subframe boundary may be shifted. Assuming that data at L2/L3 queue may be scheduled to the next available subframe, the average latency may be 0.5*TTI. Assuming that UL subframe boundary is shifted by decoding latency of data channel, the latency to get the data at L2 at the destination side (without considering HARQ process) may be around 2*TTI.

[154]

[155] A. Frame structure for URLLC in FDD

[156] If HARQ process is considered, in FDD, since UL can be available anytime, the latency to encode ACK/NACK and TA may be added with HARQ retransmission latency. Overall, it may become 2.8*TTI (around 3*TTI).

[157] Table 1 shows an example of numerologies for normal CP and extended CP with 30 kHz spacing.

[158] [Table 1]

	eMBB - NCP	eMBB - ECP	URLLC - NCP	URLLC - ECP
OFDM symbol	33.34	33.34	33.34	33.34
Number of OFDM symbols in a TTI	14	12	4/3/4/3 in 0.5 ms	Option 1: 3 symbolsOption 2: 4 symbols
TTI length	0.5 ms	0.5 ms	0.1425/0.1075/0.1425/0.1075 ms	0.125 (with Option 1)0.16667 (with Option 2)
CP length	Half of LTE CP in NCP case	8.33us	Half of LTE CP in NCP case	8.33us

[159] Table 2 shows an example of numerologies for normal CP and extended CP with 15 kHz spacing.

[160] [Table 2]

	eMBB - NCP	eMBB - ECP	URLLC - NCP	URLLC - ECP
OFDM symbol	66.67 us	66.67 us	66.67 us	66.67 us
Number of OFDM symbols in a TTI	14	12	2	2 symbols
TTI length	1 ms	1 ms	0.143 ms	0.1667
CP length	Half of LTE CP in NCP case	Half of LTE CP in ECP case	Half of LTE CP in NCP case	Half of LTE CP in ECP case

[161] Table 3 shows an example of numerologies for normal CP and extended CP with 60 kHz spacing.

[162] [Table 3]

	eMBB - NCP	eMBB - ECP	URLLC - NCP	URLLC - ECP
OFDM symbol	16.67 us	16.67 us	16.67 us	16.67 us
Number of OFDM symbols in a TTI	14	10 (option 1)12 (option 2)	7	5 symbols (option 1)6 symbols (option 2)
TTI length	0.25 ms	0.25 ms	0.125 ms	0.125
CP length	Half of LTE CP in NCP case	8.33us (option 1)4.16 us (option 2)	Half of LTE CP in NCP case	8.33us (option 1)4.16 us (option 2)

[163] If 3 symbol short TTI is used (e.g. URLLC / 30 kHz / option 2), one short TTI may cross the slot boundary of eMBB subframe if slot is defined. More generally, short TTI may be defined over one or multiple subframes. One example is to aggregate two subframes and divide two subframe into multiple short TTIs (e.g. with 14 OFDM symbols of eMBB subframe, 4 OFDM symbol * 7 short TTIs may be constructed over two subframes for URLLC use case). In this case, where the short TTI starts (e.g. every even subframe or every odd subframe) needs to be clarified and may be defined in the specification or determined via initial access procedure.

[164]

[165] B. Frame structure for URLLC in TDD

[166] In TDD, since the ACK/NACK timing may be dependent on the availability of UL, if there is unavailable UL, the latency may be increased. Thus, to support low latency, in every short TTI, it is expected to have UL portion which can be dynamically created, whenever there is UL transmission. In TDD, if UL subframe boundary is shifted, UL transmission may occur in the middle of subframe. This may be handled by the network if the network and/or UE support (semi) full duplex capability. Or, larger delay budget may be assumed for TDD (e.g. 2 * TTI + TA without HARQ, 3 * TTI with HARQ). In TDD, even without subframe offset, as DL portion is relatively smaller compared to FDD, overall decoding latency may also be reduced (which in turn may lead less peak data rate with low latency). For TDD, the similar TTI length and the number of OFDM symbol per TTI may be considered.

[167] FIG. 14 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. In FIG. 14, 2 OFDM symbol length frame structure is supported in TDD. In order to support 2 OFDM symbol length with 15 kHz or other subcarrier spacing, one OFDM symbol may be assumed for DL portion, and

double subcarrier spacing for uplink portion may be assumed (e.g. 30 kHz with 15 kHz DL subcarrier spacing) with keeping the same CP overhead for UL. The remaining part may be used for guard period (GP) including TA and DL/UL switching time.

[168] FIG. 15 shows another example of a frame structure for a new RAT according to an embodiment of the present invention. In FIG. 15, 3 OFDM symbol length frame structure is supported in TDD.

[169] For multiplexing of different use cases from the network perspective, different numerology or different subcarrier spacing may be used where the same CP may be still assumed between two different use cases. For this, 1 OFDM symbol for DL and 1 OFDM symbol for GP and 1 OFDM symbol for UL may be define in 3 OFDM symbol TTI length. Alternatively, similar to 2 OFDM symbol case, only UL portion may use different subcarrier spacing to allow more DL OFDM symbols available.

[170] More generally, this approach may be explained that URLLC can be utilized with extended CP with larger subcarrier spacing compared to eMBB to maintain the same level of CP. The remaining time may be applied towards GP between UL/DL switching and TA. Having larger GP in URLLC, TDD may be beneficial to allow more decoding time and UL transmission preparation. This case may be beneficial to reserve more processing time or allow larger GP which may be beyond one OFDM symbol length in 3 OFDM symbol short TTI case in TDD.

[171] FIG. 16 shows an example of different subcarrier spacing between URLLC and eMBB which are multiplexed in a same carrier or frequency band. From a UE perspective, each portion may be managed by individual transmission point or a cell such that initial access can be achieved separately per use cases. However, URLLC provided by shorter TTI with the same numerology with eMBB may also share the initial access procedure with host eMBB case. In this sense, via the initial access, whether to support short TTI or regular TTI may be informed.

[172] In determining UL portion for short TTI for URLLC, the portion or the number of OFDM symbol for UL portion in each short TTI may also depend on the necessity of demodulation RS (DM-RS) transmission. For example, if a UE requires to transmit DM-RS at least in one subframe in every 7 OFDM symbol, short TTIs within 7 OFDM symbol may not need to transmit DM-RS multiple times. In this sense, the first short TTI in every 7 OFDM symbol may have at least two OFDM symbols for UL portion and the remaining short TTIs may have one OFDM symbol for UL portion. Accordingly, dynamic determination of UL portion size may be supported depending on the necessity of DM-RS transmission in a given short TTI or not. This may also impact the behavior of DL reception, where a UE may puncture or not receiving the last DL OFDM symbol to shift UL portion one symbol forward. This may be restricted in case of 3 OFDM symbol short TTI. In this case, alternative approach is to transmit GP and

DM-RS in one OFDM symbol with different subcarrier spacing or by other means.

[173]

[174] 5. Above 6 GHz frequency

[175] The above description of the present invention may be applied for a frequency band below 6 GHz. The above description of the present invention may be applied for a frequency band above 6 GHz as well. In a frequency band above 6 GHz, analog beam may be used. In this case, the unit of beam switching may be used similar to one TTI mentioned for FS1 and FS2. However, the unit of beam switching for data transmission may be assumed for the unit size. For example, if beam switching occurs in every OFDM symbol for PSS/SSS or control channel transmission, whereas beam switching occurs only once per TTI for data transmission, the basic unit for beam switching may be 1 TTI. If beam switching for data transmission occurs in every 1/2 TTI, the basic unit for beam switching may be 1/2 TTI. When configuring sidelink resources, beam direction of each resource may be indicated such that UEs can communicate each other based on beam direction and based on each other's location information. The same size of subcarrier spacing among different applications may be used for frequencies above 6GHz.

[176]

[177] 7. DM-RS sharing

[178] For PUSCH, depending on coverage level, the network may configure the number of TTIs used for PUSCH transmission. As DM-RS for one OFDM symbol TTI in UL is very challenging (similar issue may be in DL as well, yet the problem may become more significant in UL due to SC-FDM characteristic and PAPR issue), the TTI of UL can be represented a bit differently in consideration of potentially DM-RS sharing among different TTIs.

[179] FIG. 17 shows an example of DM-RS sharing according to an embodiment of the present invention. FIG. 17-(a) shows a case of level 5 (i.e. 1 OFDM symbol short TTI) with discontinuous DM-RS. In this case, one symbol short TTIs share the DM-RS in the middle of legacy slot. Potentially different cyclic shift (CS) may be configured or preconfigured per each OFDM symbol to allow multiplexing of different TTIs. If a UE schedules more than one TTIs sharing the same DM-RS, it may continue using the first DM-RS scrambling/sequence of the first transmission among multiple TTIs. FIG. 17-(b) shows a case of level 4 (i.e. 2 OFDM symbols short TTI) with no DM-RS sharing.

[180] FIG. 17-(c) shows a case of level 4 (i.e. 2 OFDM symbols short TTI) for physical sidelink shard channel (PSSCH) with DM-RS sharing. FIG. 17-(d) also shows a case of level 4 (i.e. 2 OFDM symbols short TTI) for PSSCH with DM-RS sharing. For Level 4 with DM-RS sharing, there may be two different approaches.

[181] - Approach 1: DM-RS sharing does not occur between adjacent short TTIs with 2 OFDM symbols, and DM-RS sharing occurs between short TTIs with 1 OFDM symbol and 2 OFDM symbols. This approach corresponds to FIG. 17-(c).

[182] - Approach 2: DM-RS sharing occurs over all TTIs similar to level 5. One DM-RS symbol is shared by multiple short TTIs. This corresponds to FIG. 17-(d). Similar level 5, CS may be predefined or configured per OFDM symbol, and the first OFDM symbol mapped scrambling/CS/sequence is used if the short TTI size is larger than 1.

[183] FIG. 17-(e) shows a case of level 3 (i.e. 3/4 OFDM symbols short TTI) for physical uplink control channel (PUCCH) with no DM-RS sharing. FIG. 17-(f) shows a case of level 3 (i.e. 3/4 OFDM symbols short TTI) for PSSCH with DM-RS sharing. For level 3, if DM-RS sharing is considered, the fourth OFDM symbol in each slot may be used for DM-RS sharing.

[184] Additional DM-RS within a short TTI may be added which may or may not be shared among different short TTIs. For example, if PUCCH transmission is considered, with DM-RS sharing, additional DM-RS (the same DM-RS or with different CS) may be used in each TTI as well.

[185] FIG. 18 shows an example of PUSCH scheduling with DM-RS sharing according to an embodiment of the present invention. Referring to FIG. 18, PUSCHs of level 4 share DM-RS, and PUSCHs of level 3 with 2 short TTIs may also share DM-RS.

[186] FIG. 19 shows an example of PUCCH scheduling without DM-RS sharing according to an embodiment of the present invention. Referring to FIG. 19, there is no DM-RS sharing.

[187]

[188] 8. ACK/NACK transmission

[189] For ACK/NACK transmission or UCI transmission via PUCCH, the network may also indicate the number of TTIs used for ACK/NACK transmission or PUCCH transmission via DCI or higher layer signaling. As the coverage of ACK/NACK transmission may also be dependent on the number of ACK/NACK bits or UCI bits, it may be dynamically indicated by DL grant. For example, the timing and frequency offset of ACK/NACK transmission, and also the number of TTIs used for ACK/NACK transmission may be configured in DL grant. Or, the length may be determined by the number of UCI bits. The number of TTIs used for PUCCH may be semi-statically configured. In terms of baseline timing of ACK/NACK, (sPDSCH transmission duration + sPDSCH transmission duration (for decoding) or higher layer configured decoding latency + 2 * sTTI for UL for ACK/NACK preparation) may be assumed. If there is offset configured in the DL grant, the offset may be added to the baseline timing of ACK/NACK.

[190]

[191] 9. Short TTI indexing

[192] To indicate a short TTI within the largest TTI, assuming the largest TTI uses the subframe index, separate indexing of short TTI may be considered. In one subframe, K maximum short TTI may be placed. In terms of configuration of e.g. semi-persistent scheduling (SPS), CSI, etc., or any periodic configuration, periodicity may be represented by TTI length or multiple of TTIs. The periodicity may start from SFN=0 and subframe index = 0. Alternatively, periodicity may be represented in two level, i.e. periodicity in subframes and periodicity within a subframe.

[193]

[194] 10. Short TTI length for each channel

[195] There are a couple of aspects to determine right shot TTI length for each channel, e.g. the file size, system resource utilization, UE geometry, etc. Overall, smaller file size in a lighted loaded scenario for good coverage UEs may lead best performance gain, whereas very little or even worse performance may be expected with short TTI for poor coverage UEs with large file sizes. In this sense, it seems considerable to apply UE-specific TTI length at least based on UE geometry. However, the file size also impacts on the overall performance gain due to the associated protocol overhead and control overhead. In this sense, mechanisms to allow dynamic change of sPDSCH/sPUSCH may be beneficial to address the case where a UE has multiple transmission control protocol (TCP) sessions with different file sizes. As packets from different TCP sessions are not differentiable from the physical layer perspective, it may be beneficial to consider dynamic TTI length adaptation via DCI.

[196] To support this, the following overall approaches may be considered.

[197] (1) Dynamic TTI length for all channels: The TTI length of sPDCCH may be dynamically changed which are blindly monitored by a UE. Based on the scheduled sPDCCH, the UE may determine the TTI length for sPDSCH/sPUSCH. This approach however requires some mechanism to identify the length of sPDCCH. One approach is to assume that FDM between sPDCCH and sPDSCH is used such that sPDCCH is transmitted always over the entire short TTI. Or, explicit indication in DCI may be necessary.

[198] (2) Fixed TTI length for sPDCCH with dynamic indication via DCI: Alternatively, the TTI length used for sPDCCH may be higher layer configured, and the TTI length of scheduled sPDSCH or sPUSCH may be dynamically adapted by the signaling in DCI.

[199] The first approach may offer benefits to adapt sPDCCH resource in time domain (if sPDCCH and sPDSCH is multiplexed partially or fully by FDM). This however may be also achieved by different aggregation levels. Furthermore, it seems that both approaches may require potentially explicit indication via DCI. Thus, the clear benefits of

the first approach while it restricts the flexibility are not clear. In this sense, to simplify the UE blind decoding, refer the second approach may be preferred. In other words, supporting different TTI length for data channel may be supported by a multiple TTI scheduling manner.

[200] When variable/multi-TTI length scheduling is supported, the issue with multiplexing between sPDSCH with different TTI lengths may be also considered in terms of processing latency For example, if decoding latency is same as the length of sPDSCH, if longer TTI scheduling occurs before shorter TTI scheduling happens, the decoding or processing of following shorter TTI can be delayed (unless pre-emption is assumed). Thus, depending on the scheduling, the overall latency till ACK/NACK transmission can be changed. To address different cases, asynchronous HARQ-ACK feedback timing for sPDSCH may be considered as well where ACK/NCK timing can be signaled via DL scheduling DCI. Further, the shorter TTI of PUCCH transmission may reduce the overall coverage. This may be all right for good coverage UEs whereas it may impact on the cell edge UEs. In this sense, the TTI length for sPUCCH transmission may be semi-statically configured. Based on the semi-statically configured TTI length for sPDCCH and sPUCCH, timing of DL and UL may be respectively determined which are used for resources for DL and UL transmissions.

[201]

[202] FIG. 20 shows a method for configuring a frame structure for a new RAT by a network node according to an embodiment of the present invention. The present invention described above may be applied to this embodiment.

[203] In step S100, the network node configures a first frame which has one legacy TTI and a second frame which has multiple short TTIs. In step S110, the network node communicates with a UE by using at least one of the first frame and the second frame.

[204] The second frame may have the nested frame structure described above. The second frame may contain different number of short TTIs per a number of symbols in each short TTI. The number of symbols in each short TTI may be identical. In this case, at least one symbol may be shared between adjacent short TTIs.

[205] The second frame may contain at least one of a symbol for DL control, a symbol for UL control, a symbol for a sidelink DL control or a symbol for a sidelink UL control. The symbol for DL control may be placed in a first symbol of the second frame, and the symbol for UL control may be placed in a last symbol of the second frame. The symbol for sidelink DL control may be placed in a second last symbol of the second frame, and the symbol for sidelink UL control may be placed in a second symbol of the second frame. Further, a gap may be configured between the symbol for DL control and the symbol for sidelink UL control, or between the symbol for sidelink DL control and the symbol for UL control.

[206] A synchronization signal may be transmitted in a minimum system bandwidth with minimum density in the second frame. The synchronization signal may be shared among the first frame and the second frame. The synchronization signal may be repeated in a frequency domain or a time domain.

[207] The first frame and the second frame may be configured according to one of different baseband bandwidth capability, different processing capability, different number of possible UEs accessing a cell, different synchronization requirement, different subcarrier spacing or different coverage requirement. The UE may be a one of an mMTC UE, a URLL) UE or an eV2X UE.

[208] FIG. 21 shows a wireless communication system to implement an embodiment of the present invention.

[209] A network node 800 may include a processor 810, a memory 820 and a transceiver 830. The processor 810 may be configured to implement proposed functions, procedures and/or methods described in this description. Layers of the radio interface protocol may be implemented in the processor 810. The memory 820 is operatively coupled with the processor 810 and stores a variety of information to operate the processor 810. The transceiver 830 is operatively coupled with the processor 810, and transmits and/or receives a radio signal.

[210] A UE 900 may include a processor 910, a memory 920 and a transceiver 930. The processor 910 may be configured to implement proposed functions, procedures and/or methods described in this description. Layers of the radio interface protocol may be implemented in the processor 910. The memory 920 is operatively coupled with the processor 910 and stores a variety of information to operate the processor 910. The transceiver 930 is operatively coupled with the processor 910, and transmits and/or receives a radio signal.

[211] The processors 810, 910 may include application-specific integrated circuit (ASIC), other chipset, logic circuit and/or data processing device. The memories 820, 920 may include read-only memory (ROM), random access memory (RAM), flash memory, memory card, storage medium and/or other storage device. The transceivers 830, 930 may include baseband circuitry to process radio frequency signals. When the embodiments are implemented in software, the techniques described herein can be implemented with modules (e.g., procedures, functions, and so on) that perform the functions described herein. The modules can be stored in memories 820, 920 and executed by processors 810, 910. The memories 820, 920 can be implemented within the processors 810, 910 or external to the processors 810, 910 in which case those can be communicatively coupled to the processors 810, 910 via various means as is known in the art.

[212] In view of the exemplary systems described herein, methodologies that may be im-

plemented in accordance with the disclosed subject matter have been described with reference to several flow diagrams. While for purposed of simplicity, the methodologies are shown and described as a series of steps or blocks, it is to be understood and appreciated that the claimed subject matter is not limited by the order of the steps or blocks, as some steps may occur in different orders or concurrently with other steps from what is depicted and described herein. Moreover, one skilled in the art would understand that the steps illustrated in the flow diagram are not exclusive and other steps may be included or one or more of the steps in the example flow diagram may be deleted without affecting the scope of the present disclosure.

[213]

Claims

[Claim 1] A method for configuring a frame structure by a network node in a wireless communication system, the method comprising:
configuring a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs; and
communicating with a user equipment (UE) by using at least one of the first frame and the second frame.

[Claim 2] The method of claim 1, wherein the second frame contains different number of short TTIs per a number of symbols in each short TTI.

[Claim 3] The method of claim 2, wherein the number of symbols in each short TTI is identical.

[Claim 4] The method of claim 3, wherein at least one symbol is shared between adjacent short TTIs.

[Claim 5] The method of claim 1, wherein the second frame contains at least one of a symbol for downlink (DL) control, a symbol for uplink (UL) control, a symbol for a sidelink DL control or a symbol for a sidelink UL control.

[Claim 6] The method of claim 5, wherein the symbol for DL control is placed in a first symbol of the second frame, and
wherein the symbol for UL control is placed in a last symbol of the second frame.

[Claim 7] The method of claim 5, wherein the symbol for sidelink DL control is placed in a second last symbol of the second frame, and
wherein the symbol for sidelink UL control is placed in a second symbol of the second frame.

[Claim 8] The method of claim 5, wherein a gap is configured between the symbol for DL control and the symbol for sidelink UL control, or between the symbol for sidelink DL control and the symbol for UL control.

[Claim 9] The method of claim 1, wherein a synchronization signal is transmitted in a minimum system bandwidth with minimum density in the second frame.

[Claim 10] The method of claim 9, wherein the synchronization signal is shared among the first frame and the second frame.

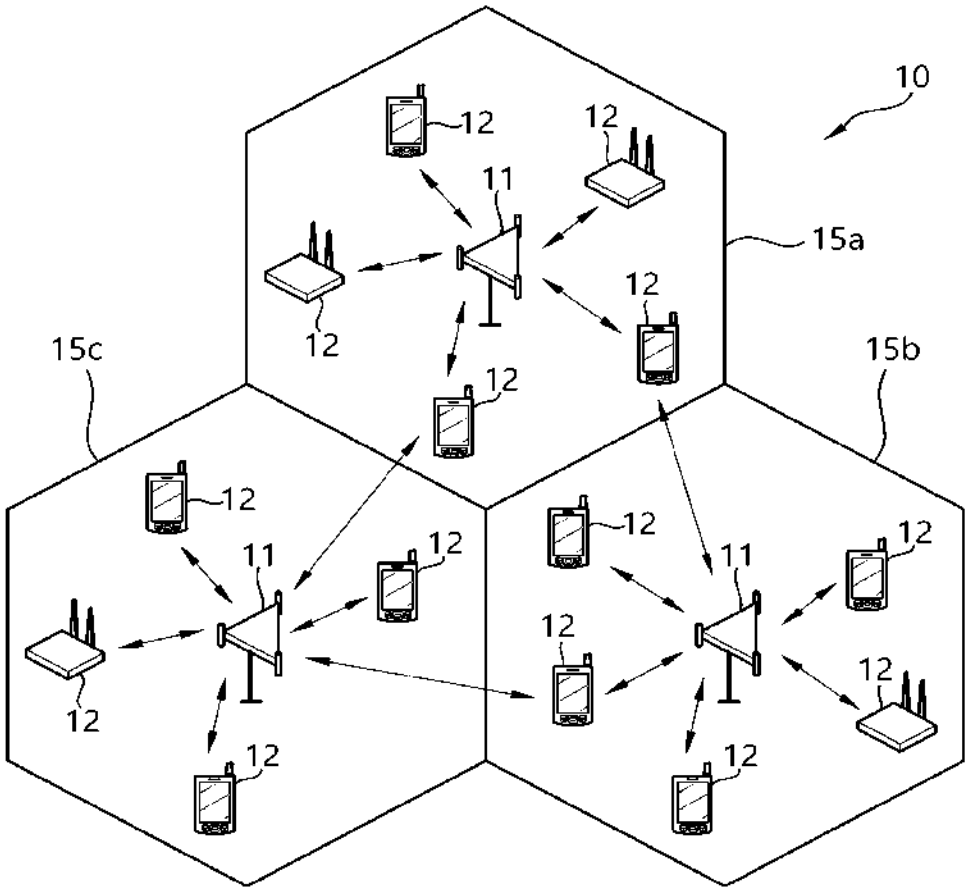
[Claim 11] The method of claim 9, wherein the synchronization signal is repeated in a frequency domain or a time domain.

[Claim 12] The method of claim 1, wherein the first frame and the second frame

are configured according to one of different baseband bandwidth capability, different processing capability, different number of possible UEs accessing a cell, different synchronization requirement, different subcarrier spacing or different coverage requirement.

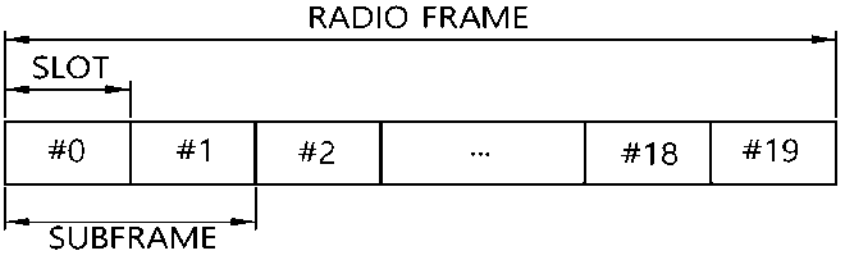
[Claim 13] The method of claim 1, wherein the UE is a one of a massive machine-type communication (mMTC) UE, an ultra-reliable and low latency communication (URLLC) UE or an enhanced vehicle-to-everything (eV2X) UE.

[Claim 14] A network node in a wireless communication system, the network node comprising:



a memory;

a transceiver; and



a processor, coupled to the memory and the transceiver, that:

configures a first frame which has one legacy transmission time interval (TTI) and a second frame which has multiple short TTIs, and controls the transceiver to communicate with a user equipment (UE) by using at least one of the first frame and the second frame.

(54) Title: METHODS AND APPARATUSES FOR DOWNLINK CONTROL INFORMATION TRANSMISSION AND RECEIVING

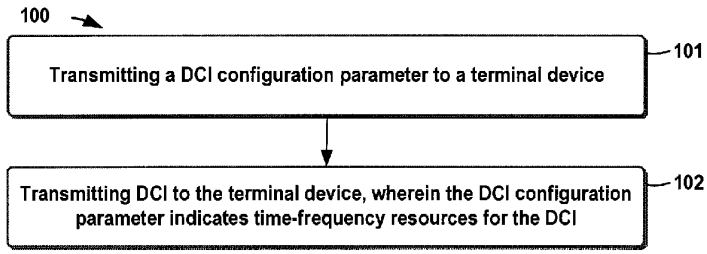

Fig. 1

(57) Abstract: Embodiments of the present disclosure relate to methods and apparatuses for downlink control information (DCI) transmission and receiving in a wireless communication system. A DCI configuration parameter can be first transmitted to a terminal device; and then DCI is transmitted to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI. With embodiments of the present disclosure, the UE could perform a flexible DCI monitoring according to the DCI configuration parameter and thus it may support the DCI monitoring occasion change due to numerology and scheduling unit size.

WO 2018/126401 A1

METHODS AND APPARATUSES FOR DOWNLINK CONTROL INFORMATION TRANSMISSION AND RECEIVING

FIELD OF THE INVENTION

[0001] The non-limiting and exemplary embodiments of the present disclosure generally relate to the field of wireless communication techniques, and more particularly relate to methods and apparatuses for downlink control information (DCI) transmission and receiving in a wireless communication system.

BACKGROUND OF THE INVENTION

[0002] New radio access system, which is called as new RAT (NR) system or network for short, is the next generation communication system. In Radio Access Network (RAN) #71 meeting for the third generation Partnership Project (3GPP) working group, study of NR system was approved. The NR system will consider frequency ranging up to 100Ghz with an object of a single technical framework addressing all usage scenarios, requirements and deployment scenarios defined in Technical Report TR 38.913, which include requirements such as enhanced mobile broadband, massive machine-type communications, ultra reliable and low latency communications.

[0003] Especially, in the NR network, different numerologies will coexist in the same carrier and a mini-slot will be introduced to carry Ultra-reliable low latency communication (URLLC) traffic. As a result, DCI monitoring may be performed per symbol based on the specific numerology. Thus, a terminal device like user equipment (UE) needs to know when to monitor the DCI for scheduling related operations.

[0004] In current LTE system, DCI monitoring is performed per subframe or per slot if the UE is in on duration of the discontinuous reception (DRX) active state. The DRX periodicity can be configured by higher layers.

[0005] However, with the current DCI monitoring solution in LTE, it cannot support the DCI monitoring occasion change due to numerology and scheduling unit size.

SUMMARY OF THE INVENTION

[0006] In patent cooperation treaty (PCT) application publication No. WO2016190970A1, there were proposed techniques for selecting data communications with shortened time duration wherein a two-stage grant for communication scheduling was introduced, the first stage grant could include an indication to activate/deactivate ultra-low latency (ULL) communication.

[0007] In US application US20160119969A1, there was proposed a solution for MAC enhancement for concurrent legacy and enhanced component carrier (ECC) operation, wherein a two stage Semi-Persistent Scheduling (SPS) solution was introduced and a first stage grant could contain parameters that may not change much over the course of a given SPS instance while the second stage grant could contain the actual resource for the SPS scheduling.

[0008] In another PCT application publication No. WO2016069270A1, there was proposed another two-stage PDCCH wherein a fast DCI could include a DCI flag and DCI format size indicator to indicate the existence and the size of the slow DCI in the same TTI.

[0009] However, none of the above solutions can address the problems as presented in the back ground.

[0010] To this end, in the present disclosure, there is provided a new solution for DCI transmission and receiving in a wireless communication system, to mitigate or at least alleviate at least part of the issues in the prior art.

[0011] According to a first aspect of the present disclosure, there is provided a DCI transmission in a wireless communication system. The method comprises transmitting a DCI configuration parameter to a terminal device; and transmitting DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

[0012] According to a second aspect of the present disclosure, there is provided a method of DCI receiving in a wireless communication system. The method comprises receiving a DCI configuration parameter at a terminal device; and receiving DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

[0013] According to a third aspect of the present disclosure, there is provided

an apparatus of DCI transmission in a wireless communication system. The apparatus comprises: a parameter transmission module and a DCI transmission module. The parameter transmission module may be configured to transmit a DCI configuration parameter to a terminal device. The DCI transmission module may be configured to transmit DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI

[0014] According to a fourth aspect of the present disclosure, there is provided an apparatus of DCI receiving in a wireless communication system. The apparatus comprises: a parameter receiving module and a DCI receiving module. The parameter receiving module may be configured to receive DCI configuration parameter at a terminal device. The DCI receiving module may be configured to receive DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

[0015] According to a fifth aspect of the present disclosure, there is provided a computer-readable storage media with computer program code embodied thereon, the computer program code configured to, when executed, cause an apparatus to perform actions in the method according to any embodiment in the first aspect.

[0016] According to a sixth aspect of the present disclosure, there is provided a computer-readable storage media with computer program code embodied thereon, the computer program code configured to, when executed, cause an apparatus to perform actions in the method according to any embodiment in the second aspect.

[0017] According to a seventh aspect of the present disclosure, there is provided a computer program product comprising a computer-readable storage media according to the fifth aspect.

[0018] According to an eighth aspect of the present disclosure, there is provided a computer program product comprising a computer-readable storage media according to the sixth aspect.

[0019] With embodiments of the present disclosure, a DCI configuration parameter can be first transmitted to the terminal device, and then the DCI is transmitted to the terminal device. Thus, the terminal device may monitor the transmitted DCI based on the received DCI configuration parameter, which means a flexible DCI monitoring solution and thus can support the DCI monitoring occasion change due to

numerology and scheduling unit size.

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] The above and other features of the present disclosure will become more apparent through detailed explanation on the embodiments as illustrated in the embodiments with reference to the accompanying drawings, throughout which like reference numbers represent same or similar components and wherein:

[0021] Fig. 1 schematically illustrates a flow chart of a method of DCI transmission according to an example embodiment of the present disclosure;

[0022] Fig. 2 schematically illustrates DCI occurrence occasions with different numerologies according to example embodiments of the present disclosure;

[0023] Figs. 3A to 3C schematically illustrate DCI occurrence occasions at different levels according to examples embodiments of the present disclosure;

[0035] Fig. 14 further illustrates a simplified block diagram of an apparatus 1410 that may be embodied as or comprised in a serving node like a base station in a wireless network and an apparatus 1420 that may be embodied as or comprised in a terminal device like UE as described herein.

DETAILED DESCRIPTION OF EMBODIMENTS

[0036] Hereinafter, the solution as provided in the present disclosure will be described in details through embodiments with reference to the accompanying drawings. It should be appreciated that these embodiments are presented only to enable those skilled in the art to better understand and implement the present disclosure, not intended to limit the scope of the present disclosure in any manner.

[0037] In the accompanying drawings, various embodiments of the present disclosure are illustrated in block diagrams, flow charts and other diagrams. Each block in the flowcharts or blocks may represent a module, a program, or a part of code, which contains one or more executable instructions for performing specified logic functions, and in the present disclosure, a dispensable block is illustrated in a dotted line. Besides, although these blocks are illustrated in particular sequences for performing the steps of the methods, as a matter of fact, they may not necessarily be performed strictly

according to the illustrated sequence. For example, they might be performed in reverse sequence or simultaneously, which is dependent on natures of respective operations. It should also be noted that block diagrams and/or each block in the flowcharts and a combination of thereof may be implemented by a dedicated hardware-based system for performing specified functions/operations or by a combination of dedicated hardware and computer instructions.

[0038] Generally, all terms used in the claims are to be interpreted according to their ordinary meaning in the technical field, unless explicitly defined otherwise herein. All references to "a/an/the/said [element, device, component, means, step, etc.]" are to be interpreted openly as referring to at least one instance of said element, device, component, means, unit, step, etc., without excluding a plurality of such devices, components, means, units, steps, etc., unless explicitly stated otherwise. Besides, the indefinite article "a/an" as used herein does not exclude a plurality of such steps, units, modules, devices, and objects, and etc.

[0039] Additionally, in a context of the present disclosure, a user equipment (UE) may refer to a terminal, a Mobile Terminal (MT), a subscriber station, a portable subscriber station, Mobile Station (MS), or an Access Terminal (AT), and some or all of the functions of the UE, the terminal, the MT, the SS, the portable subscriber station, the MS, or the AT may be included. Furthermore, in the context of the present disclosure, the term "BS" may represent, e.g., a node B (NodeB or NB), an evolved NodeB (eNodeB or eNB), gNB (Node B in NR), a radio header (RH), a remote radio head (RRH), a relay, or a low power node such as a femto, a pico, and so on.

[0040] As mentioned hereinbefore, none of the prior arts can support the DCI monitoring occasion change due to numerology and scheduling unit size. Thus, in the present disclosure, there is proposed a new DCI transmission and receiving solution. In the proposed solution, a DCI configuration parameter can be first transmitted to the terminal device, and then the DCI is transmitted to the terminal device. Thus, the terminal device may monitor the DCI based on the received DCI configuration parameter, which means a flexible DCI monitoring solution and thus can support the DCI monitoring occasion change due to numerology and scheduling unit size.

[0041] Hereinafter, reference will be made to Figs. 1 to 14 to describe the DCI transmission and receiving solution.

[0042] Fig.1 schematically illustrates a flow chart of a method 100 of DCI transmission in a wireless communication system according to an embodiment of the present disclosure. The method 100 can be performed at a serving node, for example a BS, like a node B (NodeB or NB).

[0043] As illustrated in Fig. 1, first in step 101, a DCI configuration parameter is transmitted to a terminal device, and the DCI configuration parameter indicates time-frequency resources for a following DCI.

[0044] In an embodiment of the present disclosure, the DCI configuration parameter comprises at least one of: a numerology to be used; a valid duration for the DCI configuration parameter; a duration for a single DCI; and DCI occurrence occasions.

[0045] In NR system, different numerologies might be used, whereas different numerologies might use different transmission parameters, for example different subcarrier spacings. The different subcarrier spacings mean different symbol lengths. For example, for 15 kHz subcarrier spacing, its symbol will have a time length four times as that for 60 kHz subcarrier spacing, as illustrated in Fig. 2. Thus, the numerology to be used can be used to define a symbol.

[0046] The valid duration for the DCI configuration parameter indicates a duration in which the DCI configuration parameter is valid. The valid duration can be a number of symbols (for example, numerology specific) or a number of frames (for example numerology common). In an embodiment of the present disclosure, the values of the start of the valid duration can be an absolute value with respect to the reference numerology. For example, if the configuration signaling is received in symbol 7 of the subframe 2 of frame 6, the starting can be defined as symbol 0 of subframe 0 of frame 6. The definition of the absolute value can be predetermined or configured by a high layer signaling like RRC signaling. In another embodiment of the present disclosure, the first symbol carrying the configuration signaling can be used as the start of the valid duration no matter whether the configuration signaling is configured by DCI or by a RRC signaling.

[0047] The duration for a single DCI indicates the length of the DCI, it can be a number of symbols. Thus, parameter may indicate the length of DCI. It is also possible to use a predetermined length and in such a case, this parameter can be omitted.

[0048] DCI occurrence occasions indicate occasions at which DCI occurs in frames. In an embodiment of the present disclosure, the DCI occurrence occasions can be at a slot level, at subframe level (multi-slot), or at symbol level, as illustrated in Figs. 3A to 3C respectively.

[0049] The DCI occurrence occasions can be periodic. That is to say, the DCI monitoring will be performed periodically, for example every a predetermined number of slots, every a predetermined number of symbols. Fig 3A and Fig. 3B illustrate two examples of periodic DCI occurrence occasions. In Fig. 3A, the DCI occurrence occasions are per slot; in other words, the DCI monitoring is performed every slot, like in slots 0, 1,…,. In Fig. 3B, the DCI occurrence occasions are per multi-slot (e.g., 2 slots, a subframe); that is to say, the DCI monitoring can be performed per multi-slot. In such a case, the DCI occurrence occasions can be indicated by the periodicity and an offset of the DCI occurrence. The periodicity can be, for example, a predetermined number of symbols, slots, or frames.

[0050] Alternatively, the DCI occurrence occasions can also be aperiodic. Fig. 3C illustrates an aperiodic DCI occurrence occasion. In Fig. 3C, the DCI occurrence occasions are per symbol but aperiodic. In such a case, it may predefine a set of possible aperiodic patterns in specification or pre-configure the possible set of aperiodic patterns by a higher layer signaling. In the set of aperiodic patterns, each aperiodic pattern contains one or more symbols within a valid duration. In such a way, the network can inform the aperiodic pattern index to the terminal device in DCI configuration parameter.

[0051] It should be noticed that although the DCI occurrence occasions per slot and multi-slot in Fig.3A and 3B are periodic and the DCI occurrence occasions per symbol in Fig.3C is aperiodic, the present disclosure is not limited thereto. In fact, in each of the DCI occurrence occasions per slot, per multi-slot, per symbol, the DCI occurrence occasions can be periodic or aperiodic.

[0052] As another alternative, the DCI occurrence occasions can be a combination of periodic and aperiodic occasions. In other word, in a time period, it contains an aperiodic pattern including one or more symbols but the aperiodic pattern will repeat by the time period in the valid duration. In such a case, the DCI occurrence occasions can be indicated by the periodicity and the aperiodic pattern.

[0053] In another embodiment of the present disclosure, the DCI configuration parameter may comprise at least one of: frequency domain resource unit; and frequency hopping pattern.

[0054] The frequency domain resource unit indicates the resource unit to be used for DCI in the frequency domain, it could be a control channel element (CCE), a subband, a physical resource block (PRB), or physical resource group (REG). In addition, the frequency domain resource unit can be numerology common, which mean the frequency domain resource unit is same for all numerologies, or numerology specific, which mean that different numerologies might use different frequency domain resource units.

[0055] The frequency hopping pattern indicates a pattern in which the frequency hopping is used. This parameter is required when the frequency hopping pattern is used. An explicit signaling can be used to indicate the frequency resource in each DCI occurrence occasion. The hopping pattern can be a predetermined pattern which is known at both network and the terminal device, or a pattern configured by the network. The hopping pattern can be used to calculate the frequency resource position.

[0056] Figs. 4A to 4C illustrate use of frequency hopping in different DCI occurrence occasions according to embodiments of the present disclosure. DCI occurrence occasions as illustrated in Fig.4A to Fig. 4C are same with those in Fig. 3A to 3C in the time domain but in the frequency domain, the frequency hopping is used for the DCI occurrence occasions. It should be noticed that although the DCI occurrence occasions per slot and per multi-slot in Fig.4A and 4B are periodic and the DCI occurrence occasions per symbol in Fig.4C is aperiodic, the present disclosure is not limited thereto. In fact, in each of the DCI occurrence occasions per slot, per multi-slot, per symbol, the DCI occurrence occasions can be periodic or aperiodic.

[0057] Reference is made back to Fig. 1, in step 102, the DCI can be transmitted to the terminal device. With the DCI configuration parameter, the terminal device may learn the time-frequency resource for the DCI from the DCI configuration parameter and monitor the DCI within the time-frequency resource.

[0058] In an embodiment of the present disclosure, the DCI configuration parameter can be transmitted to the terminal device by a higher layer signaling like a

RRC signaling. That is to say, in the two-stage solution, for the first stage, the higher layer signaling can be used to transmit the DCI configuration indicating the time-frequency resource for the following DCI in the second stage.

[0059] In another embodiment of the present disclosure, the DCI configuration parameter can be transmitted to the terminal device dynamically by another DCI. In such a case, a first DCI is used to transmit the DCI configuration parameter for the following DCI. The actual data scheduling related information is located in the following DCI.

[0060] In addition, considering the payload size of the first DCI, it is also possible to use a combination of DCI and high layer signaling. That is to say, a part of DCI configuration parameter can be transmitted by DCI and another part of the DCI configuration parameter can be transmitted by a high layer signaling.

[0061] In the two stage DCI solution, the first DCI can be cell specific, beam specific, TRP specific, common for a UE group or UE specific. In an embodiment of the present disclosure, the DCI can be scrambled with a specific RNTI. The periodicity of the first DCI can be larger than the second DCI. The occurrence occasions of the first DCI can predetermined or configured by a higher layer signaling such a RRC signaling. The first DCI can be located in common search space. Or alternative, the first DCI can also be located in UE specific search space.

[0062] It shall be noted that there may be a valid duration for the DCI configuration parameter but there is no any restriction on DCI configuration parameter and scheduling unit size. For example, with slot-level DCI monitoring configuration, UE can also be configured with a scheduling unit starting and ending from the symbol boundary rather than a slot boundary. In such a case, the remaining blank symbols can be allocated to other UE with symbol level DCI monitoring configuration. Or alternatively, the remaining blank symbols can also be allocated to other UE with slot-level or multi-slot level DCI configuration.

[0063] In a further embodiment of the present disclosure, the DCI configuration parameter may comprise at least two sets of parameters, from which the terminal device can select a set of parameters based on its requested traffic types. In other words, DCI monitoring can be adapted at UE side after resource requirement by means of random access procedure/scheduling request (SR).

[0064] After a random access procedure, the terminal device starts DL/UL transmission/reception with the eNB. Thus, the DCI monitoring behavior can be based on the reason for random access. If URLLC scheduling request is the reason for random access, the DCI monitoring should be more frequent. If eMBB scheduling request is the reason for random access, the DCI monitoring can be less frequent. By providing two or more different sets of DCI configuration parameters predefined or configured by RRC signaling, the terminal device could choose the suitable parameter set based on its request traffic type. In such a way, it is possible for UE to perform DCI monitoring based on its required traffic type.

[0065] In another aspect of the present disclosure, there is also provided another two-DCI solution for different traffic type multiplexing. In these solutions, two DCIs are used, one of which can be called as prepositive control region (DCI), the other of which can be called as postpostive control region (DCI). The prepositive control region can be used to indicate resource that is allocated to a first traffic type (such as eMBB traffic) but is to be occupied by a second traffic type (such as URLLC traffic), the postpositive control region can be used to indicate resource that allocated to a first traffic type (such as eMBB traffic) but was already occupied by the second traffic type (such as abrupt URLLC traffic). Hereinafter, the URLLC traffic and the eMBB traffic will be taken as examples of different traffic types to describe the two-DCI solution; however, those skilled in the art can readily know that the present disclosure is not limited thereto.

[0066] In an embodiment of the present disclosure, the prepositive control region can include at least one of following fields:

- a field to indicate puncture or rate-matching around some time-frequency resource in a following pattern of time-frequency resource;
- a field to schedule on a following pattern of time-frequency resource (e.g. can be contiguous or non-contiguous symbols/frequency bands);
- a field to indicate re-transmission of previous punctured part;
- a field to indicate the end of one transmission block.

[0067] In an embodiment of the present disclosure, the postpositive region can include at least one of following fields:

- a field to indicate puncture or no puncture of some time-frequency

resources in the previous pattern of time-frequency resource

- a field to indicate re-transmission or no re-transmission of previous punctured part
- a field to indicate the end of one transmission block

[0068] It shall be noted that patterns of time-frequency resource in prepositive and postpositive control regions can be complementary. For example, the two patterns can compose a whole time-frequency resource of a region (subframe). Alternatively, the two patterns can be also partially overlapped.

[0069] Fig. 5A illustrates a two-DCI solution for different traffic type multiplexing according to an embodiment of the present disclosure. The resource of eMBB can be split into two parts as illustrated in Fig. 5, the first one is to be scheduled by the prepostive control region and the other one is to be scheduled by the postpostive control region. For some resources such as first several symbols, the scheduling of URLLC can be known, thus the eMBB UE can be indicated of rate-matching or puncture for the occupied resource in the prepositive control region if it is occupied by the URLLC. While, for some resources, for example when the URLLC occurs abruptly, the scheduling of URLLC cannot be known in the prepositive control region, and thus the eMBB UE can be indicated to puncture for the occupied resources in the postpositive control region.

[0070] In Fig. 5A, it is shown that the control regions and the data regions are multiplexed in the time domain. In another embodiment of the present disclosure, the control regions and data regions can be multiplexed in the frequency domain. Fig. 5B illustrates a two-DCI solution for different traffic type multiplexing according to an embodiment of the present disclosure. Fig. 5B is similar with Fig. 5A but differs in that in Fig. 5B, the control regions and data regions are multiplexed in the frequency domain.

[0071] It should also be noted that resource indicated to eMBB UE can be resource occupied by URLLC or resource reserved as empty for forward phase.

[0072] In addition, it shall also be noted that the split resource parts can also be multiplexed in many different ways, which will be described with reference to Fig. 6A to Fig. 7D.

[0073] Fig. 6A illustrates a two-DCI solution according to an embodiment of

the present disclosure, in which the control region and the data region are multiplexed in TDM and two split parts are multiplexed in time domain multiplexing (TDM). Fig. 6A is substantially same as that in Fig. 5A, and in the two DCI solution, the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region in TDM.

[0074] Fig. 6B illustrates another two-DCI solution according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in TDM and the two split parts are multiplexed in TDM by symbols. Compared with that illustrated in Fig. 6A, in Fig. 6B, the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region also in TDM but by symbol; that is to say, in Fig. 6B, the symbols belonging to each part are not continuous.

[0075] Fig. 6C illustrates a further two-DCI solution according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in TDM and the two split parts are multiplexed in frequency domain multiplexing (FDM). Different from that illustrated in Fig. 6A and Fig. 6B, in Fig. 6C the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region in FDM, i.e., they respectively occupy different frequency domain resources.

[0076] Fig. 6D illustrates a further two-DCI solution according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in TDM and the two split parts are multiplexed in TDM and frequency domain multiplexing (FDM). As illustrated in Fig. 6D, the part scheduled by the prepostive control region is multiplexed with the part scheduled by the postpostive control region in a combination of TDM and FDM.

[0077] Figs. 7A to 7D illustrate two-DCI solutions according to an embodiment of the present disclosure, wherein the control region and the data region are multiplexed in FDM and two split parts are multiplexed in different manners respectively. In Fig. 7A, the two split parts are multiplexed in TDM; in Fig. 7B, the two split parts are multiplexed in TDM by symbol; in Fig. 7C, the two split parts are multiplexed in FDM; and Fig. 7D, the two split parts are multiplexed in TDM and FDM.

[0078] The two split parts can be decoded in any suitable manner. In an embodiment of the present disclosure, the two split part can be separately decoded. In another embodiment of the present disclosure, the two parts can be cascaded to decode, i.e. when UE receives the two parts, then it decodes them immediately or it decodes them after UE receiving the postpositive control region.

[0079] In a further embodiment of the present disclosure, the resource for eMBB can be split for several parts, wherein first parts are to be scheduled by the preposition control region and seconds parts are to be scheduled by the postpostive control region. The several parts are further divided into two segments in the time domain, i.e., segment 1 and segment 2. For some resources such as first several symbols, the scheduling of URLLC can be known, thus the eMBB UE can be indicated of rate-matching or puncture for the occupied resource in the prepositive control region if it is occupied by the URLLC. While, for some resources, for example when the URLLC occurs abruptly, the scheduling of URLLC cannot be known in the prepositive control region, and thus the eMBB UE can be indicated to puncturing or not puncturing for the occupied resources in the postpositive control region. For some resources in the second segment, they may be reserved for re-transmission or be punctured part of transmission in the first segment. This punctured part can be for example a subset of the first segment, and the remaining of the first segment can be used for new transmission. Fig. 8 illustrates a two-DCI solution wherein there is no re-transmission in the second segment; while Fig. 9 illustrates a two-DCI solution wherein, in the second segment, there is a re-transmission of punctured part of the first segment as indicated by blocks filled with cross lines.

[0080] In addition, similarly to solutions as illustrate in Figs. 6A to 7D, the first parts and the second parts can be multiplexed in time and/or frequency domain. Moreover, these parts can be cascaded to decode, i.e. when UE receives the two parts, then it decodes them immediately or it decodes them after UE receiving the postpositive control region.

[0081] In a further aspect of the present disclosure, one transmission block can also be split into several parts. The first part can be scheduled by, for example, prepositive control region, and the second part can be scheduled by, for example, postpositive control region. The UE can decode after receiving the whole transmission

block. The end of the transmission can be indicated in a control region. For example, UE may obtain frequency and time domain mapping for data, then obtain the mapping over resources preempted by URLLC, and after that it decodes the block.

[0082] In another embodiment of the present disclosure, preemption of URLLC can be indicated implicitly. For example, it is possible to use tracking RS to implicitly indicate preemption of URLLC. For example, if the tracking RS is interrupted on some symbols, this means these symbols are occupied by URLLC, and thus this can be used to indicate preemption of URLLC.

[0083] In a further embodiment of the present disclosure, DCI can be cascaded with K-stage DCI. For example, a first stage DCI contains resource allocation field; the second stage DCI contains information of MCS and other information for data transmission (which may also contain detailed information of resource allocation). In such a case, the UE can cascades the two-stage DCI for control information.

[0084] In addition, the first stage DCI can be shared by different UEs, e.g. URLLC UE and eMBB UE, as illustrated in Fig. 10. The URLLC UE could obtain the shared first stage DCI and the second stage DCI for control and/or data transmission. The eMBB UE could obtain the shared first stage DCI for the resource allocation for puncturing or rate-matching. The shared common DCI can be scrambled with shared RNTI, e.g. a resource allocation RNTI calculated considering the resource index.

[0085] In a further embodiment of the present disclosure, the first DCI can include full scheduling information; while the second DCI may include indication of the resource occupied by URLLC or not. In addition, the second DCI can be reduced for some cases. For example, when no MCS needed, the second DCI can be omitted. If the resource is semi-statically reserved for URLLC and known to eMBB UE, the resource allocation is no needed and the second DCI can be reduced as well. In another case, if the resource is known by eMBB UE, and the time-frequency of remaining resource is fixed, then only an indication is needed in the second DCI, which indicates whether the time-frequency resource is occupied. If yes, the resource is for re-transmission or just keeps punctured; if not, the resource will be used for new data transmission.

[0086] It shall be noted that although the aspects and embodiments are described separately, they can also be combined together to achieve more benefits.

[0087] Fig. 11 further schematically illustrates a flow chart of method for DCI receiving according to an example embodiment of the present disclosure. The method 1100 can be implemented at a terminal device, for example UE, or other like terminal devices.

[0088] As illustrated in Fig. 11, the method starts from step 11, in which the terminal device like UE receiving a DCI configuration parameter. The DCI configuration parameter indicates the time-frequency resources for the following DCI.

[0089] In an embodiment of the present disclosure, the DCI configuration parameter may comprise at least one of: numerology to be used; a valid duration for the DCI configuration parameters; a duration for a single DCI; DCI occurrence occasions.

[0090] In another embodiment of the present disclosure, the DCI configuration parameter may comprise at least one of: a frequency domain resource unit; and a frequency hopping pattern.

[0091] In a further embodiment of the present disclosure, the receiving DCI configuration parameter may comprise receiving the DCI configuration parameter in a higher layer signaling.

[0092] In a further embodiment of the present disclosure, the receiving DCI configuration parameter may comprise receiving the DCI configuration parameter in another DCI.

[0093] In addition, considering the payload size of the first DCI, it is also possible to use a combination of DCI and high layer signaling. That is to say, a part of DCI configuration parameter can be received by a first DCI and another part of the DCI configuration parameter can be transmitted by a high layer signaling.

[0094] The first DCI can be cell specific, beam specific, TRP specific, common for a UE group or UE specific. In an embodiment of the present disclosure, the DCI can be scrambled with a specific RNTI. The periodicity of the first DCI can be larger than the second DCI. The occurrence occasions of the first DCI can predetermined or configured by a higher layer signaling such a RRC signaling. The first DCI can be located in common search space. . Or alternative, the first DCI can also be located in UE specific search space.

[0095] Next, in step 1102, DCI is received within time-frequency resources indicated by the DCI configuration parameter at the terminal device. That is to say, at

the terminal device, the terminal device may perform DCI monitoring based on the DCI configuration parameter, which means a flexible DCI monitoring solution and thus can support the DCI monitoring occasion change due to numerology and scheduling unit size.

[0096] In a still further embodiment of the present disclosure, the DCI configuration parameter comprises at least two sets of parameters. In such a case, further in step 1103, the UE may select a set of parameters based on its requested traffic types. In other words, DCI monitoring can be adapted at UE side after resource requirement by means of random access procedure/SR.

[0097] After random access procedure, the terminal device starts DL/UL transmission/reception with the eNB. Thus, the DCI monitoring behavior can be based on the reason for random access. If URLLC scheduling request is the reason for random access, the DCI monitoring should be more frequent. If eMBB scheduling request is the reason for random access, the DCI monitoring can be less frequent. By providing two or more different sets of DCI configuration parameters predefined or configured by RRC signaling, the terminal device could choose the suitable parameter set based on its request traffic type. In such a way, it is possible for UE to perform DCI monitoring based on its required traffic type.

[0098] Besides, in the present disclosure, there are also provided apparatuses for DCI transmission and receiving at the serving node and terminal device in a wireless communication system respectively, which will be described next with reference to Figs. 12 and 13.

[0099] Fig. 12 schematically illustrates a block diagram of an apparatus 1200 for DCI transmission in a wireless communication system according to an embodiment of the present disclosure. The apparatus 1200 can be implemented at a serving node, for example a BS, like a node B (NodeB or NB).

[00100] As illustrated in Fig. 12, the apparatus 1200 may comprise a parameter transmission module 1201 and a DCI transmission module 1202. The parameter transmission module 1201 can be configured to transmit a DCI configuration parameter to a terminal device. The DCI transmission module 1202 can be configured to transmit DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

[00101] In an embodiment of the present disclosure, the sequence position information may comprise any of: a numerology to be used; a valid duration for the DCI configuration parameters; a duration for a single DCI; DCI occurrence occasions; a frequency domain resource unit; and a frequency hopping pattern.

[00102] In another embodiment of the present disclosure, the parameter transmission module 1201 may be configured to transmit the DCI configuration parameter to the terminal device by a higher layer signaling.

[00103] In a further embodiment of the present disclosure, the parameter transmission module 1201 is configured to transmit the DCI configuration parameter to the terminal device dynamically by another DCI.

[00104] In a still further embodiment of the present disclosure, the another DCI may have a larger periodicity than the DCI.

[00105] In a yet further embodiment of the present disclosure, the DCI configuration parameter may comprise at least two sets of parameters, from which the terminal device can select a set of parameters based on its requested traffic type.

[00106] Fig. 13 further schematically illustrates a block diagram of an apparatus 1300 for DCI receiving in a wireless communication system according to an embodiment of the present disclosure. The apparatus 1300 can be implemented at a terminal device, for example UE, or other like terminal devices.

[00107] As illustrated in Fig. 13, the apparatus 1300 may include a parameter receiving module 1301 and a DCI receiving module 1302. The parameter receiving module 1301 may be configured to receive DCI configuration parameter at a terminal device. The DCI receiving module 1302 can be configured to receive DCI within time-frequency resources indicated by the DCI configuration parameter at a terminal device.

[00108] In an embodiment of the present disclosure, the sequence position information may comprise any of: a numerology to be used; a valid duration for the DCI configuration parameters; a duration for a single DCI; DCI occurrence occasions; a frequency domain resource unit; and a frequency hopping pattern.

[00109] In another embodiment of the present disclosure, the parameter receiving module 1301 may be further configured to receive the DCI configuration parameter in a higher layer signaling.

[00110] In another embodiment of the present disclosure, the parameter receiving module 1301 may be further configured to receive the DCI configuration parameter in another DCI.

[00111] In a still further embodiment of the present disclosure, the another DCI may have a larger periodicity than the DCI.

[00112] In a yet further embodiment of the present disclosure, the DCI configuration parameter may comprise at least two sets of parameters. In such a case, the apparatus 1300 may further comprise a parameter set selection module 1303. The apparatus 1300 may be configured to select a set of parameters based on a traffic type requested by the terminal device and wherein the time-frequency resources are those indicated by the selected set of parameters

[00113] Hereinbefore, the apparatuses 1200 and 1300 are described with reference to Figs. 12 and 13. It is noted that the apparatuses 1200 and 1300 may be configured to implement functionalities as described with reference to Figs. 1 to 11. Therefore, for details about the operations of modules in these apparatuses, one may refer to those descriptions made with respect to the respective steps of the methods with reference to Figs. 1 to 11.

[00114] It is further noted that the components of the apparatuses 1200 and 1300 may be embodied in hardware, software, firmware, and/or any combination thereof. For example, the components of apparatuses 1200 and 1300 may be respectively implemented by a circuit, a processor or any other appropriate selection device.

[00115] Those skilled in the art will appreciate that the aforesaid examples are only for illustration not limitation and the present disclosure is not limited thereto; one can readily conceive many variations, additions, deletions and modifications from the teaching provided herein and all these variations, additions, deletions and modifications fall the protection scope of the present disclosure.

[00116] In addition, in some embodiment of the present disclosure, apparatuses 1200 and 1300 may comprise at least one processor. The at least one processor suitable for use with embodiments of the present disclosure may include, by way of example, both general and special purpose processors already known or developed in the future. Apparatuses 1200 and 1300 may further comprise at least one memory.

The at least one memory may include, for example, semiconductor memory devices, e.g., RAM, ROM, EPROM, EEPROM, and flash memory devices. The at least one memory may be used to store program of computer executable instructions. The program can be written in any high-level and/or low-level compliable or interpretable programming languages. In accordance with embodiments, the computer executable instructions may be configured, with the at least one processor, to cause apparatuses 1200 and 1300 to at least perform operations according to the method as discussed with reference to Figs. 1 to 11 respectively.

[00117] Fig. 14 further illustrates a simplified block diagram of an apparatus 1410 that may be embodied as or comprised in a serving node like a base station in a wireless network and an apparatus 1420 that may be embodied as or comprised in a terminal device like UE as described herein.

[00118] The apparatus 1410 comprises at least one processor 1411, such as a data processor (DP) and at least one memory (MEM) 1412 coupled to the processor 1411. The apparatus 1410 may further comprise a transmitter TX and receiver RX 1413 coupled to the processor 1411, which may be operable to communicatively connect to the apparatus 1420. The MEM 1412 stores a program (PROG) 1414. The PROG 1414 may include instructions that, when executed on the associated processor 1411, enable the apparatus 1410 to operate in accordance with embodiments of the present disclosure, for example the method 100. A combination of the at least one processor 1411 and the at least one MEM 1412 may form processing means 1415 adapted to implement various embodiments of the present disclosure.

[00119] The apparatus 1420 comprises at least one processor 1421, such as a DP, and at least one MEM 1422 coupled to the processor 1421. The apparatus 1420 may further comprise a suitable TX/ RX 1423 coupled to the processor 1421, which may be operable for wireless communication with the apparatus 1410. The MEM 1422 stores a PROG 1424. The PROG 1424 may include instructions that, when executed on the associated processor 1421, enable the apparatus 1420 to operate in accordance with the embodiments of the present disclosure, for example to perform the method 1100. A combination of the at least one processor 1421 and the at least one MEM 1422 may form processing means 1425 adapted to implement various embodiments of the present disclosure.

[00120] Various embodiments of the present disclosure may be implemented by computer program executable by one or more of the processors 1411, 1421, software, firmware, hardware or in a combination thereof.

[00121] The MEMs 1412 and 1422 may be of any type suitable to the local technical environment and may be implemented using any suitable data storage technology, such as semiconductor based memory devices, magnetic memory devices and systems, optical memory devices and systems, fixed memory and removable memory, as non-limiting examples.

[00122] The processors 1411 and 1421 may be of any type suitable to the local technical environment, and may include one or more of general purpose computers, special purpose computers, microprocessors, digital signal processors DSPs and processors based on multicore processor architecture, as non-limiting examples.

[00123] In addition, the present disclosure may also provide a carrier containing the computer program as mentioned above, wherein the carrier is one of an electronic signal, optical signal, radio signal, or computer readable storage medium. The computer readable storage medium can be, for example, an optical compact disk or an electronic memory device like a RAM (random access memory), a ROM (read only memory), Flash memory, magnetic tape, CD-ROM, DVD, Blue-ray disc and the like.

[00124] The techniques described herein may be implemented by various means so that an apparatus implementing one or more functions of a corresponding apparatus described with one embodiment comprises not only prior art means, but also means for implementing the one or more functions of the corresponding apparatus described with the embodiment and it may comprise separate means for each separate function, or means that may be configured to perform two or more functions. For example, these techniques may be implemented in hardware (one or more apparatuses), firmware (one or more apparatuses), software (one or more modules), or combinations thereof. For a firmware or software, implementation may be made through modules (e.g., procedures, functions, and so on) that perform the functions described herein.

[00125] Exemplary embodiments herein have been described above with reference to block diagrams and flowchart illustrations of methods and apparatuses. It will be understood that each block of the block diagrams and flowchart illustrations, and combinations of blocks in the block diagrams and flowchart illustrations, respectively,

can be implemented by various means including computer program instructions. These computer program instructions may be loaded onto a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions which execute on the computer or other programmable data processing apparatus create means for implementing the functions specified in the flowchart block or blocks.

[00126] While this specification contains many specific implementation details, these should not be construed as limitations on the scope of any implementation or of what may be claimed, but rather as descriptions of features that may be specific to particular embodiments of particular implementations. Certain features that are described in this specification in the context of separate embodiments can also be implemented in combination in a single embodiment. Conversely, various features that are described in the context of a single embodiment can also be implemented in multiple embodiments separately or in any suitable sub-combination. Moreover, although features may be described above as acting in certain combinations and even initially claimed as such, one or more features from a claimed combination can in some cases be excised from the combination, and the claimed combination may be directed to a sub-combination or variation of a sub-combination.

[00127] It will be obvious to a person skilled in the art that, as the technology advances, the inventive concept can be implemented in various ways. The above described embodiments are given for describing rather than limiting the disclosure, and it is to be understood that modifications and variations may be resorted to without departing from the spirit and scope of the disclosure as those skilled in the art readily understand. Such modifications and variations are considered to be within the scope of the disclosure and the appended claims. The protection scope of the disclosure is defined by the accompanying claims.

WHAT IS CLAIMED IS:

1. A method of downlink control information (DCI) transmission in a wireless communication system, the method comprising:

transmitting a DCI configuration parameter to a terminal device; and

transmitting DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

2. The method of Claim 1, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameter;

a duration for a single DCI; and

DCI occurrence occasions.

3. The method of Claim 1 or 2, wherein the DCI configuration parameter comprises at least one of:

a frequency domain resource unit; and

a frequency hopping pattern.

4. The method of any of Claims 1 to 3, wherein the transmitting DCI configuration parameter to a terminal device comprises transmitting the DCI configuration parameter to the terminal device by a higher layer signaling.

5. The method of any of Claims 1 to 4, wherein the transmitting DCI configuration parameter to a terminal device comprises transmitting the DCI configuration parameter to the terminal device dynamically by another DCI.

6. The method of Claim 5, wherein the another DCI has a larger periodicity than the DCI.

7. The method of any of Claims 1 to 6, wherein the DCI configuration parameter comprises at least two sets of parameters, from which the terminal device can select a

set of parameters based on its requested traffic type.

8. A method of downlink control information (DCI) receiving in a wireless communication system, the method comprising:

receiving a DCI configuration parameter at a terminal device; and

receiving DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

9. The method of Claim 8, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameters;

a duration for a single DCI;

DCI occurrence occasions;

a frequency domain resource unit; and

a frequency hopping pattern.

10. The method of Claim 8 or 9, wherein the receiving DCI configuration parameter comprises receiving the DCI configuration parameter in a higher layer signaling.

11. The method of any Claims 8 to 10, wherein the receiving DCI configuration parameter comprises receiving the DCI configuration parameter in another DCI.

12. The method of Claim 11, wherein the another DCI has a larger periodicity than the DCI.

13. The method of any of Claims 8 to 12, wherein the DCI configuration parameter comprises at least two sets of parameters, wherein the method further comprises selecting a set of parameters based on a traffic type requested by the terminal device and wherein the time-frequency resources are those indicated by the selected set of parameters.

14. An apparatus of downlink control information (DCI) transmission in a wireless communication system, the apparatus comprising:

a parameter transmission module configured to transmit a DCI configuration parameter to a terminal device; and

a DCI transmission module configured to transmit DCI to the terminal device, wherein the DCI configuration parameter indicates time-frequency resources for the DCI.

15. The apparatus of Claim 14, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameter;

a duration for a single DCI;

DCI occurrence occasions;

a frequency domain resource unit; and

a frequency hopping pattern .

16. The apparatus of Claim 14 or 15, wherein the parameter transmission module is further configured to transmit the DCI configuration parameter to the terminal device by a higher layer signaling.

17. The apparatus of any of Claims 14 to 16, wherein the parameter transmission module is further configured to transmit the DCI configuration parameter to the terminal device dynamically by another DCI.

18. The apparatus of Claim 17, wherein the another DCI has a larger periodicity than the DCI.

19. The apparatus of any of Claims 14 to 18, wherein the DCI configuration parameter comprises at least two sets of parameters, from which the terminal device can select a set of parameters based on its requested traffic type.

20. An apparatus of downlink control information (DCI) receiving in a wireless

communication system, the apparatus comprising:

a parameter receiving module configured to receive DCI configuration parameter at a terminal device; and

a DCI receiving module, configured to receive DCI within time-frequency resources indicated by the DCI configuration parameter at the terminal device.

21. The apparatus of Claim 20, wherein the DCI configuration parameter comprises at least one of:

a numerology to be used;

a valid duration for the DCI configuration parameters;

a duration for a single DCI;

DCI occurrence occasions;

a frequency domain resource unit; and

a frequency hopping pattern .

22. The apparatus of Claim 20 or 21, wherein the parameter receiving module is further configured to receive the DCI configuration parameter in a higher layer signaling.

23. The apparatus of any of Claims 20 to 22, wherein the parameter receiving module is further configured to receive the DCI configuration parameter in another DCI.

24. The apparatus of Claim 23, wherein the another DCI has a larger periodicity than the DCI.

25. The apparatus of any of Claims 20 to 24, wherein the DCI configuration parameter comprises at least two sets of parameters, wherein the apparatus further comprises a parameter set selection module, configured to select a set of parameters based on a traffic type requested by the terminal device and wherein the time-frequency resources are those indicated by the selected set of parameters.

(54) Title: METHODS AND MACHINE TYPE COMMUNICATION, MTC, DEVICE, IMPLEMENTING PAGING PROCEDURES FOR REDUCED BANDWITH MTC DEVICES

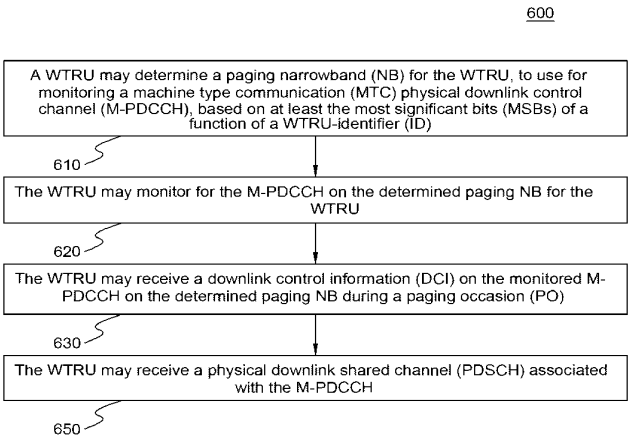

FIG. 6

(57) Abstract: Methods for paging for reduced bandwidth wireless transmit/receive units, WTRUs, in machine type communication, MTC, are provided. A WTRU determines (610) a paging narrowband, NB, for the WTRU, to use for monitoring an MTC physical downlink control channel, M-PDCCH, based on at least the most significant bits, MSBs, of a function of a WTRU-identifier, WTRU-ID. The WTRU monitors (620) for the M-PDCCH on the determined paging NB for the WTRU. The WTRU then receives (630) a downlink control information, DCI, on the monitored M-PDCCH on the determined paging NB during a paging occasion, PO.The WTRU then receives (650) a physical downlink shared channel, PDSCH, associated with the M-PDCCH. Alternatively, the WTRU monitors (420) the M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH has a starting enahnced control channel element, ECCE, index for a WTRU group containing the WTR, and wherein the M-PDCCH includes (430) the DCI.

METHODS AND MACHINE TYPE COMMUNICATION, MTC, DEVICE, IMPLEMENTING PAGING PROCEDURES FOR REDUCED BANDWITH MTC DEVICES

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Application No. 62/250,803 filed November 4, 2015, U.S. Provisional Application No. 62/290,790 filed February 3, 2016, and U.S. Provisional Application 62/308,042 filed March 14, 2016, the contents of which are hereby incorporated by reference herein.

BACKGROUND

[0002] As wireless communication systems such as Long Term Evolution (LTE) systems mature and their network deployment evolve, it may be beneficial for network operators to reduce the cost of the communication network, maintenance needs of the communication network or both. One technique to reduce the cost of the network may be to reduce the channel bandwidth and data rate used to communicate with devices.

[0003] For example, a portion of the channel bandwidth rather than the entire channel bandwidth may be supported by the devices in the network and/or the network itself when communicating with such devices. Current wireless communication systems, for example, LTE, have recently considered a bandwidth reduction for some devices including machine type communication (MTC) devices to some level, for example, 1.4 megahertz (MHz).

SUMMARY

[0004] Methods for paging for reduced bandwidth wireless transmit/receive units (WTRUs) in machine type communication (MTC) are provided. A WTRU may determine a paging narrowband (NB) for the WTRU, to use for monitoring an MTC physical downlink control channel (M-PDCCH), based on at least the most significant bits (MSBs) of a function of a WTRU-identifier (WTRU-ID). The WTRU may monitor for the M-PDCCH on the

determined paging NB for the WTRU. The WTRU may then receive a downlink control information (DCI) on the monitored M-PDCCH on the determined paging NB during a paging occasion (PO). The DCI may include a scrambled cyclic redundancy check (CRC). The CRC may be scrambled with a Paging Radio Network Temporary Identifier (P-RNTI). Also, the WTRU may receive a physical downlink shared channel (PDSCH) associated with the M-PDCCH.

[0005] In an example, the WTRU may determine the paging NB based on at least the 3 MSBs of a function of the WTRU-ID. In another example, the WTRU may determine the paging NB based on at least the 4 MSBs of a function of the WTRU-ID.

[0006] Further, the PDSCH may be scheduled by the DCI. In an example, the DCI may include a paging message. In another example, the DCI may include system information update related information. In a further example, the PDSCH may include a paging message. In an additional example, the PDSCH may include system information update related information.

[0007] In addition, a WTRU may monitor for a M-PDCCH in an M-PDCCH search space. The WTRU may receive an M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH has a starting enhanced control channel element (ECCE) index for the WTRU group containing the WTRU. Further, the WTRU may decode the M-PDCCH, wherein the M-PDCCH includes a DCI. In addition, the WTRU may receive a PDSCH associated with the M-PDCCH.

[0008] Further, the WTRU may receive, decode, and/or demodulate the PDSCH based on the DCI, wherein the PDSCH includes a paging message. The WTRU may then change operations based on the paging message. For example, the WTRU may change from idle mode to connected mode based on the paging message. In an example, the ECCE aggregation level may be 16.

BRIEF DESCRIPTION OF THE DRAWINGS

[0009] A more detailed understanding may be had from the following description, given by way of example in conjunction with the accompanying drawings wherein:

[0010] FIG. 1A is a system diagram of an example communications system in which one or more disclosed embodiments may be implemented;

[0011] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used within the communications system illustrated in FIG. 1A;

[0012] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used within the communications system illustrated in FIG. 1A;

[0013] FIG. 2 is an exemplary timing diagram which illustrates hyper frames and paging within hyper frames;

[0014] FIG. 3 is an exemplary diagram which illustrates WTRU group-specific starting enhanced control channel element (ECCE) indexes;

[0015] FIG. 4 is a diagram of an example flow chart showing a WTRU receiving a machine type communication (MTC) physical downlink control channel (M-PDCCH) with a starting ECCE index based on the WTRU group of the WTRU;

[0016] FIG. 5 is an exemplary diagram which illustrates WTRU group-specific random ECCE ordering;

[0017] FIG. 6 is a diagram of an example flow chart showing a WTRU using a WTRU-ID to determine a paging narrowband (NB) to use for monitoring an M-PDCCH;

[0018] FIG. 7 is a diagram illustrating an example of code-block segment multiplexing in a physical downlink shared channel (PDSCH), which may be scheduled by an associated physical downlink control channel (PDCCH) in a paging occasion (PO); and

[0019] FIG. 8 is a diagram illustrating an example of code-block segments transmitted via multiple PDSCHs, which may be scheduled by an associated PDCCH in a PO.

DETAILED DESCRIPTION

[0020] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, such as voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0021] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, 102d, a radio access network (RAN) 104, a core network 106, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include user equipment (UE), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0022] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to one or more communication networks, such as the core network 106, the Internet 110, and/or the other networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home

Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0023] The base station 114a may be part of the RAN 104, which may also include other base stations and/or network elements (not shown), such as a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In another embodiment, the base station 114a may employ multiple-input multiple-output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0024] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 116, which may be any suitable wireless communication link (for example, radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 116 may be established using any suitable radio access technology (RAT).

[0025] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, such as CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 104 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 116 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0026] In another embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 116 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0027] In other embodiments, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), and the like.

[0028] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, such as a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In another embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet another embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (for example, WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106.

[0029] The RAN 104 may be in communication with the core network 106, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, such as user authentication. Although not shown in

FIG. 1A, it will be appreciated that the RAN 104 and/or the core network 106 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 104 or a different RAT. For example, in addition to being connected to the RAN 104, which may be utilizing an E-UTRA radio technology, the core network 106 may also be in communication with another RAN (not shown) employing a GSM radio technology.

[0030] The core network 106 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, such as the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include another core network connected to one or more RANs, which may employ the same RAT as the RAN 104 or a different RAT.

[0031] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0032] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any

sub-combination of the foregoing elements while remaining consistent with an embodiment.

[0033] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0034] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (for example, the base station 114a) over the air interface 116. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In another embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet another embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0035] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (for example, multiple

antennas) for transmitting and receiving wireless signals over the air interface 116.

[0036] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, such as UTRA and IEEE 802.11, for example.

[0037] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (for example, a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, such as the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In other embodiments, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, such as on a server or a home computer (not shown).

[0038] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (for example, nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0039] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (for example, longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 116 from a base station (for example, base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0040] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0041] FIG. 1C is a system diagram of the RAN 104 and the core network 106 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 106.

[0042] The RAN 104 may include eNode-Bs 140a, 140b, 140c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 140a, 140b, 140c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 140a, 140b, 140c may implement MIMO technology. Thus, the eNode-B 140a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0043] Each of the eNode-Bs 140a, 140b, 140c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1C, the eNode-Bs 140a, 140b, 140c may communicate with one another over an X2 interface.

[0044] The core network 106 shown in FIG. 1C may include a mobility management entity gateway (MME) 142, a serving gateway 144, and a packet data network (PDN) gateway 146. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0045] The MME 142 may be connected to each of the eNode-Bs 140a, 140b, 140c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 142 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 142 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, such as GSM or WCDMA.

[0046] The serving gateway 144 may be connected to each of the eNode Bs 140a, 140b, 140c in the RAN 104 via the S1 interface. The serving gateway 144 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 144 may also perform other functions, such as anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0047] The serving gateway 144 may also be connected to the PDN gateway 146, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0048] The core network 106 may facilitate communications with other networks. For example, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 106 may include, or may communicate with, an IP gateway (for example, an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 106 and the PSTN 108. In addition, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0049] Other network 112 may further be connected to an IEEE 802.11 based wireless local area network (WLAN) 160. The WLAN 160 may include an access router 165. The access router may contain gateway functionality. The access router 165 may be in communication with a plurality of access points (APs) 170a, 170b. The communication between access router 165 and APs 170a, 170b may be via wired Ethernet (IEEE 802.3 standards), or any type of wireless communication protocol. AP 170a is in wireless communication over an air interface with WTRU 102d.

[0050] As wireless communication systems such as LTE systems mature and their network deployment evolve, it may be beneficial for network operators to reduce the cost of the communication network, maintenance needs of the communication network or both. One technique to reduce the cost of the network may be to reduce the channel bandwidth and data rate used to communicate with devices. For example, a portion of the channel bandwidth rather than the entire channel bandwidth may be supported by the devices in the network and/or the network itself when communicating with such devices. Current wireless communication systems, for example, LTE, have recently considered a bandwidth reduction for some devices including machine type communication (MTC) devices to some level, for example, 1.4 megahertz (MHz). The considered level may enable more compatibility with legacy systems and reduce the time and/or cost of a new design, since, for

example LTE may already support operation with a system bandwidth of 1.4 MHz. Further bandwidth reduction, however, may be desirable for some devices, for example, smart watches and alarms, for example to reduce costs even further. Further reduction of the bandwidth, for example, on the order of 200 kilohertz (kHz), has been suggested. Additional system design may be needed to support operation with a reduced bandwidth which may be less compatible with legacy system operation.

[0051] A reduced bandwidth (BW) WTRU may be a WTRU which may support or may only support a certain limited BW, for example, RF BW or a certain limited number of resource blocks (RBs) in the downlink (DL) and/or uplink (UL), which may be independent of the BW of the eNode-B or cell with which the WTRU may communicate. For example, a reduced BW WTRU, which may also be referred to as a limited BW WTRU, may support or may only support a certain number of RBs, for example, 6 RBs or 1 RB, or a certain BW, for example, 1.4 MHz or 180 kHz, for transmission and/or reception. Such a WTRU may communicate with an eNode-B or cell for which the BW may be larger, for example, 20 MHz or 100 RBs.

[0052] An enhanced machine type communication (eMTC) WTRU may be a limited BW WTRU which may support a first number of RBs and/or a BW of a first bandwidth. A first number may be represented by N1 and a first bandwidth may be represented by B1. N1 may, for example, be 6 and B1 may, for example be 1.4 MHz. In an example, 6 RBs may correspond to a BW of 1.4 MHz. An eMTC WTRU may be used to represent a non-limiting example of a limited BW WTRU. Another WTRU which may be referred to as a narrowband LTE (NB-LTE) or narrowband internet of things (NB-IoT) WTRU may be a limited BW WTRU which may support a second number of RBs and/or a BW of a second bandwidth. A second number may be represented by N2 and a second bandwidth may be represented by B2. N2 may be less than N1. B2 may be less than B1. N2 may, for example, be 1 and B2 may, for example, be 180 kHz. In an example, 1 RB may correspond to a BW of 180 kHz. An NB-LTE WTRU and/or NB-IoT WTRU may be used to represent a non-limiting example of a limited BW WTRU. A narrowband (NB) WTRU may be used to

represent a non-limiting example of a WTRU or limited BW WTRU. WTRU, limited BW WTRU, BW limited WTRU, reduced BW WTRU, limited capability WTRU, low cost-MTC (LC-MTC) WTRU, low-complexity WTRU, MTC WTRU, eMTC WTRU, NB-IoT WTRU, eMTC, NB-IoT, and NB WTRU may be used interchangeably herein. An RB may be a physical RB (PRB). The terms RB and PRB may be used interchangeably herein.

[0053] A limited BW WTRU may use or require special procedures to operate in a portion of the full BW of the cell. Reduced bandwidth, limited bandwidth, and bandwidth limited may be used interchangeably herein. A WTRU which may support the full BW of a cell may be referred to as a full BW WTRU. BW may include a number of RBs and/or a location in a band such as the center of the band.

[0054] A WTRU may at least sometimes communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent, with that of a full BW WTRU and may also at least sometimes, for example, some other times than when operating as a full BW WTRU, communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent, with that of a reduced BW WTRU. For example, a WTRU which may support the full BW of a cell may communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent with that of a reduced BW WTRU at certain times such as when it may be coverage limited or when it may operate in a coverage enhanced mode. A WTRU, such as this example WTRU, may be or may be considered a full BW WTRU at times and/or a reduced BW WTRU at times, for example at other times.

[0055] A WTRU may be or may be considered to be a reduced BW WTRU while it may, may need to, or may intend to behave or operate like, or for example, at least partially like, a reduced BW WTRU. A WTRU that may communicate, for example, with an eNode-B, behave, or operate in a manner which may be consistent, or for example, at least partially consistent with that of a reduced BW WTRU may be or may be considered to be a reduced BW WTRU, for example at least sometimes, such as when the WTRU may

communicate, behave, or operate in a manner which may be consistent, or for example, at least partially consistent, with that of a reduced BW WTRU.

[0056] It should be noted that the terms eNB, eNode-B and cell may be used interchangeably herein. Embodiments and examples described for reduced BW WTRUs may be applied to coverage limited WTRUs and vice versa.

[0057] Coverage limited and reduced BW WTRUs are examples of WTRUs which may use the example methods and procedures described herein. These coverage limited and reduced BW WTRUs are non-limiting examples of such example WTRUs. Application to a WTRU of any kind, with any capabilities, or reduced capabilities may still be consistent with the example methods and procedures described herein.

[0058] The term physical downlink control channel (PDCCH) may be replaced by enhanced PDCCH (EPDCCH), machine type communication (MTC) physical downlink control channel (M-PDCCH), or another DL control channel, and vice versa and still be consistent with the example methods and procedures described herein. The terms component carrier (CC) and serving cell may be used interchangeably herein. The terms WTRU, WTRU medium access control (MAC) entity, and MAC entity may be used interchangeably herein.

[0059] The terms a WTRU, a certain WTRU or certain WTRUs may be replaced by at least a WTRU, at least a certain WTRU or at least certain WTRUs and still be consistent with the example methods and procedures described herein. The phrase intended for may be replaced by at least intended for or intended for at least and still be consistent with the example methods and procedures described herein.

[0060] The example methods and procedures described herein may be described for a random access response (RAR), paging channel (PCH), or physical downlink shared channel (PDSCH) carrying or which may carry a RAR or PCH. These are used as non-limiting examples. RAR may be replaced by PCH or PCH PDSCH and vice versa and still be consistent with the example methods and procedures described herein. The channel or other

contents which may be carried by the PDSCH may be replaced with any channel or contents and still be consistent with the example methods and procedures described herein.

[0061] Example methods and procedures involving coverage enhancement (CE) are disclosed herein. A coverage enhanced WTRU may be a WTRU which may require coverage enhancement or a WTRU which may employ coverage enhancement techniques or may support a CE mode. The terms coverage limited WTRU and coverage enhanced WTRU may be used interchangeably herein. CE may refer to extending or improving coverage, for example for low data rate applications. CE may refer to extending or improving coverage, for example to enable communication with devices with reduced capabilities such as devices employing a single receiver or devices using a reduced bandwidth. CE may refer to extending or improving coverage, for example to enable communication with devices for which communication may be hampered such as indoor devices or devices in basements where penetration losses may impede communication. In at least some examples, CE may involve extending or improving coverage by reducing the data rate. In at least some examples, CE may involve extending or improving coverage by employing repetition techniques. In at least some examples, CE may be used for MTC applications. In at least some examples, CE may be used for NB or NB-IoT applications. The terms CE operation and coverage enhanced operation may be used interchangeably herein.

[0062] A repetitive transmission of a physical channel may be used for CE. The CE level may be determined based on the number of repetitions, for example, that may be needed or used to achieve the intended coverage improvement. The terms repetition number, number of repetitions, repetition level, and CE level may be used interchangeably herein.

[0063] A CE mode may be used with one or more CE levels, or for example, repetition levels. The CE levels or repetition levels supported within a CE mode may be changed dynamically.

[0064] An eMTC WTRU may be for example, a low-cost WTRU. An eMTC WTRU may be for example, a WTRU with limited or reduced

capabilities. Limited or reduced capabilities may include at least one of a limited or reduced BW capability, for example a BW using 6 RBs , low throughput performance, and a single RF chain at the receiver. An eMTC WTRU may be delay tolerant. An eMTC WTRU may be served in an LTE network which may or may not have a system BW larger than the eMTC supportable BW that may for example be a BW of 1.4 MHz.

[0065] An eMTC WTRU may support coverage enhanced operation. For example, two CE modes of operation may be supported such as CE mode-A and CE mode-B. Normal and small CE levels may be supported in CE mode-A, and medium and large CE levels may be supported in CE mode-B. Normal CE may be the same as normal operation or no CE, which may involve for example, no use of repetitions for CE.

[0066] An NB-IoT WTRU may be, for example, a low-cost WTRU. An NB-IoT WTRU may be, for example, a WTRU with limited or reduced capabilities that may, for example, be more limited or reduced more than the capabilities of an eMTC WTRU in at least one aspect. For example an NB-IoT WTRU may support or use a further reduced BW, for example, a BW of 1 RB, that may be smaller than the supportable BW for an eMTC WTRU.

[0067] An NB-IoT WTRU may, or may be intended to, support CE, for example, with up to 20 decibel (dB) CE, with a battery life that may be longer than the intended or expected battery life of an eMTC WTRU. An NB-IoT WTRU may be intended or expected to support a battery life such as 10 years. The population of NB-IoT WTRUs in a cell may be significantly larger than for other types of devices.

[0068] Example methods and procedures of paging are discussed herein. As used herein, paging may refer to network initiated connection setup. As used herein, paging may refer to a mechanism that a network may use to provide information such as system information modification information or warning system information, for example Earthquake and Tsunami Warning System (ETWS) information, to one or more WTRUs that may, for example, employ techniques for battery saving such as discontinuous reception (DRX). In some examples, paging may be used when a WTRU is in idle mode. In other

examples, paging may be used when a WTRU is in connected mode. A WTRU may, for example periodically, monitor a PDCCH for a DL control information (DCI) or DL assignment on a PDCCH masked with a Paging Radio Network Temporary Identifier (P-RNTI), for example in idle mode and/or in connected mode. When a WTRU detects or receives a DCI or DL assignment using a P-RNTI, the WTRU may demodulate the associated or indicated PDSCH RBs and/or may decode a Paging Channel (PCH) that may be carried on an associated or indicated PDSCH. A PDSCH which may carry PCH may be referred to as a PCH PDSCH. The terms paging, paging message, and PCH may be used interchangeably herein. As used herein, the terms downlink control channel, DL control channel for NB WTRU, M-PDCCH, PDCCH, NB PDCCH (NB-PDCCH), internet of things PDCCH (IoT-PDCCH), and NB IoT-PDCCH (NB-IoT-PDCCH) may be used interchangeably.

[0069] The paging frame (PF) and subframe within that PF, for example, the paging occasion (PO), that a WTRU may monitor for the paging channel, for example in idle mode, may be determined based on the WTRU identifier (ID), for example, WTRU_ID or UE_ID, and parameters which may be specified by the network. The parameters may include the Paging Cycle (PC) length, for example in frames, which may be the same as a discontinuous reception (DRX) cycle and another parameter, for example, nB, which together may enable the determination of the number of PF per PC and the number of PO per PF which may be in the cell. The WTRU ID, in an example, may be the WTRU international mobile subscriber identity (IMSI) mod 1024. The terms WTRU ID, WTRU-ID, and WTRU_ID may be used interchangeably herein.

[0070] From the network perspective, there may be multiple PFs per paging cycle and multiple POs within a PF, for example, more than one subframe per paging cycle may carry PDCCH masked with a P-RNTI. Additionally, from the WTRU perspective, a WTRU may monitor a PO per paging cycle, and such a PO may be determined based on the parameters specified herein, which may be provided to the WTRU via system information, dedicated signaling information, and the like. POs may include pages for one

or more specific WTRUs, or they may include system information change pages which may be directed to each of the WTRUs, multiple WTRUs, or all WTRUs. In idle mode, a WTRU may receive pages for reasons such as an incoming call or system information update changes.

[0071] In connected mode, a WTRU may receive pages related to system information change, for example, and the WTRU may not receive WTRU-specific pages such as those that may be used for an incoming call. As such, a WTRU in connected mode may not monitor a specific PO. Additionally, for frequency division duplex (FDD), the PO subframes may be limited to certain subframes such as subframes 0, 4, 5 and 9 and/or for time division duplex (TDD), the PO subframes may be limited to certain subframes such as subframes 0, 1, 5 and 6.

[0072] As used herein, DRX may refer to a WTRU monitoring for DL control signaling or a DL control channel at certain times, for example only at certain times, during a cycle. For example, a WTRU using DRX may monitor for a DL control channel during certain time periods, for example only during certain time periods. During other time periods, the WTRU may switch off at least part of its receiver circuitry and reduce power consumption. A time period may, for example, be a subframe. Example methods for operation using DRX are discussed herein.

[0073] In idle mode, for example, radio resource control (RRC) idle mode and/or evolved packet system (EPS) connection management (ECM) idle mode, a WTRU may monitor for or listen to a paging message to know about one or more of: an incoming call, a system information change, an Earthquake and Tsunami Warning System (ETWS) notification for ETWS capable WTRUs, a commercial mobile alert service (CMAS) notification and an extended access barring (EAB) parameters modification.

[0074] A WTRU may monitor PDCCH for P-RNTI discontinuously, for example to reduce battery consumption when there may be no pages for the WTRU. DRX may be or may include the process of monitoring PDCCH discontinuously. In idle mode, DRX may be or may include the process of

monitoring PDCCH discontinuously for P-RNTI, for example to monitor or listen for a paging message during RRC idle state.

[0075] The terms idle mode, idle state, RRC idle mode, RRC idle state, and RRC_IDLE mode or state may be used interchangeably herein. The terms RRC idle and ECM idle may be used interchangeably herein. DRX may also be enabled and/or used in connected mode. When in connected mode, if DRX is configured, the MAC entity may monitor the PDCCH discontinuously, for example using DRX operation. The terms connected mode, connected state, and RRC_CONNECTED mode or state may be used interchangeably herein.

[0076] Examples of operation in idle mode DRX are discussed herein. A WTRU may use one or more DRX parameters that may be broadcast, for example in a system information block (SIB) such as a SIB2, to determine the PF and/or PO to monitor for paging. The WTRU may, for example, alternatively, use one or more WTRU specific DRX cycle parameters that may be signaled to the WTRU, for example by the MME through non-access stratum (NAS) signaling.

[0077] Table 1 provides examples of DRX parameters including example ranges and an example source of the DRX parameter, for example, an eNode-B or an MME.

Table 1. Example DRX Cycle Parameters.

DRX parameter	Notation	Value Range	Configuring Network Node
WTRU Specific DRX cycle	TWTRU	32, 4, 128 and 256 radio frames where each radio frame may be 10 milliseconds (ms)	MME, for example, via NAS signaling
Cell specific DRX cycle	TCELL	32, 4, 128 and 256 radio frames	eNode-B, for example, via system information such as a SIB2
Number of POs per DRX cycle, for example, DRX cycle across all users in the cell	nB	4T, 2T, T, T/2, T/4, T/8, T/16, T/32 where T may be the DRX cycle of the WTRU, for example, TCELL or the smaller of TWTRU, if provided, and TCELL	eNode-B, for example, via system information such as a SIB2

[0078] The DRX cycle T of a WTRU may indicate the number of radio frames in the paging cycle. A larger value of T may result in less WTRU battery power consumption. A smaller value of T may increase WTRU battery power consumption. A DRX cycle may be cell specific or WTRU specific.

[0079] A DRX cycle provided by an eNode-B may be cell specific and may be provided to at least some, or for example all, WTRUs in a cell. The DRX cycle that may be provided by the eNode-B may be the default paging cycle. A DRX cycle provided by an MME may be WTRU specific. The WTRU may use the smaller of the default paging cycle and the WTRU specific DRX cycle as its DRX or paging cycle. An MME may provide a WTRU specific DRX cycle to a WTRU using NAS signaling, for example as 'WTRU specific DRX cycle'. An MME may provide a WTRU specific DRX cycle to an eNode-B in a PAGING S1 AP message, as 'Paging DRX', for example, for an MME initiated paging message that may be intended for the WTRU.

[0080] The WTRU and/or eNode-B may use the minimum of the default and WTRU specific DRX cycle. For example, T = Min (T_{WTRU}, T_{CELL}) in radio

frames. A WTRU with a DRX cycle of N (for example, 128) radio frames may wake up or may need to wake up every N x frame time (for example, every 1.28 seconds for a frame time of 10 ms) and look for a paging message.

[0081] The parameter nB may indicate the number of paging occasions or POs in a cell specific DRX cycle. The parameter may be cell specific. Configuration of the nB value may depend on the paging capacity that may be desired or used in a cell. A larger value of nB may be used, for example to increase paging capacity. A smaller value of nB may be used, for example for a smaller paging capacity.

[0082] The eNode-B and/or WTRU may calculate the WTRU's PFs according to the following relation: a PF is given by the following equation or occurs when SFN mod T = (T div N)*(WTRU_ID mod N), where N = min (T, nB) and div may represent division. The WTRU specific PO within the PF may be determined from a set of paging subframes. The set may be a function of predefined allowed subframes for paging and/or the number of POs per PF which may be a function of at least nB and/or T. The system frame number (SFN) may have a range of values such as 0 through 1023.

[0083] Examples of connected mode DRX are discussed herein. In connected mode, a PF and PO may be determined in a similar manner as in idle mode. The DRX cycle parameters may be different for idle and connected modes. A WTRU may monitor a PO, for example, any PO, in a PC in connected mode, for example to obtain system information change information.

[0084] Extended DRX (eDRX) is disclosed herein. It may be desirable to have extended or longer DRX cycles, for example for devices such as MTC devices. Extended or longer DRX cycles may be useful for some devices such as delay tolerant devices and may, for example, reduce battery consumption and/or increase battery life for those devices. A new time unit, for example, a hyper frame (HF), may be used, for example, with, as an extension of, or on top of radio frames and/or SFN timing, for example, legacy SFN timing.

[0085] FIG. 2 is an exemplary timing diagram which illustrates HFs and paging within HFs. One HF may include an SFN cycle, for example, 1024 radio frames or 10.24 s. A HF may have a Hyper-System Frame Number (H-

SFN). An H-SFN cycle may be 1024 SFN cycles. An H-SFN cycle may last 1024*1024*10 ms, for example, 174.76 minutes. In an example shown in timing diagram 200, HF 210 may have H-SFN 0 and may contain an SFN cycle of 1024 radio frames, from radio frame 0 through radio frame 1023. Likewise, HF 220 may have H-SFN 1023 and contain its own SFN cycle of 1024 radio frames. H-SFN cycle 230 may contain 1024 HFs, including HF 210 through HF 220.

[0086] An idle mode extended DRX (I-eDRX) cycle may include up to 256 H-SFN cycles and may, for example, last 256*1024*10 ms, for example, 43.69 minutes. The H-SFN may be broadcast by the cell. The H-SFN may increment at SFN cycle boundaries.

[0087] The H-SFN in which a WTRU may become reachable for paging may be referred to as a paging hyper frame (PH) or as the WTRU's PH. The PH may be applicable, or only applicable, in ECM-IDLE. The PH may be computed as a function of the extended DRX cycle and/or WTRU ID, for example, IMSI mod 1024. Within a PH, the determination of the PF and/or PO may follow the regular DRX rules and/or formulas. A WTRU's paging window (PW) may be the window or time span corresponding to the set of PFs in the WTRU's PH during which the WTRU may monitor for paging and/or may be paged. The PW may include a subset of the available PFs in the PH. In an example shown in timing diagram 200, PW 250 may include PF 260, PF 270 and PF 280. PF 260, PF 270 and PF 280 may be PFs within PH 290. eDRX cycle 295 may include PH 290. The PW may be signaled to the WTRU, for example by the MME in a NAS message. In a PF, a WTRU may monitor or only monitor one PO. Paging to a WTRU may be repeated in one or more of a WTRU's PFs in its PW, for example if the WTRU does not respond to a previous page.

[0088] A cell's support of idle mode extended DRX may be implicitly indicated by the broadcast of H-SFN. For long DRX cycles, it may be useful for the MME to have some awareness of when the WTRU may be become reachable, for example to avoid storing paging requests at the eNode-B for a long time. In connected mode, the DRX cycle may be extended up to the SFN

limit, for example, by extending the range of values for long DRX cycles to 10.24 seconds.

[0089] A large population of NB WTRUs may be multiplexed within a limited number of paging resources. If the distribution of WTRUs among paging resources is based on WTRU-ID, for example IMSI or IMSI modulo 1024, there may, for example still be a large number of WTRUs sharing the same paging resources in time and/or frequency, for example sharing the same PO and/or paging NB.

[0090] A NB WTRU may monitor M-PDCCH in a PO or each of its POs. If the M-PDCCH, or a DCI in the M-PDCCH, indicates the scheduling of an associated PDSCH for paging message, the NB WTRU may receive the associated PDSCH, for example, to check if there may be a paging message targeted to the NB WTRU.

[0091] Since a large number of NB WTRUs may share the same paging resources, a NB WTRU may receive the associated PDSCH when the paging message may not be targeted to the NB WTRU. The reception of an associated PDSCH that may not be intended for the WTRU may, for example, increase the WTRU's battery consumption unnecessarily. If the NB WTRU is in a CE level that may use a large number of repetitions, the impact to the WTRU may be worse, and may be, for example, significantly worse.

[0092] A NB WTRU may monitor M-PDCCH, for example in a PO or in each PO, in a NB WTRU specific or a NB WTRU group specific manner. The M-PDCCH may implicitly or explicitly indicate the necessity of receiving and/or decoding the M-PDCCH and/or an associated PDSCH, for example by a WTRU or group of WTRUs. For example, the M-PDCCH may implicitly or explicitly indicate the intended recipient or recipients of the M-PDCCH, an associated PDSCH, a page, a paging message or a PDSCH carrying a paging message or channel. Further, an implicit indication of paging reception, the need for paging reception, or the intended recipient or recipients of a M-PDCCH, a PDSCH, a page, a paging message or a PDSCH carrying a paging message or channel may be employed which uses one or more of: a scrambling indication; a scrambling sequence such as a scrambling sequence for M-

PDCCH randomization, a WTRU group-specific or WTRU-specific scrambling sequence, an information type specific scrambling sequence, or a scrambling sequence for paging reception; a starting enhanced control channel element (ECCE) index for M-PDCCH randomization, a bit interleaver for M-PDCCH randomization; and/or one or more Radio Network Temporary Identifiers (RNTIs).

[0093] In an example, a scrambling sequence may be used to randomize a bit sequence of an M-PDCCH. A WTRU that may use the same scrambling sequence to descramble the received bits may receive or may be able to receive the M-PDCCH. In an example, only a WTRU that may use the same scrambling sequence to descramble the received bits may receive or may be able to receive the M-PDCCH.

[0094] The bit sequence of an M-PDCCH may be a bit sequence before the modulation of M-PDCCH. For example, the bit sequence of an M-PDCCH may be a bit sequence after rate matching. A coded bit sequence may be an input bit sequence of the rate matching and an output bit sequence of the rate matching may be the bit sequence of an M-PDCCH. A DCI with cyclic redundancy check (CRC) scrambled by an RNTI may be an input bit sequence of the channel coding block and an output bit sequence may be a coded bit sequence.

[0095] The bit sequence of an M-PDCCH may be a bit sequence before the channel coding. For example, a DCI with CRC scrambled by an RNTI may be the bit sequence of an M-PDCCH.

[0096] For the RNTI, one or more of following examples may apply. The RNTI may be a P-RNTI, for example, if the DCI may be used for the paging. In another example, the RNTI may be a group-specific P-RNTI which may be associated with a scrambling sequence. In a further example, the RNTI may be the N least significant bits (LSBs) of a WTRU-ID that may be used for paging. N may be the number of CRC bits, which may be referred to as NCRC. For example, the 16 LSBs of a WTRU-ID, for example, IMSI or System Architecture Evolution (SAE)-Temporary Mobile Subscriber Identity (s-TMSI), may be used. The N bits used for the RNTI may be the same N bits that

correspond to WTRU-ID modulo (2^N), for example, IMSI modulo (2^N), where N may be 16.

[0097] In an example, a bit sequence of M-PDCCH $b(0),\ldots,b(M_{\text{bit}}-1)$ may be scrambled with a certain scrambling sequence, $c(i)$, where M_{bit} may be the number of bits in the bit sequence of an M-PDCCH. The result of a WTRU-specific or a WTRU group-specific scrambling sequence may be referred to as $\tilde{b}(0),\ldots,\tilde{b}(M_{\text{bit}}-1)$.

[0098] In an example, the $\tilde{b}(0),\ldots,\tilde{b}(M_{\text{bit}}-1)$ bit sequence may be determined based on $\tilde{b}(i)=(b(i)+c(i))\text{mod}2$, where mod2 may be modulo-2 operation. Further, the scrambling sequence $c(i)$ may be a Pseudo-random sequence that may be determined based on an initialization value, c_{init}, where i may be a bit index of the bit sequence.

[0099] The certain scrambling sequence may be determined based on at least one of whether the M-PDCCH or scrambling sequence may be WTRU-specific or WTRU group-specific, information type in the associated DCI and information type in the associated PDSCH. The initialization value (c_{init}) may be determined based on at least the WTRU-ID, at least the associated WTRU group number, at least the information type in the associated DCI, at least the information type in the associated PDSCH and/or an RNTI.

[0100] In an example, a WTRU which may monitor or attempt to decode a bit sequence of M-PDCCH may use its associated scrambling sequence. The associated scrambling sequence may be determined based on at least one of whether the M-PDCCH or scrambling sequence may be WTRU-specific or WTRU group-specific, and/or information type in the DCI. For example, the associated scrambling sequence may be determined based on the type of the information in the DCI for which the WTRU may be monitoring, such as WTRU-specific or WTRU group-specific paging. In an example, the WTRU may perform descrambling with an input bit sequence of the channel decoder. Also, the WTRU may perform descrambling with an output bit sequence of the channel decoder. In an example, if the bit sequence of M-PDCCH received at the WTRU receiver is $d(0),\ldots,d(M_{\text{bit}}-1)$, the $\tilde{d}(0),\ldots,\tilde{d}(M_{\text{bit}}-1)$ sequence may be

referred to as a descrambled bit sequence with the associated scrambling sequence $c(i)$. As an example, the WTRU may perform descrambling with $\tilde{d}(i) = (d(i) + c(i)) \bmod 2$.

[0101] A WTRU-specific scrambling sequence and/or a WTRU group-specific scrambling sequence may be provided and/or used. In an example, a WTRU-specific or WTRU group-specific scrambling sequence, for example a first scrambling sequence, may be used to scramble a bit sequence of an M-PDCCH, for example in a PO or each PO. In an example, a WTRU or a WTRU group that may use the same scrambling sequence, for example the first scrambling sequence, may decode or may be able to decode the M-PDCCH. For example only a WTRU or a WTRU group that may use the same scrambling sequence, for example the first scrambling sequence, may decode or may be able to decode the M-PDCCH.

[0102] In an example of using a WTRU group-specific scrambling sequence, N_g scrambling sequences may be used for N_g WTRU groups for a PO and a bit sequence of M-PDCCH intended or targeted for a WTRU group, for example a first WTRU group, within N_g WTRU groups may be scrambled with the corresponding scrambling sequence, for example a first scrambling sequence. In an example, the WTRU group using the corresponding scrambling sequence, for example the first scrambling sequence, may receive or may be able to receive the M-PDCCH. In a further example, only the WTRU group using the corresponding scrambling sequence, for example the first scrambling sequence, may receive or may be able to receive the M-PDCCH. The WTRU group-specific scrambling sequence may be determined based on at least one of following: a modulo operation that may, for example, be based on at least N_g and the WTRU-ID; a hashing function that may, for example, be based on N_g and the WTRU-ID; and the WTRU group number that may, for example, be determined based on at least a CE level.

[0103] A modulo operation may be used where the modulo operation may be based on at least N_g and the WTRU-ID (N_{WTRUID}). The WTRU group number (N_{group}) may be determined by WTRU-ID modulo N_g (for example

$N_{group} = (N_{WTRUID}) \bmod N_g$). A subframe number and/or a frame number (for example SFN) may be used. For example, $N_{group} = (N_{WTRUID} \cdot N_{Frame}) \bmod N_g$.

[0104] A hashing function may be used where the hashing function may be based on N_g and the WTRU-ID. In this case, for example, $N_{group} = (A \cdot N_{WTRUID}) \bmod N_g$, where the A may be a prime number (for example A = 39,827), or $N_{group} = ((A \cdot N_{WTRUID}) \bmod D) \bmod N_g$, where the D may be a prime number which may be different from A (for example D = 65,537). The hashing function may be based on a subframe number and/or a frame number.

[0105] The WTRU group number may be determined based on at least a CE level. For example, WTRUs with a first CE level (for example CE level-1) may be grouped as a first WTRU group and WTRUs with a second CE level (for example CE level-2) may be grouped as a second WTRU group.

[0106] The WTRU-ID may be at least one of an RNTI allocated for a WTRU, IMSI, and s-TMSI, and/or a part of at least one of the allocated RNTI, IMSI, and s-TMSI. For example, WTRU-ID may be IMSI modulo M or s-TMSI modulo N. M and/or N may be 1024. A and/or D may be a function of N_g. A and/or D may be fixed and/or configured, for example, by the eNode-B via signaling. A N_{WTRUID} may be the WTRU-ID or a portion of or function of the WTRUs IMSI or s-TMSI. For example N_{WTRUID} for a WTRU may be IMSI-10, or IMSI modulo X, where X may be a number less than or equal to 1024.

[0107] In an example of using a WTRU specific scrambling sequence, a WTRU specific scrambling sequence may be used for a bit sequence of M-PDCCH intended or targeted for a WTRU, where the WTRU specific scrambling sequence may be determined based on at least a WTRU-ID or a part of a WTRU-ID. In MME initiated paging, the WTRU-ID may be provided by the MME to the eNode-B in an S1 paging message or request.

[0108] In an example, the scrambling sequence may be determined based on the specific information type which may be carried in the DCI. For example, a first scrambling sequence may be used for a bit sequence of an M-PDCCH in which the DCI may carry a first information type and a second

scrambling sequence may be used for a bit sequence of an M-PDCCH in which the DCI may carry a second information type.

[0109] The first information type may include, but not be limited to, at least one or more system information update indications such as system information modification indication, an ETWS indication, a CMAS indication, and an EAB parameter modification indication. One or more system information indications may be a single bit to indicate the system information update or multiple bits to indicate the system information update of multiple SIs, for example, SIBs or SI-messages. An additional indicator may be included, for example, a flag bit to indicate a DCI format or a DCI type. The scrambling sequence for the first information type may be based on at least one of cell-specific parameters, such as for example, a physical cell-ID.

[0110] The second information type may be at least scheduling information of the associated PDSCH. The scrambling sequence for the second information type may be based on at least one of WTRU-specific parameters, such as for example, a WTRU-ID.

[0111] In another example, the scrambling sequence may be determined based on the information type carried in a DCI and/or WTRU-ID. For example, a first scrambling sequence may be used for a bit sequence of an M-PDCCH in which the DCI may carry a first information type, and a second scrambling sequence may be used for a bit sequence of an M-PDCCH in a which the DCI may carry a second information type. The first scrambling sequence may be predefined. The second scrambling sequence may be determined based on a WTRU-ID.

[0112] In an example, the PO for the first information type and the second information type may the same. Further, a WTRU may monitor M-PDCCH for both the first information type and the second information type. Also, a WTRU may monitor M-PDCCH for the first information type in a subset of POs or all POs. A WTRU may monitor M-PDCCH for the second information type in a subset of POs or all POs.

[0113] In another example, the PO for the first information type and the second information type may be different. The time and/or frequency location

of the PO for the first information type may be determined based on at least one cell-specific parameter. The cell-specific parameters may include, for example, a physical cell-ID, a system bandwidth, a subframe number, a frame number such as an SFN and the like. The time and/or frequency location of the PO for the second information type may be determined based on at least one WTRU-specific parameter, such as, for example, a WTRU-ID.

[0114] Examples which include the use of a scrambling sequence for paging reception are disclosed herein. A WTRU may determine a bit scrambling sequence, for example, an M-PDCCH bit scrambling sequence according to one or more examples described herein. In an example, the WTRU may monitor for an M-PDCCH in a PO. The WTRU may descramble the received signal or M-PDCCH using the bit scrambling sequence. The WTRU may determine if the descrambled M-PDCCH may carry a DCI masked with an RNTI that the WTRU may use for paging. The RNTI may be, for example, a P-RNTI. If the WTRU determines the DCI is masked with the RNTI, such as, for example, the P-RNTI, the WTRU may read the contents of the DCI to obtain one or more of system information update information and/or PDSCH scheduling information. The WTRU may use the scheduling information to receive an associated PDSCH that may carry one or more paging records or paging messages.

[0115] Examples using a starting ECCE index for M-PDCCH randomization are disclosed herein. In an example, an M-PDCCH search space may be used for monitoring for an M-PDCCH or a DCI, where the starting ECCE index, for example for monitoring, may be determined based on at least one WTRU-specific parameter. For example, a WTRU may use an M-PDCCH search space for monitoring for a an M-PDCCH or a DCI, where the starting ECCE index, for example for monitoring, may be determined based on at least one WTRU-specific parameter. As used herein, control channel element (CCE), ECCE and NB-IoT control channel element (NCCE) may be used interchangeably.

[0116] FIG. 3 is an exemplary diagram which illustrates WTRU group-specific starting ECCE indexes. Diagram 300 shows an example of ECCEs in a

subframe 310 at ECCE aggregation level 16. In other examples, other ECCE aggregation levels such as 1, 2, 4, 8 and 32 may be used. In an example shown in FIG. 3, a WTRU may use a different starting ECCE index depending upon the group the WTRU is in. For example, the WTRUs may be divided among four WTRU groups, numbered WTRU group #1 through WTRU group #4. WTRUs in WTRU group #1 may use a starting ECCE index 330 with a starting ECCE of 1, WTRUs in WTRU group #2 may use a starting ECCE index 350 with a starting ECCE of 5, WTRUs in WTRU group #3 may use a starting ECCE index 370 with a starting ECCE of 9, and WTRUs in WTRU group #4 may use a starting ECCE index 390 with a starting ECCE of 12.

[0117] FIG. 4 is a diagram of an example flow chart showing a WTRU receiving a machine type communication (MTC) physical downlink control channel (M-PDCCH) with a starting ECCE index based on the WTRU group of the WTRU. In an example shown in chart 400, a WTRU may monitor for an M-PDCCH in an M-PDCCH search space 410. The WTRU may monitor for the M-PDCCH using a starting ECCE index for the WTRU group containing the WTRU. The WTRU may then receive the M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH may have a starting ECCE index for the WTRU group containing the WTRU 420. In an example corresponding to the WTRU groups shown in FIG. 3, the WTRU may be in WTRU group #2 and may therefore monitor for and/or receive an M-PDCCH with a starting ECCE index 350 of 5. Further, the WTRU may decode the M-PDCCH, wherein the M-PDCCH includes a DCI 430. The WTRU may receive a PDSCH associated with the M-PDCCH 440 or the DCI, for example a PDSCH scheduled by the M-PDCCH or the DCI. In an example, the WTRU may receive, decode, attempt to decode, demodulate, and/or attempt to demodulate the PDSCH based on the DCI, wherein the PDSCH may include a paging message. As a result, the WTRU may change its operation based on the paging message. For example, the WTRU may change from idle mode to connected mode based on the paging message. The WTRU may then begin to transmit and receive in connected mode. In another example, the WTRU may already be in connected

mode and may change its system operation based on system information change information in the page message.

[0118] In another example, an M-PDCCH search space may be used for a DCI monitoring, where the starting ECCE index and ordering (for example, an ascending order, a descending order, a random order and/or a predefined order) may be used to determine an M-PDCCH candidate. For example, if a number of ECCEs, $N_{ECCE,}$ is available in the search space and an ECCE aggregation level is the same as N_{ECCE} for an M-PDCCH candidate, one or more M-PDCCH candidates may be determined based on the starting ECCE index and/or ordering.

[0119] An M-PDCCH candidate may be defined or configured with N_{ECCE} ECCEs which may be aggregated in an ascending order, descending order, ascending order with a starting ECCE index, or descending order with a starting ECCE index. In an example, the starting ECCE index and/or ordering may be determined based on at least one WTRU-specific parameter. In a further example, the starting ECCE index and/or ordering may be determined based on at least information type carried in the DCI.

[0120] In another example, an M-PDCCH search space may be used for a DCI monitoring, where the ECCE aggregation may be based on a sequence. The sequence for the ECCE ordering may be determined based on at least one WTRU-specific parameter.

[0121] FIG. 5 is an exemplary diagram which illustrates WTRU group-specific random ECCE ordering. A sequence for the ECCE ordering may be determined based on at least one WTRU-specific parameter as shown in diagram 500. Similar to FIG. 3, FIG. 5 shows an example of ECCEs in a subframe 510, at ECCE aggregation level 16. In an example, a sequence may determine the ECCE ordering for ECCE aggregation. In a further example, the sequence for ECCE ordering may be determined based on at least one of: a WTRU-specific parameter, an information type carried in the DCI, an RNTI that may be used for CRC scrambling, a DCI format used and a CE level or repetition number such as, for example a repetition number of an M-PDCCH candidate.

[0122] In yet a further example, a set of random sequences may be predefined or configured, for example for a group of WTRUs. A sequence may correspond to a starting ECCE index. A sequence may correspond to ECCE aggregation ordering.

[0123] In an example shown in FIG. 5, a WTRU may use a different starting ECCE index depending upon a random sequence that may be defined, configured and/or used by or for the group the WTRU is in. For example, the WTRUs may be divided among four WTRU groups, numbered WTRU group #1 through WTRU group #4. WTRUs in WTRU group #1 may use a first random sequence 530 that may correspond to a starting ECCE index of 4, WTRUs in WTRU group #2 may use a second random sequence 550 that may correspond to a starting ECCE index of 5, WTRUs in WTRU group #3 may use a third random sequence 570 that may correspond to a starting ECCE index of 9, and WTRUs in WTRU group #4 may use a fourth random sequence 590 that may correspond to a starting ECCE index of 12. A random sequence, for example, within the set, may be determined based on at least one of: a WTRU-specific parameter, an information type carried in the DCI, an RNTI that may be used for CRC scrambling, a DCI format used, or a CE level or repetition number, such as, for example, a repetition number of an M-PDCCH candidate.

[0124] Examples using a bit interleaver for M-PDCCH randomization are disclosed herein. In an example, a bit sequence for an M-PDCCH may be interleaved with an interleaving sequence. The interleaving sequence may be a sequence with the length of the bit sequence. The bit positions may be interleaved based on the interleaving sequence. In an example, the interleaving sequence may be determined based on one or more of at least one WTRU-specific parameter, an information type carried in the DCI, an RNTI that may be used for CRC scrambling, a DCI format used, and a CE level or repetition number such as, for example a repetition number of an M-PDCCH candidate. In a further example, a WTRU may use the interleaving sequence to de-interleave the received bit sequence before it may attempt to decode the received bit sequence.

[0125] In an example, one or more RNTIs may be used for a DCI, for example to indicate to a WTRU whether to decode an associated PDSCH. For example, a cell-specific P-RNTI and one or more WTRU group specific P-RNTIs may be used. A WTRU may attempt to decode the M-PDCCH with the cell-specific P-RNTI and/or an associated WTRU group specific P-RNTI in a PO. In an example, a first P-RNTI may be used for a DCI carrying a first information type. In a further example, a second P-RNTI may be used for a DCI carrying a second information type. Also, in a PO, a WTRU may attempt to decode a DCI with the first P-RNTI and/or the second P-RNTI.

[0126] A first P-RNTI may be used for a DCI carrying a first information type. The first P-RNTI may be a cell-specific P-RNTI. The first information type may include but not be limited to at least one or more system information update indications such as a system information modification indication, an ETWS indication, a CMAS indication, and an EAB parameter modification indication. One or more system information indications may be a single bit to indicate the system information update or multiple bits to indicate the system information update of multiple SIs, such as, for example, SIBs or SI-messages. An additional indicator may be included, such as, for example a flag bit to indicate a DCI format or a DCI type. The first P-RNTI may be based on at least one cell-specific parameter, such as, for example a physical cell-ID.

[0127] A second P-RNTI may be used for a DCI carrying a second information type. A set of P-RNTIs may be predefined or configured for the second P-RNTI and one of the predefined or configured P-RNTIs may be determined in a WTRU-specific or a WTRU group specific manner. A modulo operation with a WTRU-ID and/or the number of P-RNTIs configured may be used to determine the associated P-RNTI. A hashing function may be used with a WTRU-ID and/or the number of P-RNTIs configured to determine the associated P-RNTI.

[0128] In a PO, a WTRU may attempt to decode a DCI with the first P-RNTI. The WTRU may also attempt to decode a DCI with the second P-RNTI which may be associated with the WTRU. If a WTRU may successfully decode a DCI with the first P-RNTI, then the WTRU may not monitor a DCI with the

second P-RNTI. If a WTRU may not successfully decode a DCI with the second P-RNTI, then the WTRU may assume that the associated PDSCH may not be scheduled.

[0129] An explicit indication of paging reception is disclosed herein including the use of: a paging occasion type; a monitoring indicator for a paging occasion, a paging type, a paging message, a paging window, among others; multiple monitoring indicators; and multiple monitoring indicators with explicit and implicit indications. In examples, one or more paging occasion types may be used, configured, or defined, for example for a RRC idle WTRU and/or a RRC connected WTRU.

[0130] A first paging occasion type may be used for a paging message transmission in which a WTRU may monitor for a paging message. The paging message may include one or more paging records and/or one or more system information update indications. In an example, the paging message may be carried in a DCI. In a further example, the paging message may be carried in a PDSCH and the scheduling information of the PDSCH may be provided in an associated DCI. Also, the paging message may be carried in a PDSCH without an associated DCI for the scheduling information. Further, the contents of the paging message may be indicated from the associated DCI. For example, a DCI may indicate the information type included in the paging message.

[0131] In an example, a second paging occasion type may be used for one or more system information update indications. In a further example, one or more paging occasion types may be located in a same time/frequency resource and monitored separately.

[0132] The time/frequency locations for one or more paging occasion types may be determined independently. A time/frequency location of a first paging occasion type may be determined based on at least one WTRU-specific parameter, such as, for example, a WTRU-ID. A time/frequency location of a second paging occasion type may be determined based on at least one cell-specific parameter, such as, for example, a physical cell-ID, (e)DRX cycle, system bandwidth and the like.

[0133] In an example, a DCI format or DCI contents may be different according to the paging occasion type. Further, an associated RNTI may be different according to the paging occasion type.

[0134] In an example, an indication for monitoring, for example, a monitoring indicator, of one or more of PO types may be transmitted in a broadcast channel, such as, for example, in a MIB, in a DCI in common search space and the like. For example, a broadcast channel may be transmitted in every x ms and one or more POs may be associated with a broadcast transmission. The broadcast transmission may indicate if a WTRU may need to monitor one or more POs associated with the broadcast transmission. A WTRU may attempt to decode or read a broadcast channel which may carry the monitoring indicator before it may monitor one or more POs. In an example, a monitoring indicator may be associated with one or more PO types. For example, the monitoring indicator may be associated with a first PO type. In a further example, the monitoring indicator may be associated only with a first PO type. In another example, the monitoring indicator may be associated with a second PO type. In a still further example, the monitoring indicator may be associated only with a second PO type. In an example, the monitoring indicator may be set to TRUE or FALSE. Based on the monitoring indicator, a WTRU may monitor a WTRU-group specific PO which may be determined based on at least one of a WTRU-specific parameter, such as, for example a WTRU-ID, or a cell-specific PO that may be determined based on at least one cell-specific parameter, such as, for example, a physical cell-ID.

[0135] A monitoring indicator may be associated with one or more POs. For example, a monitoring indicator may be associated with POs within a certain time window. If a WTRU receives the monitoring indicator, the WTRU may attempt to receive or monitor POs within the certain time window.

[0136] A monitoring indicator may indicate a WTRU group index and a WTRU group associated with the monitoring indicator may monitor the POs. In an example, the monitoring indicator may indicate which WTRU group may need to monitor POs. The WTRU group may include all WTRU groups for a system information update. In another example, the monitoring indicator

may have a number of states, such as four states and may indicate at least one of the states. The states may, for example include cell common paging, a first WTRU group, a second WTRU group, and a third WTRU group. In an example, the cell common page may be or occur in a cell-specific PO. A WTRU may monitor a PO or monitor for a page according to a monitoring indicator state.

[0137] A monitoring indicator may indicate a PO type and a WTRU may monitor POs corresponding to the PO type. In an example, a WTRU may receive a monitoring indicator which indicates a first PO type, and then the WTRU may monitor POs corresponding to the first PO type. Further, a WTRU may receive a monitoring indicator which indicates a first PO type, and then the WTRU may monitor POs corresponding to the first PO type only.

[0138] In another example, a monitoring indicator may be used with a WTRU group specific M-PDCCH scrambling sequence, a WTRU group specific RNTI, a WTRU group specific starting ECCE index, and/or a WTRU group specific interleaver. A monitoring indicator may be used to indicate if a WTRU may need to monitor POs associated with it and an implicit indication of paging reception schemes may be used in each PO. A WTRU may, for example, attempt to decode, receive, or monitor the monitoring indicator and, if the monitoring indicator indicates that the WTRU may need to monitor the POs, the WTRU may attempt to decode or monitor the POs, for an M-PDCCH, for example, with its associated scrambling sequence, starting ECCE index, RNTI, and/or interleaving sequence. Further, a WTRU may first attempt to decode, receive, or monitor the monitoring indicator and, if the monitoring indicator indicates that the WTRU may need to monitor the POs, the WTRU may attempt to decode or monitor the POs, for an M-PDCCH, for example, with its associated scrambling sequence, starting ECCE index, RNTI, and/or interleaving sequence.

[0139] In an example, one or more monitoring indicators may be used and a WTRU may determine if the WTRU may need to monitor, receive, or attempt to decode an M-PDCCH and/or a PDSCH carrying paging related information. A monitoring indicator may be used to determine if a WTRU

needs to monitor or attempt to decode a M-PDCCH in a PO, which may be referred to as a PO (paging occasion) monitoring indicator. A monitoring indicator may be used to determine if a WTRU needs to receive an associated PDSCH which may carry a paging message (PM), which may be referred to as a PM monitoring indicator. A monitoring indicator may be used to determine if a WTRU needs to monitor POs within a paging window (PW), which may be referred to as a PW monitoring indicator. A PW may include one or more POs for a WTRU. A PW may be defined or determined based on a number of POs. For example, a PW may be defined to include N_{PO} POs where N_{PO} may be a positive integer number.

[0140] A monitoring indicator may be used to determine if a WTRU needs to receive, attempt to decode, or monitor a subsequent monitoring indicator. A WTRU may receive a monitoring indicator before it may decode, monitor, attempt to decode, receive, or attempt to receive a signal, for example an M-PDCCH or a PDSCH, in a PO. Two monitoring indicators may be used and a first monitoring indicator may be a PO monitoring indicator and a second monitoring indicator may be a PM monitoring indicator. The first monitoring indicator may be transmitted in a broadcast channel. The second monitoring indicator may be transmitted in a DCI, for example in an M-PDCCH.

[0141] A PM monitoring indicator may be comprised of one or more bits to indicate at least one of the following: a presence of an associated PDSCH which may carry a paging message; a WTRU group index, or WTRU group ID, which may be associated with a paging message; and a type of information carried in a paging message.

[0142] In another example, one or more monitoring indicators may be used and each monitoring indicator may be used to indicate a WTRU group, a WTRU group index or a WTRU group ID. A WTRU which may be associated with a WTRU group, a WTRU group index or a WTRU group ID may need to monitor or receive a paging message, for example when a monitoring indicator for the WTRU group, the WTRU group index or the WTRU group ID indicates to monitor or read a paging message. A hierarchical WTRU group index may

be used, where a first WTRU group index may include a set of WTRUs or WTRU-IDs and a second WTRU group index may include a subset of WTRUs or WTRU-IDs within the set of WTRUs or WTRU-IDs indicated from the first WTRU group index. The first WTRU group index may be determined based on a WTRU-ID, for example, IMSI, and the second WTRU group index may be determined based on a different WTRU-ID, for example, s-TMSI. The first WTRU group index may be determined based on a modulo operation based on WTRU-ID and the number of WTRU groups for the first WTRU group index, and the second WTRU group index may be determined based on a hashing function with a WTRU-ID and the number of WTRU groups for the second WTRU group index.

[0143] A combination of a first monitoring indicator and a second monitoring indicator may be used to determine a WTRU group index. If N1 WTRU groups for a first monitoring indicator and N2 WTRU groups for a second monitoring indicator are used, the combined WTRU group may be indicated as N1 x N2 WTRU groups.

[0144] Examples of using multiple monitoring indicators for paging with explicit and implicit indications are discussed herein. In an example, one or more monitoring indicators may be used and a first monitoring indicator may be based on one or more explicit bits while a second monitoring indicator may be based on an RNTI. For example, a WTRU may receive or receive an indication from a PO monitoring indicator in a first channel and the WTRU may receive or receive an indication from a PM monitoring indicator in a second channel.

[0145] In an example, the first channel may be a broadcast channel and the second channel may be a physical downlink control channel, for example, an M-PDCCH. In another example, the first channel may be an M-PDCCH monitored in a cell-specific time/frequency resource, such as, for example, a common search space, and the second channel may be an M-PDCCH monitored in a WTRU-specific or WTRU-group specific time/frequency resource, such as, for example, a WTRU-specific or WTRU group-specific search space. In a further example, the PO monitoring indicator may be one or

more bits transmitted in a broadcast channel. Also, the PM monitoring indicator may be a set of RNTIs reserved for the PM monitoring indication.

[0146] Example methods for a WTRU to perform a paging NB determination are discussed herein. A WTRU may determine the NB to use for paging in its PO, for example based on at least one of its WTRU ID, the number of paging NBs, , and the DL system bandwidth. The WTRU ID may be an IMSI or an s-TMSI. An option is to use IMSI modulo 1024 to determine the NB, for example, since IMSI modulo 1024 may be used to determine the WTRU's PO. The number of paging NBs may be broadcast, may be received via broadcast signaling, and/or may be received via system information. A paging NB may be a NB that may be used for paging. In an example, a NB may be or may represent a set of RBs or subcarriers within a system BW.

[0147] The parameters used for paging may include DRX cycle, nB and the like. Depending on the parameters that may be used for paging and the number of NBs, the use of IMSI modulo 1024 to determine the NB, however, may result in some or all WTRUs in a given PO determining the same NB. This may defeat the purpose of having multiple NBs for paging.

[0148] Several example solutions are discussed herein for a WTRU to better determine a NB for paging. In an example solution, IMSI-10 may be used to represent IMSI modulo 1024 or the least significant 10 bits of an IMSI. For MME initiated paging of a WTRU, the MME may include the IMSI-10 and/or the s-TMSI for the WTRU in the S1 paging message to the eNode-B to request the page. When paging a WTRU, an eNode-B may know the IMSI-10 and/or the s-TMSI of the WTRU. The WTRU and/or eNode-B may use one or both of these values to determine the WTRU's NB for paging. For example, the WTRU and/or eNode-B may use one or both of these values to determine the WTRU's NB for paging in the WTRU's PO.

[0149] A function, such as a hashing function, that may be based on at least the WTRU ID may be used by a WTRU and/or eNode-B to determine the NB for paging. For example, the function may be based on at least IMSI-10 or IMSI modulo X. In an example, the hashing function may be based on at least IMSI-10 or IMSI modulo X.

[0150] For example, a function such as a hashing function may be used based on N_b and/or the WTRU ID. In an example, N_b may be the number of NBs. In a further example, N_b may be the number of NBs to use for paging or that may be used for paging. For example, the NB for a WTRU, NB_{WTRU}, may be determined, for example, by the WTRU and/or eNode-B according to:

$$NB_{WTRU} = (A \cdot N_{WTRUID}) \bmod N_b \quad \text{Equation (1)}$$

where the A may be a prime number, for example, A = 39827. In a further example, NB_{WTRU}, may be determined according to:

$$NB_{WTRU} = ((A \cdot N_{WTRUID}) \bmod D) \bmod N_b \quad \text{Equation (2)}$$

where D may be a prime number which may be different from A, for example, D = 65537.

[0151] A and/or D may be a function of N_b. A and/or D may be fixed and/or configured, for example, by the eNode-B via signaling. N_{WTRUID} may be the WTRU ID or a portion of or function of the WTRU's IMSI or s-TMSI. For example N_{WTRUID} for a WTRU may be IMSI-10, IMSI modulo X, where X may be a number less than or equal to 1024 or IMSI modulo Y, where Y may be a number less than or equal to 16,384. The number of NBs for paging may be provided by the eNode-B and/or received by the WTRU in signaling such as higher layer signaling which may be broadcast, for example, in system information.

[0152] Additional IMSI bits or an additional portion or function of the IMSI may be used by a WTRU and/or eNode-B to determine the NB for paging. The MME may include the additional bits in the S1 paging message to the eNode-B. The eNode-B may receive the additional bits and may use them to determine the NB in which to page the WTRU.

[0153] For example, the most significant B bits of IMSI modulo Z may be used to determine the NB for paging, where Z may be at least one of (2^B) x 1024, (2^C) x 1024 and a number less than or equal to 16,384. In an example, C may be a number or integer that may be different than B. Further, the B MSBs, for example the value of the B MSBs, MB, may be used to determine the NB, for example according to MB modulo N_b.

[0154] In an example, if there are up to 16 narrowbands for paging, B may be 4. The 4 MSBs of IMSI modulo 16,384 may be used to determine the NB for paging, where IMSI modulo 16,384 may be derived from IMSI modulo Z and Z = (2^B) x 1024. Since B may be 4, then (2^4) x 1024 = 16 x 1024 = 16,384. Further, since B may be 4, the 4 MSBs, M4, may be used to determine the NB, for example according to M4 modulo N_b. M4 may be used to represent the 4 MSBs or the value of the 4 MSBs.

[0155] In another example, B may be 3 and C may be 4. The 3 MSBs of IMSI modulo 16,384 may be used to determine the NB for paging, where IMSI modulo 16,384 may be derived from IMSI modulo Z and Z = (2^C) x 1024. Since C may 4, then (2^4) x 1024 = 16 x 1024 = 16,384. Further, since B may be 3, the 3 MSBs, M3, may be used to determine the NB, for example according to M3 modulo N_b. M3 may be used to represent the 3 MSBs or the value of the 3 MSBs.

[0156] In other examples, different numbers of narrowbands for paging may be used and still be consistent with the examples discussed herein. Further, in other examples, different values for B, for C or for both may be used.

[0157] The 14 bits, IMSI-14, that may correspond to IMSI modulo 16,384 may be used to determine the NB, for example according to IMSI-14 modulo N_b. Further, the 14 bits, IMSI-14, that may correspond to IMSI modulo 16,384 may be used to determine the NB, for example according to IMSI-14 modulo N_b modified by one or more other parameters.

[0158] FIG. 6 is a diagram of an example flow chart showing a WTRU using a WTRU-ID to determine a paging NB to use for monitoring an M-PDCCH. As shown in flow chart 600, a WTRU may determine a paging NB for the WTRU, to use for monitoring an M-PDCCH, based on at least the MSBs of a function of a WTRU-ID 610. The WTRU may monitor for the M-PDCCH on the determined paging NB for the WTRU 620. For example, the WTRU may monitor for the M-PDCCH on the determined paging NB in or during a PO that may be a PO of the WTRU. The WTRU may monitor for an M-PDCCH masked with a P-RNTI or for an M-PDCCH or DCI with a CRC scrambled

with a P-RNTI. The WTRU may then receive a DCI on the monitored M-PDCCH on the determined paging NB during a PO 630 that may be a PO of the WTRU. The DCI may include a CRC that may be scrambled with a P-RNTI. The WTRU may receive a physical downlink shared channel (PDSCH) associated with the M-PDCCH 650 or the DCI, for example a PDSCH scheduled by the M-PDCCH or the DCI. The WTRU may receive system information update related information and/or a paging message in or from the DCI or the PDSCH.

[0159] In a further example, the most significant N bits of IMSI-10 may be used to determine the NB for paging. N may be a function of the number of NBs configured or available, for example, in a PO, for paging.

[0160] In the embodiments and examples described herein, the term mobile subscriber identification number (MSIN) may be substituted for IMSI and vice versa and still be consistent with embodiments and examples disclosed herein. Further, various example numbers of digits may be used for MSIN and IMSI, including but not limited to 8, 10, 14, 16, 32, 64 and the like.

[0161] Examples of a WTRU determining a paging HF are discussed herein. Within a PH, WTRUs with the same IMSI modulo 1024 may determine the same PF and the same PO. Depending on the paging parameters, WTRUs may not be distributed well among the PFs and the PO.

[0162] IMSI may be comprised of decimal digits (0 through 9) and may include one or more of mobile country code (MCC), mobile network code (MNC) and MSIN. An IMSI may use binary-coded decimal (BCD) representation. IMSI may comprise 64 bits where each digit may by coded over 4 separate bits. The digits 0 to 9 may be encoded 0000 to 1001 and there may be two digits per octet. For the function IMSI modulo X, IMSI may be the decimal representation of the IMSI, the BCD representation of the IMSI, the hexadecimal representation of the IMSI, or another representation of the IMSI.

[0163] One or more of the examples described herein for the determination of a paging NB, for example, for and/or by a WTRU, may be applied to the determination of one or more of PH, PF, and PO, for example,

for and/or by a WTRU. A separate, for example, different function, aspect, or portion of the WTRU-ID, for example, IMSI or s-TMSI, may be used for each of PH and PF determination for and/or by a WTRU.

[0164] A $WTRU_ID_{PH}$ may represent the function, aspect, or portion of the WTRU-ID that may be used in the PH calculation. $WTRU_ID_{PF}$ may represent the function, aspect, or portion of the WTRU-ID that may be used in the PF calculation. $WTRU_ID_{PH}$-10 may represent $WTRU_ID_{PH}$ modulo 1024. $WTRU_ID_{PF}$-10 may represent $WTRU_ID_{PF}$ modulo 1024. For MME initiated paging of a WTRU, the MME may include $WTRU_ID_{PH}$-10 and/or $WTRU_ID_{PF}$-10 in the S1 paging message to the eNode-B to request the page.

[0165] A $WTRU_ID_{PH}$-10 and/or the $WTRU_ID_{PF}$-10 may be given to the eNode-B by the MME. A $WTRU_ID_{PH}$-10 and/or the $WTRU_ID_{PF}$-10 may be given to the eNode-B by the MME as a bit string of size 10. The bits may follow the normal binary representation or the BCD representation.

[0166] When paging a WTRU, an eNode-B may know $WTRU_ID_{PH}$-10 and/or $WTRU_ID_{PF}$-10. The WTRU and/or eNode-B may use one or both of these values to determine the WTRU's PH and/or PF. The WTRU and/or eNode-B may use $WTRU_ID_{PH}$-10 to determine the WTRU's PH or PHs for paging. The WTRU and/or eNode-B may use $WTRU_ID_{PF}$-10 to determine the WTRU's PF or PFs for paging.

[0167] In an example, $WTRU_ID_{PH}$ may be the WTRU's MSIN. MSIN may be the least N1, for example, 9, significant decimal digits of the IMSI in decimal representation, for example, if the concatenation of MCC and MNC is 6 digits. MSIN may be the least N2, for example, 10, significant decimal digits of the IMSI, for example, if the IMSI is 15 digits. $WTRU_ID_{PF}$ may be the WTRU's IMSI. $WTRU_ID_{PH}$-10 may be MSIN modulo 1024 and/or the $WTRU_ID_{PF}$-10 may be IMSI modulo 1024.

[0168] In another example, $WTRU_ID_{PH}$ may be the IMSI and $WTRU_ID_{PF}$ may be the MSIN. In another example, if the concatenation of the MCC and MNC part of the IMSI is an even number, the IMSI may be transformed such that the concatenation of the MCC and the MNC part of the

IMSI is an odd number. For example, one may be added or subtracted from the concatenation of the MCC and MNC part of the IMSI.

[0169] In another example, MSIN-10Q may be used to represent FLOOR [MSIN/1024] or (FLOOR [MSIN/1024]) modulo 1024. $WTRU_ID_{PH}$-10 may be MSIN-10Q.

[0170] Modified paging reception examples are disclosed herein. In an example, a WTRU may determine its PH, PF, and PO according to a set of rules, such as, for example, regular rules. The WTRU may receive and/or use additional configuration or information to determine when to monitor or skip monitoring for paging, for example, when to monitor or skip monitoring for a M-PDCCH masked with a paging RNTI, and/or receive or skip receiving an associated PDSCH or PCH.

[0171] At least some of the configuration and/or information may be provided by or received from an MME via NAS signaling or via an eNode-B via RRC signaling. The WTRU may maintain the configuration and/or information while in idle mode. A WTRU may monitor for paging in the PFs of its PW in one PH per I-eDRX cycle. In an example, a WTRU may be configured to skip its PH in one or more I-eDRX cycles and/or to skip one or more PFs in its PW.

[0172] In an example, whether the WTRU ID is an odd or even number may be used to determine whether a WTRU may read or receive, or may skip reading or receiving, a page in a PF and/or a PH. Reading and/or receiving a page may correspond to monitoring for M-PDCCH with a paging RNTI. Reading and/or receiving a page may correspond to receiving, decoding, and/or reading a PDSCH which may be associated with, indicated by, or allocated by an M-PDCCH with a paging RNTI. Reading and/or receiving a page may correspond to receiving, decoding, and/or reading a PDSCH that may carry a paging message. Skipping reading or receiving a page may be the same as not reading or receiving or not attempting to read or receive a page. Skipping reading or receiving a page may be the same as skipping one or more of a PO, PF or a PH.

[0173] A WTRU may read or monitor for a page, for example, in a PO, if WTRU ID is an odd number and skip reading or monitoring for a page, for example, in a PO, if WTRU ID is an even number, for example if reading and/or monitoring by a WTRU with an odd number WTRU ID is indicated. A WTRU may read or monitor for a page, for example, in a PO if the WTRU ID is an even number and skip reading or monitoring for a page, for example, in a PO if WTRU ID is an odd number, for example if reading and/or monitoring by a WTRU with an even number WTRU ID is indicated.

[0174] $WTRU_ID_{PH}$-10 and/or $WTRU_ID_{PF}$-10 may be substituted for WTRU ID and still be consistent with this disclosure. WTRU ID may be IMSI modulo 1024, MSIN modulo 1024, and/or FLOOR [MSIN/1024], among others.

[0175] Whether odd numbered WTRUs or even numbered WTRUs may receive a page in a PF or PO may be determined based on one or more of: a WTRU ID odd/even indicator; a PH odd/even indicator; and/or a PF odd/even indicator.

[0176] One bit may be used for an indicator. One state of the bit may be used to indicate even and the other state may be used to indicate odd. 0 may be used for even and 1 for odd or vice versa. One or more of the indicators may be signaled, for example, by the eNode-B, for example in the MIB, in a SIB, or in the M-PDCCH for paging.

[0177] A WTRU may read one or more of the indicators prior to at least one of its PHs and/or PFs and/or POs. The WTRU may read one or more of the indicators in an M-PDCCH for paging in one of its POs. The WTRU may determine the state of one or more of the indicators and based on the state or states the WTRU may determine whether to monitor for a page and/or receive a PDSCH that may carry a page. An indicator in the MIB may be used by a WTRU to determine whether to monitor for a paging M-PDCCH in one or more POs. An indicator in the M-PDCCH for paging may be used by a WTRU to determine whether to reads a PDSCH associated with the M-PDCCH that may carry a paging message.

[0178] For example, for WTRU ID odd/even = even and PH odd/even = odd, a WTRU with an even WTRU ID may read or monitor for a page in, for

example, only in, an odd numbered PH. The WTRU may skip reading or monitoring for a page in an even numbered PH. A WTRU with an odd WTRU ID may skip reading or monitoring for a page when WTRU odd/even is set to even, for example, in one or more, for example, both odd and even PHs.

[0179] In an example, (0,0) may mean the WTRU ID is even and PH is even, (1,0) may mean the WTRU ID is odd and PH is even, (0,1) may mean the WTRU ID is even and PH is odd, and (1,1) may mean the WTRU ID and PH are odd. The eNode-B may use one of these codes as a paging reading indicator, for example, at any time.

[0180] In another example, a single bit for odd/even WTRU ID may be used. A WTRU with an even WTRU ID may read or monitor for a page when WTRU odd/even is set to even and may skip reading or monitoring for a page when WTRU odd/even is set to odd. A WTRU with an odd WTRU ID may read or monitor for a page when WTRU odd/even is set to odd and may skip reading or monitoring for a page when WTRU odd/even is set to even.

[0181] The eNode-B may signal some or all of the bits of the current value of the paging reading indicator in the MIB, or in the SIB or in M-PDCCH (or PDCCH). The WTRU may make the determination to skip a PH based on the value of the paging indicator signaled by the eNode-B. The WTRU may make the determination to skip a PF based on the value of the paging reading indicator.

[0182] The eNode-B may use a paging reading indicator to indicate to one or more WTRUs to skip or read a page in a PH and/or PF. The eNode-B may use separate paging reading indicators to indicate to skip or read a page in a PF and to skip or read pages in all the PFs in a PH.

[0183] Odd/even indication may be replaced by a group ID that may represent another way to distinguish groups. More bits may be used as is appropriate. For example, there may be 4 groups and the least significant 2 bits of the WTRU ID may be used for the determination of which WTRUs may read or monitor for pages.

[0184] In a PO, multiple paging messages intended for multiple WTRUs may be multiplexed into a transport block and jointly coded by a channel

coder, where the WTRUs may have a different coverage level, thus requiring repetitions targeting for a worst coverage case. This may result in resource waste for paging transmissions.

[0185] In an example, multiple paging messages may be separately coded as code-block segments within a PDSCH transmission. For example, a PDSCH, for example, an NB-PDSCH carrying one or more paging message(s) may be scheduled by an associated PDCCH, for example, an NB-PDCCH, in each PO. The paging messages multiplexed in the PDSCH may be split into one or more code-block segments.

[0186] Each code-block segment may be coded separately by a channel code, for example, a turbo code, convolutional code, or block code. Each code-block segment may be attached with a CRC. A code-block segment may be associated with one or more paging messages. A code-block segment may be associated with one or more coverage levels. A code-block segment may be associated with a WTRU-ID. The WTRU-ID used for PO determination and code-block segment determination may be different. For example, the PO may be determined based on a first WTRU-ID, for example, IMSI-10, while the code-block segment may be determined based on a second WTRU-ID, for example, s-TMSI.

[0187] FIG. 7 is a diagram illustrating an example of code-block segment multiplexing in a PDSCH which may be scheduled by an associated PDCCH in a PO. The paging message, paging information, and paging record may be used interchangeably. As shown in diagram 700, code-block segments 710, 720 and 780 may be each associated with one or more respective coverage levels or CE levels. For example, code-block segment 710 may be associated with CE level 1, code-block segment 720 may be associated with CE level 2 and code-block segment 780 may be associated with CE level 3.

[0188] A PDSCH carrying one or more paging messages may be transmitted over multiple subframes. The number of subframes used for the PDSCH transmission may be indicated from the associated PDCCH. The number of subframes for the PDSCH transmission may be determined based on the transport block size, where the transport block size may include all

code-block segments multiplexed in the PDSCH. The number of repetitions may be indicated from the associated PDCCH. For example, the number of subframes Ns for the PDSCH transmission may be determined as a function of the transport block size and the number of repetitions Nrep may be indicated from the associated PDCCH. The total number of subframes used for the PDSCH transmission including repetitions may be Ns x Nrep.

[0189] A NB-subframe may include one of more subframes. The NB-subframe length may be determined based on the transport block size of the PDSCH transmission.

[0190] A code-block segment may be transmitted within an NB-subframe, where the NB-subframe length, for example, as a number of subframes, TTIs, ms, or the like, may be determined based on the size of the code-block segment. Multiple code-block segments may be multiplexed in a PDSCH. In an example shown in FIG. 7, code-block segments 710, 720 and 780 may be multiplexed in PDSCH 790. In an example, if Nc code-block segments are multiplexed in a PDSCH, the PDSCH may be transmitted over Nc NB-subframes. A NB-subframe length associated with a code-block segment may be determined based on the code-block segment size. The size of code-block segments may be indicated in the associated PDCCH. Based on the code-block segment sizes, a WTRU may determine the NB-subframe length of each code-block segment.

[0191] One or more code-block segments may be multiplexed in a PDSCH and the time/frequency resource locations for each code-block segment may be predefined. A WTRU may monitor all code-block segments within the PDSCH or a WTRU may monitor a subset of code-block segments. Each code-block segment may be associated with a CE level and a WTRU with a certain CE level may monitor, attempt to decode, or receive a code-block segment associated with the CE level. Each code-block segment may be associated with a WTRU-ID or a WTRU-group ID, and a WTRU may monitor, attempt to decode, or receive a code-block segment associated with the WTRU-ID or a WTRU-group ID.

[0192] In an example, multiple paging messages may be separately coded as code-block segments and each code-block segment may be transmitted in a PDSCH. For example, if Nc code-block segments are transmitted, the Nc PDSCHs may be transmitted and the Nc PDSCHs may be scheduled in an associated PDCCH in a PO. Each PDSCH carrying a code-block segment may be transmitted in one or more subframes. The starting subframe of each PDSCH carrying a code-block segment may be determined based on the last subframe of the associated PDCCH. Alternatively, the starting subframe of each PDSCH carrying a code-block segment may be determined based on the last subframe of the associated PDCCH and the size of the code-block segment. The number of subframes for a PDSCH carrying a code-block segment may be determined based on the size of the code-block segment. The size of the code-block segment may be a number of bits for the code-block segment after coding and rate-matching.

[0193] FIG. 8 is a diagram illustrating an example of code-block segments transmitted via multiple PDSCHs which may be scheduled by an associated PDCCH in a PO. An associated PDCCH transmitted in a PO may schedule one or more PDSCHs carrying paging messages. A PDSCH may be associated with a code-block segment.

[0194] As shown in diagram 800, code-block segments 810, 820 and 860 may be each associated with one or more respective coverage levels or CE levels, in a manner similar to that in FIG. 7. For example, code-block segment 810 may be associated with CE level 1, code-block segment 820 may be associated with CE level 2 and code-block segment 860 may be associated with CE level 3. However, in FIG. 8, each different respective PDSCH may be associated with each different respective code-block segment. For example, code-block segment 810 may be associated with PDSCH 870, code-block segment 820 may be associated with PDSCH 880 and code-block segment 860 may be associated with PDSCH 890.

[0195] The PDSCHs may be multiplexed in the time domain. For example, the PDSCHs may be transmitted in a different time (e.g., different

time window). The starting subframe of the PDSCHs may be predetermined based on the last subframe of the associated PDCCH.

[0196] In another example, the PDSCHs carrying code-block segments may be transmitted without an associated PDCCH. In each PO, one or more time windows may be configured, used, or allocated and a WTRU may attempt to decode, monitor, or receive a PDSCH carrying a code-block segment in a time window. The code-block segment size for a PDSCH may be predefined. One or more code-block segment sizes may be used and a WTRU may attempt to decode all candidate code-block segment sizes. The time windows for PDSCHs may be non-overlapped. Each time window may be associated with a CE level or WRTU-ID.

[0197] In another example, one or more PDSCHs carrying code-block segments may be transmitted and a first PDSCH may be scheduled by an associated PDCCH and the subsequent PDSCH(s) may be scheduled based on the previous PDSCH. An indication may be transmitted in a PDSCH to indicate whether a subsequent PDSCH carrying code-block segment may follow or may be transmitted. The indication may be based on a sequence masked in the CRC. For example, if the CRC is masked with a first sequence, there may not be a subsequent PDSCH while if the CRC is masked with a second sequence, there may be a subsequent PDSCH. The indication may be a bit transmitted in a code-block segment. A scheduling information may be transmitted with the indication. The first PDSCH may be based on the highest CE level, for example, a largest repetition number, and a subsequent PDSCH may be based on a lower CE level. The terms code-block segment and paging message may be interchangeably used herein.

[0198] The following examples include sending a direct indication in a paging DCI without PDSCH scheduling. When an eNode-B updates, or changes, a frequency location of an anchor RB, for example an anchor PRB, which may contain a synchronization signal and/or broadcasting signals such as a NB master information block (NB-MIB) and/or a NB-SIB, the eNode-B may need to indicate the update, or changes, via paging for WTRUs that are in RRC idle mode. If the indication bits are transmitted in a paging message, the

resource overhead may be increased significantly since the eNode-B may need to send this signal in all POs.

[0199] In an example, a WTRU may monitor or attempt to decode a DCI located in a NB-PDCCH search space. The NB-PDCCH may be in a PO. The NB-PDCCH and/or the PO may be intended for the WTRU. The DCI may carry one or more information types. The terms information type and DCI contents may be used interchangeably herein. One or more of following example parameters may apply.

[0200] A first information type may be scheduling information of the associated PDSCH carrying a paging message. A second information type may be a direct indication which may be related to a system configuration. The second information type may not include scheduling information of the associated PDSCH.

[0201] The information type related to system configuration may include at least one of following parameters or indications: a system information update indication; a public warning indication, such as an ETWS or a CMAS indication; an access barring parameter, such as an EAB parameter modification indication; scheduling information of one or more SIBs, where one or more SIBs may be transmitted without an associated DL control channel (NB-PDCCH); configuration information related to the anchor RB, for example the anchor PRB, for NB-IoT; a same-physical cell-ID (PCI) indicator, which may indicate if the PCI for a cell-specific reference signal (CRS) port and the PCI for an NB reference signal (NB-RS) are the same; and a valueTag, which may include one or more bits to indicate which SIB or SIBs are updated.

[0202] The scheduling information of a SIB or SIBs may include at least one of the following parameters: transport block size (TBS), frequency location, frequency hopping related information, and coverage level, which may be, for example, a repetition number. As described herein, an anchor RB, for example an anchor PRB, may include or may include transmission of at least one of the following: a synchronization signal (for example, a NB primary synchronization signal (NB-PSS), a NB secondary synchronization signal NB-

SSS and the like), a broadcast signal (for example, an NB physical broadcast channel (NB-PBCH), an NB-SIB and the like), and a NB-PDCCH common search space. The configuration information for an anchor RB, for example an anchor PRB, may include at least one of the following parameters: a RB location, for example a PRB location, within a system bandwidth, a raster offset, and a PCI of the NB-Sync.

[0203] In an example, the information type for the DCI may be determined based on a flag field in the DCI. For example, the flag field may indicate the information type carried. In another example, the information type for the DCI may be determined based on a RNTI used for the DCI. A first RNTI (e.g., P-RNTI-1) may be used if the DCI carries scheduling information of a corresponding PDSCH. A second RNTI (e.g., P-RNTI-2) may be used if the DCI carries direct information such as one or more indications related to a system configuration. In other examples, the information type for the DCI may be determined based on a scrambling sequence used for the DCI or a starting ECCE index used.

[0204] In examples, an eNode-B may page one or more WTRUs to indicate or provide a broadcast transmission or a multicast transmission. For example, for a downlink burst transmission to a group of WTRUs or all WTRUs in a cell, such as, for example, for or to perform a software upgrade of one or more NB-IoT devices, an eNode-B may page or may need to page the group of WTRUs or all WTRUs in the cell. For example, the eNode-B may need to page the group of WTRUs or all WTRUs in the cell if the WTRUs are in RRC idle. The eNode-B may need to transmit the downlink burst for each WTRU via WTRU-dedicated resources. This may result in inefficient resource utilization and WTRU battery consumption. A downlink burst transmission may be used herein as a non-limiting example of a broadcast or multicast transmission.

[0205] In an example, a common PO may be used for a downlink burst transmission. For example, a DCI scrambled with a certain RNTI, such as, for example, a downlink burst RNTI (DB-RNTI), may be monitored by a WTRU in

a PDCCH search space in the common PO. The DCI may schedule a PDSCH carrying a downlink burst traffic.

[0206] A WTRU may monitor or attempt to decode the DCI in a PDCCH search space. The PDCCH search space may be located in a certain time/frequency resource configured or used for the common PO. The time/frequency resource for a common PO may be determined based on at least one of the following parameters: system parameters, such as, for example, system bandwidth, physical cell-ID, duplex mode, TDD subframe configuration; subframe number and/or radio frame number, for example SFN; WTRU-ID, such as, for example, full or partial information of IMSI, s-TMSI and the like; operation mode, such as, for example, in-band, guard-band, and stand-alone operation; one or more coverage levels, which may be represented by, for example, repetition numbers; WTRU category and/or WTRU capabilities; and paging NBs, which may be configured or determined.

[0207] The DCI may activate and/or deactivate the PDSCH transmission for downlink burst transmission. The PDSCH may be transmitted in predefined time/frequency resources. The predefined time/frequency resources may be transmitted with a duty cycle.

[0208] In an example, a scheduling information of the downlink burst may be transmitted in a broadcast channel or in system information, such as, for example, in a MIB or a SIB. A WTRU may receive an indication or may be indicated, triggered, or informed to read the broadcast channel or the system information. The indication may be signaled in a paging message or as a direct indication in a DCI for paging. The scheduling information of the downlink burst may be transmitted in a broadcast channel or in system information. A WTRU may receive or attempt to decode the broadcast channel or system information if the WTRU receives a system information update indication.

[0209] In an example, an ordered PDSCH transmission may be used for the downlink burst transmission. For example, downlink burst traffic may be split into *N*_burst transport blocks and may be numbered in an increasing order. Each transport block may be transmitted in a PDSCH transmission. Scheduling information for the downlink burst transmission may indicate the

number of transport blocks, represented by, for example *N*_burst, for the downlink burst transmission. Scheduling information for a PDSCH carrying one or more downlink burst transport blocks may indicate the ordering number of the PDSCH.

[0210] Each transport block may be transmitted in a certain time and/or frequency resource. A transport block with a certain transport block number may be associated with a certain subframe number, a certain SFN and/or a certain hyper frame number. Therefore, a WTRU may determine, assume, or understand which transport block may be transmitted in a certain time/frequency resource for the burst transmission. If a WTRU fails to receive a subset of the transport blocks of the *N*_burst transport blocks, the WTRU may receive the failed transport blocks in a next downlink burst transmission. A transport block with a certain transport block number may be associated with a certain frequency resource. The certain time/frequency resources may be configured via higher layer signaling.

[0211] Each PDSCH carrying a transport block may be transmitted with a repetition, where the repetition number may be indicated in the scheduling information. The repetition number may include a value of "1" as a no repetition case.

[0212] In an example, a WTRU that fails to receive one or more PDSCH transmissions for a downlink burst transmission may perform one or more of following actions. The WTRU may attempt to receive the failed PDSCH transmission in a following transmission or a following transmission window. A maximum number of attempts may be predefined or configured by higher layers. The maximum number of attempts may include a value of "1".

[0213] If the WTRU fails to receive one or more PDSCH transmissions after the maximum number of attempts, the WTRU may attempt to change operation mode, such as, for example, from RRC idle mode to RRC connected mode, and/or the WTRU may initiate a random access or random access channel (RACH) procedure.

[0214] In another example, a WTRU that fails to receive one or more PDSCH transmissions for a downlink burst transmission may perform one or

more of the following actions. The WTRU may send a corresponding hybrid automatic repeat request acknowledgement (HARQ-ACK) transmission in an associated HARQ-ACK resource. A HARQ transmission for reception failure may be a negative acknowledgement (NACK). A subset of physical random access channel (PRACH) resources may be reserved as an associated HARQ-ACK resource for the downlink burst transmission. For example, a WTRU may send a HARQ transmission that may be a NACK on a PRACH resource when it fails to receive one or more PDSCH transmissions for a downlink burst transmission. A set of physical uplink control channel (PUCCH) resources may be configured, indicated, or used for HARQ transmission, for example for NACK transmission. For example, a WTRU may send a HARQ transmission that may be a NACK on a PUCCH resource that may be configured or indicated when it fails to receive one or more PDSCH transmissions for a downlink burst transmission.

[0215] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element can be used alone or in any combination with the other features and elements. In addition, the methods described herein may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, and optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, UE, terminal, base station, RNC, or any host computer.

CLAIMS

What is claimed is:

1. A method performed in a machine type communication (MTC) wireless transmit/receive unit (WTRU), the method comprising:

determining, by the WTRU, a paging narrowband (NB) for the WTRU, to use for monitoring an MTC physical downlink control channel (M-PDCCH), based on at least the most significant bits (MSBs) of a function of a WTRU-identifier (WTRU-ID);

monitoring, by the WTRU, for the M-PDCCH on the determined paging NB for the WTRU;

receiving, by the WTRU, a downlink control information (DCI) on the monitored M-PDCCH on the determined paging NB during a paging occasion (PO); and

receiving, by the WTRU, a physical downlink shared channel (PDSCH) associated with the M-PDCCH.

2. The method of claim 1, wherein the WTRU determines the paging NB based on at least the 3 MSBs of a function of the WTRU-ID.

3. The method of claim 1, wherein the WTRU determines the paging NB based on at least the 4 MSBs of a function of the WTRU-ID.

4. The method of claim 1, wherein the DCI includes a cyclic redundancy check (CRC) that is scrambled with a Paging Radio Network Temporary Identifier (P-RNTI).

5. The method of claim 1, wherein the PDSCH is scheduled by the DCI.

6. The method of claim 1, wherein the DCI includes system information update related information.

7. The method of claim 1, where in the PDSCH includes system information update related information.

8. The method of claim 1, wherein the PDSCH includes a paging message.

9. The method of claim 1, wherein the WTRU-ID is a WTRU international mobile subscriber identity (IMSI).

10. The method of claim 9, wherein the function includes IMSI mod 16,384.

11. The method of claim 1, wherein determining the paging NB for the WTRU is further based on a number of NBs for paging.

12. A machine type communication (MTC) wireless transmit/receive unit (WTRU), the WTRU comprising:

a processor configured to determine a paging narrowband (NB) for the WTRU, to use for monitoring an MTC physical downlink control channel (M-PDCCH), based on at least the most significant bits (MSBs) of a function of a WTRU-identifier (WTRU-ID);

a transceiver operatively coupled to the processor, the transceiver and processor configured to monitor for the M-PDCCH on the determined paging NB for the WTRU;

the transceiver and processor configured to receive a downlink control information (DCI) on the monitored M-PDCCH on the determined paging NB during a paging occasion (PO); and

the transceiver and processor configured to receive a physical downlink shared channel (PDSCH) associated with the M-PDCCH.

13. The WTRU of claim 12, wherein the WTRU determines the paging NB based on at least the 3 MSBs of a function of the WTRU-ID.

14. The WTRU of claim 12, wherein the WTRU determines the paging NB based on at least the 4 MSBs of a function of the WTRU-ID.

15. The WTRU of claim 12, wherein the DCI includes a cyclic redundancy check (CRC) that is scrambled with a Paging Radio Network Temporary Identifier (P-RNTI).

16. The WTRU of claim 12, wherein the PDSCH is scheduled by the DCI.

17. The WTRU of claim 12, wherein the DCI includes system information update related information.

18. The WTRU of claim 12, wherein the PDSCH includes system information update related information.

19. The WTRU of claim 12, wherein the PDSCH includes a paging message.

20. The WTRU of claim 12, wherein the WTRU-ID is a WTRU international mobile subscriber identity (IMSI).

21. The WTRU of claim 20, wherein the function includes IMSI mod 16,384.

22. The WTRU of claim 12, wherein the determining the paging NB for the WTRU is further based on a number of NBs for paging.

23. A method performed in a machine type communication (MTC) wireless transmit/receive unit (WTRU), the method comprising:

monitoring, by the WTRU, for an MTC physical downlink control channel (M-PDCCH) in an M-PDCCH search space;

receiving, by the WTRU, an M-PDCCH in the M-PDCCH search space, wherein the M-PDCCH has a starting enhanced control channel element (ECCE) index for a WTRU group containing the WTRU;

decoding, by the WTRU, the M-PDCCH, wherein the M-PDCCH includes a downlink control information (DCI); and

receiving, by the WTRU, a physical downlink shared channel (PDSCH) associated with the M-PDCCH.

24. The method of claim 23, further comprising:

demodulating, by the WTRU, the PDSCH based on the DCI, wherein the PDSCH includes a paging message.

25. The method of claim 24, wherein the WTRU changes operations based on the paging message.

26. The method of claim 25, wherein the WTRU changing operations includes the WTRU changing from idle mode to connected mode based on the paging message.

27. The method of claim 23, wherein an ECCE aggregation level is 16.

28. The method of claim 23, further comprising:

receiving, by the WTRU, the PDSCH based on the DCI, wherein the PDSCH includes a paging message.

29. The method of claim 23, further comprising:

decoding, by the WTRU, the PDSCH based on the DCI, wherein the PDSCH includes a paging message.

(54) **Title**: IMPROVED PAGING PROCEDURES FOR USER EQUIPMENTS REQUIRING COVERAGE EXTENSION

(57) **Abstract**: The present disclosure relates to a method for paging coverage extension UEs in a cell controlled by a radio base station. At least one regularly-occurring coverage-extension-specific paging possibility (CE-specific paging possibility), is defined for paging CE UEs. The CE-UEs in the cell regularly monitor the at least one CE-specific paging possibility. When the radio base station determines to page all the user equipments in the cell, it pages the CE user equipments in the cell at the CE-specific paging possibility, using a coverage extension technique. The present disclosure also relates to a method for paging a CE UE, which performs radio measurements by the CE-capable user equipment to determine whether coverage extension is necessary. The radio base station is informed about whether the CE-capable user equipment needs coverage extension or not and then pages the CE UEs applying or not applying a CE technique depending on whether coverage extension is necessary or not.

WO 2016/136143 A1

Description

Title of Invention: IMPROVED PAGING PROCEDURES FOR USER EQUIPMENTS REQUIRING COVERAGE EXTENSION

Technical Field

[0001] The present disclosure relates to methods for paging one or several user equipments in a cell of a radio base station, where the user equipment(s) do require coverage extension to be reliably paged. The present disclosure is also providing the user equipment and radio base station for participating in the methods described herein.

Background

[0002] Long Term Evolution (LTE)

Third-generation mobile systems (3G) based on WCDMA radio-access technology are being deployed on a broad scale all around the world. A first step in enhancing or evolving this technology entails introducing High-Speed Downlink Packet Access (HSDPA) and an enhanced uplink, also referred to as High Speed Uplink Packet Access (HSUPA), giving a radio access technology that is highly competitive.

[0003] In order to be prepared for further increasing user demands and to be competitive against new radio access technologies, 3GPP introduced a new mobile communication system which is called Long Term Evolution (LTE). LTE is designed to meet the carrier needs for high speed data and media transport as well as high capacity voice support for the next decade. The ability to provide high bit rates is a key measure for LTE.

[0004] The work item (WI) specification on Long-Term Evolution (LTE) called Evolved UMTS Terrestrial Radio Access (UTRA) and UMTS Terrestrial Radio Access Network (UTRAN) is finalized as Release 8 (LTE Rel. 8). The LTE system represents efficient packet-based radio access and radio access networks that provide full IP-based functionalities with low latency and low cost. In LTE, scalable multiple transmission bandwidths are specified such as 1.4, 3.0, 5.0, 10.0, 15.0, and 20.0 MHz, in order to achieve flexible system deployment using a given spectrum. In the downlink, Orthogonal Frequency Division Multiplexing (OFDM) based radio access was adopted because of its inherent immunity to multipath interference (MPI) due to a low symbol rate, the use of a cyclic prefix (CP) and its affinity to different transmission bandwidth arrangements. Single-carrier frequency division multiple access (SC-FDMA) based radio access was adopted in the uplink, since provisioning of wide area coverage was prioritized over improvement in the peak data rate considering the restricted transmit power of the user equipment (UE). Many key packet radio access techniques are employed including multiple-input multiple-output

(MIMO) channel transmission techniques and a highly efficient control signaling structure is achieved in LTE Rel. 8/9.

[0005] LTE architecture

The overall architecture is shown in Fig. 1 and a more detailed representation of the E-UTRAN architecture is given in Fig. 2. The E-UTRAN consists of an eNodeB, providing the E-UTRA user plane (PDCP/RLC/MAC/PHY) and control plane (RRC) protocol terminations towards the user equipment (UE). The eNodeB (eNB) hosts the Physical (PHY), Medium Access Control (MAC), Radio Link Control (RLC) and Packet Data Control Protocol (PDCP) layers that include the functionality of user-plane header-compression and encryption. It also offers Radio Resource Control (RRC) functionality corresponding to the control plane. It performs many functions including radio resource management, admission control, scheduling, enforcement of negotiated uplink Quality of Service (QoS), cell information broadcast, ciphering/ deciphering of user and control plane data, and compression/ decompression of downlink/uplink user plane packet headers. The eNodeBs are interconnected with each other by means of the X2 interface.

[0006] The eNodeBs are also connected by means of the S1 interface to the EPC (Evolved Packet Core), more specifically to the MME (Mobility Management Entity) by means of the S1-MME and to the Serving Gateway (SGW) by means of the S1-U. The S1 interface supports a many-to-many relation between MMEs/Serving Gateways and eNodeBs. The SGW routes and forwards user data packets, while also acting as the mobility anchor for the user plane during inter-eNodeB handovers and as the anchor for mobility between LTE and other 3GPP technologies (terminating S4 interface and relaying the traffic between 2G/3G systems and PDN GW). For idle state user equipments, the SGW terminates the downlink data path and triggers paging when downlink data arrives for the user equipment. It manages and stores user equipment contexts, e.g. parameters of the IP bearer service, network internal routing information. It also performs replication of the user traffic in case of lawful interception.

[0007] The MME is the key control-node for the LTE access-network. It is responsible for idle mode user equipment tracking and paging procedure including retransmissions. It is involved in the bearer activation/deactivation process and is also responsible for choosing the SGW for a user equipment at the initial attach and at time of intra-LTE handover involving Core Network (CN) node relocation. It is responsible for authenticating the user (by interacting with the HSS). The Non-Access Stratum (NAS) signaling terminates at the MME and it is also responsible for generation and allocation of temporary identities to user equipments. It checks the authorization of the user equipment to camp on the service provider's Public Land Mobile Network (PLMN) and enforces user equipment roaming restrictions. The MME is the ter-

mination point in the network for ciphering/integrity protection for NAS signaling and handles the security key management. Lawful interception of signaling is also supported by the MME. The MME also provides the control plane function for mobility between LTE and 2G/3G access networks with the S3 interface terminating at the MME from the SGSN. The MME also terminates the S6a interface towards the home HSS for roaming user equipments.

[0008] LTE RRC states

LTE is based on only two main states: "RRC_IDLE" and "RRC_CONNECTED".

[0009] In RRC_IDLE the radio is not active, but an ID is assigned and tracked by the core network. More specifically, a mobile terminal in RRC_IDLE performs cell selection and reselection – in other words, it decides on which cell to camp. The cell (re)selection process takes into account the priority of each applicable frequency of each applicable Radio Access Technology (RAT), the radio link quality and the cell status (i.e. whether a cell is barred or reserved). An RRC_IDLE mobile terminal monitors a paging channel to detect incoming calls, and also acquires system information. The system information mainly consists of parameters by which the network (E-UTRAN) can control the cell (re)selection process and also how the mobile terminal accesses the network. RRC specifies the control signalling applicable for a mobile terminal in RRC_IDLE, namely paging and system information. The mobile terminal behaviour in RRC_IDLE is specified in more detail e.g. in TS 36.304, current version 12.0.0(NPL 1), chapter 4 "General description of Idle mode" incorporated herein by reference.

[0010] In RRC_CONNECTED the mobile terminal has an active radio operation with contexts in the eNodeB. The E-UTRAN allocates radio resources to the mobile terminal to facilitate the transfer of (unicast) data via shared data channels. To support this operation, the mobile terminal monitors an associated control channel which is used to indicate the dynamic allocation of the shared transmission resources in time and frequency. The mobile terminal provides the network with reports of its buffer status and of the downlink channel quality, as well as neighbouring cell measurement information to enable E-UTRAN to select the most appropriate cell for the mobile terminal. These measurement reports include cells using other frequencies or RATs. The UE also receives system information, consisting mainly of information required to use the transmission channels. To extend its battery lifetime, a UE in RRC_CONNECTED may be configured with a Discontinuous Reception (DRX) cycle. RRC is the protocol by which the E-UTRAN controls the UE behaviour in RRC_CONNECTED.

[0011] The various functions of the mobile terminal in RRC Protocol for and including Connected Mode are described in 3GPP TS 36.331, current version 12.4.1(NPL 2), in

Ch. 4 "Functions", incorporated herein by reference.

[0012] Paging

The present application will differentiate between two types of paging, namely the paging initiated from the non-access stratum (NAS) (termed exemplarily in the following "Paging-NAS") and the paging initiated from the eNodeB (termed exemplarily in the following "Paging-eNB"). Paging-NAS relates to the paging of a particular UE e.g. when paging a UE in connection with an incoming data connection e.g. a mobile-terminating (MT) call. On the other hand, paging-eNB relates to the paging of all the UEs in the cell, and e.g. is used to inform them about a system information change, ETWS message (Earthquake and Tsunami Warning System), CMAS message (Commercial Mobile Alert System) etc. Furthermore, depending on whether the UE is in RRC idle or connected state, the actual paging messages are transmitted differently to the UE. However, the two paging procedures have a lot in common too.

[0013] In general, the UE in RRC_Idle state monitors for paging to detect incoming calls, system information change, for ETWS capable UEs, ETWS notification, and for CMAS capable UEs, CMAS notification. The UE in RRC_Connected state monitors for paging and/or System Information Block Type 1 contents to detect system information change, for ETWS capable UEs, ETWS notification, and for CMAS capable UEs, CMAS notification (see 3GPP TS 36.331, current version v12.4.1, subclause 4.2.1, incorporated herein by reference).

The general paging procedure for transmitting the paging message from EUTRAN to the UE is defined in TS 36.331, current version 12.4.1, subclause 5.3.2 incorporated herein by reference, describing that the purpose of the paging procedure is:

[0014] - to transmit paging information to a UE in RRC_IDLE (Paging-NAS) and/ or;

- to inform UEs in RRC_IDLE and UEs in RRC_CONNECTED about a system information change (Paging-eNB) and/ or;

- to inform about an ETWS primary notification and/ or ETWS secondary notification (Paging-eNB) and/ or;

- to inform about a CMAS notification (Paging-eNB).

[0015] The paging information received in the UE is provided to upper layers, which in response e.g. may the initiate RRC connection establishment to receive an incoming call.

[0016] E-UTRAN performs the paging procedure by transmitting the Paging message at the UE's paging occasion as specified in TS 36.304. E-UTRAN may address multiple UEs within a Paging message by including one PagingRecord for each UE.

[0017] To receive paging messages from E-UTRAN, UEs in idle mode monitor the PDCCH channel for an RNTI value used to indicate paging: the P-RNTI (Paging radio network

temporary identity) which is a common RNTI, i.e. not allocated to any UE explicitly. The UE only needs to monitor the PDCCH channel at certain UE-specific paging possibilities, i.e. at specific subframes within specific radio frames as will be discussed in more detail in the following. The E-UTRAN configures which of the radio frames and subframes can be used for paging in its cell. Each cell broadcasts a default paging cycle Tc, and in addition, upper layers may use dedicated signaling to configure a UE-specific paging cycle TUE; if both are configured, the UE applies the lowest value for the DRX cycle T of the UE.

[0018] In order to explain the procedure for paging as currently defined for LTE-A, the following exemplary cases A, B, and C are defined, as taken from the book LTE – The UMTS Long Term Evolution – From Theory to Practice, Edited by: Stefania Sesia, Issam Toufik, and Matthew Baker, Second Edition, ISBN 9780470660256, section 3.4(NPL 3).

[0019] [Table 1]

Case	UE_ID	T_C	T_{UE}	T	nB	N	Ns	PF	i_s	PO
A	147	256	256	256	64	64	1	76	0	9
B	147	256	128	128	32	32	1	76	0	9
C	147	256	128	128	256	128	2	19	1	4

[0020] The following parameters are used in said respect:

- "TC" is the cell-specific default paging cycle, and can be 32, 64, 128, or 256 radio frames,

- "TUE" is the UE-specific paging cycle of the UE, and can be 32, 64, 128, or 256 radio frames,

- "N" is the number of paging frames within the paging cycle of the UE, and is min (T, nB),

- Ns is the number of paging subframes in a radio frame that may be used for paging, and is max (1, nB/T),

[0021] - nB is the number of paging subframes per paging cycle (across all UEs in the cell), and can be 4T, 2T, T, T/2, T/4, T/8, T/16, T/32; the parameter determines to a large extent the paging capability of the eNB across all UEs in the cell. In general, if nB is set equal to or larger than T, all radio frames may be used for paging (see also parameter N), and there are nB/T POs per PF (see also parameter Ns). In turn, if nB is set lower than T, only a fraction nB/T of the radio frames may be used for paging (see also parameter N), and there is one PO per PF (see also parameter Ns).

[0022] - "T" is the DRX cycle of the UE (also termed paging cycle), is min of TC and TUE,

and specifies how frequently a UE monitors for paging, where a shorter DRX cycle decreases the time for paging but increases battery consumption.

[0023] For example, for cases A and B E-UTRAN has configured one out of every four radio frames and specifically one subframe in each of those radio frames, to be used for paging (see T, Ns, respectively). For case C, there are two subframes in each radio frame that can be used for paging, i.e. Ns=2, and 128 paging frames within the UE's paging cycle, i.e. N=128, available for paging the UEs in the cell. Furthermore, for case B, there are 32 paging frames within the UE's paging cycle (N=32). Across these generally-available paging opportunities configured by the eNB, the paging possibilities for paging the UEs are distributed based on the UE identity.

[0024] In said respect, the particular radio frame and subframe used for paging a particular UE is calculated as follows. A Paging Occasion (PO) is a subframe where there may be a P-RNTI (Paging radio network temporary identity) transmitted on PDCCH addressing the paging message. A Paging Frame (PF) is a radio frame, which may contain one or multiple Paging Occasion(s). In the context of this patent application, the term paging possibility shall refer to the combination of the paging frame and paging subframe.

[0025] The paging frames and paging occasions are defined for example in 3GPP TS 36.304, current version 12.0.0, subclause 7, incorporated herein by reference. Accordingly, the paging frame number (SFN) is calculated according to the following formula:

SFN mod T = (T div N)*(UE_ID mod N)

where UE_ID is IMSI mod 1024.

[0026] When assuming an UE_ID of 147 for all three cases A, B, and C, calculating the above formula results in the paging frame 76 for cases A and B, and paging frame 19 for case C. Furthermore, i_s would be calculated to be 0 for cases A and B, and be 1 for case C.

[0027] The paging occasion has values in the range of [0, 1, ... 9], as in LTE there are 10 subframes within one radio frame. The paging occasion number is selected from a preconfigured table based on the parameters Ns and i_s calculated according to the following formula:

i_s= floor(UE_ID / N) mod Ns.

[0028] The following table is taken from TS 36.304, current version 12.0.0, and is used to determine the Paging Occasion for a particular UE, based on the above parameters Ns and i_s. The following table is intended for FDD.

[0029]

[Table 2]

	PO when i_s=0	PO when i_s=1	PO when i_s=2	PO when i_s=3
1	9	N/A	N/A	N/A
2	4	9	N/A	N/A
4	0	4	5	9

[0030] Therefore, for case A and B, with Ns=1 and i_s=0, the table would yield the subframe number 9, such that the UE for cases A and B would be paged regularly in subframe 9 of radio frame 76 of every paging cycle; i.e. for case A next radio frame 332 and for case B next radio frame 204 etc. For case C, the UE would be paged regularly in subframe 4 of radio frame 19 of every paging cycle, i.e. next radio frame 147 etc.

[0031] The paging frame and paging occasion for the above-discussed cases B and C, is exemplarily depicted in Fig. 3.

[0032] Paging-NAS

For instance, in order to re-establish a connection towards a UE in idle mode, the MME - having been informed e.g. by the UE's P/SGW - sends a paging request message to all eNBs that are part of the so-called tracking area(s) to which the UE belongs and within which the UE can move without having to perform the Tracking Area Update (TAU) procedure (except the periodic TAU procedure).

[0033] When receiving the paging request, the eNodeB(s) of the tracking area(s) then broadcast(s) another paging message over the radio interface in the cells The UE is notified about the paging based on the P-RNTI on the PDCCH and then receives the paging message transmitted over the PDSCH, in the radio resources as indicated by the PDCCH paging notification. When the UE in RRC idle receives the paging message/ signal, it transfers from IDLE to CONNECTED state and establishes an RRC connection with that eNB where it is camped in IDLE mode (e.g. the UE initiates the RRC connection establishment procedure).

[0034] A system overview and message exchange is exemplarily illustrated in Fig. 4, assuming that the UE to be paged by the MME (as triggered by the SGW) is registered at tracking areas TAC1 and TAC3. Consequently, the MME will provide the S1AP paging request to the eNBs of those tracking areas, which in turn will transmit a page at the UE-specific paging possibility (i.e. the PDCCH notification) and then the paging message on the PDSCH resources. The UE is consequently notified about the paging, receives the paging message on the PDSCH, and after confirming its own identity in the paging message, processes the paging message and responds to the paging by e.g. by sending a service request to the MME.

[0035] In the current LTE system, the paging message transmitted from the MME to the eNB, and its content, are defined e.g. by 3GPP TS 36.413, current version 12.4.0(NPL 4), in sub-clauses 8.5 and 9.1.6, incorporated herein by reference. The paging message from the MME to the eNB contains amongst other the following information:

[0036] - UE_ID Index Value: known as UE_ID, which is calculated by (IMSI mod 1024). Correspondingly, the UE_ID may have values in the range of [0, 1 ... 1023].

[0037] - UE Paging Identity: can be the IMSI (as stored on the SIM card) or the SAE-Temporary Mobile subscriber ID (S-TMSI) assigned to the UE during the attach procedure. The UE Paging Identity is transmitted from the eNB to the UE in a paging message over the radio interface (i.e. Uu interface).

[0038] - Paging DRX cycle: is the Discontinuous Reception (DRX) cycle configured in the UE (using NAS signalling) or the default DRX cycle broadcast in the System Information Block (SIB). The default DRX cycle is also known as Paging Cycle in the RadioResourceConfigCommon SIB. The UE may use discontinued reception in IDLE mode in order to reduce power consumption. The DRX cycle is a time interval between monitoring Paging Occurrences for a specific UE. The values of the default DRX/paging cycle broadcast in the SIB are 32, 64, 128 or 256 radio frames.

- UE radio Capability for paging: including the radio access capabilities of the UE, including the coverage extension capability.

[0039] The paging message transmitted from the eNodeB is broadcast in a defined paging possibility as explained above. Paging possibilities are known to the eNodeB and the UE so that they send/listen to the paging message at the same time.

[0040] When Discontinues Reception (DRX) is used, the UE needs only to monitor one PO per DRX cycle.

[0041] As mentioned before, the paging initiated by the non-access stratum (NAS) is UE specific. Consequently, the UE is paged by using the IMSI (or S-TMSI) of the UE as paging identity in the paging message sent in the PDSCH. Therefore, for each UE a separate paging message has to be transmitted from the MME to the eNB(s), which has then to be broadcast from the corresponding eNB(s).

[0042] The paging message transmitted from the eNodeB to the UE is defined in TS 36.331, current version 12.4.1, subclause 6.2.2 Message definition, section "Paging", incorporated herein by reference. This message may contain the following:

[0043] - cmas-Indication: if present, indication of a CMAS notification

- cn-Domain: indicates the origin of paging

- eab-ParamModification: if present, indication of an EAB parameter (SIB14) modification

- etws-Indication: if present, indication often ETWS primary/secondary notification

- imsi: The International Mobile Subscriber Identity, a globally unique permanent

subscriber identity; can also be part of the Paging UE-Identity below

- systemInfoModification: if present, indication of a BCCH modification, other than SIB10-SIB12, SIB14

- ue-Identity: provides the NAS identity of the UE that is being paged

[0044] In the above description, it has been assumed that the UE is in an idle state when receiving the paging, such that the paging message is sent to the UE addressed to the P-RNTI on PDCCH at the UE-specific paging possibilities (based on IMSI of this UE) where the UE verifies that the paging message is indeed intended for it by checking the IDs in the included paging records.

[0045] However, also UEs in RRC connected state may be paged. In this case a downlink information transfer (DLInformationTransfer), containing the paging related information from the NAS, is sent to the UE addressed to the C-RNTI (Cell-RNTI, a unique ID used for identifying RRC connection and scheduling dedicated to a particular UE) on the PDCCH. The DLInformationTransfer message is used for the downlink transfer of NAS or non-3GPP dedicated information. The RRC layer is transparent for this information. For more information, reference is made to TS 36.331, current version 12.4.1, subclause 5.6.1 "DL information transfer" and 6.2.2 "Message definitions" section DLInformationTransfer, incorporate herein by reference.

[0046] Paging from eNB

One of the reasons for an eNodeB to page the UE is a change of system information. In general a change of system information only occurs at specific radio frames, thus implementing the concept of a modification period. System information may be transmitted a number of times with the same content within a modification period. When the network changes (some of) the system information, it first notifies the UEs about this change, which may be done throughout a modification period. In the next modification period, the network then transmits the updated system information. Upon receiving a change notification, the UE acquires the new system information immediately from the start of the next modification period. A paging message is used to inform the UEs in RRC idle and UEs in RRC connected state about a system information change (as mentioned e.g. in TS 36.304, current version 12.0.0, subclause 6.1). If the UE receives a paging message including the systemInfoModification, it knows that the system information will change at the next modification period and boundary. In said case, the UE does not need to check for the UE_ID (not included in the paging message), in view of the presence of the systemInfoModification. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.3, incorporated herein by reference.

[0047] Another reason for the eNodeB to page the UEs is an ETWS (Earthquake and Tsunami Warning system) notification, where the paging message is used to inform

ETWS-capable UEs in RRC idle and in RRC connected state about the presence of an ETWS primary/secondary notification. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.4, incorporated herein by reference. The paging message may also be used to inform CMAS-capable UEs in RRC idle and RRC connected state about the presence of one or more CMAS (Commercial Mobile Alert System) notifications. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.5, incorporated herein by reference. Still another reason for the eNB to page UEs in its cell relates e.g. to Enhanced Access Barring for MTC devices, EAB, as explained for example in TS 36.331, current version 12.4.1, subclause 5.2.1.6 incorporated herein by reference.

[0048] For UEs in both RRC connected and idle state the eNB sends a paging notification to the UE(s) addressed to the P-RNTI on the PDCCH at all possible paging occasions (e.g. at subframes 0, 4, 5, and 9) and at all possible paging frames (e.g. N different radio frames in total, calculated according to SFN mod T=T/N (UE_ID mod N) for every possible "UE_ID mod N" value) irrespective of the IMSI of a particular UE in the cell. By transmitting the paging message at all possible paging possibilities within a paging cycle, the eNB ensures that all the UEs receive the paging message. The detailed definitions for determining the paging occasions and paging frames are given above.

[0049] Machine Type Communication (MTC)

As LTE deployments evolve, operators strive to reduce the cost of overall network maintenance by minimizing the number of RATs. In this respect, Machine-Type Communications (MTC) devices is a market that is likely to continue expanding in the future.

[0050] Many MTC devices are targeting low-end (low cost, low data rate) applications that can be handled adequately by GSM/GPRS. Owing to the low cost of these devices and good coverage of GSM/GPRS, there is very little motivation for MTC device suppliers to use modules supporting the LTE radio interface.

[0051] As more and more MTC devices are deployed in the field, this naturally increases the reliance on GSM/GPRS networks. This will cost operators not only in terms of maintaining multiple RATs, but also prevent operators reaping the maximum benefit out of their spectrum (given the non-optimal spectrum efficiency of GSM/GPRS). With users and traffic becoming denser, using more spectral-efficient technologies, such as Long Term Evolution (LTE), allow the operators to utilize their spectrum in a much more efficient way.

[0052] Given the likely high number of MTC devices, the overall resource they will need for service provision may be correspondingly significant, and inefficiently assigned (for further details on objectives for MTC, see for example 3GPP, RP-111112, Vodafone:

"Provision of low-cost MTC UEs based on LTE"(NPL 5), section 4, available at http://www.3gpp.org and incorporated herein by reference).

[0053] Approaches to lower the cost of LTE presently regard the volume of products as the primary reason. The impact of volume can be seen in two possible ways, depending on how low-cost MTC is developed. Firstly, if low-cost MTC may be very similar to mainline LTE and included in LTE chipsets, MTC has the benefit of the volume of LTE. Secondly, a low-cost MTC based on LTE may have significantly lower cost than mainline LTE. Although it appears not to have the volume benefit of LTE, the volume of MTC devices can be even larger due to a potentially greater number of supported MTC applications and scenarios.

[0054] In this respect, the following approaches to lower the cost of LTE, i.e. defining low-cost MTC are discussed and found to have significant UE cost impact (for further details on low-cost MTC devices, see for example 3GPP, R1-112912, Huawei, HiSilicon, CMCC: "Overview on low-cost MTC UEs based on LTE"(NPL 6), section 4, available at http://www.3gpp.org and incorporated herein by reference):

[0055] - Reduction in supported bandwidth for the low-cost LTE: The low cost of 1.4 MHz (6 RB) downlink bandwidth could cover most application scenarios of MTC. However, 3 MHz (15 RB) or 5 MHz (25 RB) could be considered given that the complexity does not increase much. Given that the uplink may have a larger requirement for MTC services, the possibility of reduced transmit power, and small baseband complexity (relative to downlink reception), any reduction in minimum transmission bandwidth in the UE should be carefully justified.

[0056] - Modified PDCCH-related design for the low-cost LTE to simplify the PDCCH blind decoding and give efficient channel access for a large number of MTC devices. A reduction in maximum bandwidth (e.g., 1.4MHz) decreases PDCCH blind decoding naturally.

[0057] - Protocol simplification including HARQ consideration, MAC, RLC and RRC protocol. Signaling reduction between low duty cycle MTC devices and the base station.

- Transmission modes down-selection to maintain coverage and balance complexity.

[0058] Further considerations on low-cost MTC devices relate to an improved indoor coverage. A number of applications require indoor deployment of Machine Type Communication, MTC, devices, e.g. in an apartment basement, or on indoor equipment that may be close to the ground floor etc. These UEs would experience significantly greater penetration losses on the radio interface than normal LTE devices. This effectively means that indoor coverage should be readily available and reliable: i.e. should provide a significant improvement on existing coverage.

[0059] Additionally, regarding the power consumption of low-cost MTC devices it is noted

that many applications require devices to have up to ten years of battery life. In this respect, presently available Power Save Modes appear not sufficient to achieve the envisaged battery life. In this respect, it is anticipated that further techniques are proposed to significantly cut down the power usage of MTC devices e.g. by optimizing signaling exchanges in the system, in order to realize battery life of up to ten years.

[0060] Enhanced Coverage mode (EC mode)

For improving indoor coverage (for low-cost MTC devices), recent developments have focused on an Enhanced Coverage, EC, mode that is applicable to UEs e.g. operating delay tolerant MTC applications. Another term is "Coverage Extension". The corresponding Work Item in 3GPP Release 12 "Low cost & enhanced coverage MTC UE for LTE" came to the conclusion that further complexity reduction of LTE devices for MTC can be achieved if additional complexity reduction techniques are supported, as apparent from the study report TR 36.888. The study report TR 36.888 concluded that a coverage improvement target of 15-20 dB for both FDD and TDD in comparison to a normal LTE footprint could be achieved to support the use cases where MTC devices are deployed in challenging locations, e.g. deep inside buildings, and to compensate for gain loss caused by complexity-reduction techniques. MTC coverage enhancements are now expected to be introduced in 3GPP Release 13.

[0061] The general objective is to specify a new UE for MTC operation in LTE that allows for enhanced coverage and lower power consumption. Some of the additional objectives are given below:

- Reduced UE bandwidth of 1.4 MHz in downlink and uplink.

-- Bandwidth reduced UEs should be able to operate within any system bandwidth.

-- Frequency multiplexing of bandwidth reduced UEs and non-MTC UEs should be supported.

-- The UE only needs to support 1.4 MHz RF bandwidth in downlink and uplink.

-- The allowed re-tuning time supported by specification (e.g. ~0 ms, 1 ms) should be determined by RAN4.

[0062] - Reduced maximum transmit power.

-- The maximum transmit power of the new UE power class should be determined by RAN4 and should support an integrated PA implementation.

[0063] - Reduced support for downlink transmission modes.

[0064] - The following further UE processing relaxations can also be considered within this work item:

-- Reduced maximum transport block size for unicast and/or broadcast signalling.

-- Reduced support for simultaneous reception of multiple transmissions.

-- Relaxed transmit and/or receive EVM requirement including restricted modulation scheme. Reduced physical control channel processing (e.g. reduced number of blind

decoding attempts).

-- Reduced physical data channel processing (e.g. relaxed downlink HARQ time line or reduced number of HARQ processes).

-- Reduced support for CQI/CSI reporting modes.

[0065] A relative LTE coverage improvement - corresponding to 15 dB for FDD - for the UE category/type defined above and other UEs operating delay-tolerant MTC applications with respect to their respective normal coverage shall be possible. At least some of the following techniques, which shall be applicable for both FDD and TDD, can be considered to achieve this:

[0066] - Subframe bundling techniques with HARQ for physical data channels (e.g. PDSCH, PUSCH)

- Elimination of use of control channels (e.g. PCFICH, PDCCH)

- Repetition techniques for control channels (e.g. PBCH, PRACH, (E)PDCCH)

- Either elimination or repetition techniques (e.g. PBCH, PHICH, PUCCH)

- Uplink PSD boosting with smaller granularity than 1 PRB

- Resource allocation using EPDCCH with cross-subframe scheduling and repetition (EPDCCH-less operation can also be considered)

[0067] - New physical channel formats with repetition for SIB/RAR/Paging

- A new SIB for bandwidth reduced and/or coverage enhanced UEs

- Increased reference symbol density and frequency hopping techniques

- Relaxed "probability of missed detection" for PRACH and initial UE system acquisition time for PSS/SSS/PBCH/SIBs can be considered as long as the UE power consumption impact can be kept on a reasonable level.

- Spreading: Spreading refers to spreading of information across resources including time-frequency domain resources or even spreading using Scrambling (or Channelization) codes.

[0068] There can be also other techniques than those listed above.

The amount of coverage enhancement should be configurable per cell and/or per UE and/or per channel and/or group of channels, such that different levels of coverage enhancements exist. The different levels of coverage enhancement could mean different level of CE techniques being applied to support the CE-device transmission and reception. Relevant UE measurements and reporting to support this functionality should be defined.

[0069] For more details, see for example 3GPP RP-141865 "Revised WI: Further LTE Physical Layer Enhancements for MTC"(NPL 7) sourced by Ericsson, available at http://www.3gpp.org and incorporated herein by reference.

[0070] Notably, coverage enhancements of 15/ 20 dB for UEs in the Enhanced Coverage mode with respect to their nominal coverage means that the UEs have to be capable of

receiving extremely low signal strengths. This applies not only to the initial scanning operation, the cell search and the cell selection operation but also the subsequent communication scheme to be performed by the UE.

[0071] Early attempts to define the Enhanced Coverage mode have focused on modifications of the radio transmissions. In this respect, discussions have focused on repeated transmissions as being the main technique to improve the coverage. Repetitions can be applied to every channel for coverage improvement.

[0072] An exemplary implementation of these repeated transmissions prescribes that the same data is transmitted across multiple sub-frames. Yet, it will become immediately apparent that these repeated transmissions will use more resource blocks (time-frequency) resources than required for normal coverage UEs.

Summary

[0074] One non-limiting and exemplary embodiment provides an improved method for paging all user equipments in a cell, particularly involving user equipments which need coverage extension. Another non-limiting and exemplary embodiment provides an improved method for paging one user equipment in a cell, particularly a user equipment which needs coverage extension.

The independent claims provide non-limiting and exemplary embodiments. Advantageous embodiments are subject to the dependent claims.

According to a first aspect, the present disclosure improves the paging procedure by which a radio base station can page the user equipments in its cell, particularly for the case where the paging shall also reach user equipments which require coverage extension, i.e. user equipments that are in poor radio conditions but support coverage extension techniques as explained in the background section. The first aspect refers to the case were paging is initiated by the radio base station and shall reach all user equipments in the cell of the radio base station; in other words, the paging is not UE specific but cell specific, and can be for example used so as to broadcast a warning message or to inform UEs about an imminent system information change.

[0075] Consequently, the paging must reach user equipments that require coverage extension as well as "normal" user equipments which do not require coverage extension. One main idea of the first aspect is the definition of a coverage-extension-specific paging possibility, which is specifically defined for those user equipments that support coverage extension techniques, and more precisely which need coverage extension to be reliably reached. Correspondingly, the CE-UEs not only monitor the UE-specific paging possibility, calculated based on their identities, but additionally monitor a (at least one) different paging possibility dedicated to achieve coverage extension paging. Both CE-user equipments in idle and connected state can be configured to monitor this CE-specific paging possibility. Consequently, in order to reach those CE-UEs, the radio base station pages the CE-UEs at said CE-specific paging possibility, and uses one of the plurality of available techniques (e.g. repetition or increased transmission power) for extending the coverage of the paging and thus to reliably reach the CE-UE.

[0076] Like a usual UE-specific paging possibility, this CE-specific paging possibility is defined by a particular radio frame number and subframe number, and occurs regularly e.g. at every paging cycle.

[0077] Since the CE-specific paging possibility shall preferably only be monitored by CE-UEs, the radio base station still needs to reach the other non-CE-UEs and can thus, as described in the background section, perform the paging at all possible paging possibilities of a paging cycle, so as to reach all UEs in the cell. In this case the radio base station would not use a coverage extension technique, since the radio base station can be sure that the CE-UEs will be reached by the paging at the CE-specific paging possibility and not for all possible.

[0078] One advantage of the above-described first aspect is that, by providing one dedicated paging possibility for CE-UEs, downlink resources can be saved. The coverage extension techniques, which can be a heavy burden to the radio base station(s) are applied in a very limited manner, namely for just one paging possibility.

[0079] One set of variants of the first aspect differs as to how this CE-specific paging pos-

sibility is defined. In general, it can be said that the CE-specific paging possibility must be known to both the CE-UE(s) and the radio base station(s), so as to ensure that the paging can be successful. However, how exactly the CE-specific paging possibility is defined can vary. One solution is that the radio frame number and the subframe number of the CE-specific paging possibility is fixed beforehand such that corresponding information can be e.g. pre-stored at the radio base station and the CE-UE (e.g. in the USIM), or the radio base station can broadcast same in its cell. Another possible solution is that a plurality of possible paging subframes, generally configured for the system by the radio base station, is divided to be used either as a UE-specific paging subframe or as a CE-specific paging subframe. By correspondingly configuring the paging parameter(s) (e.g. nB) of normal UEs and CE-UEs it is possible that CE-UEs are assigned e.g. one normal UE-specific paging subframe and one CE-specific paging subframe. Still another solution is based on an additional CE-specific UE identity that is assigned exclusively to CE-UEs and which can be used for calculating the CE-specific paging possibility; in addition, as in the prior art, the UE-specific paging possibility is calculated based on the usual identity of the CE-UE (e.g. IMSI).

[0080] According to a second aspect, the paging procedure by which a radio base station pages a user equipment which requires coverage extension in its cell is improved. This second aspect refers to the case where the paging is initiated in the core network (NAS) and is destined to a single UE (or a very limited number of UEs), in contrast to the first aspect dealing with cell-wide paging initiated by the eNB. The paging which is directed at a particular CE-UE shall reliably reach the CE-UE, and thus the radio base station shall use one appropriate coverage extension technique for the CE paging. In order to avoid unnecessary CE paging from the radio base station, the CE-capable UEs will implement a measurement and reporting procedure according to which the radio base station is informed as to the current CE status of the UE. The radio base station will thus only perform a CE paging for a CE-capable UE that is indeed currently in the CE status, i.e. currently requiring coverage extension. CE-UEs, although CE capable, will not be paged with a coverage extension technique, if the status of the CE-capable UE, informed to the radio base station, indicates that no coverage extension is actually required by this CE-capable UE at the moment.

[0081] Appropriate radio measurements are regularly performed by the CE-capable UE(s) to determine whether coverage extension is necessary or not at the moment. The measurements could also be triggered by the radio base station or a core network entity when being interested in the current CE status. These measurements could include e.g. at least one of RSRQ, RSRP, channel quality, block error rate, or any other suitable measurement parameter. Appropriate threshold(s) can be defined to which the CE-capable UE(s) compare(s) the measurement results to determine whether it requires or

not coverage extension.

[0082] Consequently, a particular CE-capable UE can change it CE-status, i.e. toggle between being a CE-UE (i.e. indeed requiring coverage extension) and a non-CE-UE (i.e. supporting CE but not requiring CE at the moment).

[0083] The radio base station is kept updated on the current CE status of the CE-capable UE and thus (should) knows at the time of paging whether coverage extension is indeed necessary or not for the paging. In order to limit uplink traffic, the informing of the radio base station could be limited to the cases where the CE status of the CE-capable UE is changed, i.e. from non-CE-UE to CE-UE and vice versa. Of course it should also be possible for the CE-capable UE to measure and report such information/ measurements periodically even in the absence of said toggling. In this case, the eNB could, based on its implementation, perform some averaging of the received information including measurement reports and determine that a toggling of CE state is indeed helpful. The step of informing may be done, e.g. directly between the CE-capable UE and the radio base station, e.g. for CE-capable UEs that are in connected state and thus may provide the corresponding CE status to the radio base station. Alternatively, the CE-capable UE may report to a core network entity, which in turn may inform the radio base station, at the latest when triggering for paging; this may be done e.g. for those cases where the CE-capable UE is in idle state and thus has no active connection with the radio base station.

[0084] Correspondingly, the paging for CE-UE is performed by the radio base station by using a CE technique, whereas paging for a non-CE-UE is performed without using a CE technique. The CE-capable UE appropriately receives the CE paging or normal paging.

[0085] Correspondingly, in one general first aspect, the techniques disclosed here feature a method for paging all user equipments in a cell controlled by a radio base station in a mobile communication system. At least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment. The CE user equipments in the cell regularly monitor the at least one CE-specific paging possibility. When the radio base station determines to page all the user equipments in the cell, the radio base station pages the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0086] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities is defined for paging a specific user equipment in the cell of the radio base station. The

CE user equipments and non-CE user equipments each monitor a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities. The radio base station — upon determining to page all the user equipments in the cell - additionally performs paging at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension. According to a further example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0087] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and subframe number and is repeated every paging cycle. The at least one CE-specific paging possibility is only monitored by CE user equipments. For example, the at least one CE-specific paging possibility is monitored by CE user equipments in idle state and CE user equipments in connected state.

[0088] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the step of paging includes transmitting by the radio base station a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and includes transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification. For example, the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[0089] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the plurality of techniques for achieving the coverage extension comprise at least one of a repetition technique where a message is repeated by the radio base station for a pre-configured number of times, an increase in transmission power, where a message is transmitted by the radio base station with an increased transmission power, a bundling technique where a .same message is transmitted in a plurality of consecutive subframes, and a spreading technique where a message is transmitted by a larger resource, e.g. via a larger frequency-time resource or channelization code.

[0090] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the step of determining by the radio base station to page all user equipments in the cell is triggered by a change of system information applicable to the cell controlled by the radio base station or by the presence of a message, e.g. a warning message, to be broadcast in the cell controlled by the radio base station.

[0091] According to an advantageous variant of the first aspect which can be used in

addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. For example, information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment, or broadcast by the radio base station in the cell. Further exemplary, the pre-configured subframe number is 1, 2, 3, 6, 7, or 8.

[0092] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of paging possibilities are defined for paging in the cell of the radio base station, wherein a first value of at least one parameter for calculating the UE-specific paging possibility is different from a second value of the at least one parameter for calculating a CE-specific paging possibility such that the plurality of paging possibilities are divided to be used either as the CE-specific paging possibility or the UE-specific paging possibility. CE user equipments are configured to use the first value of the at least one parameter for calculating the UE-specific paging possibility and to use the second value of the at least one parameter for calculating the CE-specific paging possibility. Non-CE user equipments are configured to use the first value of the at least one parameter for calculating the UE-specific paging possibility and to not calculate the CE-specific paging possibility.

[0093] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, 6, wherein CE user equipments are assigned a CE-specific user equipment identity based on which the CE-specific paging possibility is calculated by the radio base station and the CE user equipments. For example, the CE-specific user equipment identity is the same for all CE-configured user equipments, and the CE-specific user equipment identity is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment or broadcast by the radio base station in the cell. Further for example, a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific user equipment identity is defined.

[0094] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, wherein a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific paging possibility is defined for paging the CE user equipments configured for that level of coverage extension.

[0095] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the radio base station determines whether there are CE user equipments in idle state in its cell by performing a counting procedure

where the CE user equipments in idle state inform the radio base station about their presence in the cell controlled by the radio base station. For example, the determination is only performed in case there are no CE user equipments in connected state in the cell.

[0096] Correspondingly, in one general first aspect, the techniques disclosed here feature a user equipment located in a cell controlled by a radio base station in a mobile communication system. The user equipment, in short CE user equipment, requires coverage extension, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for the CE user equipment. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE user equipment. A processor of the CE user equipment regularly monitors the at least one CE-specific paging possibility. A receiver of the CE user equipment receives a paging from the radio base station at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0097] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities is defined for paging a specific user equipment in the cell of the radio base station. The processor of the CE user equipment monitors a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities. In a further example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0098] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and subframe number and is repeated every paging cycle. In a further example, the at least one CE-specific paging possibility is monitored by the CE user equipment when in idle state and when in connected state.

[0099] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the receiver receiving the paging includes: receiving a first paging notification at radio resources of a control channel specific by the at least one CE-specific paging possibility, and includes receiving a second paging message at radio resources of another channel specific by the first paging notification. In a further example, the technique for achieving the coverage extension is used by the CE user equipment to both receive the first paging notification and receive the second paging message.

[0100] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging pos-

sibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. In a further example, a memory of the CE user equipment is adapted to store information to determine the pre-configured radio frame number and the pre-configured subframe number. Exemplarily, the memory is a Universal Subscriber Identity Module, USIM, of the CE user equipment. Or, the receiver of the CE user equipment receives information to determine the pre-configured radio frame number and the pre-configured subframe number, broadcast by the radio base station in the cell.

[0101] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the CE user equipment is assigned a CE-specific user equipment identity, wherein the processor of the CE user equipment is adapted to calculate the CE-specific paging possibility based on the CE-specific user equipment identity. Exemplarily, the CE-specific user equipment identity is the same for all CE-configured user equipments. In a further example, a plurality of different levels of coverage extension is defined. For each level of coverage extension a different CE-specific user equipment identity is defined.

[0102] Correspondingly, in one general first aspect, the techniques disclosed here feature a radio base station for paging all user equipments in a cell controlled by the radio base station in a mobile communication system. At least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment. A processor of the radio base station determines whether to page all the user equipments in the cell. A transmitter of the radio base station pages the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0103] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities are defined for paging a specific user equipment in the cell of the radio base station, wherein transmitter of the radio base station – upon the processor determining to page all the user equipments in the cell – additionally pages at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension. For example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0104] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the transmitter of the radio base station is

adapted to transmit a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and to transmit a second paging message at radio resources of another channel specified by the first paging notification. Exemplarily, the technique for achieving the coverage extension is applied to both the transmitting of the first paging notification and the transmitting of the second paging message.

[0105] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the processor determines to page all the user equipments in the cell when being triggered by a change of system information applicable to the cell controlled by the radio base station or by the presence of a message, e.g. a warning message, to be broadcast in the cell controlled by the radio base station.

[0106] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. Exemplarily, information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in the radio base station, wherein the transmitter of the radio base station broadcasts the information to determine the pre-configured radio frame number and subframe number.

[0107] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a CE-specific user equipment identity is assigned to the CE user equipments, wherein the processor of the radio base station is adapted to calculate the CE-specific paging possibility based on the CE-specific user equipment identity. Exemplarily, the transmitter of the radio base station is adapted to broadcast the CE-specific user equipment identity in the cell.

[0108] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the processor of the radio base station determines whether there are CE user equipments in idle state in its cell by performing a counting procedure. Exemplarily, the determination is only performed in case there are no CE user equipments in connected state in the cell.

[0109] Correspondingly, in one general second aspect, the techniques disclosed here feature a method for paging a user equipment in a cell controlled by a radio base station in a mobile communication system. The user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. Radio measurements are performed by the CE-capable user equipment, which determines whether coverage extension is necessary or not, based on the results of the

radio measurements. The radio base station is informed about whether the CE-capable user equipment needs coverage extension or not, based on the determination result. When paging the CE-capable user equipment, the radio base station applies or not applies one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[0110] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[0111] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of determining whether coverage extension is necessary comprises the step of comparing by the CE-capable user equipment the result of the radio measurements with a first threshold to determine whether coverage extension is necessary. For example, the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold. The step further comprises comparing by the CE-capable user equipment the result of the radio measurements with a second threshold to determine whether coverage extension is not necessary. For example, the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[0112] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of informing the radio base station about the CE-capable user equipment needing coverage extension or not, includes the steps of either transmitting by the CE-capable user equipment information about whether the CE-capable user equipment needs coverage extension or not to the radio base station. In this case, for example the CE-capable user equipment is in a connected state. In a further example, it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state. Alternatively, the step of informing includes the steps of transmitting by the CE-capable user equipment information about whether the CE-capable user equipment needs coverage extension or not to a core network entity. In this case, the core network entity provides the received information to the radio base station. For example, the CE-capable user equipment is in a connected state or in an idle state. In a further example, the core network entity is a mobility management entity.

[0113] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio base station is triggered to page the CE-capable user equipment by a core network entity that initiates and controls the paging,

preferably wherein the core network entity initiating the paging is a mobility management entity.

[0114] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the steps of performing the radio measurements and of determining whether coverage extension is necessary or not is performed regularly at a pre-configured time interval and/or triggered by the radio base station.

[0115] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of informing the radio base station is only performed when the result of the determination is different from the result of the determination previously informed to the radio base station.

[0116] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio base station determines whether the CE-capable user equipment needs coverage extension or not based on the radio resources selected by the CE-capable user equipment for initially attaching to the radio base station; for example, based on the selected preamble or access slot used for a random access procedure performed by the CE-capable user equipment when initially attaching to the radio base station.

[0117] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of paging the CE-capable user equipment comprises the steps of transmitting by the radio base station a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE-capable user equipment, and transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification. In a further example, the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[0118] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, upon successfully being paged by the radio base station, the CE-capable user equipment informs the radio base station about the successful paging, and the radio base station can inform a core network entity responsible for initiating the paging about the successful paging.

[0119] Correspondingly, in one general second aspect, the techniques disclosed here feature a user equipment located in a cell controlled by a radio base station in a mobile communication system. The user equipment, in short CE user equipment, supports coverage extension techniques. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. A processor of the CE user equipment performs radio measurements, and determines whether coverage extension is necessary or not, based on the results of the

radio measurements. A transmitter of the CE user equipment informs the radio base station about whether the CE-capable user equipment needs coverage extension or not, based on the determination result. A receiver of the CE user equipment receives paging from the radio base station, applying or not applying one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not.

[0120] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[0121] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the processor determines whether coverage extension is necessary or not by comparing the result of the radio measurements with a first threshold to determine whether coverage extension is necessary. For example, the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold. Furthermore, the result of the radio measurements is compared with a second threshold to determine whether coverage extension is not necessary. For example, the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[0122] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter informs the radio base station by transmitting information about whether the CE-capable user equipment needs coverage extension or not to the radio base station. For example, the CE-capable user equipment is in a connected state, and furthermore it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state. Alternatively, information about whether the CE-capable user equipment needs coverage extension or not is transmitted to a core network entity. The core network entity provides the received information to the radio base station, preferably wherein the CE-capable user equipment is in a connected state or in an idle state.

[0123] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the processor performing the radio measurements and determining whether coverage extension is necessary or not is performed regularly at a pre-configured time interval and/or triggered by the radio base station.

[0124] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter informs the radio base station

only when the result of the determination is different from the result of the determination previously informed to the radio base station.

[0125] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the receiver receiving the paging includes receiving a first paging notification at radio resources of a control channel specific by a paging possibility specific to the CE-capable user equipment, and receiving a second paging message at radio resources of another channel specific by the first paging notification. For example, the technique for achieving the coverage extension is used by the CE user equipment to both receive the first paging notification and receive the second paging message.

[0126] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter is further adapted to inform the radio base station about the successful paging.

[0127] Correspondingly, in one general second aspect, the techniques disclosed here feature a radio base station for paging a user equipment in a cell controlled by the radio base station in a mobile communication system. The user equipment supports coverage extension techniques. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. A receiver of the radio base station receives information about whether the CE-capable user equipment needs coverage extension or not. A transmitter of the radio base station, when paging the CE-capable user equipment, applies or not applies one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[0128] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the receiver receiving the information includes receiving from the CE-capable user equipment or from a core network entity the information about whether the CE-capable user equipment needs coverage extension or not.

According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter of the radio base station transmit a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE user equipment, and transmit a second paging message at radio resources of another channel specified by the first paging notification. For example, the technique for achieving the coverage extension is applied to both the transmitting of the first paging notification and the transmitting of the second paging message.

[0129] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, a receiver of the radio base station receives in-

formation about the successful paging of the CE user equipment, and the transmitter of the radio base station informs a core network entity responsible for initiating the paging about the successful paging.

[0130] Additional benefits and advantages of the disclosed embodiments will be apparent from the specification and Figures. The benefits and/or advantages may be individually provided by the various embodiments and features of the specification and drawings disclosure, and need not all be provided in order to obtain one or more of the same.

[0131] These general and specific aspects may be implemented using a system, a method, and a computer program, and any combination of systems, methods, and computer programs.

Description of Embodiments

[0133] A mobile station or mobile node or user terminal or user equipment is a physical entity within a communication network. One node may have several functional entities. A functional entity refers to a software or hardware module that implements and/or offers a predetermined set of functions to other functional entities of a node or the network. Nodes may have one or more interfaces that attach the node to a commu-

nication facility or medium over which nodes can communicate. Similarly, a network entity may have a logical interface attaching the functional entity to a communication facility or medium over which it may communicate with other functional entities or correspondent nodes.

[0134] The term "radio resources" as used in the set of claims and in the application is to be broadly understood as referring to physical radio resources, such as time-frequency resources.

The term "paging possibility" as used in the set of claims and in the application is to be broadly understood as referring to physical radio resources (frequency-time resources) of a control channel (e.g. the PDCCH), which are defined by a radio frame number (also termed paging frame, PF) and a subframe number (also termed paging occasion, PO).

[0135] The expression "coverage-extension UE" (or "CE UE") as used in the set of claims and in the application is to be broadly understood as referring to a UE which requires coverage extension, e.g. because it is in a bad radio condition. The expression "CE-capable UE" shall be used for a UE supporting the coverage extension techniques, irrespective of whether or not the UE indeed requires coverage extension, i.e. a UE can support coverage extension techniques but can still be understood as a "non-CE UE" in case that no coverage extension is currently necessary. From eNB-perspective, it may be unclear at any particular point in time whether a CE-capable UE indeed requires coverage extension or not. The second embodiment is directed at said drawback.

[0136] Correspondingly, the expression "non-CE-UE" as used in the set of claims and in the application is to be broadly understood as referring to a UE which either does not require coverage extension (even when actually supporting the corresponding CE techniques) or does not support coverage extension techniques.

[0137] The expression "UE-specific paging possibility" as used in the set of claims and in the application is to be broadly understood as that paging possibility which is calculated based on the UE-ID (e.g. IMSI), and should be understood in the context of the CE-specific paging possibility which is specific to only coverage extension. As described in the background section, there is only a limited amount of paging possibilities available, across which the UEs are then disposed depending on their IDs. Although a particular paging possibility may be monitored by several UEs, the paging possibilities are UE-specific in the sense that the paging possibility to be monitored by a UE is determined based on the respective UE-ID.

[0138] The terms "paging notification" and "paging message" are distinguished in the set of claims and in the application to respectively refer to the first PDCCH message (which is basically an indication notifying about a paging message e.g. by use of the common P-RNTI) and the subsequent PDSCH message with the actual paging information. The

term "paging" does not make this distinction and shall cover both.

[0139] The term "CE-page" or "CE-paging" as used in the application shall refer broadly to a paging where one out of a plurality of coverage extension techniques is used. For example, when considering the repetition technique as the CE-technique used by an eNB, the "CE-page" will involve repeating the transmission of both paging messages, i.e. the paging notification on the PDCCH and the actual paging message on the PDSCH, for a pre-configured number of times as defined for the repetition technique.

[0140] As explained in the background section, coverage extension techniques are to be implemented for (MTC) devices, and it is unclear how the coverage extension shall be achieved for the paging procedure. However, expenditure is quite high for any of these techniques, such that they should be only used when necessary. For the paging which is initiated by the eNB, and is directed to all UEs in the cell, the currently-implemented paging is applied to all possible paging possibilities so as to reach all UEs. In order to reach also the CE-UEs, a coverage extension technique may be applied to the paging at all possible paging possibilities, which however results in a high expenditure of resources.

[0141] For the paging which is initiated by the NAS, and is directed to one UE only (or a very limited number of UEs), the MME inform the eNB over the S1 interface about the capability of a RRC_Connected UE to allow coverage extension and thus to support the coverage enhancement techniques mentioned above. However, it is unclear whether the UE is actually requiring coverage extension at the time of the page, (e.g. the UE, e.g. MTC device, moved from the cellar to open terrain). Consequently, the eNB might page the UE at the UE-specific paging possibility by using one of the CE techniques, even though the UE is in a good radio condition and would not have needed a coverage extension page. Again, resources are wasted.

[0142] The following exemplary embodiments are conceived by the inventors to mitigate the problems explained above.

[0143] Some of these are to be implemented in the wide specification as given by the 3GPP standards and explained partly in the background section, with the particular key features as explained in the following pertaining to the various embodiments. It should be noted that the embodiments may be advantageously used for example in a mobile communication system, such as 3GPP LTE-A (Release 10/11/12/13) communication systems as described in the Technical Background section above, but the embodiments are not limited to its use in this particular exemplary communication networks.

[0144] The explanations should not be understood as limiting the scope of the disclosure, but as a mere example of embodiments to better understand the present disclosure. A skilled person should be aware that the general principles of the present disclosure as laid out in the claims can be applied to different scenarios and in ways that are not ex-

plicitly described herein. Correspondingly, the following scenarios assumed for explanatory purposes of the various embodiments shall not limit the present disclosure and its embodiments as such.

[0145] In the following a set of embodiments will be explained. Although in the following embodiment, the broad expressions UE, CE-UE, CE-capable UE, are used, the embodiments may be equally applied for MTC devices, i.e. a CE-MTC device or CE-capable MTC device etc.

[0146] First embodiment

According to a first exemplary embodiment, a paging procedure according to which the eNB can page all the UEs in its cell, including those UEs which require coverage extension (and of course also support coverage extension), is presented.

[0147] For this first embodiment it is assumed that the paging is initiated (i.e. triggered) by the eNB itself; in contrast to paging being initiated by the Non-Access-Stratum for which the second embodiment provides an improved paging procedure. As already explained in the background section, paging may be initiated by the eNB for several reasons. For example, system information applicable to the cell may change, and the eNB wants to notify the UEs in its cell such that the UEs may acquire the updated system information immediately from the start of the next modification period. Another reason is that a warning message shall be broadcast in the cell, such as a message from the ETWS or CMAS system, or a message in relation to EAB (Enhanced Access Barring for MTC devices). More detailed information is omitted here, and reference is made to the corresponding passages in the background section which equally apply to the first embodiment.

[0148] Consequently, due to nature of those reasons, the eNB wants to make sure that the paging reaches all UEs in the cell, including those UEs which need coverage extension to be successfully reached. According to the first embodiment, a paging possibility is established for specifically paging those CE-UEs, termed in the following CE-specific paging possibility. More precisely, a CE-specific paging frame and a CE-specific subframe are defined referring to radio resources of the PDCCH that can be used for the CE-paging. In a similarly manner as for the UE-specific paging possibilities defined in the current systems, the CE-specific paging possibility shall occur regularly, e.g. in a cyclic manner according to the paging cycle followed by the UE. The CE-specific paging possibility can be defined in addition to the normal UE-specific paging possibilities already established by the prior art, as discussed in the background section. The CE-specific paging possibility is independent from the UE's identity and shall be the same for a plurality of CE-UEs, e.g. CE-UEs of a particular cell or all CE-UEs in general (or at least all CE-UEs of a specific CE level as will be explained later); this is different from the normal UE-specific paging possibility which – even though

several UEs may monitor the same paging possibility - is specific to the UE due to being calculating based on the ID of the UE(s). This CE-specific paging possibility is known at least to the eNB and the CE-UEs; non-CE-UEs may or may not be informed about this CE-specific paging possibility; however, these non-CE-UEs shall not monitor the CE-specific paging possibility since they may be reached by "normal", i.e. non-CE, paging.

[0149] Furthermore, the paging initiated by the eNB shall reach both UEs in RRC-idle state as well as UEs in RRC-connected state. Consequently, the CE-specific paging possibility shall be monitored by UEs in RRC-idle state and UEs in RRC-connected state.

[0150] The CE-UEs regularly monitor the CE-specific paging possibility to receive the CE-paging, thereby ensuring that they can be successfully paged.

[0151] From the perspective of the eNB, when a page is triggered (e.g. by a system information change), in order to reach the CE-UEs, the eNB will wait for the corresponding paging opportunity given by the CE-specific paging possibility and will then perform a CE page at the CE-specific paging possibility which is monitored by all the CE-UEs in its cell. In a similar manner as for the UE-specific paging possibility, this particularly involves the transmission of the paging notification on the PDCCH at that radio frame and subframe of the CE-specific paging possibility and the corresponding transmission of the paging message on resources of the PDSCH as indicated by the paging notification on the PDCCH. This transmission of the two messages of the CE page is performed by using one appropriate technique of the plurality of CE techniques which are foreseen for achieving the coverage extension, e.g. a repetition technique or a technique where a significantly increased power is used for the transmission.

[0152] The CE-UE(s) in the cell of the eNB monitor the CE-specific paging possibility and thus will receive the paging notification on the PDCCH and subsequently the paging message on the PDSCH. Furthermore, since the eNB will use a coverage extension technique for the paging, which is known to the CE-UE(s), the CE-UE(s) will correspondingly react to the CE-paging by e.g. additionally receiving the repetitions of the paging notification and paging message.

[0153] The paging message will inform the CE-UE(s) about e.g. the system information change or a warning message etc. Depending on the content of the paging message on the PDSCH, the CE-UE will react accordingly, e.g. by acquiring the system information at the next modification period or by providing the warning message to the user of the CE-UE.

[0154] Of course, in a preferred first embodiment the eNB will also want to page the other (non-CE) UEs and for said purpose will page them at all possible paging possibilities, as discussed in the background section, i.e. this will be done without using any CE technique. The non-CE-UEs will each monitor their UE-specific paging possibility and

will thus receive one of the paging performed by the eNB.

[0155] In general, the CE-specific paging possibility may be different from any of the UE-specific paging possibilities, assignable for the UEs, although this is not strictly necessary for the functioning of the first embodiment. For example, only subframes 1, 2, 3, 6, 7, and 8 might be possible for the CE-specific paging possibility, considering that the other subframes 0, 4, 5, 9 are candidates for being selected/calculated as the UE-specific paging possibilities.

[0156] In one possible embodiment, the CE-UEs may keep on regularly monitoring their UE-specific paging possibility, calculated based on their identity as explained in the background section, in addition to the CE-specific paging possibility. Alternatively, the CE-UEs may not monitor the CE-specific paging possibility and the UE-specific paging possibility at the same time, but may only monitor the CE-specific paging possibility.

[0157] Fig. 5 shows, in a similar manner as Fig. 3, the paging possibilities monitored by two different CE-UEs, UE1 and UE2. As apparent from Fig. 5, it is assumed that CE-UE1 monitors a UE-specific paging possibility at radio frame number 76 and number 204 (76+128) etc., respectively at subframe 9 (see also Fig. 3, case B), and that CE-UE2 monitors a UE-specific paging possibility at radio frame number 19 and 147 (19+128) etc., respectively at subframe 4 (see also Fig. 3, case C). In addition, both CE-UE1 and CE-UE2 monitor the same CE-specific paging possibility, which in this exemplary illustration, is assumed to occur at CE-specific paging frames 36, 164 (36+128) etc. and at respective CE-specific subframe 1.

[0158] Fig. 6 shows a sequence diagram for the behavior of a CE-UE for an exemplary variant of the first embodiment. Particularly, it is assumed, in concordance with Fig. 5, that the CE-UE monitors both the CE-specific paging possibility as well as the UE-specific paging possibility, and when it receives the paging notification, the CE-UE will proceed to receive the corresponding paging message at the PDSCH resources indicated by the PDCCH paging notification, either applying or not applying a CE technique. Depending on the content of the paging message, the CE-UE will then react accordingly.

[0159] Fig. 7 shows a sequence diagram for the corresponding behavior of an eNB which wants to perform a paging. After the eNB decides to perform a paging of all UEs in its cell (e.g. due to system information change), it will proceed to perform the usual page at all possible UE-specific paging possibilities to reach all non-CE-UEs, without using any CE technique. On the other hand, to also reach the CE-UEs, the eNB will perform the CE paging at the CE-specific paging possibility, by using one appropriate CE-technique (e.g. repetition or increased transmission power).

[0160] The first embodiment as explained above has the advantage that the use of the

coverage extension technique(s) is limited to one particular CE-specific paging possibility, instead of having to be applied to all possible UE-specific paging possibilities. By using one paging possibility, all (or at least a plurality) of CE-UEs can be paged at the same time. Corresponding downlink resources can thus be saved. Furthermore, the CE-specific paging possibility is independent from the real IMSI of any CE-UE.

[0161] The CE-specific paging possibility can be defined in a number of different ways, but must always provide a CE-specific paging radio frame number and CE-specific paging subframe number, known to both the CE-UE(s) and the eNB(s).

[0162] According to a first variant of the first embodiment, the CE-specific paging possibility is fixed beforehand, e.g. not calculated but directly indicated. In one example, the numbers for the CE-specific paging radio frame and subframe are directly defined e.g. in the CE-UE (e.g. in its USIM, UICC etc) and the eNB; in other words, the CE-UE and the eNB would have information indicating particular radio frame and subframe numbers (such as radio frame number 36 and subframe number 1, as for the example of Fig. 4) for the CE-specific paging possibility. This information need not be pre-stored in the CE-UE (e.g. by use of the USIM) but could also be broadcast by the eNB in its cell, e.g. as part of the system information or indicated with a dedicated message when possible, such that the CE-UE(s) learn about the CE-specific paging possibility to be used for CE-paging from the eNB. This would allow different CE-specific paging possibilities to be used by different eNBs.

[0163] Alternatively, instead of directly indicating the CE-specific subframe number, the parameters Ns and i_s (already known from the calculation of the UE-specific paging possibility) could be reused in said respect. In particular, the following exemplary extended table can be used, which, in comparison with the table available from TS 36.304 as explained in the background section, includes at least one additional row for e.g. Ns= 5 (any other unused Ns number can be used of course) with the possible POs at subframes 1, 2, 3, and 6.

[0164] [Table 3]

Ns	PO when i_s=0	PO when i_s=1	PO when i_s=2	PO when i_s=3
1	9	N/A	N/A	N/A
2	4	9	N/A	N/A
4	0	4	5	9
5	1	2	3	6

[0165] For this alternative, Ns and i_s values would be pre-configured for the CE-specific paging possibility such that the CE-UE and eNB could determine, based on the exemplary table above, which CE-specific paging subframe to use. The CE-specific

paging radio frame would in this example still be directly indicated by a corresponding radio frame number.

[0166] The advantage of this first variant is that the CE-UE(s) would not need to calculate Ns and i_s, but may directly use the indicated numbers for the radio frame and subframe of the CE-specific paging possibility.

[0167] According to a second variant of the first embodiment to define the CE-specific paging possibility vis-a-vis the UE-specific paging possibility, the CE-specific paging possibilities are defined by providing different parameter values to the CE-UE(s) than to the non-CE-UEs. It is assumed, that the CE-specific paging subframe is calculated following the equations and principles explained for the UE-specific paging possibility in the background section. By using different parameter values for the same UE, the calculation of the UE-specific paging subframe yields different subframe numbers than the corresponding subframe numbers of the CE-specific paging possibility. As with the first variant explained above, the radio frame number for the CE-specific paging possibility is fixed.

[0168] In one example, the parameter with the different value is "nB", i.e. indicating the number of paging subframes per paging cycle (across all UEs in the cell), where one value is defined for CE-UEs and another value is defined for non-CE-UEs. There could however be another parameter broadcasted by the network for indicating rather directly the segregation of paging subframes between CE-UEs and non-CE-UEs.

[0169] According to a third variant of the first embodiment to define the CE-specific paging possibility, a CE-specific UE identity (e.g. CE-IMSI) is introduced. When considering the various CE levels a CE-UE can be configured for, a CE-level-specific UE identity can be introduced for each CE level. In any case, the CE-IMSI(s) is known to both the eNB and the CE-UE(s). The CE-specific UE identity(ies) can be provided to the CE-UEs beforehand, e.g. broadcast in the cell, or pre-stored in the SIM/ USIM or UICC or even in the Mobile Device, ME. A particular CE-UE and the network will use one of these identities corresponding to the required level of coverage extension support required e.g. one CE-UE deep down in bad radio and the network will use UE-identity1; whereas the same UE when coming back in relatively better radio, but still requiring CE support, will rather use UE-identity2 which is the corresponding use UE-identity for this level of Coverage Extension required. For this to work, it is important that the UE-identity to be used and the corresponding coverage extension required is known to both the network and the CE-UE e.g. by way of specification, or broadcasting etc. and there is a hand-shake between the CE-UE and the network about what level applies to the particular CE-UE at any given point in time. The hand-shake includes the measurement configuration and reporting as described previously.

[0170] It is assumed that basically the same calculation and principles are applied when cal-

culating the CE-specific paging possibility as explained for the UE-specific paging possibility in the background section. Both the eNB and the CE-UE(s) can calculate the same CE-(level)-specific paging possibility by the CE-(level)-specific IMSI instead of using the CE-UE's real IMSI.

[0171] As already mentioned in the background section, different coverage extension levels can be defined (e.g. 15dB, 13 dB etc.), where the respective coverage extension technique can be adapted appropriately to ensure achieving the corresponding coverage extension level. When e.g. considering the repetition CE technique, a coverage extension level to ensure 15dB might require 100 repetitions, whereas less or more repetitions may be necessary to ensure a different CE level. Similarly considerations apply to the other CE-techniques.

[0172] A particular CE-UE is configured for one of those coverage extension levels. Correspondingly, according to further examples of the first embodiment, one CE-specific paging possibility is defined per CE level, i.e. a CE-level-specific paging possibility, such that a CE-UE will only monitor the CE-level-specific paging possibility of the CE-level for which it is configured but not other CE-level-specific paging possibilities that are defined for other CE-levels.

[0173] A further improvement to the first embodiment is that CE-UEs which are in RRC-connected mode may try to read and receive paging at the UE-specific paging possibilities of other UEs. The UE_ID, which is IMSI mod 1024, can only take up to 1024 different values, and the radio frame is calculated based on "UE_ID mod N" such that only N different radio frames are used in each paging cycle. Consequently, a CE-UE could be configured to monitor some or all of the possible radio frames and subframes available for other UEs. This allows the network to not make as many repetitions as would otherwise be required if the UE was not receiving paging other than the UE-specific paging possibilities.

[0174] A further improvement to the first embodiment focuses on when to actually perform a CE page. Until now it has been (silently) assumed that there would be always a CE-UE in a cell, such that any eNB, at any time when paging is triggered, would perform the CE-paging at the CE-specific paging possibility(ies). The eNB is aware of all (CE-)UEs that are in RRC-Connected mode, since these have an active connection with the eNB, and thus the eNB determines whether a CE-UE that require coverage extension is in its cell or not. However, the eNB is not aware of which CE-UEs in RRC-Idle mode are currently in its cell. Consequently, assuming that no CE-UEs in RRC-Connected mode are in the cell of the eNB, the eNB is unaware of whether there is at least one CE-UE in RRC-Idle mode in its cell. To make sure that any possible CE-UEs in Idle mode are reached too, in these cases, the eNB will always have to performing the CE paging. This however may result in a waste of resources for the

case where no CE-UE(s) in RRC-Idle mode were in its cell either.

[0175] According to this improvement, this waste of resources shall be avoided by providing a procedure that allows the eNB to determine whether any CE-UEs are in its cell, be it in RRC-Idle or RRC-Connected state. To said end, the eNB might first determine whether there are any CE-UEs in RRC-Connected mode, which could be done e.g. by maintaining a table with UE-capability information received from the MME or UE. Subsequently, in case the eNB determines that there are no CE-UEs in RRC-Connected mode, a counting procedure is initiated which allows the eNB to determine/ estimate the number of CE-UEs in RRC-idle state in its cell. In one example of a counting procedure the UEs in RRC-Idle on a more or less round robin fashion go to RRC-Connected state and inform the network about the presence of the CE UE in RRC-Idle mode (i.e. about itself). The round robin method can e.g. be implemented using a persistence check method wherein the Idle UEs compare a randomly drawn number against a number broadcasted by the network. Only the one(s) drawing a smaller value will transit to RRC Connected to inform the network. The network can keep the broadcasted value to be small enough so that only a very small percentage of UEs should really pass this test at a given time. This is similar to what is done in MBMS Counting procedure as depicted in RRC specification 3GPP TS 36.331, current version 12.4.1 incorporated herein by reference.

[0176] In consequence, the eNB will only perform the CE page when it has determined that there is at least one CE-UE in its cell, be it in RRC-Idle or RRC-Connected state. As a result, the additional resources for a CE-page are not used in vain.

[0177] Second embodiment

As explained above, the first embodiment relates to an improvement for a paging procedure initiated by the eNB, which then shall page all UEs in its cell. The second embodiment to be presented relates to an improvement for a paging procedure that is initiated by the NAS (Non-Access-Stratum), e.g. the MME, and which is dedicated to just a single UE, or a rather limited number of UEs.

[0178] In particular, for this second embodiment it is assumed that the paging is initiated by the NAS, for instance in order to establish a call with a particular CE-UE; details in said respect have already been provided in the background section (see also Fig. 4) and apply equally to the second embodiment. In this respect the "call" need not be just a voice call but can also refer to other terminating service like SMS, MMS or Pager etc. For instance, the MME – in response to a corresponding trigger from the SGW in the core network – sends a paging message to all eNBs that belong to the tracking area(s) for which the CE-UE is currently registered. Particularly, the MME does not know where a CE-UE in RRC idle is located. Each eNB belonging to one of the TAs in an associated TA-list, in turn, then has to perform paging so as to page this CE-UE to

which the call is destined. Finally, the CE-UE being paged can then establish a connection with the eNB where it is camped and then proceed to accept the incoming call (see also Fig. 4).

[0179] In the above-described scenario, the MME informs the eNBs (over the S1 interface) about the capability(ies) of a (CE-)UE, e.g. whether the UE is capable of supporting coverage extension (and optionally which level of coverage extension). As explained before, this general capability information however gives no information on whether a particular CE-capable UE indeed requires coverage extension at the moment or not; e.g. while a CE-capable UE might have been in a basement for a long time, i.e. thus requiring coverage extension for compensating the bad radio conditions, this very same CE-capable UE might in mean time have emerged from the basement and thus might no longer require coverage extension or still require coverage extension but corresponding to a less demanding coverage extension level.

[0180] Consequently, according to the second embodiment, a procedure is implemented according to which the eNB can learn whether a CE-capable UE is indeed requiring coverage extension or not at the time of paging. To said end, a new measurement and reporting procedure is implemented between the UE and the eNB as will be explained in detail below.

[0181] The CE-capable UE is configured to perform radio measurements that allow determining whether the CE-capable UE is currently indeed requiring coverage extension or not. The radio measurements could refer for example to one or more of the following: Reference Signal Received Power (RSRP), Reference Signal Received Quality (RSRQ), channel quality etc. e.g. as defined in Chapter 5 of 3GPP TS36.214 v10.1.0(NPL 8), or even current Block Error Rate (BLER) estimates or HARQ operating point and any other suitable measurement target. In any case, a skilled person is well aware of how to determine the current radio conditions of a CE-capable UE that allow, in a subsequent step, to determine whether coverage extension is indeed necessary or not.

[0182] After performing the appropriate radio measurements, the CE-capable UE shall then determine whether coverage extension is necessary based on the results of the measurements. In one example, two appropriate thresholds can be defined, to which the measurements results are compared by the CE-capable UE so as to determine the current CE status of the CE-capable UE. For example, an upper threshold can be defined, where if the measurements results (e.g. RSRP or RSRQ) exceed the upper threshold, the CE-capable UE would determine that it does not require coverage extension, i.e. that it currently is a non-CE-UE. Conversely, a different lower threshold can be defined, where if the measurement results (e.g. again RSRP or RSRQ) fall below the lower threshold, the CE-capable would conclude that it does require

coverage extension, i.e. that is currently is a CE-UE. Instead of using two thresholds, the determination of whether CE is required or not, could of course also be determined by simply using one threshold, where measurements results exceeding the threshold would mean that coverage extension is not necessary, and measurements results falling below the threshold would mean that coverage extension is necessary. The same technique can also be used for other measurement possibility like for HARQ operating point i.e. where HARQ operating point exceeding the corresponding HARQ operating point-threshold would mean that coverage extension is not necessary, and HARQ operating point falling below the HARQ operating point-threshold would mean that coverage extension is necessary.

[0183] The radio measurements and CE status determination can be performed regularly by the CE-capable UE, i.e. at specific, pre-configured, intervals, and/or event triggered (one even for exceeding the threshold in either direction as described above), e.g. , and/or triggered by the eNB. In addition to the absolute threshold for the corresponding measurement, the network might also provide the corresponding Hysteresis and Time to Trigger values as described in 3GPP TS 36.331, current version 12.4.1. Hysteresis basically gives a margin or allowance in breaching the threshold in either direction, and the Time to Trigger (TTT) indicates at least how long the said threshold should remain breached/ exceeded for the UE to trigger the corresponding event.

[0184] Which radio measurements shall be performed, at which intervals, against which threshold(s) the measurement results should be compared, and any other necessary information can be pre-configured in the CE-capable UE or provided to the CE-capable UEs from the eNB, e.g. within a corresponding control message which could be signaled by RRC or Layer2 (MAC) or Layer1 (Physical layer signal) and may contain additional parameters including Hysteresis, TTT and the target object like current/ serving and neighbor cell list.

[0185] The CE-capable UE has to make sure that the eNB is kept updated on the current CE status, i.e. on whether the CE-capable UE needs coverage extension or not. This may be done e.g. by reporting every change of CE status to the eNB, such that the eNB knows at the time of paging whether a coverage extension technique shall be applied to the paging or not. Of course the same information can be used for DL messages other than paging and also to UL messages including paging response and other non-paging related messages. Depending on whether the CE-capable UE is in idle mode or connected mode, the reporting of the CE status to the eNB may be different. If the CE-capable UE is in RRC connected state and thus has an active connection with the eNB, the CE-capable UE can directly transmit a CE-status report, e.g. RRC Measurement Report, to the eNB.

[0186] Since such a direct report is not possible for CE-capable UEs in RRC-IDLE (since no

active connection with the eNB is available), the CE-capable UE in idle will report the CE status to the MME, which thus knows whether coverage extension is indeed required or not (independent from the CE-capability of a UE). The MME may either keep the eNB(s) regularly up to date in said respect, or might only provide the corresponding information to the eNB(s) when also triggering the eNB for paging. Of course, also CE-capable UEs in RRC connected could inform the MME, instead of or in addition to the eNB.

[0187] In another alternative, the CE-capable UE in idle will report the CE status and UE NAS identity directly to the serving eNB where the UE is camped in currently e.g. upon cell Selection and Reselection(s), which thus knows whether coverage extension is indeed required or not by maintaining a new Table including the UE NAS identity and CE-requirement.

[0188] Alternatively, another improvement provides that the CE-capable UEs do not change into RRC-idle state and thus remain all the time in RRC-connected state, such that the CE-capable UE can always transmit the measurement report directly to the eNB. The eNB can ensure that the UE remains in connected state by never sending the RRC Connection Release message to the UE i.e. basically ignoring any inactivity timer in the eNB for this UE.

[0189] In any case, the eNB, when being triggered to page a particular CE-capable UE, will be informed about and will consider whether said CE-capable UE indeed requires coverage extension or not. Based on the thus known current CE status of the UE, the eNB will or will not apply an appropriate CE technique to the paging of the CE-capable UE. As explained in detail for the first embodiment already, applying the CE technique to paging involves applying the CE technique to both the paging notification transmitted on the PDCCH and the actual paging message transmitted on the PDSCH as addressed by the PDCCH.

[0190] In other words, two measurement events are defined, one referring to the case where the radio measurements indicate that coverage extension is required, and the other referring to the case where the radio measurements indicate that coverage extension is not required. When any of the two events occur, this is reported to the eNB (either directly or via the core network entity, e.g. MME).

[0191] Fig. 8 shows a message sequence diagram for an exemplary paging procedure according to the second embodiment. As apparent therefrom, a measurement control message is provided from the eNB to the UE, which is assumed to include all information necessary to configure the UE to perform the radio measurements and to determine the CE-status based on the measurement results. Fig. 8 also shows the measurement report message from the UE to the eNB, which is transmitted to the eNB to allow the eNB to update the CE status of the UE. This allows in consequence that the

eNB performs the paging of the UE by using or not using a CE technique depending on the CE status of the UE.

[0192] Fig. 9 shows a simplified sequence process diagram for the CE-capable UE for one particular exemplary second embodiment as explained above where the measurement and reporting procedure is depicted in parallel to the page monitoring procedure.

[0193] Fig. 10 shows a simplified sequence process diagram for the eNB as explained above including the reception and update procedure for the CE status of the UE, and the parallel paging procedure which depends on the CE status.

[0194] Fig. 8 additionally shows an optional determination of the initial coverage extension status of the UE, which can be done directly upon the initial access of the UE to the eNB (see dashed box). In particular, the UE when initially attaching to a cell (and to the corresponding eNB) usually performs a RACH procedure, which involves e.g. the selection of an appropriate preamble, access slot etc. The CE-capable UE would, during initial access, determine its CE status in order to appropriately select the RACH resources (e.g. preamble, access slot, etc). Now, the eNB can estimate the radio conditions of the UE, and thus the CE status of the UE, based on the parameters, like preambles, preamble format or even the physical resources that the UE selected to perform the RACH procedure.

[0195] Another improvement of the second embodiment, which is also illustrated in Fig. 8 by use of a dashed arrow, refers to a feedback message transmitted from the eNB to the UE about the successful reception of the measurement report, i.e. CE status update, and confirmation that the toggling (between CE and non-CE) is successfully applied at the network side and therefore the UE should also toggle and transmit/ receive according to the new toggled state. By e.g. sending back information on the current CE status, the eNB can make sure that the CE-capable UE and the eNB have the same understanding of the CE status, and behave accordingly in a same manner. For instance, if the measurement report is lost, or decoded incorrectly at the eNB, the eNB would not change the CE status, and the UE and eNB would have different CE status (e.g. until the next, successful, measurement report is received by the eNB). Also, even successful reception of the measurement report is not a guarantee that eNB is fine with the toggling for reasons like admission control or for independent toggling evaluation at the eNB side. In this respect, the triggering of a measurement event is just one of the input parameter for the eNB to decide about the said toggling of CE state, and eNB may take the final decision based on cell and System specific considerations. In absence of the feedback message transmitted from the eNB to the UE about the successful reception of the measurement report and confirming that the toggling (between CE and non-CE) is successfully applied at the network side, obviously, different CE status might lead to a waste of radio resources or to an unsuccessful

paging, which is avoided by providing a feedback on the successful CE status update.

[0196] Still a further improvement of the second embodiment is also illustrated in Fig. 8. As indicated by the dashed arrow, the UE can inform the eNB immediately when a CE page was successful. In particular, instead of waiting to receive e.g. all repetitions of the CE page, as soon as the CE page is successfully received (e.g. the actual paging message was successfully decoded/delivered to the higher layer), the CE-capable UE informs the eNB in said respect. In turn, the eNB can inform the MME in the core network, which may then abort the page in the other eNBs of all the tracking areas (not shown in Fig. 8) pertaining to a corresponding TA-list. Radio resources are thus not wasted by other eNBs.

[0197] Third embodiment

According to a third embodiment, the first embodiment and the second embodiments are combined such that CE devices can be paged both at the NAS level and the AS level (i.e. initiated by NAS and initiated by eNB). Thus, the separation of NAS and AS is maintained as in legacy systems. Furthermore, the first and second embodiments are simple to implement and have no impact on legacy procedures.

[0198] Hardware and Software Implementation of the present disclosure

Other exemplary embodiments relate to the implementation of the above described various embodiments using hardware and software. In this connection a user terminal (mobile terminal) and an eNodeB (base station) are provided. The user terminal and base station is adapted to perform the methods described herein, including corresponding entities to participate appropriately in the methods, such as receiver, transmitter, processors.

[0199] It is further recognized that the various embodiments may be implemented or performed using computing devices (processors). A computing device or processor may for example be general purpose processors, digital signal processors (DSP), application specific integrated circuits (ASIC), field programmable gate arrays (FPGA) or other programmable logic devices, etc. The various embodiments may also be performed or embodied by a combination of these devices.

[0200] Further, the various embodiments may also be implemented by means of software modules, which are executed by a processor or directly in hardware. Also a combination of software modules and a hardware implementation may be possible. The software modules may be stored on any kind of computer readable storage media, for example RAM, EPROM, EEPROM, flash memory, registers, hard disks, CD-ROM, DVD, etc.

[0201] It should be further noted that the individual features of the different embodiments may individually or in arbitrary combination be subject matter to another embodiment.

[0202] It would be appreciated by a person skilled in the art that numerous variations and/or

modifications may be made to the present disclosure as shown in the specific embodiments. The present embodiments are, therefore, to be considered in all respects to be illustrative and not restrictive.

Claims

[Claim 1] A method for paging all user equipments in a cell controlled by a radio base station in a mobile communication system, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment, the method comprising the steps of:
regularly monitoring by the CE user equipments in the cell the at least one CE-specific paging possibility,
determining by the radio base station to page all the user equipments in the cell, and
paging by the radio base station the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 2] The method according to claim 1, wherein a plurality of UE-specific paging possibilities are defined for paging a specific user equipment in the cell of the radio base station, wherein the CE user equipments and non-CE user equipments each monitor a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities,
wherein the radio base station — upon determining to page all the user equipments in the cell - additionally performs paging at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension,
preferably wherein each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[Claim 3] The method according to claim 1 or 2, wherein the step of paging includes:
transmitting by the radio base station a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and
transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification,
preferably wherein the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[Claim 4] The method according to one of claims 1 to 3, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility, preferably wherein information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment, or broadcast by the radio base station in the cell, and preferably wherein the pre-configured subframe number is 1, 2, 3, 6, 7, or 8.

[Claim 5] The method according to one of claims 1 to 3, wherein CE user equipments are assigned a CE-specific user equipment identity based on which the CE-specific paging possibility is calculated by the radio base station and the CE user equipments,
preferably wherein the CE-specific user equipment identity is the same for all CE-configured user equipments,
preferably wherein the CE-specific user equipment identity is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment or broadcast by the radio base station in the cell;
preferably wherein a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific user equipment identity is defined.

[Claim 6] A user equipment located in a cell controlled by a radio base station in a mobile communication system, the user equipment, in short CE user equipment, requiring coverage extension, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for the CE user equipment, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE user equipment, the CE user equipment comprising:
a processor adapted to regularly monitor the at least one CE-specific paging possibility,
a receiver adapted to receive a paging from the radio base station at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 7] The user equipment according to claim 6, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control

channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility, preferably wherein a memory of the CE user equipment is adapted to store information to determine the pre-configured radio frame number and the pre-configured subframe number, preferably wherein the memory is a Universal Subscriber Identity Module, USIM, of the CE user equipment, or

preferably wherein the receiver of the CE user equipment is further adapted to receive information to determine the pre-configured radio frame number and the pre-configured subframe number, broadcast by the radio base station in the cell.

[Claim 8] A radio base station for paging all user equipments in a cell controlled by the radio base station in a mobile communication system, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment, the radio base station comprising:

a processor adapted to determine whether to page all the user equipments in the cell, and

a transmitter adapted to page the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 9] A method for paging a user equipment in a cell controlled by a radio base station in a mobile communication system, wherein the user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the method comprising the steps of:

performing radio measurements by the CE-capable user equipment,

determining by the CE-capable user equipment whether coverage extension is necessary or not, based on the results of the radio measurements,

wherein the radio base station is informed about whether the CE-capable user equipment needs coverage extension or not, based on the determination result,

when paging the CE-capable user equipment, applying or not applying by the radio base station one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[Claim 10] The method according to claim 9, wherein the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[Claim 11] The method according to claim 9 or 10, wherein the step of determining whether coverage extension is necessary comprises the steps of:
comparing by the CE-capable user equipment the result of the radio measurements with a first threshold to determine whether coverage extension is necessary, preferably wherein the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold,
comparing by the CE-capable user equipment the result of the radio measurements with a second threshold to determine whether coverage extension is not necessary, preferably wherein the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[Claim 12] The method according to one of claims 9 to 11, wherein the step of paging the CE-capable user equipment comprises the steps of:
transmitting by the radio base station a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE-capable user equipment, and
transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification, preferably wherein the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[Claim 13] A user equipment located in a cell controlled by a radio base station in a mobile communication system, the user equipment, in short CE user equipment, supporting coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the user equipment comprising:
a processor adapted to perform radio measurements,

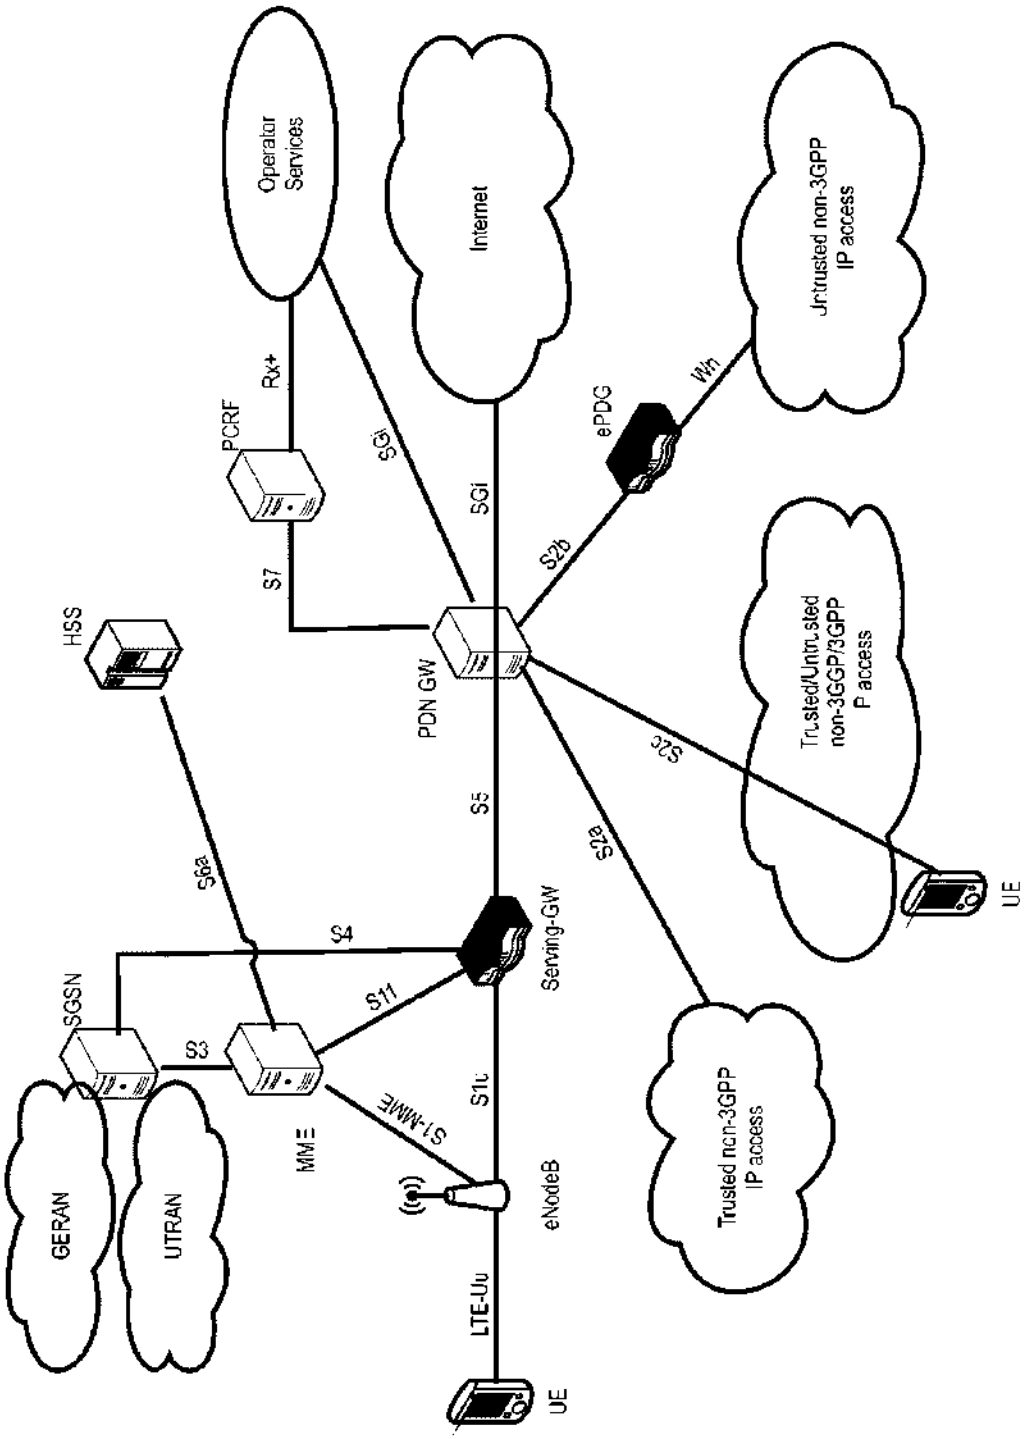
the processor being further adapted to determine whether coverage extension is necessary or not, based on the results of the radio measurements,

a transmitter adapted to inform the radio base station about whether the CE-capable user equipment needs coverage extension or not, based on the determination result,

a receiver adapted to receive paging from the radio base station, applying or not applying one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not.

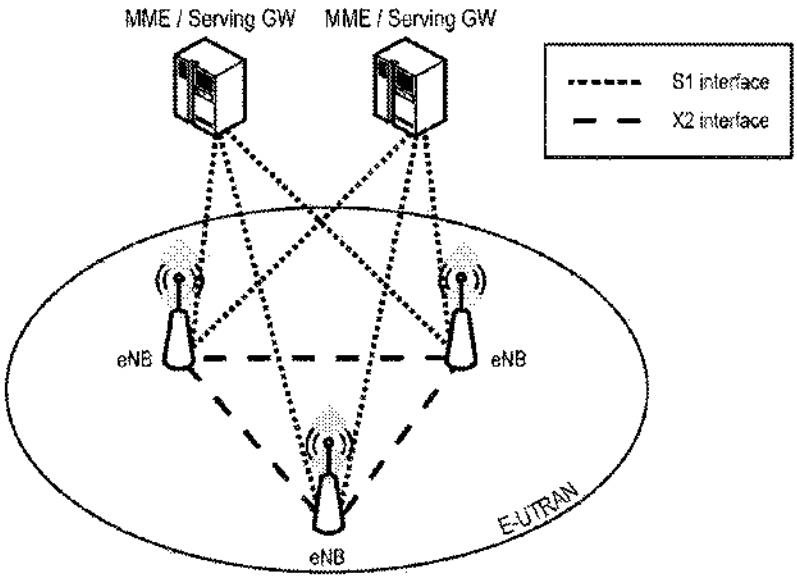
[Claim 14] The user equipment according to claim 13, wherein the transmitter informs the radio base station by:

transmitting information about whether the CE-capable user equipment needs coverage extension or not to the radio base station, preferably wherein the CE-capable user equipment is in a connected state, preferably wherein it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state, or



transmitting information about whether the CE-capable user equipment needs coverage extension or not to a core network entity, and wherein the core network entity provides the received information to the radio base station, preferably wherein the CE-capable user equipment is in a connected state or in an idle state.

[Claim 15] A radio base station for paging a user equipment in a cell controlled by the radio base station in a mobile communication system, wherein the user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the radio base station comprising:



a receiver adapted to receive information about whether the CE-capable user equipment needs coverage extension or not,

a transmitter being adapted to, when paging the CE-capable user equipment, apply or not apply one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

Method for receiving/transmitting paging information, related network node and user device

Abstract

The invention discloses a method for receiving/transmitting paging information, a related network node and a user device. The method comprises steps of receiving an indication to a physic resource block set for transmitting the paging information, wherein the index of physic resource block set in a sub frame is determined according to the level of the paging information; and receiving the paging information on the indicated physic resource block set. The technical scheme of the invention provides a paging information transmission mechanism targeting the enhanced coverage MTC user device and/or low complexity or low cost MTC user device.

(54)发明名称

寻呼消息的接收、发送方法及相关网络节点和用户设备

(57)摘要

本发明提供了寻呼消息接收、发送方法以及相应网络节点、用户设备。该方法包括：接收对用户发送寻呼寻呼消息的物理资源块集的指示，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的；以及在所指示的物理资源块集上接收所述寻呼消息。根据该技术方案，可实现同时对覆盖增强和/或用户设备和/或低复杂度或低成本的MTC用户设备的寻呼消息传输机制。

CN 101841920 A

1. 一种用户设备接收寻呼消息的方法，包括：

接收对用于发送所述寻呼消息的物理资源块集的指示，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的；以及

在所指示的物理资源块集上接收所述寻呼消息。

2. 根据权利要求1所述的方法，其中，所述寻呼消息的等级是通过以下方式之一获得的：

由基站通过广播信息和/或用户设备专用无线电资源控制信令配置；

由网络侧通过NAS信令配置；以及

由所述用户设备根据其测量结果确定。

3. 根据权利要求1所述的方法，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

4. 根据权利要求1所述的方法，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

5. 根据权利要求1所述的方法，其中，所述物理资源块集的大小根据所述寻呼消息的等级确定。

6. 根据权利要求1所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

7. 根据权利要求1所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔的大小。

8. 根据权利要求1所述的方法，其中，接收对用于发送所述寻呼消息的物理资源块集的指示包括：

通过广播系统信息和/或用户设备专用无线电资源控制信令从基站接收所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小；或

通过非接入层信令从网络侧设备接收所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小。

9. 根据权利要求1所述的方法，其中，所述用户设备使用的系统带宽包括6个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

10. 根据权利要求1所述的方法，其中，当所述用户设备使用的系统带宽大于6个物理资源块时，所述系统带宽包括多个子频带，所述多个子频带中的每一个包含不多于6个的物理资源块，所述寻呼消息在所述多个子频带中由网络节点确定的一个子频带上接收。

11. 一种网络节点发送寻呼消息的方法，包括：

根据所述寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；

向作为所述寻呼消息的接收方的用户设备通知对所述物理资源块集的指示，以及

在所确定的物理资源块集上发送所述寻呼消息。

12. 根据权利要求11所述的方法，其中，所述寻呼消息的等级是通过以下方式之一获得的：

由所述网络节点预先存储；

由上级网络节点通知；或

用户设备根据其测量结果确定并通知所述网络节点。

13. 根据权利要求 11 所述的方法，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

14. 根据权利要求 11 所述的方法，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

15. 根据权利要求 11 所述的方法，其中，所述物理资源块集的大小根据所述寻呼消息的等级确定。

16. 根据权利要求 11 所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道、物理上行共享信道、物理下行控制信道和 / 或增强型物理下行控制信道、物理上行控制信道和物理随机接入信道的重复次数。

17. 根据权利要求 11 所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道、物理上行共享信道、物理下行控制信道和 / 或增强型物理下行控制信道、物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

18. 根据权利要求 11 所述的方法，其中，向作为所述寻呼消息的接收方的用户设备通知对所述物理资源块集的指示包括：

如果所述网络节点是基站，通过广播系统信息和 / 或用户设备专用无线电资源控制信令向所述用户设备发送所述物理资源块集在子帧中的索引和 / 或所述物理资源块集的大小；或

如果所述网络节点是网络侧设备，通过非接入层信令向所述用户设备发送所述物理资源块集在子帧中的索引和 / 或所述物理资源块集的大小。

19. 根据权利要求 11 所述的方法，其中，所述网络节点为用户设备分配的系统带宽包括 6 个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

20. 根据权利要求 11 所述的方法，还包括：当所述网络节点为用户设备分配的系统带宽大于 6 个物理资源块时，将所述系统带宽划分为包含不多于 6 个物理资源块的多个子频带，以及确定所述多个子频带中要在其上向所述用户设备发送寻呼消息的一个子频带。

21. 一种用户设备，包括：

接收单元，用于接收对用于发送所述寻呼消息的物理资源块集的指示，以及用于在所指示的物理资源块集上接收所述寻呼消息，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的。

22. 根据权利要求 21 所述的用户设备，其中，所述寻呼消息的等级是由基站通过广播信息和 / 或用户设备专用无线电资源控制信令配置或由网络侧通过 NAS 信令配置，并通过所述接收单元接收的；或者

所述用户设备还包括：

测量单元，用于测量信道状态；以及

等级确定单元，用于根据所述测量单元的测量结果确定所述寻呼消息的等级。

23. 根据权利要求 21 所述的用户设备，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

21. 根据权利要求 20 所述的用户设备，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

25. 根据权利要求 21 所述的用户设备，其中，所述物理资源块集的大小由网络节点根据所述寻呼消息的等级确定，并通过广播信息和 / 或用户设备专用无线电资源控制信令由所述接收单元接收。

26. 根据权利要求 21 所述的用户设备，其中，对所述物理资源块集的指示包括所述物理资源块集在子帧中的索引以及所述物理资源块集的大小；以及

所述接收单元还用于通过广播系统信息和 / 或用户设备专用无线电资源控制信令从基站接收所述物理资源块集在子帧中的索引和 / 或所述物理资源块集的大小；或

所述接收单元还用于通过非接入层信令从网络侧设备接收所述物理资源块集在子帧中的索引和 / 或所述物理资源块集的大小。

27. 根据权利要求 21 所述的用户设备，其中，所述用户设备使用的系统带宽包括 6 个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

28. 根据权利要求 21 所述的用户设备，其中，当所述用户设备使用的系统带宽大于 6 个物理资源块时，所述系统带宽包括多个子频带，所述多个子频带中的每一个包含不多于 6 个的物理资源块，所述寻呼消息由所述接收单元 310 在所述多个子频带中由网络节点确定的一个子频带上接收。

29. 一种网络节点，包括：

块集索引确定单元，用于根据寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；以及

发送单元，用于向作为所述寻呼消息的接收方的用户设备通知对所述块集索引确定单元确定的物理资源块集的指示，以及用于在所述确定的物理资源块集上发送所述寻呼消息。

30. 根据权利要求 29 所述的网络节点，还包括接收单元，

其中，所述寻呼消息的等级由所述网络节点预先存储，或者由上级网络节点通知，或者由用户设备根据测量结果确定并通知所述网络节点，并由所述接收单元接收。

31. 根据权利要求 29 所述的网络节点，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

32. 根据权利要求 29 所述的网络节点，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

33. 根据权利要求 29 所述的网络节点，还包括：块集大小确定单元，用于根据所述寻呼消息的等级确定所述物理资源块集的大小。

34. 根据权利要求 29 所述的网络节点，还包括：重复次数确定单元，用于根据所述寻呼消息的等级确定一个或多个物理下行共享信道、物理上行共享信道、物理下行控制信道和 / 或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

35. 根据权利要求 29 所述的网络节点，还包括：调制大小确定单元，用于根据所述寻呼消息的等级确定一个或多个物理下行共享信道、物理上行共享信道、物理下行控制信道和 / 或增强型物理下行控制信道、物理上行控制信道和物理随机接入信道的传输时间间隔调制大小。

36. 根据权利要求 29 所述的网络节点，其中，对所述物理资源块集的指示包括所述物理资源块集在子帧中的索引以及所述物理资源块集的大小；以及

如果所述网络节点是基站，所述发送单元通过广播系统信息和 / 或用户设备专用无线电资源控制信令向用户设备发送所述物理资源块集在子帧中的索引和 / 或所述物理资源块集的大小；或

如果所述网络节点是网络侧设备，所述发送单元通过非接入层信令向用户设备发送所述物理资源块集在子帧中的索引和 / 或所述物理资源块集的大小

37. 根据权利要求 29 所述的网络节点，其中，所述网络节点为用户设备分配的系统带宽包括 6 个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

38. 根据权利要求 29 所述的网络节点，还包括：

子频带划分单元，用于当所述网络节点为用户设备分配的系统带宽大于 6 个物理资源块时，将所述系统带宽划分为包含不多于 6 个物理资源块的多个子频带；以及

子频带确定单元，用于确定所述子频带划分单元划分的所述多个子频带中要在其上向用户设备发送上行消息的一个子频带

寻呼消息的接收/发送方法及相关网络节点和用户设备

技术领域

[0001] 本发明涉及无线通信技术领域，更具体地，本发明涉及寻呼消息的接收/发送方法以及相关网络节点/用户设备。

背景技术

[0002] 第三代移动通信合作计划组织(3GPP)部署的长期演进项目(LTE)旨在提供日益多样化的未来移动通信服务，无线宽带通信已经成为大众生活和工作中不可或缺的一部分。在3GPP LTE的第八版(即Release-8)中，引入了正交频分多址(OFDMA)和多天线(MIMO)技术。3GPP的Release-10版本经国际电信联盟的评估和测试，正式成为了第四代全球移动通信标准LTE-Advanced。在LTE-Advanced标准中，引入了载波聚合(CA)和中继技术，增强了上行、下行MIMO技术，同时支持异构网络(HetNet)的部署。

[0003] 为了满足未来家庭设备通信的市场需求和规模庞大的物联网(IOT)部署，3GPP决定在LTE及其升级版本中引入低成本机器间通信技术(MTC:Machine Type Communication)，将MTC服务由目前的GSM网络支持迁移至LTE网络支持，并定义了若干种新的LTE用户设备(UE:User Equipment)的类型，其一称之为低成本MTC用户设备(Low-cost MTC UE)，该MTC用户设备在现有LTE网络的所有双工模式中支持MTC服务，并具有这样的性能：1)单接收天线；2)下行和上行最大的传输模块大小(TBS:Transport Block Size)为1000比特(bit)；下行链路数据信道的基带带宽降低为1.4MHz，下行链路控制信道的带宽与网络侧系统带宽保持一致、上行链路信道带宽以及下行链路的射频部分与现有LTE网络中的用户设备保持一致；3)下行、上行链路控制信道和数据信道的基带带宽降低为1.4MHz。

[0004] MTC是一种不需要人为参与的数据通信服务。大规模的MTC用户设备部署，可以用于安全、跟踪、付账、测量以及消费电子等领域，具体涉及的应用包括视频监控、供货链跟踪、智能电表、远程监控等。MTC用户设备要求较低的功率消耗、支持较低的数据传输速率和较低的移动性。目前LTE系统主要是针对人与人(H2H)的通信服务。因此，实现MTC服务的规模竞争优势及应用前景，关键环节在于LTE网络支持低成本的MTC设备能够低成本、低复杂性的工作。

[0005] 一些MTC用户设备需要安装在居民楼地下室或者由绝缘络层、金属护窗或者传统建筑物的厚墙保护的位置，相比较LTE网络中常规设备终端(如手机、平板电脑等)，这些设备的空中接口将明显遭受更严重的穿透损失。3GPP决定研究LTE网络提供MTC用户设备附加20dB-15dB覆盖增强服务的方案设计与性能评估，值得注意的是，位于精确网络覆盖区域的MTC用户设备具有这样的特点：非常低的数据传输速率、非常宽松的延时要求、以及有限的移动性。针对MTC用户设备特点，LTE网络可以进一步优化一些信令和一些信道用以支持MTC用户设备。3GPP要求为新定义的MTC用户设备以及其他具有MTC服务(如非常宽松的延迟要求)的用户设备提供一定的LTE网络覆盖增强。其中，对于LTE频分双工(FDD)网络提供15dB的网络覆盖增强。另外，并不是所有的运用MTC服务的用户设备都需

发相同网络覆盖增强

[0006] 在2011年6月举行的3GPP RAN#64次全会上，提出了一个新的面向Rel-13的低复杂性和覆盖增强的MTC的工作项目（参见非专利文献：RP-110990New Work Item on Even Lower Complexity and Enhanced Coverage LTE UE For MTC, Ericsson, NSN）。在该工作项目的描述中，LTE Rel-13系统需要支持上下行1.4MHz射频带宽的MTC用户设备（User Equipment，UE，以下称为窄带MTC UE）工作在任意的系统带宽（例如1.4MHz、3MHz、5MHz、10MHz、15MHz、20MHz等等）下，并且为该类MTC用户提供覆盖增强功能。在系统设计时，低成本MTC用户和覆盖增强MTC用户要采用统一的设计方案，降低MTC用户设备的能耗是该工作项目的主要目标之一。

[0007] 针对3GPP LTE用户设备运行MTC业务并处于覆盖增强模式下，物理层信道如PDCCH/PDSCH/PUCCH/PUSCH的覆盖增强设计与配置是一个需要标准化的工作。根据3GPP RAN1#74会议的讨论，在完成初始接入过后，任何一个需要重复传输的物理信道，其配置模式取决于基站端。而MTC用户设备合并解调大量重复数据会引入2至10ms的延迟。这样的延迟会增加MTC用户设备的耗电量。根据3GPP RAN1#76bis会议的决定，对于需要覆盖增强的MTC用户设备数据信道的传输应在控制信道传输完成之后。因此为了减少用户设备的耗电量，对于需要覆盖增强的MTC用户设备的寻呼消息传输可以不需要控制信道。同时由于低复杂度MTC用户设备（Low complexity MTC UE）与覆盖增强的MTC用户设备具有相似的信息传输机制，需要设计一种同时针对覆盖增强MTC用户设备和/或低复杂度或低成本的MTC用户设备的寻呼消息传输机制。因此在Rel-13及其之后版本中，针对覆盖增强模式下MTC用户设备和/或低复杂度或低成本的MTC用户设备的寻呼消息传输需要重新标准化。

发明内容

[0008] 本发明旨在提供同时针对例如覆盖增强MTC用户设备和/或低复杂度或低成本的MTC用户设备的寻呼消息传输机制。

[0009] 根据本发明的一个方案，提供了一种用户设备接收寻呼消息的方法。该方法包括：接收对用于发送所述寻呼消息的物理资源块集的指示，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的；以及在所指示的物理资源块集上接收所述寻呼消息。

[0010] 根据本发明的另一个方案，提供了一种网络节点发送寻呼消息的方法。该方法包括：根据所述寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；向作为所述寻呼消息的接收方的用户设备通知对所述物理资源块集的指示，以及在所确定的物理资源块集上发送所述寻呼消息。

[0011] 根据本发明的另一个方案，提供了一种用户设备。该用户设备包括：接收单元，用于接收对用于发送所述寻呼消息的物理资源块集的指示，以及用于在所指示的物理资源块集上接收所述寻呼消息，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的。

[0012] 根据本发明的另一个方案，提供了一种网络节点。该基站包括：块集索引确定单元，用于根据寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；以及发送单元，用于向作为所述寻呼消息的接收方的用户设备通知对所述块集索引确

定单元确定的物理资源块集的指示，以及用于在所述确定的物理资源块集上发送所述寻呼消息。

[0013] 本发明的上述方案简单易行，并且由于用于发送寻呼消息的物理资源块的参数（例如索引）取决于寻呼消息的等级，而该寻呼消息等级同样可用于对MTC用户设备进行覆盖增强，因此该方案同时适用于覆盖增强MTC用户设备和/或低复杂度或低成本的MTC用户设备的寻呼消息传输。

附图说明

[0014] 通过下文结合附图的详细描述，本发明的上述和其它特征将会变得更加明显，其中：

[0015] 图1示出了根据本发明的接收寻呼消息的方法的流程图；

[0016] 图2示出了根据本发明的发送寻呼消息的方法的流程图；

[0017] 图3示出了根据本发明的用于接收寻呼消息的用户设备的示意性框图；

[0018] 图4示出了根据本发明的用于发送寻呼消息的基站的示意性框图；

[0019] 图5示出了不同等级的寻呼消息的占用的相同大小资源块集的示意图；

[0020] 图6示出了不同等级的寻呼消息与相应的资源块起始位置索引的对应关系的示意图；

[0021] 图7示出了不同等级的寻呼消息的占用的不同大小资源块集的示意图；

[0022] 图8示出了不同等级的寻呼消息与相应占用的资源块集的大小的对应关系的示意图；

[0023] 图9示出了不同寻呼等级与相应的资源块起始位置索引的对应关系的另一示意图；

[0024] 图10示出了将系统频带划分为多个子频带的示意图；

具体实施方式

[0025] 以下将结合附图和具体实施例，对本发明所提出的针对需要额外覆盖增强的MTC用户设备或者低复杂度、低成本MTC用户设备的寻呼消息在物理资源上的发送/接收方法、网络节点和用户设备(UE)进行详细阐述。应当注意的是，虽然本发明是针对需要额外覆盖增强或者低复杂度、低成本MTC用户设备来阐述的，但其同样也适用于其他支持延迟容忍服务和/或需要一定覆盖增强的用户设备。应当注意的是，本发明不应局限于下文所述的具体实施例。另外，为了简便起见，省略了对与本发明没有直接关联的公知技术的详细描述，以防止对本发明的理解造成混淆。

[0026] 下文以LTE移动通信系统及其后续的演进版本作为示例应用环境，具体描述了根据本发明的多个实施例。然而，需要指出的是，本发明不限于以下实施例，而是可适用于更多其它的无线通信系统，例如今后的5G蜂窝通信系统或现有的其他通信系统，只要其要求提供同时针对覆盖增强MTC用户设备和/或低复杂度或低成本的MTC用户设备的寻呼消息传输机制。

[0027] 图1示出了根据本发明的一个实施例的寻呼消息接收方法。在图1的步骤110中，用户设备接收对用于发送寻呼消息的物理资源块集的指示，其中，物理资源块集在子帧中

的索引是根据寻呼消息的等级确定的。在步骤 120 中，用户设备在所指示的物理资源块集上接收寻呼消息。

[0028] 在本发明的一些实施例中，寻呼消息的等级是通过以下方式之一获得的：由基站通过广播系统信息和 / 或用户设备专用无线电资源控制信令配置；由网络侧通过 NAS 信令配置；以及由用户设备根据其测量结果确定。

[0029] 在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

[0030] 在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

[0031] 在本发明的另一些实施例中，物理资源块集的大小根据寻呼消息的等级确定。

[0032] 在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理下行共享信道，物理下行控制信道和 / 或增强型物理下行控制信道，物理下行控制信道和物理随机接入信道的重复次数。

[0033] 在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理下行共享信道，物理下行控制信道和 / 或增强型物理下行控制信道，物理下行控制信道和物理随机接入信道的传输时间间隔调制大小。

[0034] 在本发明的一些实施例中，接收对用于发送寻呼消息的物理资源块集的指示包括：通过广播系统信息和 / 或用户设备专用的无线电资源控制 (UE dedicated Radio Resource Control) 信令从基站接收物理资源块集在子帧中的索引和 / 或物理资源块集的大小；或通过非接入层 (NAS) 信令从网络侧设备接收物理资源块集在子帧中的索引和 / 或物理资源块集的大小。

[0035] 在本发明的一些实施例中，该用户设备使用的系统带宽包括 6 个物理资源块。在该情况下，物理资源块集是系统带宽的子集。

[0036] 然而，也可能存在系统带宽大于 6 个物理资源块的情况。在本发明的一些实施例中，当系统带宽大于 6 个物理资源块时，系统带宽可包括多个子频带。该多个子频带中的每一个包含不多于 6 个的物理资源块。例如，在系统带宽中包含的物理资源块的数目能够被 6 整除时，该多个子频带中的每一个包含 6 个物理资源块。然而当系统带宽中包含的物理资源块的数目不能够被 6 整除时，该多个子频带中的一个子频带包含的物理资源块可以小于 6 个，而其他子频带可以均包含 6 个物理资源块。也可以存在其他的子频带分配方式，例如在其他通信系统中可以使用除 6 之外的其他物理资源块数目。只要寻呼消息对应的物理资源块的数目小于该子频带具有的资源块的总数目，便可以使用本文上述的方案确定该子频带中用于该寻呼消息的资源块集的起始位置索引和大小。本发明不受限于系统带宽一个子频带中包含的具体资源块的数目。

[0037] 在上述任一情况下，寻呼消息在多个子频带中由网络节点 (例如基站或网络侧) 确定的一个子频带上接收。

[0038] 图 2 示出了根据本发明的一个实施例的网络节点侧的寻呼消息发送方法。在图 2 所示的流程图中，该方法包括：步骤 210，根据寻呼消息的等级确定用于发送寻呼消息的物理资源块集在子帧中的索引；步骤 220，向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示；以及步骤 230，在所确定的物理资源块集上发送寻呼消息。

[0039] 在本发明的一些实施例中，寻呼消息的等级是通过以下方式之一获得的：由网络节点预先存储、由上级网络节点通知（例如，在网络节点是基站的情况下，由网络可通过 S1 寻呼消息指示）；以及用户设备根据其测量结果确定并通知网络节点。

[0040] 在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

[0041] 在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

[0042] 在本发明的一些实施例中，物理资源块集的大小根据寻呼消息的等级确定。

[0043] 在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道、物理下行共享信道、物理下行控制信道和 / 或增强型物理下行控制信道、物理下行控制信道和物理随机接入信道的重复次数。

[0044] 在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道、物理下行共享信道、物理下行控制信道和 / 或增强型物理下行控制信道、物理下行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

[0045] 在本发明的一些实施例中，向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示包括：如果网络节点是基站，通过广播系统信息和 / 或用户设备专用的无线电资源控制信令向用户设备发送物理资源块集在子帧中的索引和 / 或物理资源块集的大小；或如果网络节点是网络侧设备，通过下接入层信令向用户设备发送物理资源块集在子帧中的索引和 / 或物理资源块集的大小。然而本发明不限于此，例如基站也可以使用其他的群发机制（例如、多播机制等）来发送物理资源块集在子帧中的索引。

[0046] 在本发明的一些实施例中，网络节点为用户设备分配的系统带宽包括 6 个物理资源块。在该情况下，物理资源块集是所述系统带宽的子集。

[0047] 在本发明的一些实施例中，当网络节点为用户设备分配的系统带宽大于 6 个物理资源块时，将所述系统带宽划分为包含不多于 6 个物理资源块的多个子频带，以及确定所述多个子频带中要在其上向用户设备发送寻呼消息的一个子频带。

[0048] 图 3 示出了用于根据本发明的实施例发送寻呼消息的用户设备。该用户设备至少包括：接收单元 310，用于接收对用于发送寻呼消息的物理资源块集的指示，以用于在所指示的物理资源块集上接收寻呼消息，其中，物理资源块集在子帧中的索引是根据寻呼消息的等级确定的。

[0049] 在本发明的一些实施例中，寻呼消息的等级是由基站通过广播系统信息和 / 或用户设备专用无线电资源控制信令配置或由网络侧通过 NAS 信令配置，并通过接收单元 310 接收的。在本发明的另一些实施例中，用户设备还包括用于测量信道状态的测量单元 320，以及用于根据测量单元的测量结果确定寻呼消息的等级的等级确定单元 330。

[0050] 在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

[0051] 在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

[0052] 在本发明的一些实施例中，物理资源块集的大小由网络节点（根据不同的实现，可以是基站或网络侧设备，如移动性管理实体 (MME)）根据寻呼消息的等级确定，并通过广

播系统信息和 / 或用户设备专用无线电资源控制信令由接收单元 310 接收。

[0053] 对物理资源块集的指示可以包括物理资源块集在子帧中的索引以及物理资源块集的大小。在本发明的一些实施例中，接收单元 310 还用于通过广播系统信息和 / 或用户设备专用的无线电资源控制 (RRC, dedicated RRC) 信令从基站接收物理资源块集在子帧中的索引和 / 或物理资源块集的大小。或者在其他一些实施例中，接收单元 310 还用于通过非接入层信令从网络侧设备接收物理资源块集在子帧中的索引和 / 或物理资源块集的大小。

[0054] 在本发明的一些实施例中，用户设备使用的系统带宽包括 6 个物理资源块，以及物理资源块集是所述系统带宽的子集。

[0055] 在本发明的一些实施例中，当用户设备使用的系统带宽大于 6 个物理资源块时，系统带宽包括多个子频带，该多个子频带中的每一个包含不多于 6 个的物理资源块。在该情况下，寻呼消息由接收单元 310 在所述多个子频带中由网络节点（基站或网络侧）确定的一个子频带上接收。

[0056] 在本发明的一些实施例中，用户设备还包括存储器 340，用于存储接收单元 310 接收到的各种信息，例如寻呼消息、物理资源块集的大小、物理资源块集在子帧中的索引以及其他用户设备接收到的信息等。存储器 350 还可以存储测量单元 320、等级确定单元 330 所使用或输出的信息，例如测量单元 320 的测量结果，在该情况下，等级确定单元 330 可从存储器 350 获得该测量结果。存储器 350 还可以存储发送单元 340 要发送的信息，例如等级确定单元 330 确定的寻呼消息的等级。

[0057] 图 1 示出了根据本发明的实施例发送寻呼消息的网络节点。图 1 示出的网络节点至少包括：块集索引确定单元 110，用于根据寻呼消息的等级确定用于发送寻呼消息的物理资源块集在子帧中的索引；以及发送单元 120，用于向作为寻呼消息的接收方的用户设备通知对块集索引确定单元 110 确定的物理资源块集的指示，以及用于在所确定的物理资源块集上发送寻呼消息。

[0058] 在本发明的一些实施例中，网络节点还包括接收单元 130。其中，寻呼消息的等级由网络节点预先存储，或者由上级网络节点通知，或由用户设备根据其测量结果确定并通知网络节点，并由接收单元 130 接收。

[0059] 在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

[0060] 在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

[0061] 在本发明的一些实施例中，网络节点还包括：块集大小确定单元 140，用于根据寻呼消息的等级确定物理资源块集的大小。

[0062] 在本发明的一些实施例中，网络节点还包括：重复次数确定单元 150，用于根据寻呼消息的等级确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和 / 或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

[0063] 在本发明的一些实施例中，网络节点还包括：捆绑大小确定单元 160，用于根据寻呼消息的等级确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和 / 或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

[0064] 在本发明的一些实施例中，如果网络节点是基站，发送单元 120 通过广播系统信息和 / 或用户设备专用的无线电资源控制 (Radio Resource Control, RRC) 信令向用户设备发送物理资源块集在子帧中的索引和 / 或物理资源块集的大小；或者如果网络节点是网络侧设备，发送单元 120 通过非接入层信令向用户设备发送物理资源块集在子帧中的索引和 / 或物理资源块集的大小。

[0065] 在本发明的一些实施例中，网络节点为用户设备分配的系统带宽包括 6 个物理资源块，在该情况下所述物理资源块集是系统带宽的子集。

[0066] 在本发明的一些实施例中，网络节点还包括：子频带划分单元 170，用于当网络节点为用户设备分配的系统带宽大于 6 个物理资源块时，将所述系统带宽划分为包含不多于 6 个物理资源块的多个子频带；以及子频带确定单元 180，用于确定所述子频带划分单元 170 划分的所述多个子频带中要在其上向用户设备发送寻呼消息的一个子频带。

[0067] 在本发明的一些实施例中，网络节点还包括存储器 190。存储器 190 可存储发送单元 120 要发送的信息，如寻呼消息，也可以存储接收单元 130 接收到的信息，例如接收单元 130 从网络侧 (例如 MME) 或用户设备接收到的寻呼消息的等级。存储器 190 还可以存储块集索引确定单元 110、块集大小确定单元 140、重复次数确定单元 150、捆绑大小确定单元 160、子频带划分单元 170、子频带确定单元 180 等单元所需的信息或输出的信息。

[0068] 本发明的上述网络节点可以是基站，也可以是网络侧设备，例如网络侧的移动性管理实体 (MME)。当然，也可以是本领域技术人员通常使用来配置传输一移动性参数的任何网络侧设备。本发明不对此进行限制。

[0069] 需要注意的是，在图 3 和图 4 中描述的用户设备和网络节点仅是为了使本领域技术人员更清楚地理解本发明而作的例，其中省略了一些对理解本发明不必要的模块、组件，本发明的保护范围不应受这些附图的具体细节所限制。此外，实际的设备中可以包括更多的模块、组件，如显示器、操作维护接口 (对于图 4 中的网络节点)、输入输出接口等等。本发明不对这些进行限制。

[0070] 下面将参考图 5 至图 10 来对图 1 和图 2 中示出的方法以及图 3 和图 4 中示出的设备进行更详细地描述。需要注意的是，本发明中多数信息的确定和发送既可以由基站完成，也可以由网络侧设备完成。因此，除非特别说明，在本说明书中可以将术语基站、网络侧设备 (如 MME) 以及网络节点交换使用。此外，如上所述，虽然本发明主要针对需要额外覆盖增强或者低复杂度、低成本 MTC 用户设备来阐述的，但其同样也适用于其他支持延迟容忍服务和 / 或需要一定覆盖增强的用户设备。

[0071] 对覆盖增强 MTC UE 而言，其上、下行物理信道需要多次重复发送，以满足信道的覆盖增强要求。处于不同地理位置的 UE 所需的信道覆盖增强程度不一样，导致处于不同地理位置的 UE 的物理信道所需重复发送的次数不同。因此，可以将物理信道的覆盖增强程度分为若干个不同的覆盖增强等级。而不同覆盖增强等级的物理信道，其所需重复发送的次数不同。例如，可以将物理信道分为四个覆盖增强等级 (CE0、CE1、CE2 和 CE3)，每个覆盖增强等级对应物理信道所需的不同覆盖增强补偿，例如，CE0 指代的是覆盖增强等级 0，即不需要覆盖增强；CE1 指代的是覆盖增强等级 1，即需要例如 1 ～ 5dB 覆盖增强，其物理信道大致需要数次重复传输；CE2 指代的是覆盖增强等级 2，即需要例如 6 ～ 10dB 覆盖增强，其物理信道大致需要十数次重复传输；CE3 指代的是覆盖增强等级 3，即需要例如 11 ～ 15dB 覆盖

增强，其物理信道大致需要数十次重复传输。然而，需要注意的是，本发明的技术方案不限于四个覆盖增强等级，而是可以根据需要采用更多或更少的覆盖增强等级。还需要注意的是，上述物理信道的重复次数仅是为了使本领域技术人员理解本发明而给出的示例，具体系统中使用的重复次数不限于上述次数，而是可以根据系统需求（限制（例如系统资源限制））选择更多或更少的次数。

[0072] 由于寻呼消息对应的控制信道不传输，因此需要给出 UE 用户设备的寻呼消息在频域上的位置。在本发明的技术方案中，网络节点（例如基站）将不同等级的寻呼消息映射到不同的资源块集（RBGroup）来指示寻呼消息在频域上的位置。在本文中，资源块集指的是寻呼消息在子帧上占用的物理资源块的集合。资源块集的大小是指寻呼消息在子帧上占用的资源块的数目。此处资源块集可以是物理资源块集（PRB group），也可以是虚拟资源块集（VRB group），物理资源块与虚拟资源块间的映射关系可参考 3GPP TS36.211v10.2.0.1。本发明不再进行赘述。在本发明的技术方案中，可以对多个资源块进行虚拟连续分配，即虚拟资源块集的集中式分配（virtual resource blocks of localized type）。此处虚拟资源块集的集中式分配指的是将虚拟资源块 n_{VRB} 直接映射到物理资源块 n_{PRB}。而虚拟资源块的大小与物理资源块的大小一致。

[0073] 寻呼消息可以占用多个子帧，不同等级的寻呼消息占用的子帧数目可以不同。不同的用户设备占用的子帧也可以不同，例如，用户设备可根据用户 ID 在不同的子帧上接收寻呼消息，或通过 3GPP 协议中用于寻呼消息的时域复用的方法来进行子帧分配。在本发明的一些实施例中，需要确定确定两个参数，承载寻呼消息的物理资源块集的起始位置及连续分配的资源块数目。然而在另一些实施例中，由于承载寻呼消息的物理资源块集的大小（即，连续分配的资源块数目）被预先确定，且对于不同等级的寻呼消息而言是相同的，仅需要确定物理资源块集的起始位置。

[0074] 再次返回图 2，在图 2 的步骤 210 中，根据寻呼消息的等级确定用于发送寻呼消息的物理资源块集在子帧中的索引。该步骤由图 1 中的块集索引确定单元 410 执行。在本发明中，物理资源块集的起始位置与物理资源块集在子帧中的索引表达相同的概念，可相互交换使用。基于承载不同等级的寻呼消息的资源块集的大小是否一致，本发明提出了两种方案。网络节点和用户设备可同时支持两种方式或其中的一种。

[0075] 图 5 示出了承载不同等级的寻呼消息的资源块集的大小一致的情况。如图 5 所示，系统带宽为 6 个物理资源块大小，且承载不同等级的寻呼消息的资源块集的大小是一样的，相应的资源块集的起始位置由基站和 / 或网络侧（例如 MME）配置，其原则可以是尽量利用子帧中的物理资源块，也可以是本领域技术人员可想到或通常使用的其他原则。在图 5 所示的示例中，资源块集的起始位置与不同等级的寻呼消息的关系可以是：覆盖增强等级 0 的寻呼消息对应的资源块集的起始位置索引为 0 或 1；覆盖增强等级 1 的寻呼消息对应的资源块集的起始位置索引为 1；覆盖增强等级 2 的寻呼消息对应的资源块集的起始位置索引为 2；覆盖增强等级 3 的寻呼消息对应的资源块集的起始位置索引为 3。在图 5 的示例中，相应的承载寻呼消息的资源块集的大小为例如 2 个资源块，然而在其他示例中也可以是更大或更小的其他数目，且可以采用与图 5 不同的索引分配模式。

[0076] 寻呼消息的等级可以由基站通过广播信息和 / 或用户设备专用 RRC 信令配置给用户设备，或者可以由网络侧（例如 MME）通过 NAS 信令配置给用户设备。在一些示例中，寻

呼消息的等级可以由用户设备根据自己的下行链路测量结果确定。例如，用户设备通过测量单元 320 执行信道测量，并使用等级确定单元 330 根据测量得到的下行信道的参考信号接收功率（RSRP）值与特定阈值比较。该特定阈值可以是在 3GPP 技术规范 TS36.101 中规定的阈值，可由用户设备通过接收单元 310 从基站、网络侧先行接收到再、并预先存储在用户设备的存储单元 350 中。如果大于或等于该阈值，则等级确定单元 330 确定寻呼消息等级为 0；小于该阈值 1 ～ 5dB，则确定寻呼消息等级为 1；小于该阈值 6 ～ 10dB，则确定寻呼消息等级为 2；小于该阈值 11 ～ 15dB，则确定寻呼消息等级为 3。

[0077] 可选地，在确定寻呼消息等级之后，用户设备、基站、网络侧可存储该寻呼消息等级，以用于下一次的资源块集起始位置确定或用于其他用途。

[0078] 在块集索引确定单元 410 确定用于发送寻呼消息的物理资源块集在子帧中的索引之后，在步骤 420 中，网络节点向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示。在一些实施例中，该对物理资源块集的指示可包括块集索引确定单元 410 确定的物理资源块集在子帧中的索引，并可选地包括物理资源块集的大小。然而在另一些实施例中，物理资源块集的大小已由被预先通知给了用户设备。

[0079] 承载不同等级的寻呼消息的资源块的数目可以是预定的，并例如可由基站通过广播信息和 / 或用户设备专用 RRC 信令配置给用户设备。在其他一些示例中，承载不同等级的寻呼消息的资源块的数目可以由网络侧（例如，MME）通过 NAS 信令配置。此外，基站可通过广播系统信息和 / 或用户设备专用 RRC 信令通知物理资源块集在子帧中的索引；或网络侧（例如、MME）可通过 NAS 信令通知该索引。在本发明中，子帧中承载寻呼消息的资源块集的索引与这些资源块中起始资源块的索引表达相同的含义，可以互换使用。

[0080] 在一些示例中，寻呼消息的等级可被基站的重复次数的确定单元 150 用于确定一个或多个物理下行共享信道、物理上行共享信道，物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

[0081] 在一些示例中，寻呼消息的等级可被基站的捆绑大小确定单元 160 用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道、物理上行控制信道和物理随机接入信道的 TTI bundle(Transmission Time Interval bundle：传输时间间隔捆绑）大小。

[0082] 图 6 示出了不同等级的寻呼消息与相应的资源块起始位置索引的对应关系的另一示意图。然而该图仅是为说明本发明而被出的示例，本发明不应被其所限制。例如，寻呼消息等级也可以对应于两个资源块起始位置，如索引 0 和 1，而不仅限于索引 0。

[0083] 图 7 示出了承载不同等级的寻呼消息的资源块集的大小不一致的情况。如图 7 所示，系统带宽为 6 个物理资源块大小，且承载不同等级的寻呼消息的资源块集的大小是不一样的，相应的资源块集的起始位置由基站和 / 或网络侧（例如、MME）配置，其原则可以是尽量利用子帧中的物理资源块，但可以是本领域技术人员可想到或还需使用的其他原则。在图 7 所示的示例中，资源块集的起始位置与不同等级的寻呼消息的关系可以是：覆盖增强等级 0 的寻呼消息对应的资源块集的起始位置索引为 0；覆盖增强等级 1 的寻呼消息对应的资源块集的起始位置索引为 2；覆盖增强等级 2 的寻呼消息对应的资源块集的起始位置索引为 2；覆盖增强等级 3 的寻呼消息对应的物理资源块集的起始位置索引为 1。

[0084] 在图 7 示出的示例中，承载不同等级的寻呼消息的资源块集的大小不一致，因此

需要对资源块集的大小进行确定。该操作可以由图1中的块集大小确定单元110执行。在一些示例中，承载不同等级的寻呼消息的资源块的数目可以是：覆盖增强等级0的寻呼消息对应的资源块的数目为2；覆盖增强等级1的寻呼消息对应的资源块的数目为3；覆盖增强等级2的寻呼消息对应的资源块的数目为4；覆盖增强等级3的寻呼消息对应的资源块的数目为5。当然，本领域技术人员也可以根据实际需求（例如系统资源限制等）选择不同的资源块集大小分配方案，理论上只要覆盖增强等级较高的寻呼消息对应更多数目的资源块即可。

[0085] 图7所示情形的其他技术特征与图5所示情形相同，在此不再赘述。

[0086] 图8示出了在承载不同等级的寻呼消息的资源块集的大小不一致的情况下，寻呼消息等级与资源块集大小的映射关系。图9示出了在承载不同等级的寻呼消息的资源块集的大小不一致的情况下，寻呼消息等级与资源块起始位置的映射关系。如上所述，这些映射关系都仅是为了说明本发明而做出的示例，本发明不应被其所限制。

[0087] 在块集索引确定单元110确定用于发送寻呼消息的物理资源块集在子帧中的索引以及块集大小确定单元110确定该物理资源块集的大小之后，在步骤220中，网络节点向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示。在一些实施例中，该对物理资源块集的指示可包括块集索引确定单元110确定的物理资源块集在子帧中的索引以及块集大小确定单元110确定的该物理资源块集的大小。

[0088] 在步骤230中，网络单元的发送单元120在所确定的物理资源块集上发送寻呼消息。

[0089] 然而，在3GPP LTE中，也可能存在系统带宽大于6个物理资源块的情况。图10示出了在该情形下根据本发明的处理。如图10所示，当系统带宽大于6个物理资源块时，可将系统带宽分成多个子频带。在每一个子频带中依然可执行图1-9中所示的技术方案。在图10所示情况下，网络节点还需要通过发送单元130向用户设备通知子频带的划分。子频带可以是连续的6个物理资源块。同样地，子频带的划分可以由基站通过广播系统信息和/或用户设备专用无线电资源控制信令配置给用户设备，或者由网络侧（例如MME）通过NAS信令配置给用户设备。

[0090] 作为一般性的实例，可以假设系统带宽包含M个PRB，并可被划分成N个子频带，其中M和N需满足N = floor(M/6)，即N是小于M除以6的最大自然数。这样整个系统带宽可划分为N个带宽大小为6个物理资源块的子频带和一个带宽大小为(M-6*N)个物理资源块的子频带。从上式可以看出，在M不是6的整倍数的情况下，可能包括子频带具有小于6个物理资源的情况。在这种情况下，只要寻呼消息对应的物理资源块的数目小于该子频带具有的资源块的总数目，依然可以使用本文上述的方案确定该子频带中用于该寻呼消息的资源块集的起始位置索引和大小。本发明不受限于系统带宽、子频带中包含的具体资源块的数目。

[0091] 用户设备需要在一个子频带上接收寻呼消息，该子频带是在配置了确定物理资源块集在子帧中的索引和/或物理资源块的大小之前确定的。在本发明的一些实施例中，可以根据寻呼消息的等级来确定用户设备所使用的子频带。例如，通过以下公式：Index of sub-band = (UE_ID) mod (the number of sub-band)来确定用户设备所使用的子频带。其中UE_ID可以是国际移动用户标识(IMSI，International Mobile Subscriber Identity)，

用于在核心网中唯一标识一个用户，该标识存储在 SIM 卡中。当然，在本发明的其他实施例中，本领域技术人员也可以使用唯一标识用户的其他可能的标识符，并对上式进行适应性修改，本发明不对此进行限制。

[0092] 在用户设备侧，用户设备的接收单元 310 在步骤 110 中接收对用于发送寻呼消息的物理资源块集的指示。该指示可以包括其用于接收寻呼消息的物理资源块集在子帧中的索引。在一些情况下，该指示还可以包括物理资源块集的大小。而在另一些情况下，物理资源块集的大小已由网络节点确定并在之前发送给用户设备（例如，物理资源块集的大小对不同寻呼消息等级而言固定的情况下）。

[0093] 然后，在步骤 120 中，用户设备可通过接收单元 310 在所指示的物理资源块集上接收寻呼消息。

[0094] 当用户设备处于 RRC_CONNECT 状态时，基站和 / 或网络侧（例如，MME）已经配置用户设备工作在一个子载带上接收数据。此时，当用户设备需要被寻呼时，该寻呼消息可在当前的子载带上传输，用于发送该寻呼消息的物理资源块集可通过根据本发明附图 1 至 9 中所述的方法来确定。

[0095] 应该理解，本发明的上述实施例可以通过软件、硬件或者软件和硬件两者的结合来实现。例如，上述实施例中的基站和用户设备内部的各种组件可以通过多种器件来实现，这些器件包括但不限于：模拟电路器件、数字电路器件、数字信号处理（DSP）电路、可编程处理器、专用集成电路（ASIC）、现场可编程门阵列（FPGA）、可编程逻辑器件（CPLD）、等等。

[0096] 在本申请中，"基站"是指具有较大发射功率和较广覆盖面积的移动通信数据和控制交换中心，包括资源分配调度、数据接收发送等功能。"用户设备"是指用户移动终端，例如包括移动电话、笔记本等可以与基站或者微站进行无线通信的终端设备。

[0097] 此外，这里所公开的本发明的实施例可以在计算机程序产品上实现。更具体地，该计算机程序产品是如下的一种产品：具有计算机可读介质，计算机可读介质上编码有计算机程序逻辑，当在计算设备上执行时，该计算机程序逻辑提供相关的操作以实现本发明的上述技术方案。当在计算系统的至少一个处理器上执行时，计算机程序逻辑使得处理器执行本发明实施例所述的操作（方法）。本发明的这种设置典型地提供为设置或编码在例如光介质（例如 CD-ROM）、软盘或硬盘等的计算机可读介质上的软件、代码和 / 或其他数据结构，或者诸如一个或多个 ROM 或 RAM 或 PROM 芯片上的固件或微代码的其他介质，或一个或多个模块中的可下载的软件图像、共享数据库等。软件或固件或这种配置可安装在计算设备上，以使得计算设备中的一个或多个处理器执行本发明实施例所描述的技术方案。

[0098] 尽管以上已经结合本发明的优选实施例示出了本发明，但是本领域的技术人员将会理解，在不脱离本发明的精神和范围的情况下，可以对本发明进行各种修改、替换和改变。因此，本发明不应由上述实施例来限定，而应由所附权利要求及其等价物来限定。

This collection of information is required by 37 CFR 1.97 and 1.98. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 1 hour to complete, including gathering, preparing and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these record s.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

(54) Title: METHOD AND DEVICE FOR INDICATING NUMEROLOGY

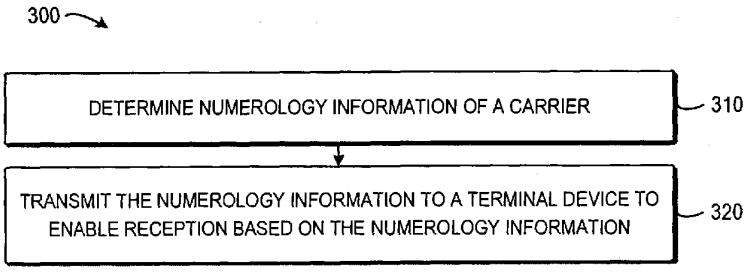

FIG. 3

(57) Abstract: Embodiments of the disclosure provide a method and device for indicating numerology. The method comprises: determining numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and transmitting the numerology information to a terminal device to enable reception based on the numerology information.

WO 2018/081913 A1

METHOD AND DEVICE FOR INDICATING NUMEROLOGY

FIELD OF THE INVENTION

[0001] Embodiments of the present disclosure generally relate to communication techniques. More particularly, embodiments of the present disclosure relate to a method and device for indicating numerology.

BACKGROUND OF THE INVENTION

[0002] Newly-developed mobile standards call for higher data transfer speeds, greater numbers of connections, and better coverage, among other improvements. The 5G standard, according to the Next Generation Mobile Networks Alliance, is expected to provide data rates of several tens of megabits per second to each of tens of thousands of users, with 1 gigabit per second to tens of workers on an office floor. Several hundreds of thousands of simultaneous connections should be supported in order to support large sensor deployments. Consequently, the spectral efficiency is expected to be enhanced to meet more requirements of the new standards.

[0003] Conventionally, for a single carrier, there is one numerology. Therefore, terminal devices have to employ the same numerology in communication with a network device. This inevitably brings undesired, delays, low spectral efficiency for some kind of traffic.

[0004] Accordingly, there is a need for development of better transmission/processing techniques for wireless data transmission to meet different requirements of different applications/users at the same time.

SUMMARY OF THE INVENTION

[0005] The present disclosure proposes a solution for indicating numerology.

[0006] According to a first aspect of embodiments of the present disclosure, embodiments of the disclosure provide a method performed by a network device. The network device determines numerology information of a carrier. The numerology information indicates numerologies of one or more basic units for the

CONFIRMATION COPY

carrier. Then the network device transmits the numerology information to a terminal device to enable reception based on the numerology information.

[0007] According to a second aspect of embodiments of the present disclosure, embodiments of the disclosure provide method performed by a terminal device. The terminal device receives numerology information of a carrier from a network device. The numerology information indicates numerologies of one or more basic units for the carrier. Then the terminal device decodes a signal based on the numerology information.

[0008] According to a third aspect of embodiments of the present disclosure, embodiments of the disclosure provide a network device. The network device comprises: a controller configured to determine numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and a transmitter the numerology information to a terminal device to enable reception based on the numerology information.

[0009] According to a fourth aspect of embodiments of the present disclosure, embodiments of the disclosure provide a terminal device. The terminal device comprises: a receiver configured to receive numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and a decoder configured to decode a signal based on the numerology information.

[0010] Other features and advantages of the embodiments of the present disclosure will also be apparent from the following description of specific embodiments when read in conjunction with the accompanying drawings, which illustrate, by way of example, the principles of embodiments of the disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] Embodiments of the disclosure are presented in the sense of examples and their advantages are explained in greater detail below, with reference to the accompanying drawings, where

[0012] FIG. 1 illustrates a schematic diagram of a communication system 100 according to embodiments of the present disclosure;

[0013] FIG. 2A illustrates a diagram 200 of a basic unit in accordance with embodiments of the present disclosure;

[0014] FIG. 2B illustrates a diagram 260 of a basic unit in accordance with further embodiments of the present disclosure;

[0015] FIG. 3 illustrates a flow chart of a method 300 for performing communication according to embodiments of the present disclosure;

[0016] FIG. 4 illustrates a diagram 400 of the distributed indication according to embodiments of the present disclosure;

[0017] FIG. 5 illustrates a diagram 500 of the centralized indication according to embodiments of the present disclosure;

[0018] FIG. 6 illustrates a diagram 600 of a guard band 610 according to embodiments of the present disclosure;

[0019] FIG. 7 illustrates a diagram 700 of indication of a guard band according to embodiments of the present disclosure;

[0020] FIG. 8 illustrates a diagram 800 of indication of a guard band according to embodiments of the present disclosure;

[0021] FIG. 9 illustrates a diagram 900 of a resource unit 910 according to embodiments of the present disclosure;

[0022] FIG. 10 illustrates a diagram 1000 of information transmission according to embodiments of the present disclosure;

[0023] FIG. 11 illustrates a flow chart of a method 1100 for performing communication according to embodiments of the present disclosure;

[0024] FIG. 12 illustrates a schematic diagram of a network device 1200 according to an embodiment of the present disclosure; and

[0025] FIG. 13 illustrates a schematic diagram of a terminal device 1300 according to an embodiment of the present disclosure.

[0026] Throughout the figures, same or similar reference numbers indicate same or similar elements.

DETAILED DESCRIPTION OF EMBODIMENTS

[0027] The subject matter described herein will now be discussed with reference to several example embodiments. It should be understood these embodiments are discussed only for the purpose of enabling those skilled persons in the art to better understand and thus implement the subject matter described herein, rather than suggesting any limitations on the scope of the subject matter.

[0028] The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of example embodiments. As used herein, the singular forms "a," "an" and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms "comprises," "comprising," "includes" and/or "including," when used herein, specify the presence of stated features, integers, steps, operations, elements and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components and/or groups thereof.

[0029] It should also be noted that in some alternative implementations, the functions/acts noted may occur out of the order noted in the figures. For example, two functions or acts shown in succession may in fact be executed concurrently or may sometimes be executed in the reverse order, depending upon the functionality/acts involved.

[0030] As used herein, the term "communication network" refers to a network following any suitable communication standards, such as Long Term Evolution (LTE), LTE-Advanced (LTE-A), Wideband Code Division Multiple Access (WCDMA), High-Speed Packet Access (HSPA), and so on. Furthermore, the communications between a terminal device and a network device in the communication network may be performed according to any suitable generation communication protocols, including, but not limited to, the first generation (1G), the second generation (2G), 2.5G, 2.75G, the third generation (3G), the fourth generation (4G), 4.5G, the future fifth generation (5G) communication protocols, and/or any other protocols either currently known or to be developed in the future.

[0031] Embodiments of the present disclosure may be applied in various communication systems. Given the rapid development in communications, there

will of course also be future type communication technologies and systems with which the present disclosure may be embodied. It should not be seen as limiting the scope of the present disclosure to only the aforementioned system.

[0032] The term "network device" includes, but not limited to, a base station (BS), a gateway, a management entity, and other suitable device in a communication system. The term "base station" or "BS" represents a node B (NodeB or NB), an evolved NodeB (eNodeB or eNB), a Remote Radio Unit (RRU), a radio header (RH), a remote radio head (RRH), a relay, a low power node such as a femto, a pico, and so forth.

[0033] The term "terminal device" includes, but not limited to, "user equipment (UE)" and other suitable end device capable of communicating with the network device. By way of example, the "terminal device" may refer to a terminal, a Mobile Terminal (MT), a Subscriber Station (SS), a Portable Subscriber Station, a Mobile Station (MS), or an Access Terminal (AT).

[0034] Now some exemplary embodiments of the present disclosure will be described below with reference to the figures. Reference is first made to FIG. 1, which illustrates schematic diagram of a communication system 100 according to embodiments of the present disclosure.

[0035] In the communication system 100, there illustrate a network device (for example, an eNB) 110 that communicates with a terminal device (for example, a UE) 120 by using a certain transmission pattern. The network device 110 sends numerology information to the terminal device 120, wherein the numerology information indicates numerologies of one or more basic units for a carrier. As such, the terminal device 120 is enabled to receive signals from the network device 110 based on the numerology information.

[0036] In the context of the present disclosure, the term "numerology" refers to a set of parameters. In an Orthogonal Frequency Division Multiplexing (OFDM)-based system, the parameters include, for example, but not limited to, a subcarrier spacing, a symbol length, a length of a cyclic prefix (CP), and so on. For instance, a numerology for a subcarrier spacing of 15KHz may include 14 symbols in one subframe, a normal CP, and so on. A numerology for a subcarrier spacing of 30KHz may include 28 symbols in one subframe, a normal CP, and so on. Such a numerology is different from the numerology for the subcarrier spacing of 15KHz.

[0037] The term "basic unit" refers to a block of time-frequency resource. The size of a basic unit may depend on the employed numerology. The basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier. In a frequency domain, the basic unit may be decided by the largest subcarrier spacing. For example, a physical resource block (PRB) with the largest subcarrier spacing may be the frequency size of a basic unit, and/or the largest symbol length may be the time size of the basic unit.

[0038] FIG. 2A illustrates a diagram of a basic unit 240 in accordance with embodiments of the present disclosure. There are three subcarriers, Sc1-Sc3, illustrated in the example of FIG. 2A. In the frequency domain, the basic unit 240 is determined based on the largest subcarrier spacing, 60KHz. That is, the frequency size of the basic unit 240 equals to one PRB of the subcarrier Sc1 of 60KHz, 2 PRBs of the subcarrier Sc2 of 30KHz, and 4 PRBs of the subcarrier Sc3 of 15KHz.

[0039] In the time domain, the basic unit 240 is determined based on the largest symbol length. Thus, the time size of the basic unit 240 equals to a symbol of Sc3 of 15KHz, which has a largest symbol length among Sc1 to Sc3.

[0040] In addition to the above, the basic unit according embodiments of the present disclosure may be implemented in other suitable forms, for example, multiples of the largest symbol length in time domain, and/or multiples of the largest subcarrier spacing, multiples of a PRB, one or multiples of the smallest subcarrier spacing. FIG. 2B illustrates a diagram 200 of another basic unit 270 in accordance with further embodiments of the present disclosure. In the example shown in FIG. 2B, the basic unit 270 is defined based on the smallest subcarrier spacing in frequency domain. The time domain duration may be indicated by other ways explicitly or implicitly. For instance, the basic unit 270 may have the same duration as the basic unit 240 in the time domain, or the time duration may be multiples of the time duration of the basic unit 240.

[0041] It is to be understood that, the above examples are discussed for purpose of illustration, rather than limitation. Those skilled in the art would appreciate that the basic unit can be implemented other suitable forms with the scope of the subject matter of the present disclosure.

[0042] Conventionally, a carrier employs a single numerology, thus spectrum

utilization may be inefficient when terminal devices have different communication demands. To solve this problem, embodiments of the present disclosure propose a solution as discussed below to employ multiple numerologies in a single carrier. By receiving numerology information indicating numerologies of one or more basic units for the carrier, the terminal devices can receive signals based on the numerology information.

[0043] Now some exemplary embodiments of the present disclosure will be described below with reference to the following figures. FIG. 3 illustrates a flow chart of a method 300 for indicating numerology according to embodiments of the present disclosure. The method 300 may be implemented by the network device 110, for example, an eNB or other suitable device.

[0044] The method 300 is entered at 310, where the network device determines numerology information of a carrier. The numerology information indicates numerologies of one or more basic units for the carrier. At 320, the network device transmits the numerology information to a terminal device to enable reception based on the numerology information.

[0045] According to embodiments of the present disclosure, there may be a variety of ways to indicate numerology. In some embodiments, the numerology information may be indicated in a distributed way, which is also referred to as "distributed indication". In this case, the numerology of each basic unit is indicated. For purpose of illustration, the basic unit 240 of FIG. 2A is discussed in these embodiments. Thus, at 310, the network device may determine numerologies for all the basic units. In some implementations, a bitmap may be used to indicate the numerologies of the basic units, that is, one or more bits may be used to indicate the numerology for each basic unit. For example, two bits may be used to indicate subcarrier spacing 15KHz, 30KHz, 60KHz, and 120KHz, respectively. If the bits are "00", it means that the subcarrier of the numerology is 15KHz *1, and if the bits are "01", it means that the subcarrier of the numerology is 15KHz *2 = 30KHz. At 320, the network device may transmit information about the numerologies for all the basic units to the terminal device. FIG. 4 illustrates a diagram 400 of the distributed indication according to embodiments of the present disclosure. As shown in FIG. 4, there are six basic units in a carrier, namely, basic units 1 to 6, and there are 6

numerology indications are used for each of the basic units 1 to 6. In this way, the numerologies may be indicated in a flexible way.

[0046] In some other embodiments, if the basic unit is defined as the basic unit 270 as discussed with reference to FIG. 2B, when the numerology is changed from a small subcarrier spacing to a larger one, numerologies of at least multiple basic units need to be the same. For example, if the basic unit is based on 15KHz subcarrier spacing, and the numerology is changed from 15KHz to 30KHz, then numerology of at least two adjacent basic units should be same; if the numerology is changed to be 60KHz, then numerology of at least four adjacent basic units should be the same.

[0047] Alternatively, in some embodiments, the numerology information may be indicated in a centralized way, which is also referred to as "centralized indication." In this case, the carrier bandwidth may be divided into several groups, and each group may have a group-specific numerology. One group may include one or more basic units. Details of group division may be defined by a pattern, for example, referred to as a grouping pattern. The grouping pattern may be predefined in several ways, for example, according to the traffic characteristics, similar as Time Division Duplex (TDD) configuration. The grouping pattern may be alternatively defined in specification. In some implementations, the grouping pattern may be carried by system information and/or a Physical broadcast channel (PBCH). In the embodiments, the network device may inform the terminal device the grouping pattern and/or the group-specific numerology. The number of groups may be decided by the grouping pattern. The number may change due to different grouping patterns. The maximum group number may be reserved. In this case, the terminal device may need to firstly decode the grouping pattern, and then decode the corresponding numerology for each group based on the pattern.

[0048] In these embodiments, at 310, the network device may determine a grouping pattern indicating groups of the basic units, and then determine a numerology for each of the groups. At 320, the network device may transmit information about the grouping pattern and/or the numerology for each of the groups to the terminal device. FIG. 5 illustrates a diagram 500 of the centralized indication according to embodiments of the present disclosure. In the example of FIG. 5, there are six basic units in a carrier, namely, basic units 1 to 6, and they are divided into three groups,

namely, groups 1 to 3. As shown, group 1 includes basic units 1 and 2, group 2 includes basic unit 3, and group 3 includes basic units 4-6. A numerology is determined for each of the groups. As such, there are three numerology indications for groups 1, 2 and 3, respectively.

[0049] In some other embodiments, if the basic unit is defined as the basic unit 270 as discussed with reference to FIG. 2B, when the numerology is changed from a small subcarrier spacing to a larger one, the basic units may be divided into groups to guarantee basic units in each group have the same numerology. Still referring to FIG. 5, if basic units 1 to 6 are each defined as the basic unit 270, and basic units 1 and 2 correspond to numerology 1, basic unit 3 corresponds to numerology 2 and basic units 4, 5 and 6 correspond to numerology 3, then the basic units 1 to 6 may be divided into three groups to guarantee basic units in each group have the same numerology when the numerology is changed from 15KHz to 30KHz.

[0050] As a further alternative, the indication may be from a numerology perspective. That is to say, one or more basic units may be indicated for a specific numerology. The indication may be similar to a legacy approach of LTE resource allocation. The basic units corresponding to a numerology may be continuous or discontinuous. In some embodiments, the numerology information may be determined as below. At 310, the network device may determine numerologies for the basic units and determine an association between the numerologies and the basic units. Then, at 320, the network device may transmit information about the numerologies and/or the association to the terminal device. In an embodiment, the numerology information may be implemented in the form of the following table 1.

	NUMEROLOGY ID	BASIC UNIT ID
1	Numerology 1	Basic unit 1, 2
2	Numerology 2	Basic unit 3
3	Numerology 3	Basic unit 4, 5, 6

[0051] Upon receipt of the numerology information, the terminal device would understand that three numerologies (i.e., Numerology 1, 2 and 3) are designed for the carrier, Basic units 1 and 2 are associated with Numerology 1, Basic unit 3 is associated with Numerology 2, and Basic units 4, 5 and 6 are associated with

Numerology 3.

[0052] As a still further alternative, the bandwidth of the carrier may be divided into groups, and each group has the same numerology distribution pattern. A numerology distribution pattern indicating numerologies for basic units in one of the groups. For example, if in a group, the ith basic unit (also referred to as basic unit i, i=1,...M, and M indicates the total number of basic units in the group) has a numerology corresponding to 15KHz, and basic unit i+4 has a numerology corresponding to 60KHz, and basic units i and i+4 within another group share the same numerology 15KHz and 60KHz, respectively, then the numerology distribution patterns are the same for these two groups. In this case, the network device may indicate the numerology distribution pattern for a single group to the terminal device, and/or information about the group division, and/or the like. The numerology distribution pattern and/or information about the group division may be specified by specification, by RRC configuration, or in other suitable ways. The numerology distribution pattern for each group can also be indicated dynamically in downlink control information. In some embodiments, the numerology information may be determined as below. At 310, the network device may divide the basic units into groups and determine a numerology distribution pattern indicating numerologies for basic units in one of the groups. Then, at 320, the network device may transmit information about the numerology distribution pattern and/or information about the groups to the terminal device.

[0053] In accordance with embodiments of the present disclosure, for different adjacent numerologies, puncturing of one or more subcarriers may be used if a guard band is necessary. From efficiency point of view, the smaller subcarrier spacing may be punctured. In some embodiments, if new waveform design can mitigate the necessity of a guard band, then the puncturing may be unnecessary. According to embodiments of the present disclosure, the guard band may be indicated in a variety of ways. A size for a unit of the guard band (also referred to as a "guard band unit" hereafter) in the frequency domain may be a subcarrier, a PRB, or other suitable length, depending on the adjacent numerologies and/or numerology bandwidth and/or transmission direction. One or more guard band units may be indicated as a guard band.

[0054] FIG. 6 illustrates a diagram 600 of a guard band 610 according to embodiments of the present disclosure. As shown in FIG. 6, there is a guard band 610 between different subcarrier spacings, Sc2 of 30KHz and Sc3 of 15 KHz. The size of the guard band unit is a subcarrier/PRB, and the guard band in this example includes 3 guard band units.

[0055] According to embodiments of the present disclosure, optionally, after 320, the network device may further determines guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units, and transmits the guard band information to the terminal device for each basic unit.

[0056] According to further embodiments of the present disclosure, optionally, after 320, the network device may further determine guard band information about a guard band between adjacent basic units based on transmission directions of the basic units. For example, a basic unit is used for downlink transmission and the adjacent basic unit is uplink transmission, then there will be a guard band between them. If the transmission direction is changed semi-statically, then the guard band information may be indicated to the terminal device in RRC signaling or PBCH. If the transmission direction, for example, downlink or uplink, is changed dynamically, then the guard band information may be indicated to a terminal device in downlink control information.

[0057] In the determination of the guard band information, the network device may detect whether there is a change between numerologies of the adjacent basic units and then determine occurrence of a guard band between the adjacent basic units based on the detection. In some embodiments, the guard band information may include: a number of subcarriers occupied by the guard band, a number of physical resource blocks occupied by the guard band, a basic unit where the guard band is located, and/or the like. The guard band information may indicate whether a guard band exists. From signaling point of view, even the guard band is to be decided not existent, it can be expressed by indicating the guard band to be 0.

[0058] After determining the guard band information, the network device may transmit the guard band information to the terminal device. In an embodiment, the guard band information may be transmitted together with the numerology information. Referring back to the embodiments of FIG. 4, the guard band information may be transmitted together with the numerology information for each basic unit. In another

embodiment, referring back to the embodiments of FIG. 5, the guard band information may be transmitted together with the numerology information for each group of basic units. More details about the indication of the guard band information will be discussed with the following embodiments with reference to FIGs. 7 and 8.

[0059] In some embodiments, the guard band may be defined by specification. In this case, the guard band may be impacted by adjacent numerology combination, and may be located in the side of the lower subcarrier spacing. For example, when a subcarrier spacing of 30KHz and a subcarrier spacing of 60KHz are located adjacently, no matter the detailed bandwidth for each subcarrier spacing, the guard band is the same and is always located in the 30KHz side. FIG. 7 illustrates a diagram 700 of indication of a guard band according to embodiments of the present disclosure. As shown in FIG. 7, there are two change points of numerologies of basic units 1-6, and two guard bands 710 and 720 defined by specification are located at the change points. In this case, the network device may inform the terminal device information about the numerology, and based on the derived numerology, the terminal device may deduce that there are guard bands 710 and 720.

[0060] Alternatively, in some embodiments, the guard band information and/or the numerology information may be transmitted or indicated by system information/PBCH or Dynamic Control Information (DCI). The indication of the guard band information may be according to the numerology distribution pattern, similar to the indication of the numerology information. In this case, the guard band may be impacted by both the adjacent numerology combination and the bandwidth of each numerology.

[0061] In an embodiment, there is a guard band for each basic unit. The guard band may be zero if no numerology change between adjacent basic units or new wave form adoption. Such guard band information may be transmitted together with the numerology information as discussed with reference to FIG. 4. For each basic unit, the numerology and the guard band are indicated. Both independent indication and joint encoding may be employed. FIG. 8 illustrates a diagram 800 of indication of a guard band according to such an embodiment.

[0062] In an alternative embodiment, there is a guard band for each numerology change. In this case, the guard band information may be transmitted together with

the numerology information as discussed with reference to FIG. 5. For example, the guard band information and/or the numerology information may indicate the numerology distribution pattern. Thus, upon receipt of the information, the terminal device may obtain a change point of numerologies based thereon, and then determine the position of the guard band according to the change point. In this embodiment, the guard band information is transmitted when numerologies of two adjacent basic units change. As such, overhead of transmitting the guard band information is reduced.

[0063] In accordance with embodiments of the present disclosure, the network device may further inform the terminal device information about resource allocation. The allocated resource may be indicated by a common index irrespectively of numerology. Thus, the terminal device may understand the resource allocated to it. In some embodiments, the network device may allocate a resource to one or more terminal devices, and then transmit information about the allocated resource to the terminal device. The information about the allocated resource may include one or more of: an index of a basic unit allocated to the terminal devices, an index of a physical resource block in a basic unit allocated to the terminal devices, and other suitable information.

[0064] In some embodiments, the basic units may be indexed from 0 to N-1, where N is a total number of the basic units. The total number may be determined in several ways. For example, if the carrier bandwidth is B and the bandwidth of the basic frequency variation units is W, then the total number may be calculated below:

$$N = \text{ceil}(B/W),$$

where "ceil" indicates an operation of rounding up.

[0065] The total PRB number (denoted as N_p) within a basic unit may be calculated as:

$$N_p = W/Sc/N_Sc$$

where Sc represents the subcarrier spacing for this basic unit, and N_Sc represents the subcarrier number within a PRB.

[0066] The network device may determine which PRB(s) and/or which basic unit(s) are allocated to terminal devices, and transmit the information about the allocated

resource to the terminal devices. The information may include index of the basic unit(s). A terminal device, for example, the terminal device 120, upon receipt of the information about the allocated resource, may identify the index of the basic unit(s) first. Then, the terminal device may determine which PRBs in the allocated basic unit(s) can be used.

[0067] In some implementations, one or more bits may be used to indicate the index of the basic unit(s). Then, one or more additional bits may be used to indicate PRBs within the basic unit. These bits may be used in both downlink and uplink to indicate the corresponding allocated frequency domain resource.

[0068] Alternatively, in some embodiments, the resource allocation information may be indicated by resource unit(s). The resource unit may be defined based on the smallest subcarrier spacing in frequency domain. For a larger subcarrier spacing, resources allocated to a single UE should consider the relationship between the smallest subcarrier spacing and the larger subcarrier spacing. By way of example, if the resource unit is based on 15KHz subcarrier spacing, and for a 60KHz resource allocation, the allocated resources may be multiple of 4, where 4 is obtained by dividing 60KHz by 15KHz. The time domain duration may be indicated by other ways explicitly or implicitly. For instance, the resource unit may have the same duration as the basic unit discussed above in the time domain, or the time duration may be multiples of the time duration of the basic unit.

[0069] FIG. 9 illustrates a diagram 900 of a resource unit 910 according to embodiments of the present disclosure. In the frequency domain, the resource unit 910 corresponds to the PRB of the smallest subcarrier spacing, namely, Sc3 of 15KHz. In the time domain, the resource unit 910 corresponds to a symbol of the smallest subcarrier spacing.

[0070] With respect the above embodiments, if different channel coding schemes are used for different information block sizes, or if the time domain transmission duration may change due to multi-subframe or mini-slot scheduling, the corresponding Modulation and Coding Scheme (MCS)/Transmission Block Size (TBS) table may change. The chosen of MCS/TBS table may be configured by Radio resource configuration (RRC) signaling.

[0071] In accordance with embodiments of the present disclosure, the network device may transmit the numerology information, and/or the guard band information, and/or the information about resource allocation in a variety of ways. In some embodiments, the network device may transmit the numerology information/guard band information in a region of the carrier corresponding to a reference numerology, and transmit the information about the allocated resource in one or more of the basic units, the region of the carrier for transmitting the reference numerology, and/or the like.

[0072] In some embodiments, the numerology information, the guard band information, and/or the information about resource allocation may be carried by PDCCH/Enhanced PDCCH (ePDCCH). The PDCCH carrying the numerology information and/or guard band information may be shared by a group of UEs, and may be scrambled by a cell specific/beam specific sequence. And the PDCCH carrying the resource allocation information may be scrambled in a UE-specific way. With respect to the terminal device, for example, a UE, it may decode received signals to obtain the numerology information and/or the guard band information. Then, the UE may decode the information about resource allocation to obtain allocated resources, MCS/TBS, transmission duration, and/or the like, which are collectively called as UE specific control information hereafter.

[0073] In some embodiments, the UE specific control information may be located at a time-frequency resource corresponding to a specific numerology. Alternatively, the UE specific control information may also be located at the time-frequency resource corresponding to the reference numerology, combined with the cell/beam-specific control information to be carried in a single PDCCH or scrambled independently to form an independent PDCCH. In some implementations, the PDCCH may occur in a periodical way or in aperiodical way. In the case of the aperiodical implementation, the UE may perform blind detection to identify the PDCCH.

[0074] In some alternative embodiments, the control information may also be carried by PBCH or RRC signaling. As a further alternative, the control information may be carried by a combination of RRC signaling and physical layer control information. In such a case, RRC signaling may be used to indicate a subset of possible

numerologies/guard band configurations, and physical layer control information may be used to indicate the numerology within the subset dynamically.

[0075] FIG. 10 illustrates a diagram 1000 of transmission of UE specific control information 1010 and numerology information/guard band 1020 according to embodiments of the present disclosure. As shown in the example of FIG. 10, the UE specific control information 1010 is transmitted via basic unit 1, and the numerology information/guard band information are transmitted in a region 1030 of the carrier corresponding to the reference numerology.

[0076] Reference is now made to FIG. 11, which illustrates a flow chart of a method 1100 for performing communication according to embodiments of the present disclosure. The method 1100 may be implemented by the terminal device 120, for example, a UE or other suitable device.

[0077] The method 1100 is entered at 1110, where the terminal device receives numerology information of a carrier from a network device. The numerology information may indicate numerologies of one or more basic units for the carrier. The basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier. For example, in the frequency domain, the basic unit may be determined based on the largest subcarrier spacing. In the time domain, the basic unit 240 may be determined based on the largest symbol length. In another example, the basic unit may also be determined based on the smallest subcarrier spacing in frequency domain, and/or determined based on the smallest symbol length in time domain.

[0078] In some embodiments, at 1110, the terminal device may receive information about numerologies for all the basic units. Alternatively, the terminal device may receive information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups. As a further alternative, the terminal device may receive information about numerologies for the basic units and/or an association between the numerologies and the basic units. As a still further alternative, the basic units are divided into groups, and the basic units in each of the groups having the same numerology distribution pattern. In this case, the terminal device may receive at least one of information about a numerology distribution

pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups.

[0079] At 1120, the terminal device decodes a signal based on the numerology information.

[0080] In some embodiments, optionally, the terminal device may further receive guard band information about a guard band between adjacent basic units. In this case, at 1120, the terminal device may decode the signal based on the numerology information and the guard band information.

[0081] In some embodiments, optionally, the terminal device may further information about allocated resource of one or more terminal devices from the network device. The information about allocated resource may include an index of a basic unit allocated to the terminal devices, an index of a physical resource block in a basic unit allocated to the terminal devices, and/or the like. In this case, at 1120, the terminal device may decode the signal based on the numerology information and the information about allocated resource (also referred to as "information about resource allocation").

[0082] In some embodiments, the numerology information may be received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource may be received in one or more of the basic units, or in the region of the carrier for transmitting the reference numerology, or other suitable regions.

[0083] FIG. 12 illustrates a schematic diagram of a network device 1200 according to an embodiment of the present disclosure. According to embodiments of the present disclosure, the network device 1200 may be implemented as the network device 110 or other suitable device in the communication system.

[0084] As shown in FIG. 12, the network device 1200 comprises: a controller 1210 configured to determine numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and a transmitter 1220 configured to transmit the numerology information to a terminal device to enable reception based on the numerology information.

[0085] In some embodiments, the basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

[0086] In some embodiments, the controller 1210 may be further configured to determine numerologies for all the basic units, and wherein the transmitter 1220 may be further configured to transmit information about the numerologies for all the basic units to the terminal device.

[0087] In some embodiments, the controller 1210 may be further configured to: determine a grouping pattern indicating groups of the basic units; and determine a numerology for each of the groups, and wherein the transmitter may be further configured to transmit information about the grouping pattern and/or the numerology for each of the groups to the terminal device.

[0088] In some embodiments, the controller 1210 may be further configured to: determine numerologies for the basic units; and determine an association between the numerologies and the basic units, and wherein the transmitter 1220 may be further configured to transmit information about the numerologies and/or the association to the terminal device.

[0089] In some embodiments, the controller 1210 may be further configured to: divide the basic units into groups; and determine a numerology distribution pattern indicating numerologies for basic units in one of the groups, and wherein the transmitter may be further configured to transmit information about the numerology distribution pattern and/or information about the groups to the terminal device.

[0090] In some embodiments, the controller 1210 may be further configured to: determine guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units; and wherein the transmitter may be further configured to transmit the guard band information to the terminal device.

[0091] In some embodiments, the controller 1210 may be further configured to: detect whether there is a change between numerologies of the adjacent basic units; and determine occurrence of a guard band between the adjacent basic units based on the detection.

[0092] In some embodiments, the guard band information may further include one or more of: a number of subcarriers occupied by the guard band, a number of physical resource blocks occupied by the guard band, and a basic unit where the guard band is located.

[0093] In some embodiments, the transmitter 1220 may be further configured to transmit the guard band information to the terminal device based on the numerology information.

[0094] In some embodiments, the controller 1210 may be further configured to allocate a resource to one or more terminal devices, and wherein the transmitter 1220 may be further configured to transmit information about the allocated resource to the terminal device, wherein the information about the allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

[0095] In some embodiments, the transmitter 1220 may be further configured to: transmit the numerology information in a region of the carrier for transmitting a reference numerology; and transmit the information about the allocated resource in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

[0096] FIG. 13 illustrates a schematic diagram of a terminal device 1300 according to an embodiment of the present disclosure. According to embodiments of the present disclosure, the terminal device 1300 may be implemented as the network device 120 or other suitable device in the communication system.

[0097] As shown in FIG. 13, the terminal device 1300 comprises: a receiver 1310 configured to receive numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and a decoder 1320 configured to decode a signal based on the numerology information.

[0098] In some embodiments, the basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

[0099] In some embodiments, the receiver 1310 may be further configured to receive at least one of: information about numerologies for all the basic units; information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups; information about numerologies for the basic units and/or an association between the numerologies and the basic units; and at least one of information about a numerology distribution pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups, the basic

units in the groups having the same numerology distribution pattern.

[00100] In some embodiments, the receiver 1310 may be further configured to receive guard band information about a guard band between adjacent basic units, wherein the decoder 1320 may be further configured to decode the signal based on the numerology information and the guard band information.

[00101] In some embodiments, the receiver 1310 may be further configured to receive information about allocated resource of one or more terminal devices from the network device, wherein the information about allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

[00102] In some embodiments, wherein the numerology information may be received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource may be received in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

[00103] It is also to be noted that the device 1200 or 1300 may be respectively implemented by any suitable technique either known at present or developed in the future. Further, a single device shown in FIG. 12 or 13 may be alternatively implemented in multiple devices separately, and multiple separated devices may be implemented in a single device. The scope of the present disclosure is not limited in these regards.

[00104] It is noted that the device 1200 or 1300 may be configured to implement functionalities as described with reference to FIGs. 3-10 or FIG. 11. Therefore, the features discussed with respect to the method 300 may apply to the corresponding components of the device 1200, and the features discussed with respect to the method 1100 may apply to the corresponding components of the device 1300. It is further noted that the components of the device 1200 or 1300 may be embodied in hardware, software, firmware, and/or any combination thereof. For example, the components of the device 1200 or 1300may be respectively implemented by a circuit, a processor or any other appropriate device. Those skilled in the art will appreciate that the aforesaid examples are only for illustration not limitation.

[00105] In some embodiment of the present disclosure, the device 1200 or 1300 may

comprise at least one processor. The at least one processor suitable for use with embodiments of the present disclosure may include, by way of example, both general and special purpose processors already known or developed in the future. The device 1200 or 1300 may further comprise at least one memory. The at least one memory may include, for example, semiconductor memory devices, e.g., RAM, ROM, EPROM, EEPROM, and flash memory devices. The at least one memory may be used to store program of computer executable instructions. The program can be written in any high-level and/or low-level compliable or interpretable programming languages. In accordance with embodiments, the computer executable instructions may be configured, with the at least one processor, to cause the device 1200 to at least perform according to the method 300 as discussed above and to cause the device 1300 to at least perform according to the method 1100 as discussed above.

[00106] Based on the above description, the skilled in the art would appreciate that the present disclosure may be embodied in an apparatus, a method, or a computer program product. In general, the various exemplary embodiments may be implemented in hardware or special purpose circuits, software, logic or any combination thereof. For example, some aspects may be implemented in hardware, while other aspects may be implemented in firmware or software which may be executed by a controller, microprocessor or other computing device, although the disclosure is not limited thereto. While various aspects of the exemplary embodiments of this disclosure may be illustrated and described as block diagrams, flowcharts, or using some other pictorial representation, it is well understood that these blocks, apparatus, systems, techniques or methods described herein may be implemented in, as non-limiting examples, hardware, software, firmware, special purpose circuits or logic, general purpose hardware or controller or other computing devices, or some combination thereof.

[00107] The various blocks shown in FIG. 3 or 11 may be viewed as method steps, and/or as operations that result from operation of computer program code, and/or as a plurality of coupled logic circuit elements constructed to carry out the associated function(s). At least some aspects of the exemplary embodiments of the disclosures may be practiced in various components such as integrated circuit chips and modules, and that the exemplary embodiments of this disclosure may be realized in an apparatus that is embodied as an integrated circuit, FPGA or ASIC that is configurable

to operate in accordance with the exemplary embodiments of the present disclosure.

[00108] While this specification contains many specific implementation details, these should not be construed as limitations on the scope of any disclosure or of what may be claimed, but rather as descriptions of features that may be specific to particular embodiments of particular disclosures. Certain features that are described in this specification in the context of separate embodiments can also be implemented in combination in a single embodiment. Conversely, various features that are described in the context of a single embodiment can also be implemented in multiple embodiments separately or in any suitable sub-combination. Moreover, although features may be described above as acting in certain combinations and even initially claimed as such, one or more features from a claimed combination can in some cases be excised from the combination, and the claimed combination may be directed to a sub-combination or variation of a sub-combination.

[00109] Similarly, while operations are depicted in the drawings in a particular order, this should not be understood as requiring that such operations be performed in the particular order shown or in sequential order, or that all illustrated operations be performed, to achieve desirable results. In certain circumstances, multitasking and parallel processing may be advantageous. Moreover, the separation of various system components in the embodiments described above should not be understood as requiring such separation in all embodiments, and it should be understood that the described program components and systems can generally be integrated together in a single software product or packaged into multiple software products.

[00110] Various modifications, adaptations to the foregoing exemplary embodiments of this disclosure may become apparent to those skilled in the relevant arts in view of the foregoing description, when read in conjunction with the accompanying drawings. Any and all modifications will still fall within the scope of the non-limiting and exemplary embodiments of this disclosure. Furthermore, other embodiments of the disclosures set forth herein will come to mind to one skilled in the art to which these embodiments of the disclosure pertain having the benefit of the teachings presented in the foregoing descriptions and the associated drawings.

[00111] Therefore, it is to be understood that the embodiments of the disclosure are not to be limited to the specific embodiments disclosed and that modifications and

other embodiments are intended to be included within the scope of the appended claims. Although specific terms are used herein, they are used in a generic and descriptive sense only and not for purpose of limitation.

WHAT IS CLAIMED IS:

1. A method performed by a network device, comprising:

determining numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and

transmitting the numerology information to a terminal device to enable reception based on the numerology information.

2. The method according to Claim 1, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

3. The method according to Claim 1, wherein determining the numerology information comprises: determining numerologies for all the basic units, and

wherein transmitting the numerology information comprises: transmitting information about the numerologies for all the basic units to the terminal device.

4. The method according to Claim 1, wherein determining the numerology information comprises:

determining a grouping pattern indicating groups of the basic units; and

determining a numerology for each of the groups, and

wherein transmitting the numerology information comprises: transmitting information about the grouping pattern and/or the numerology for each of the groups to the terminal device.

5. The method according to Claim 1, wherein determining the numerology information comprises:

determining numerologies for the basic units; and

determining an association between the numerologies and the basic units, and

wherein transmitting the numerology information comprises: transmitting information about the numerologies and/or the association to the terminal device.

6. The method according to Claim 1, wherein determining the numerology information comprises:

dividing the basic units into groups; and

determining a numerology distribution pattern indicating numerologies for basic units in one of the groups, and

wherein transmitting the numerology information comprises: transmitting information about the numerology distribution pattern and/or information about the groups to the terminal device.

7. The method according to Claim 1, further comprising:

determining guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units; and

transmitting the guard band information to the terminal device.

8. The method according to Claim 7, wherein determining the guard band information comprises:

detecting whether there is a change between numerologies of the adjacent basic units; and

determining occurrence of a guard band between the adjacent basic units based on the detection.

9. The method according to Claim 7 or 8, wherein the guard band information further includes one or more of:

a number of subcarriers occupied by the guard band,

a number of physical resource blocks occupied by the guard band, and

a basic unit where the guard band is located.

10. The method according to Claim 7, wherein transmitting the guard band information to the terminal device comprises:

transmitting the guard band information to the terminal device based on the numerology information.

11. The method according to Claim 1, further comprising:

allocating a resource to one or more terminal devices; and

transmitting information about the allocated resource to the terminal device,

wherein the information about the allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

12. The method according to Claim 11, wherein transmitting the numerology information comprises:

transmitting the numerology information in a region of the carrier for transmitting a reference numerology; and

transmitting the information about the allocated resource in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

13. A method performed by a terminal device, comprising:

receiving numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and

decoding a signal based on the numerology information.

14. The method according to Claim 13, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

15. The method according to Claim 13, wherein receiving the numerology information comprises at least one of:

receiving information about numerologies for all the basic units;

receiving information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups;

receiving information about numerologies for the basic units and/or an association between the numerologies and the basic units; and

receiving at least one of information about a numerology distribution pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups, the basic units in the groups having the same numerology distribution pattern.

16. The method according to Claim 13, further comprising:

receiving guard band information about a guard band between adjacent basic units,

wherein decoding the signal comprises: decoding the signal based on the numerology information and the guard band information.

17. The method according to Claim 13, further comprising:

receiving information about allocated resource of one or more terminal devices from the network device, wherein the information about allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

18. The method according to Claim 17, wherein the numerology information is received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource is received in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

19. A network device, comprising:

a controller configured to determine numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and

a transmitter configured to transmit the numerology information to a terminal device to enable reception based on the numerology information.

20. The network device according to Claim 19, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

21. The network device according to Claim 19, wherein the controller is further configured to determine numerologies for all the basic units, and

wherein the transmitter is further configured to transmit information about the numerologies for all the basic units to the terminal device.

22. The network device according to Claim 19, wherein the controller is further configured to:

determine a grouping pattern indicating groups of the basic units; and

determine a numerology for each of the groups, and

wherein the transmitter is further configured to transmit information about the grouping pattern and/or the numerology for each of the groups to the terminal device.

23. The network device according to Claim 19, wherein the controller is further configured to:

determine numerologies for the basic units; and

determine an association between the numerologies and the basic units, and

wherein the transmitter is further configured to transmit information about the numerologies and/or the association to the terminal device.

24. The network device according to Claim 19, wherein the controller is further configured to:

divide the basic units into groups; and

determine a numerology distribution pattern indicating numerologies for basic units in one of the groups, and

wherein the transmitter is further configured to transmit information about the numerology distribution pattern and/or information about the groups to the terminal device.

25. The network device according to Claim 19, wherein the controller is further configured to:

determine guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units; and

wherein the transmitter is further configured to transmit the guard band information to the terminal device.

26. The network device according to Claim 25, wherein the controller is further configured to:

detect whether there is a change between numerologies of the adjacent basic units; and

determine occurrence of a guard band between the adjacent basic units based on the detection.

27. The network device according to Claim 25 or 26, wherein the guard band information further includes one or more of:

a number of subcarriers occupied by the guard band,

a number of physical resource blocks occupied by the guard band, and

a basic unit where the guard band is located.

28. The network device according to Claim 25, wherein the transmitter is further configured to transmit the guard band information to the terminal device based on the numerology information.

29. The network device according to Claim 19, wherein the controller is further configured to allocate a resource to one or more terminal devices, and wherein the transmitter is further configured to transmit information about the allocated resource to the terminal device,

wherein the information about the allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

30. The network device according to Claim 29, wherein the transmitter is further configured to:

transmit the numerology information in a region of the carrier for transmitting a reference numerology; and

transmit the information about the allocated resource in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

31. A terminal device, comprising:

a receiver configured to receive numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and

a decoder configured to decode a signal based on the numerology information.

32. The terminal device according to Claim 31, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

33. The terminal device according to Claim 31, wherein the receiver is further configured to receive at least one of:

information about numerologies for all the basic units;

information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups;

information about numerologies for the basic units and/or an association between the numerologies and the basic units; and

at least one of information about a numerology distribution pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups, the basic units in the groups having the same numerology distribution pattern.

34. The terminal device according to Claim 31, wherein the receiver is further configured to receive guard band information about a guard band between adjacent basic units,

wherein the decoder is further configured to decode the signal based on the numerology information and the guard band information.

35. The terminal device according to Claim 31, wherein the receiver is further configured to receive information about allocated resource of one or more terminal devices from the network device, wherein the information about allocated resource includes at least one of: an index of a basic unit allocated to the terminal

devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

36. The terminal device according to Claim 35, wherein the numerology information is received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource is received in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

(54) Title: METHOD FOR TRANSMITTING AND RECEIVING SYSTEM INFORMATION AND TRANSMITTING AND RECEIVING DEVICES

(54) 发明名称: 系统信息发送方法、接收方法、发送装置及接收装置

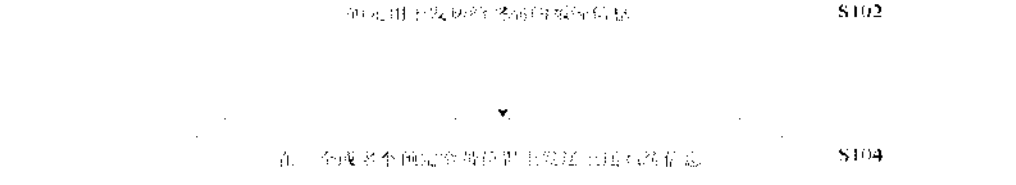

图 1

S102 DETERMINING THE SYSTEM INFORMATION TO BE TRANSMITTED TO A TERMINAL
S104 TRANSMITTING THE SYSTEM INFORMATION ON ONE OR MORE PREDEFINED NARROW BAND LOCATIONS

(57) Abstract: The present invention provides a method for transmitting and receiving system information and transmitting and receiving devices, wherein the method for transmitting system information includes: determining the system information to be transmitted to a terminal; and transmitting the system information on one or more predefined narrow band locations. The present invention solves the transmission method when downlink control information, such as system message change information, ETWS, CMAS and the like, are independently carried out in the related art, realizing an effect of efficient transmission. The present invention also solves the problem of high complexity of terminal blind detection for the downlink control information which carries the system information, thereby achieving the effect of reducing the complexity of terminal blind detection for the system message.

(57) 摘要: 本发明提供了一种系统信息发送方法、接收方法、发送装置及接收装置, 其中, 该系统信息发送方法包括: 确定用于发送给终端的系统信息; 在一个或多个预定义窄带位置上发送该系统信息。通过本发明, 解决了相关技术中独立承载系统消息变更信息、ETWS、CMAS 等消息等控制信息时的发送方式问题, 达到高效发送的效果; 也解决了相关技术中有关终端盲检测承载系统消息的下行控制信息的复杂度高的问题, 进而达到了降低终端盲检测系统消息的复杂度的效果。

系统信息发送方法、接收方法、发送装置及接收装置

技术领域

本发明涉及通信领域，具体而言，涉及一种系统信息发送方法、接收方法、发送装置及接收装置。

背景技术

机器类型通信（Machine Type Communication，简称为 MTC）用户终端（User Equipment，简称为 UE），又称，机器到机器（Machine to Machine，简称为 M2M）用户通信设备，是主要物联网的主要应用形式。近年来，由于长期演进（Long-Term Evolution，简称为 LTE）高级长期演进系统（Long-Term Evolution Advance，简称为 LTE-Advance 或 LTE-A）的频谱效率高，越来越多的移动运营商选择 LTE/LTE-A 作为宽带无线通信系统的演进方向。基于 LTE/LTE-A 的 MTC 多种类数据业务也将更具吸引力。为了重用 GSM 频谱业务提出了窄带 LTE（Narrowband LTE，简称为 NB-LTE）技术，也可以支持 MTC 多种类型的业务。

现有的 LTE/LTE-A 系统是基于每个子帧动态调度进行传输的，即每个子帧均可以传输不同的控制信息。

LTE/LTE-A 中定义了物理下行控制信道（Physical Downlink Control Channel，简称为 PDCCH）和增强物理下行控制信道（Enhanced Physical Downlink Control Channel，简称为 EPDCCH）。PDCCH/EPDCCH 用于承载下行控制信息（Downlink Control Information，简称为 DCI），包括：上、下行调度信息，以及上行功率控制信息。

通常 MTC 终端可以通过在每个子帧解调 PDCCH/EPDCCH 信道获得 DCI，以便实现对物理下行共享信道（Physical Downlink Share Channel，简称为 PDSCH）的解调和物理上行共享信道（Physical Uplink Share Channel，简称为 PUSCH）的调度指示信息。对于寻呼 Paging 消息，同样是通过 PDSCH 信道承载，由基站通过下行控制信道调度指示在终端相应的寻呼机会（Paging Occasion，简称为 PO）发送 Paging 消息。

在 MTC 应用终端中，至少区分两种类型终端，一类终端由于射频及收发带宽受限除之为低成本终端，另一类为低成本终端所处位置或自身特性受限从而导致覆盖性能显著下降，称之为覆盖增强终端。例如智能抄表类 MTC 终端大多固定安装在地下室等低覆盖场景环境下，其主要发送小包数据，对数据速率的要求低，能够容忍较大的数据传输时延。对于覆盖增强终端通过时域上的多次重复发送等方式来保证数据的正确传输。

无论对于 LTE 系统还是 NB-LTE 系统，低成本终端还是覆盖增强终端，由于有在寻 Paging 消息中的系统消息，如系统消息变更信息、地震和海啸警系统（Earthquake and Tsunami Warning System，简称为 ETWS）通知信息、商业移动告警服务（Commercial Mobile Alert Service，简称为 CMAS）通知信息就立承载在下行控制信息中发送的需求，其由需要考虑对

于该类型的下行控制信息如何发送，采用相关技术中的系统消息的发送方法会增加终端盲检测系统消息的复杂度的问题。

针对相关技术中存在的上述问题，目前尚未有效地解决方案。

发明内容

本发明提供了一种系统信息发送方法、接收方法、发送装置及接收装置，以至少解决相关技术中存在的终端盲检测系统消息的复杂度高的问题。

根据本发明的一个方面，提供了一种系统信息发送方法，包括：确定用于发送给终端的系统信息；在一个或多个预定窄带位置上发送所述系统信息。

可选地，所述系统信息包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道射频资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息。

可选地，当所述系统信息位于第一下行控制信息 DCI 中，且所述第一 DCI 中仅包括所述系统信息时，在一个或多个预定窄带位置上发送所述系统信息包括：在预定时刻时，在一个或多个预定窄带位置上发送所述第一 DCI。

可选地，所述预定窄带为基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 窄带；所述预定时刻为所述基站的所述预定小区内的所有终端均能够接收检测的寻呼时刻 PO。

可选地，在预定时刻时，在一个或多个预定窄带位置上发送所述第一 DCI 包括：在预先确定的所述系统信息的变更周期内，在一个或多个预定窄带位置上发送一次或多次所述系统信息。

可选地，在发送所述第一 DCI 时，采对应调度的物理下行共享信道 PDSCH。

可选地，当所述系统信息位于第二下行控制信息 DCI 中，且所述第二 DCI 中还包括除所述系统信息外的其他下行控制信息时，在一个或多个预定窄带位置上发送所述系统信息包括：根据所述终端的标识，在一个或多个寻呼时刻 PO 时，在一个或多个所述预定窄带位置上发送所述第二 DCI。

可选地，所述系统信息在所述第二 DCI 中的以下至少之一的位置上：所述第二 DCI 中的预留比特 bit；所述第二 DCI 中的发上行空闲状态的 bit 域；所述第二 DCI 中的处于非空闲状态的 bit 域其余分 bit。

可选地，当将所述系统信息携带在所述第二下行控制信息 DCI 中进行发送时，通过预定

方式指示所述第一DCI的类型：当所述系统信息携带在所述第一DCI中或者承载于物理下行共享信道PDSCH中进行发送时，通过所述预定方式指示所述系统信息位于所述第一DCI中还是承载于所述PDSCH中；其中，所述类型包括未携带所述系统信息的普通DCI、携带所述系统信息和其他下行控制信息的普通DCI；所述预定方式包括以下至少之一：使用所述第一DCI中的空闲比特bit进行指示的方式；将所述第一DCI置于特定状态的方式；利用无线网络临时标识RNTI的特定值的方式。

可选地，在所述第一DCI或所述第二DCI中，还携带有用于指示物理下行共享信道PDSCH的存无的指示信息，其中，在指示为无PDSCH时，相应的具体系统更新消息在系统信息块SIB中发送；在指示为有PDSCH时，相应的具体系统更新消息在PDSCH中发送。

可选地，在一个或多个预定窄带位置上发送所述系统信息之前，还包括：将用于指示所述一个或多个预定窄带位置的指示信息通过系统信息中的主信息块MIB或系统信息块SIB或无线资源控制RRC消息发送给所述终端。

根据本发明的另一方面，提供了一种系统信息接收方法，包括：确定一个或多个预定窄带位置；在确定的所述一个或多个预定窄带位置上接收来自基站的系统信息。

可选地，所述系统信息包括以下至少之一：系统消息变更信息、地震和海啸预警系统ETWS通知信息、商业移动告警服务CMAS通知信息、扩展接入控制EAB参数变更通知信息、控制格式指示信息CFI、时分双工系统配置信息、基站eNB支持的最大覆盖增强等级max CE level、基站eNB支持的覆盖增强等级CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道PRACH配置信息、窄带跳变Hopping配置信息、除PRACH信道以外其他信道物理资源配置信息、上行频点和带宽信息、多播广播单频网络MBSFN子帧配置信息。

可选地，确定所述一个或多个预定窄带位置包括以下之一：通过系统信息中的消息信息块MIB或系统信息块SIB或无线资源控制RRC消息接收所述基站预先发送的用于指示所述一个或多个预定窄带位置的指示信息，根据所述指示信息确定所述一个或多个预定窄带位置；根据预配置的用于标识所述一个或多个预定窄带位置的协议确定所述位置。

可选地，在确定的所述一个或多个预定窄带位置上接收来自基站的系统信息包括：在预定时刻时，在确定的所述一个或多个预定窄带位置上接收来自基站的承载所述系统信息的第二DCI。

可选地，所述预定窄带为所述基站为预定小区内的所有终端为能够接收检测的公有搜索空间CSS窄带；所述预定时刻为所述基站的所述预定小区内的所有终端为能够接收检测的寻呼时刻PO。

可选地，在预定时刻时，在确定的所述一个或多个预定窄带位置上接收来自基站的承载所述系统信息的所述第二DCI包括：在预先确定的所述系统信息的变更周期内，在一个或多个预定窄带位置上接收一次或多次所述第二DCI。

可选地，在确定的所述一个或多个预定窄带位置上接收来自基站的系统信息包括：在确

定的所述一个或多个预定义带位置上接收来自基站的第四下行控制信息 DCI；根据所述第四 DCI 中的用于进行指示的 bit、所述第四 DCI 的状态以及预先确定的无线网络临时标识 RNTI 的 RNTI 值中的至少之一确定所述第四 DCI 的类型或者确定所述系统信息位于所述第四 DCI 中还是承载于物理下行共享信道 PDSCH 中，其中，所述类型包括未携带所述系统信息的普通 DCI、携带所述系统信息和其他下行控制信息的普通 DCI；根据确定结果接收所述系统信息。

根据本发明的另一方面，提供了一种系统信息发送装置，包括：第一确定模块，设置为确定用于发送给终端的系统信息；第一发送模块，设置为在一个或多个预定义带位置上发送所述系统信息。

可选地，所述系统信息包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道射频资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息。

可选地，所述装置还包括：第二发送模块，设置为在一个或多个预定义带位置上发送所述系统信息之前，将用于指示所述一个或多个预定义带位置的指示信息通过系统信息中的消息信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息发送给所述终端。

根据本发明的另一方面，提供了一种系统信息接收装置，包括：第二确定模块，设置为确定一个或多个预定义带位置；接收模块，设置为在确定的所述一个或多个预定义带位置上接收来自基站的系统信息。

可选地，所述系统信息包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道射频资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息。

可选地，所述第二确定模块包括以下之一：第一确定单元，设置为通过系统信息中的消息信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息接收所述基站预先发送的用于指示所述一个或多个预定义带位置的指示信息，根据所述指示信息确定所述一个或多个预定义带位置；第二确定单元，设置为根据预配置的用于标识所述一个或多个预定义带位置的索引确定所述位置。

本发明另一实施例提供了一种计算机存储介质，所述计算机存储介质存储有执行指令，所述执行指令用于执行上述实施例中的方法。

通过本发明，采用确定用于发送给终端的系统信息：在一个或多个预定义带或物理资源

块组位置上发送所述系统信息，解决了相关技术中触发承载系统消息变更信息、ETWS、CMAS等的下行控制信息时的发送方式问题，达到高效发送的效果；还解决了相关技术中存在的终端自检测承载系统消息的下行控制信息的复杂度高的问题，进而达到了降低终端自检测系统消息的复杂度的效果。

附图说明

此处所说明的附图用来提供对本发明的进一步理解，构成本申请的一部分，本发明的示意性实施例及其说明用于解释本发明，并不构成对本发明的不当限定。在附图中：

图 1 是根据本发明实施例的系统信息发送方法的流程图；

图 2 是根据本发明实施例的在公共CSS 空间和公共 PO 时刻位置发送专用 DCI 的示意图；

图 3 是根据本发明实施例的在公共CSS 空间和公共 PO 时刻位置发送专用 DCI 的示意图；

图 4 是根据本发明实施例的系统信息接收方法的流程图；

图 5 是根据本发明实施例的系统信息发送装置的结构框图；

图 6 是根据本发明实施例的系统信息发送装置的优选结构框图；

图 7 是根据本发明实施例的系统信息接收装置的结构框图；

图 8 是根据本发明实施例的系统信息接收装置中第一确定模块 72 的结构框图；

图 9 是根据本发明实施例的在多个 CSS 空间发送含有下行信息的调度寻呼 Paging 消息的DCI 的示意图

具体实施方式

下文中将参考附图并结合实施例来详细说明本发明。需要说明的是，在不冲突的情况下，本申请中的实施例及实施例中的特征可以相互组合。

需要说明的是，本发明的说明书和权利要求书及上述附图中的术语“第一”、“第二”等是用于区别类似的对象，而不必用于描述特定的顺序或先后次序。

在本实施例中提供了一种系统信息发送方法，图 1 是根据本发明实施例的系统信息发送方法的流程图，如图 1 所示，该流程包括如下步骤：

步骤 S102，确定用于发送给终端的系统信息；

步骤 S104，在一个或多个预定寻呼位置上发送上述系统信息。

其中，上述的窄带也可以称为物理资源块组 PRB（Physical Resource Block） group，执行上述操作的可以是基站，上述的一个或多个预定窄带位置也可以是基站和终端预先协商好的位置，在发送上述系统消息时，可以在下行控制信道上承载发送。因此，可以降低终端的盲检测的复杂度。解决了相关技术中缺乏承载系统消息变更信息、ETWS、CMAS 等的下行控制信息时的发送方式问题，达到高效发送的效果；还解决了相关技术中存在的终端盲检测承载系统消息的下行控制信息的复杂度高的问题，进而达到了降低终端盲检测系统消息的复杂度的效果。

在一个可选的实施例中，上述的系统信息可以包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息，商业移动告警服务 CMAS、通知信息，扩展接入控制（Extended Access Barring，简称为 EAB）参数变更通知信息、控制格式指示信息（Control format Indicator，简称为 CFI）、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道（Physical Random Access Channe，简称为 PRACH）配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道频资源配置信息、上行频点和带宽信息、多播广播单频网络（Multicast Broadcast Single Frequency Network，简称为 MBSFN）子帧配置信息、或小区专有有效子帧配置信息。其中，优选的系统消息组合包括以下组合至少之一：组合 1：系统消息变更信息、ETWS、CMAS；组合 2：系统消息变更信息、ETWS、CMAS、CFI、TDD configuration；组合 3：系统消息变更信息、ETWS、CMAS、max CE level、等等，也可以是其他组合形式，在此不一一列举。

在发送上述系统消息时，可以将上述系统消息作为专用的 DCI（即，专用仅包含上述系统消息的专用 DCI 进行发送）或者作为 DCI 中的一部分，上述的预定窄带优选为 CSS 窄带，即可以通过下行控制信道承载的上述系统消息信息在一个或多个 CSS 窄带中发送。在一个可选的实施例中，当上述系统信息位于第一下行控制信息 DCI 中，且该第一 DCI 中仅包括上述系统信息（该第一 DCI 为专用 DCI）时，在一个或多个预定窄带位置上发送上述系统信息包括：在预定时刻时，在一个或多个预定窄带位置上发送上述第一 DCI，上述系统信息作为专用 DCI，不使用调度普通 Paging 消息的 DCI，即不包含资源分配、调制编码方式等的指示，在预定窄带和预定时刻发送，即发送位置是基站和 UE 所会知上本区分特定 UE 的。

在一个可选的实施例中，上述预定窄带为基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 窄带；上述预定时刻为基站的预定小区内的所有终端均能够接收检测的寻呼时刻 PO，优选地，小区内所有终端在同一 PO 时刻使用相同的一个 CSS 窄带，如图 2 所示，图 2 是根据本发明实施例的在公共 CSS 窄带和公共 PO 时刻位置发送专用 DCI 的示意图一，在相同的 PO 时刻或 PO 时刻组接收相应的上述下行信息，这里的 PO 时刻或 PO 时刻组为所有终端都能够接收的时刻，即，公共接收时刻。在不同的 PO 时刻可以使用相同的一个 CSS 窄带，如图 2 所示，也可以使用不同的 CSS 窄带，如图 3 所示，图 3 是根据本发明实施例的在公共 CSS 窄带和公共 PO 时刻位置发送专用 DCI 的示意图二，但是对于一个确定的 PO 时刻而言，可以仅使用一个 CSS 窄带。

在一个可选的实施例中，在预定时刻时，在一个或多个预定窄带位置上发送所述第一 DCI 包括：在预先确定的所述系统信息的变更周期内，在一个或多个预定窄带位置上发送一次或多次所述系统信息。即，一个所述的变更周期内可以包括一个或多个上述的预定时刻，可以在每个预定时刻内发送上述系统消息，因此，可以在一个变更周期内发送一次或多个上述系统消息。其中，在上述的一次或多次发送系统消息时，系统信息内容未发生变化，使得在系统信息变更周期内发送一次或多次系统消息可以保证小区内所有终端以较大概率接收到上述系统信息。

在一个可选的实施例中，在发送上述第一 DCI 时，无对应调度的物理下行共享信道 PDSCH。可选地，上述第一 DCI 中，专用 DCI 仅承载上述系统信息时，并且无相应的资源分配、调制编码方式等传统下行控制信息所包含的调度指示信息时，此时该专用 DCI 无对应调度的 PDSCH。终端在接收该专用 DCI 之后不再接收相应的 PDSCH 信道

在一个可选的实施例中，在一个或多个预定窄带或物理资源块组位置上发送上述系统消息包括：将上述系统消息承载在物理下行共享信道 PDSCH 上，在一个或多个预定窄带位置上发送上述系统消息。上述系统信息还可以位于普通 DCI 中，其中，该普通 DCI 为调度普通 Paging 消息的 DCI。在一个可选的实施例中，当上述系统信息位于第二下行控制信息 DCI 中，上该第二 DCI 中还包括除上述系统信息外的其他下行控制信息时，在一个或多个预定窄带位置上发送上述系统信息包括：根据上述终端的标识 UE ID，在一个或多个寻呼时刻 PO 时，在一个或多个所述预定窄带位置上发送上述第二 DCI。即，该第二 DCI 为普通 DCI。

在一个可选的实施例中，上述系统信息可以位于 DCI 中或 PDSCH 中，其中该 DCI 可以为调度普通 Paging 消息的 DCI（即，上述的第一 DCI）。优选地，此时有对应调度的 PDSCH 信道，承载相应的部分用户或全部用户的 Paging 消息。基站 eNB 可以根据 UE ID 在一个或多个 CSS 窄带/物理资源块组 PRB group 和一个或多个 PO 发送该 DCI。即基站对于部分用户的 Paging record 信息承载在同一条 Paging 消息中，eNB 根据这些用户（到上述的终端）的 UE ID 均包含所述下行信息的调度该条 Paging 消息在一个 CSS 窄带以及一个或多个 PO 时刻进行发送。对于另一部分用户的 Paging record 信息承载在另一条 Paging 消息中，eNB 根据所述另一部分用户的 UE ID 将包含所述下行信息的调度该条 Paging 消息在另一个 CSS 窄带以及一个或多个 PO 时刻进行发送。如图 3 所示从 eNB 角度来看，发送承载所述下行信息的调度普通 Paging 消息的 DCI 位于多个 CSS 窄带，对于终端而言，在同一 PO 时刻仅能在一个 CSS 窄带中接收所述下行信息。优选的，终端可以通过 UE ID 隐含得到自己需要接收的 CSS 窄带位置。

在一个可选的实施例中，上述系统信息在第二 DCI 中的以下至少之一的位置上：第二 DCI 中的空闲比特 bit；第二 DCI 中的处于空闲状态的 bit 域；第二 DCI 中的处于非空闲状态的 bit 域的部分 bit。下面进行具体说明：使用调度普通 Paging 消息的 DCI 的 padding bit 或空闲状态，具体为当所述 DCI 消息中存在空闲 bit，如 Padding bit，使用空闲 bit 来载上述系统信息，其中下行信息的大小小于或等于空闲 bit 的数量，或者使用普通 DCI 消息的空闲状态，如指示传输功率控制 TPC 的 2bit 信息此时并无具体指示含义，处于空闲状态，此时上述系统信息使用该比特域进行传输，其中系统信息的大小小于或等于空闲状态所对应的 bit 的数量。还可以使用

调度普通 Paging 消息的 DCI 的非空闲状态。具体的如指示资源分配比特或此，指示完所有可能的分配或指示特定后，仍存在状态剩余，使用剩余的状态指示、或者如占用资源分配比特域的部分 bit，资源分配简化指示以及前导部分开销。

在一个可选的实施例中，当将所述系统信息携带在所述第二下行控制信息 DCI 中进行发送时，可以通过预定方式标示该第二 DCI 的类型：当上述系统信息携带在第二 DCI 中或者承载于物理下行共享信道 PDSCH 中进行发送时，也可以通过下述预定方式标示该系统信息位于第二 DCI 中还是承载于 PDSCH 中；其中，该类型包括承载有上述系统信息的普通 DCI、携带上述系统信息和其他下行控制信息的普通 DCI，该预定方式包括以下至少之一：使用第二 DCI 中的空闲比特 bit 进行指示的方式；将上述第二 DCI 置于特定状态的方式；利用无线网络临时标识 RNTI 的特定值的方式。

其中，使用空闲比特指示时，可以使用 padding bit 中的 1bit 指示上述系统信息的第二 DCI 的格式/类型为调度普通 paging 消息的 DCI 还是无相应调度普通 paging 消息的 DCI，或者指示上述系统信息位于 DCI 中还是 PDSCH 中，或者使用 1bit 或 x bit（x 为大于 1 的正整数）指示第二 DCI 格式为承载了具体哪种系统信息组合的系统信息。在使用特定状态指示时，可以使用 padding bit 或资源分配或调制编码方式等之一中的 1 种状态（如全 0 比特、或特别指定的 bit 序列）指示载有上述系统信息的第二 DCI 的格式/类型为调度普通 paging 消息的 DCI 还是无相应调度普通 paging 消息的 DCI，或者指示上述系统信息位于 DCI 中还是 PDSCH 中，或者使用 1 种状态或 x 种状态（x 为大于 1 的正整数）指示上述第二 DCI 格式为承载了具体哪种系统信息组合的系统信息。在使用不同的 RNTI 取值时，可以使用两种不同的 RNTI 取值（其中一种为 P-RNTI 的取值 FFFE）指示第二 DCI 的格式/类型为调度普通 paging 消息的 DCI 还是无相应调度普通 paging 消息的 DCI，或者指示上述系统信息位于 DCI 中还是 PDSCH 中。优选的，使用 P-RNTI 指示上述第二 DCI 的格式/类型为调度普通 paging 消息的 DCI 或者指示上述系统信息位于 PDSCH 中，或者使用 x 种 RNTI 取值（x 为大于等于 2 的正整数）指示上述第二 DCI 格式为承载了具体哪种系统信息组合的系统信息。

在一个可选的实施例中，在上述第一 DCI 或第二 DCI 中，还设置有用于指示物理下行共享信道 PDSCH 的有无的指示信息，其中，在指示为无 PDSCH 时，相应的其他系统更新消息在系统信息块 SIB 中发送；在指示为有 PDSCH 时，相应的其他系统更新消息在 PDSCH 中发送。

在一个可选的实施例中，在一个或多个预定空带位置上发送上述系统信息之前，还包括：将用于指示该一个或多个预定空带位置的指示信息通过系统信息中的主信息块（Master Information Block，简称为 MIB）或系统信息块（System Information Blocks，简称为 SIB 或无线资源控制（Radio Resource Control，简称为 RRC）消息发送给上述终端。还可以根据预配置的用于标识该一个或多个预定空带位置的协议确定上述预定空带的位置。

在本发明实施例中，还提供了一种系统信息接收方法，图 4 是根据本发明实施例的系统信息接收方法的流程图，如图 4 所示，该方法包括如下步骤：

8

步骤 S402，确定一个或多个预定窄带位置；

步骤 S404，在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息。

其中，上述的窄带也可以称为物理资源块组 PRB group，约定上述操作的可以是终端，上述的一个或多个预定窄带位置也可以是基站和终端预先协商好的位置，在接收上述系统消息时，可以在确定预定窄带位置上接收，因此，可以降低终端的盲检测的复杂度，从而解决了相关技术中独立承载系统消息变更信息、ETWS、CMAS 等的下行控制信息所需的发送开销大，达到高效发送的效果；还解决了相关技术中存在的终端盲检测承载系统消息的下行控制信息的复杂度高的问题，进而达到了降低终端盲检测系统消息的复杂度的效果。

在一个可选的实施例中，上述系统信息可以包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道初始资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息（或小区专有的子帧配置信息）。

在一个可选的实施例中，确定上述一个或多个预定窄带位置包括以下之一：通过系统信息中的消息信息块 MIB 或系统信息块类型 SIB 或无线资源控制 RRC 消息接收基站预先发送的用于指示上述一个或多个预定窄带位置的指示信息，根据上述指示信息确定一个或多个预定窄带位置；根据预配置的用于标识上述一个或多个预定窄带位置的协议确定上述位置。

在一个可选的实施例中，在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息包括：在预定时刻时，在确定的上述一个或多个预定窄带位置上接收来自基站的承载上述系统信息的第一 DCI。

在一个可选的实施例中，上述预定窄带为基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 空带；上述预定时刻为基站的预定小区内的所有终端均能够接收检测的寻呼时刻 PO。

在一个可选的实施例中，在预定时刻时，在确定的一个或多个预定窄带位置上接收来自基站的承载上述系统信息的第一 DCI 包括：在预先确定的上述系统信息的变更周期内，在一个或多个预定窄带位置上接收一次或多次上述第一 DCI。

在一个可选的实施例中，在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息包括：在确定的一个或多个预定窄带位置上接收来自基站的第四下行控制信息 DCI；根据该第四 DCI 中的用于通知指示的 bit，该第四 DCI 的状态以及预先确定的无线网络临时标识 RNTI 的 RNTI 值中的至少之一，确定第四 DCI 的类型或者确定系统信息位于上述第四 DCI 中还是承载于物理下行共享信道 PDSCH 中，其中，该类型包括未携带所述系统信息的普通 DCI、携带上述系统信息和其他下行控制信息的普通 DCI；根据确定结果接收上述系统信息。

通过以上的实施方式的描述，本领域的技术人员可以清楚地了解到根据上述实施例的方法可借助软件加必需的通用硬件平台的方式来实现，当然也可以通过硬件，但很多情况下前者是更佳的实施方式。基于这样的理解，本发明的技术方案本质上或者说对现有技术做出贡献的部分可以以软件产品的形式体现出来，该计算机软件产品存储在一个存储介质（如ROM/RAM、磁碟、光盘）中，包括若干指令用以使得一台终端设备（可以是手机，计算机，服务器，或者网络设备等）执行本发明各个实施例所述的方法。

在本实施例中还提供了一种系统信息发送装置，该装置用于实现上述实施例及优选实施方式，已经进行过说明的不再赘述。如以下所使用的，术语“模块”可以实现预定功能的软件和/或硬件的组合。尽管以下实施例所描述的装置较佳地以软件来实现，但是硬件，或者软件和硬件的组合的实现也是可能并被构想的。

图 5 是根据本发明实施例的系统信息发送装置的结构框图，如图 5 所示，该装置包括第一确定模块 52 和第一发送模块 54，下面对该装置进行说明。

第一确定模块 52，设置为确定用于发送给终端的系统信息；第一发送模块 54，连接至上述第一确定模块 52，设置为在一个或多个预定窄带位置上发送上述系统信息。

在一个可选的实施例中，上述系统信息包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道时频资源配置信息、上行频点和指示信息、多播广播单频网络 MBSFN 子帧配置信息（或小区专有有效子帧配置信息）。其中，优选的系统消息组合包括以下组合至少之一：组合 1：系统消息变更信息、ETWS、CMAS；组合 2：系统消息变更信息、ETWS、CMAS、CFI、TDD configuration；组合 3：系统消息变更信息、ETWS、CMAS、max CE level。当然，也可以是其他组合类型，不一一列举。

在发送上述系统消息时，可以将上述系统消息作为专用的 DCI（即，利用仅包含上述系统消息的专用 DCI 进行发送）或者作为 DCI 中的一部分，上述的预定窄带优选为 CSS 窄带，即可以通过下行控制信道承载的上述系统消息信息在一个或多个 CSS 窄带中发送。在一个可选的实施例中，当上述系统信息位于第一下行控制信息 DCI 中，且该第一 DCI 中仅包括上述系统信息（该第一 DCI 为专用 DCI）时，在一个或多个预定窄带位置上发送上述系统信息包括：在预定时刻时，在一个或多个预定窄带位置上发送上述第一 DCI，上述系统信息作为专用 DCI，不使用调度管道 Paging 消息的 DCI，即不包含资源分配、调制编码方式等的指示在预定窄带和预定时刻发送，即发送位置是基站和 UE 所公知且不区分特定 UE 的。

在一个可选的实施例中，上述预定窄带为基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 窄带；上述预定时刻为基站的预定小区内的所有终端均能够接收检测的寻呼时刻 PO。优选地，小区内所有终端在同一 PO 时刻使用相同的一个 CSS 窄带，如图 2 所

示，在相同的 PO 时刻或 PO 时刻组接收相应的所述下行信息，这里的 PO 时刻或 PO 时刻组为所有终端都能够接收的时刻，即，公共接收时刻。在不同的 PO 时刻可以使用相同的一个 CSS 窄带，如图 2 所示，也可以使用不同的 CSS 窄带，如图 3 所示，但是对于一个确定的 PO 时刻而言，可以仅使用一个 CSS 窄带。

在一个可选的实施例中，在预定时刻时，在一个或多个预定窄带位置上发送所述第一 DCI 包括：在预先确定的所述系统信息的变更周期内，在一个或多个预定窄带位置上发送一次或多次所述系统信息，即，上述的变更周期内可以包括一个或多个上述的预定时刻，可以在每个预定时刻均发送上述系统消息，因此，可以在一个变更周期内发送一次或多个上述系统消息，其中，在上述的一次或多次发送系统消息中，系统信息内容未发生变化，优选在系统信息变更周期内发送一次或多次系统消息可以保证小区内所有终端以较大概率接收到上述系统信息。

在一个可选的实施例中，在发送上述第一 DCI 时，无对应调度的物理下行共享信道 PDSCH。可选地，上述第一 DCI（即，专用 DCI）仅承载上述系统信息时，并且无相应的资源分配、调制编码方式等传统下行控制信息所包含的调度指示信息时，此时该专用 DCI 无对应调度的 PDSCH，终端在接收该专用 DCI 之后不再接收相应的 PDSCH 信道。

在一个可选的实施例中，在一个或多个预定窄带或物理资源块组位置上发送上述系统消息包括：将上述系统消息承载在物理下行共享信道 PDSCH 上，在一个或多个预定窄带位置上发送上述系统消息。上述系统信息还可以位于普通 DCI 中，其中，该普通 DCI 为调度普通 Paging 消息的 DCI。在一个可选的实施例中，当上述系统信息位于第一下行控制信息 DCI 中，且该第一 DCI 中还包括除上述系统信息外的其他下行控制信息时，在一个或多个预定窄带位置上发送上述系统信息包括：根据上述终端的标识 UE ID，在一个或多个寻呼时刻 PO 时，在一个或多个所述预定窄带位置上发送上述第一 DCI，即，该第一 DCI 为普通 DCI。

在一个可选的实施例中，上述系统信息可以位于 DCI 中或 PDSCH 中，其中该 DCI 可以为调度普通 Paging 消息的 DCI（即，上述的第一 DCI）。优选地，此时有对应调度的 PDSCH 信道，承载相应的部分用户或全部用户的 Paging 消息。基站 eNB 可以根据 UE ID 在一个或多个 CSS 窄带/物理资源块组 PRB group 和一个或多个 PO 发送该 DCI。例如对于部分用户的 Paging record 信息承载在同一条 Paging 消息中，eNB 根据该部分用户（同上述的终端）的 UE ID 将包含所述下行信息的调度该条 Paging 消息在一个 CSS 窄带以及一个或多个 PO 时刻进行发送。对于另一部分用户的 Paging record 信息承载在另一条 Paging 消息中，eNB 根据同样另一部分用户的 UE ID 将包含所述下行信息的调度该条 Paging 消息在另一个 CSS 窄带以及一个或多个 PO 时刻进行发送。如图 3 所示从 eNB 角度来看，发送承载所述下行信息的调度普通 Paging 消息的 DCI 位于多个 CSS 窄带。对于终端而言，在同一 PO 时刻仅能在一个 CSS 窄带中接收所述下行信息。优选的，终端可以通过 UE ID 隐含得到自己需要接收的 CSS 窄带位置。

在一个可选的实施例中，上述系统信息在第一 DCI 中有以下至少之一的位置上：第一 DCI 中的空闲比特 bit；第一 DCI 中的处于空闲状态的 bit 域；第一 DCI 中的处于上至空闲状态的 bit 域的部分 bit（下面进行具体说明）；使用调度普通 Paging 消息的 DCI 的 padding bit 或空闲状态。

具体为当所述 DCI 消息中存在空闲 bit，如 Padding bit，使用空闲 bit 承载上述系统信息，其中下行信息的大小小于或等于空闲 bit 的数量，或者使用普通 DCI 消息的空闲状态。如指示传输功率控制 TPC 的 2bit 信息此时有无具体指示含义，处于空闲状态，此时上述系统信息使用该比特域进行传输，其中系统信息的大小小于或等于空闲状态所对应的 bit 的数量，还可以使用调度普通 Paging 消息的 DCI 的非空闲状态。具体为如指示资源分配比特域此、指示无所有可能的分配或指示情况后，仍存有状态剩余，使用剩余的状态指示，或者如占用资源分配比特域的部分 bit，资源分配简化指示及而重新部分开销。

在一个可选的实施例中，当将所述系统信息携带在所述第一下行控制信息 DCI 中进行发送时，可以通过预定方式标示该第一 DCI 的类型：当上述系统信息携带在第一 DCI 中或者承载于物理下行共享信道 PDSCH 中进行发送时，也可以通过上述预定方式标示该系统信息位于第一 DCI 中还是承载于 PDSCH 中；其中，该类型包括未携带上述系统信息的普通 DCI，携带上述系统信息和其他下行控制信息的普通 DCI，该预定方式包括以下至少之一：使用第一 DCI 中的空闲比特 bit 进行指示的方式；将上述第一 DCI 置于特定状态的方式；利用无线网络临时标识 RNTI 的特定值的方式。

其中，使用空闲比特指示时，可以使用 padding bit 中的 1bit 指示上述系统信息的第一 DCI 的格式/类型为调度普通 paging 消息的 DCI 还是无相应调度普通 paging 消息的 DCI，或者指示上述系统信息位于 DCI 中还是 PDSCH 中，或者使用 1bit 或 x bit（x 为大于 1 的正整数）指示第一 DCI 格式为承载了具体哪种系统信息组合的系统信息。在使用特定状态指示时，可以使用 padding bit 或资源分配或调制编码方式等之一中的 1 种状态（如全 0 比特，或特别指定的 bit 序列）指示携带上述系统信息的第一 DCI 的格式/类型为调度普通 paging 消息的 DCI 还是无相应调度普通 paging 消息的 DCI，或者指示上述系统信息位于 DCI 中还是 PDSCH 中，或者使用 1 种状态或 x 种状态（x 为大于 1 的正整数）指示上述第一 DCI 格式为承载了具体哪种系统信息组合的系统信息。在使用不同的 RNTI 取值时，可以使用两种不同的 RNTI 取值（其中一种为 P-RNTI 的取值 FFFE）指示第一 DCI 的格式/类型为调度普通 paging 消息的 DCI 还是无相应调度普通 paging 消息的 DCI，或者指示上述系统信息位于 DCI 中还是 PDSCH 中。优选的，使用 P-RNTI 指示上述第一 DCI 的格式/类型为调度普通 paging 消息的 DCI 或者指示上述系统信息位于 PDSCH 中，或者使用 x 种 RNTI 取值（x 为大于等于 2 的正整数）指示上述第一 DCI 格式为承载了具体哪种系统信息组合的系统信息。

在一个可选的实施例中，在上述第一 DCI 或第二 DCI 中，还携带有用于指示物理下行共享信道 PDSCH 的有无的指示信息，其中，在指示为无 PDSCH 时，相应的具体系统更新消息在系统信息块 SIB 中发送；在指示为有 PDSCH 时，相应的具体系统更新消息在 PDSCH 中发送。

图 6 是根据本发明实施例的系统信息发送装置的优选结构框图，如图 6 所示，该装置除包括图 5 所示的所有模块外，还包括第二发送模块 62，下面对该装置进行说明。

第二发送模块 62，连接至上述第一发送模块 54，设置为在一个或多个预定资源位置上发送上述系统信息之前，将用于指示一个或多个预定资源位置的指示信息通过系统信息中的上

信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息发送给终端。

在本发明实施例中，还提供了一种系统信息接收装置，图 7 是根据本发明实施例的系统信息接收装置的结构框图，如图 7 所示，该装置包括第一确定模块 72 和接收模块 74，下面对该装置进行说明。

第一确定模块 72，设置为确定一个或多个预定窄带位置；接收模块 74，连接至上述第一确定模块 72，设置为在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息。

在一个可选的实施例中，上述系统信息可以包括以下至少之一：系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道初始资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息、或小区专有有效子帧配置信息。

图 8 是根据本发明实施例的系统信息接收装置中第一确定模块 72 的结构框图，如图 8 所示，该第一确定模块 72 包括第一确定单元 82 或第二确定单元 84，下面对该第一确定模块 72 进行说明。

第一确定单元 82，设置为通过系统信息中的消息信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息接收基站预先发送的用于指示上述一个或多个预定窄带位置的指示信息，根据上述指示信息确定一个或多个预定窄带位置；第二确定单元 84，设置为根据预配置的用于标识上述一个或多个预定窄带位置的协议确定上述位置。

在一个可选的实施例中，在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息包括：在预定时刻时，在确定的上述一个或多个预定窄带位置上接收来自基站的承载上述系统信息的第一 DCI。

在一个可选的实施例中，上述预定窄带为基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 窄带；上述预定时刻为基站的预定小区内的所有终端均能够接收检测的寻呼时刻 PO。

在一个可选的实施例中，在预定时刻时，在确定的一个或多个预定窄带位置上接收来自基站的承载上述系统信息的第一 DCI 包括：在预先确定的上述系统信息的变更周期内，在一个或多个预定窄带位置上接收一次或多次上述第一 DCI。

在一个可选的实施例中，在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息包括：在确定的一个或多个预定窄带位置上接收来自基站的第四个行控制信息 DCI；根据该第四 DCI 中的用于进行指示的 bit、该第四 DCI 的状态以及预先确定的无线网络临时标识 RNTI 的 RNTI 值中的至少之一，确定第四 DCI 的类型或者确定系统信息位于上述第四 DCI 中还是承载于物理下行共享信道 PDSCH 中，其中，该类型包括本发明所述系统信息的普通

DCI，携带上述系统信息和其他下行控制信息的普通 DCI；根据确定结果接收上述系统信息。

通过使用本发明实施例中提出的系统信息的传输方法，可以保证在独立承载系统消息变更信息、ETWS、CMAS 等系统信息时的高效发送，且确保在非独立承载上述信息时终端识别该信息不增加盲检复杂度。

以下通过具体实施例进一步说明。在下述实施例中，系统信息也可以称为下行信息，以系统信息为系统消息变更信息、ETWS、CMAS 为例进行说明

实施例 1

本实施例对下行信息传输采用本发明所提供的方法进行详细描述说明。

基站 eNB 确定下行信息内容为系统消息变更信息、ETWS、CMAS，并且下行信息单独形成专用 DCI，在下行控制信道中传输。

eNB 在预定 CSS 空间和预定 PO 时刻中发送所述下行信息。其中，在下行信息变更周期内，所述预定 PO 时刻存在一个或多个位置。对于每个 PO 时刻，eNB 仅在一个 CSS 空带上发送所述下行信息，在 PO 时刻存在多个位置的不同 PO 时刻，所述预定 CSS 空带可以相同或不同。

当覆盖增强时，eNB 在预定 CSS 空带上在多个 PO 时刻重复发送所述下行信息。同一 PO 时刻仅对应一个 CSS 空带位置，不同 PO 时刻的 CSS 空带可以相同或不同，或者以某一跳频图样进行跳频传输，该跳频图样为预定义或 eNB 通知的

终端在预定 CSS 空带和预定 PO 时刻中接收所述下行信息。其中终端可以在一个预定 PO 时刻接收一次所述下行信息，或者在多个预定 PO 时刻接收多次所述下行信息，并且下行信息变更周期内至少接收一次。在同一 PO 时刻，所有终端都在同一 CSS 空带上接收所述下行信息。

当覆盖增强时，终端在预定 CSS 空带上在多个 PO 时刻重复接收所述下行信息。同一 PO 时刻仅对应一个 CSS 空带位置，不同 PO 时刻的 CSS 空带可以相同或不同，或者以某一跳频图样进行跳频传输，该跳频图样为预定义或 eNB 通知的

终端在接收到所述下行信息后，不再接收相应的 PDSCH 消息。如发现系统消息变更，则接收相应 SIB 消息

通过使用本发明所提出的下行信息的传输方法，可以保证在独立承载系统消息变更信息、ETWS、CMAS 的下行控制信息时的高效发送。

实施例 2

可选的，上述下行信息位于 DCI 中或 PDSCH 中，其中该 DCI 为调度普通 Paging 消息的 DCI，优选是同一个对应调度的 PDSCH 信道，承载相应的部分用户或全部用户的 Paging 消息。eNB 根据 UE ID 在一个或多个 CSS 空带/物理资源块组 PRB group 和一个或多个 PO 发送该 DCI。即此时对于部分用户的 Paging record 信息承载在同一条 Paging 消息中，eNB 根据这些用户的 UE ID 将包含所述下行信息的调度该条 Paging 消息在一个 CSS 空带以及一个或多个 PO 时刻进行发送。对于另一部分用户的 Paging record 信息承载在另一条 Paging 消息中，eNB 根据所述另一部分用户的 UE ID 将包含所述下行信息的调度该条 Paging 消息在另一个CSS 空带以及一个或多个 PO 时刻进行发送，如图 9 所示从 eNB 角度来看，发送承载所述下行信息的调度普通 Paging 消息的 DCI 位于多个 CSS 空带。对于终端而言，在同一 PO 时刻仅能在一个 CSS 空带中接收所述下行信息。其中，图 9 是根据本发明实施例的在多个 CSS 空带发送含有下行信息的调度普通 Paging 消息的 DCI 的示意图。优选的，终端通过 UE ID 隐含得到自己需要接收的 CSS 空带位置。

本实施例对下行信息传输采用本发明所提供的方法进行详细描述说明。

eNB 确定下行信息内容为系统消息变更信息、ETWS、CMAS，并且所述下行信息位于调度普通 Paging 消息的 DCI 中，在下行控制信道中传输

eNB 针对 UE1 和 UE2 的 UE ID 换算得到在第一 CSS 空带和确定 PO 时刻向 UE1 以及与 UE1 同寻呼组（第一寻呼组）的终端发送该 DCI，在第二 CSS 空带和确定 PO 时刻向 UE2 以及与 UE2 同寻呼组（第二寻呼组）的终端发送该 DCI。其中，在下行信息变更周期内，所述确定 PO 时刻存在一个或多个位置。对于其中一个 PO 时刻，eNB 对于同一寻呼组仅在一个 CSS 空带上发送所述下行信息，不同寻呼组所对应的 CSS 空带可以相同或不同，即分别在一个 PO 时刻仅有一个 CCS 空带位置，第一 CSS 空带和第二 CSS 空带独立确定，该时刻第一 CSS 空带和第二 CSS 空带可以不同或相同。在不同 PO 时刻，同一寻呼组所对应的 CSS 空带可以相同或不同，在不同 PO 时刻，第一 CSS 空带或第二 CSS 空带所处空带位置可以相同或不同。所述不同寻呼组的多个 PO 时刻位置可以相同或部分相同或完全不同，即第一寻呼组与第二寻呼组的 PO 时刻独立确定，可以相同或部分相同或完全不同。所述 DCI 与不含所述下行信息的调度普通 Paging 消息的 DCI 使用不同的 RNTI 进行加扰或空闲比特/状态指示。

当覆盖增强时，eNB 对于不同寻呼组的 UE1 和 UE2 分别在各自的确定 CSS 空带上以及在各自的多个 PO 时刻重复发送所述下行信息，同一 PO 时刻对于同一寻呼组仅对应一个 CSS 空带位置，不同寻呼组的 CSS 空带位置独立确定，可以相同或不同。不同 PO 时刻其同一寻呼组的 CSS 空带可以相同或不同，或者以是一跳频图样进行跳频传输，该跳频图样为预定义或 eNB 通知的。不同寻呼组的 PO 时刻独立确定，可以相同或部分相同或完全不同

终端在确定 CSS 空带和确定 PO 时刻中接收所述下行信息，即 UE1 在第一寻呼组所对应的第一 CSS 空带以及一个或多个 PO 时刻接收所述下行信息，UE2 在第二寻呼组所对应的第二 CSS 空带以及一个或多个 PO 时刻接收所述下行信息，终端在变更周期内至少有一次接收下行信息的机会。在同一 PO 时刻，第一 CSS 空带和第二 CSS 空带独立确定可以相同或不同。在存在多个 PO 时刻不同 PO 时刻所对应的第一 CSS 空带所在空带位置可以相同或不同，同理

第一 CSS 空间。

当激活增强时，终端在预定 CSS 空间上在多个 PO 时刻重复接收所述下行信息，UE1 在多个 PO 时刻在第一 CSS 空间接收所述下行信息，UE2 在多个 PO 时刻在第二 CSS 空间接收所述下行信息。在一个 PO 时刻所述第一 CSS 空间和第二 CSS 空间位置可以相同或不同。不同 PO 时刻的一个或多个的 CSS 空间可以相同或不同，或者以某一跳频图样进行跳频传输，该跳频图样为预定义或 eNB 通知的。

终端在接收到所述下行信息后，通过控制信息指示接收相应的 PDSCH 消息，所述 PDSCH 中可选的存在具体的系统更新消息内容。

通过使用本发明实施例所提出的下行信息的传输方法，可以保证在非独立承载系统消息变更信息，ETWS、CMAS 信息时终端识别该信息且不增加盲检复杂度。

需要说明的是，上述各个模块是可以通过软件或硬件来实现的，对于后者，可以通过以下方式实现，但不限于此：上述模块均位于同一处理器中；或者，上述模块分别位于多个处理器中。

本发明的实施例还提供了一种存储介质。可选地，在本实施例中，上述存储介质可以被设置为存储用于执行以下步骤的程序代码：

S11，确定用于发送给终端的系统信息；

S12，在一个或多个预定窄带位置上发送上述系统信息。

可选地，存储介质还被设置为存储用于执行以下步骤的程序代码：

S21，确定一个或多个预定窄带位置；

S22，在确定的上述一个或多个预定窄带位置上接收来自基站的系统信息。

可选地，在本实施例中，上述存储介质可以包括但不限于：U 盘、只读存储器（Read-Only Memory，简称为 ROM）、随机存取存储器（Random Access Memory，简称为 RAM）、移动硬盘、磁碟或者光盘等各种可以存储程序代码的介质。

可选地，在本实施例中，处理器根据存储介质中已存储的程序代码执行上述步骤 S11-12。

可选地，在本实施例中，处理器根据存储介质中已存储的程序代码执行上述步骤 S21-22。

可选地，本实施例中的具体示例可以参考上述实施例及可选实施方式中所描述的示例，本实施例在此不再赘述。

显然，本领域的技术人员应该明白，上述的本发明的各模块或各步骤可以用通用的计算装置来实现，它们可以集中在单个的计算装置上，或者分布在多个计算装置所组成的网络上，可选地，它们可以用计算装置可执行的程序代码来实现，从而，可以将它们存储在存储装置

申由自行设定来执行，并且在实际情况下，可以以不同于此处的顺序执行所示出或描述的步骤，或者将它们分别制作成各个集成电路模块，或者将它们中的多个模块或步骤制作成单个集成电路模块来实现。这样，本发明不限制于任何特定的硬件和软件结合。

以上所述仅为本发明的优选实施例而已，并不用于限制本发明，对于本领域的技术人员来说，本发明可以有各种更改和变化。凡在本发明的精神和原则之内，所作的任何修改、等同替换、改进等，均应包含在本发明的保护范围之内。

工业实用性

如上所述，本发明实施例提供的一种系统信息发送方法、接收方法、发送装置及接收装置具有以下有益效果：解决了相关技术中独立承载系统消息变更信息、ETWS、CMAS 等的下行控制信息时的发送方式问题，达到高效发送的效果；还解决了相关技术中存在的终端自检测承载系统消息的下行控制信息的复杂度高的问题，进而达到了降低终端自检测系统消息的复杂度的效果。

权 利 要 求 书

1. 一种系统信息发送方法，包括：

确定用于发送给终端的系统信息；

在一个或多个预定窄带位置上发送所述系统信息。

2. 根据权利要求 1 所述的方法，其中，所述系统信息包括以下至少之一：

系统信息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道射频资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息。

3. 根据权利要求 1 所述的方法，其中，当所述系统信息位于第一下行控制信息 DCI 中、且所述第一 DCI 中仅包括所述系统信息时，在一个或多个预定窄带位置上发送所述系统信息包括：

在预定时刻时，在一个或多个预定窄带位置上发送所述第一 DCI。

4. 根据权利要求 3 所述的方法，其中：

所述预定窄带为基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 窄带；

所述预定时刻为所述基站的所述预定小区内的所有终端均能够接收检测的寻呼时刻 PO。

5. 根据权利要求 3 所述的方法，其中，在预定时刻时，在一个或多个预定窄带位置上发送所述第一 DCI 包括：

在预先确定的所述系统信息的变更周期内，在一个或多个预定窄带位置上发送一次或多次所述系统信息。

6. 根据权利要求 3 所述的方法，其中，在发送所述第一 DCI 时，无对应调度的物理下行共享信道 PDSCH。

7. 根据权利要求 1 所述的方法，其中，当所述系统信息位于第二下行控制信息 DCI 中、且所述第二 DCI 中还包括除所述系统信息外的其他下行控制信息时，在一个或多个预定窄带位置上发送所述系统信息包括：

根据所述终端的标识，在一个或多个寻呼时刻 PO 时，在一个或多个所述预定窄带位置上发送所述第二 DCI。

8. 根据权利要求 7 所述的方法，其中，所述系统信息在所述第二 DCI 中的以下至少之一的

位置上：

所述第一DCI中的空闲比特bit；

所述第一DCI中的处于空闲状态的bit域；

所述第一DCI中的处于非空闲状态的bit域的部分bit。

9. 根据权利要求7所述的方法，其中，当携带所述系统信息规带在所述第一下行控制信息DCI中进行发送时，通过预定方式标示所述第一DCI的类型；当所述系统信息携带在所述第一DCI中或者承载一物理下行共享信道PDSCH中进行发送时，通过所述预定方式标示所述系统信息位于所述第一DCI中还是承载于所述PDSCH中；其中，所述类型包括表携带所述系统信息的普通DCI、携带所述系统信息和其他下行控制信息的普通DCI，所述预定方式包括以下至少之一：

使用所述第一DCI中的空闲比特bit进行指示的方式；

将所述第一DCI置于特定状态的方式；

采用无线网络临时标识RNTI至指定值的方式。

10. 根据权利要求3或7所述的方法，其中，在所述第一DCI或所述第一DCI中，还携带有用于指示物理下行共享信道PDSCH的存无的指示信息，其中，在指示为无PDSCH时，相应的具体系统更新消息在系统信息块SIB中发送；在指示为有PDSCH时，相应的具体系统更新消息在PDSCH中发送。

11. 根据权利要求1所述的方法，其中，在一个或多个预定空带位置上发送所述系统信息之前，还包括：

将用于指示所述一个或多个预定空带位置的指示信息通过系统信息中的主信息块MIB或系统信息块SIB或无线资源控制RRC消息发送给所述终端。

12. 一种系统信息接收方法，包括：

确定一个或多个预定空带位置；

在确定的所述一个或多个预定空带位置上接收来自基站的系统信息。

13. 根据权利要求12所述的方法，其中，所述系统信息包括以下至少之一：

系统消息变更信息、地震和海啸预警系统ETWS通知信息、商业移动广警服务CMAS、通知信息、扩展接入控制EAB参数变更通知信息、控制格式指示信息CFI、时分双工系统配置信息、基站eNB支持的最大覆盖增强等级max CE level、基站eNB支持的覆盖增强等级CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道PRACH配置信息、频率跳变Hopping配置信息、除PRACH信道以外其他信道时频资源配置信息、上行响应和带宽信息、多播广播单频网络MBSFN子帧配置信息。

14. 根据权利要求 12 所述的方法，其中，确定所述一个或多个预定窄带位置包括以下之一：

通过系统信息中的消息信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息接收所述基站预先发送的用于指示所述一个或多个预定窄带位置的指示信息，根据所述指示信息确定所述一个或多个预定窄带位置；

根据预配置的用于标识所述一个或多个预定窄带位置的特定确定所述位置。

15. 根据权利要求 12 所述的方法，其中，在确定的所述一个或多个预定窄带位置上接收来自基站的系统信息包括：

在预定时刻时，在确定的所述一个或多个预定窄带位置上接收来自基站的承载所述系统信息的第一 DCI。

16. 根据权利要求 15 所述的方法，其中：

所述预定窄带为所述基站的预定小区内的所有终端均能够接收检测的公有搜索空间 CSS 窄带；

所述预定时刻为所述基站的所述预定小区内的所有终端均能够接收检测的公共时刻 PO。

17. 根据权利要求 15 所述的方法，其中，在预定时刻时，在确定的所述一个或多个预定窄带位置上接收来自基站的承载所述系统信息的所述第一 DCI 包括：

在预先确定的所述系统信息的变更周期内，在一个或多个预定窄带位置上接收一次或多次所述第一 DCI。

18. 根据权利要求 12 所述的方法，其中，在确定的所述一个或多个预定窄带位置上接收来自基站的系统信息包括：

在确定的所述一个或多个预定窄带位置上接收来自基站的第四下行控制信息 DCI；

根据所述第四 DCI 中的用于指示的 bit、所述第四 DCI 的状态以及预先确定的无线网络临时标识 RNTI 的 RNTI 值中的至少之一，确定所述第四 DCI 的类型或者确定所述系统信息位于所述第四 DCI 中还是承载于物理下行共享信道 PDSCH 中，其中，所述类型包括未携带所述系统信息的普通 DCI、携带所述系统信息和其他下行控制信息的普通 DCI；

根据确定结果接收所述系统信息。

19. 一种系统信息发送装置，包括：

第一确定模块，设置为确定用于发送给终端的系统信息；

第一发送模块，设置为在一个或多个预定窄带位置上发送所述系统信息。

20. 根据权利要求 19 所述的装置，其中，所述系统信息包括以下至少之一：

系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道时频资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息。

21. 根据权利要求 19 所述的装置，其中，还包括：

第二发送模块，设置为在一个或多个预定窄带位置上发送所述系统信息之前，利用于指示所述一个或多个预定窄带位置的指示信息通过系统信息中的消息信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息发送给所述终端。

22. 一种系统信息接收装置，包括：

第三确定模块，设置为确定一个或多个预定窄带位置；

接收模块，设置为在确定的所述一个或多个预定窄带位置上接收来自基站的系统信息。

23. 根据权利要求 22 所述的装置，其中，所述系统信息包括以下至少之一：

系统消息变更信息、地震和海啸预警系统 ETWS 通知信息、商业移动告警服务 CMAS 通知信息、扩展接入控制 EAB 参数变更通知信息、控制格式指示信息 CFI、时分双工系统配置信息、基站 eNB 支持的最大覆盖增强等级 max CE level、基站 eNB 支持的覆盖增强等级 CE levels、小区接入相关信息、系统消息调度信息、物理随机接入信道 PRACH 配置信息、窄带跳变 Hopping 配置信息、除 PRACH 信道以外其他信道时频资源配置信息、上行频点和带宽信息、多播广播单频网络 MBSFN 子帧配置信息。

24. 根据权利要求 22 所述的装置，其中，所述第三确定模块包括以下之一：

第一确定单元，设置为通过系统信息中的消息信息块 MIB 或系统信息块 SIB 或无线资源控制 RRC 消息接收所述基站预先发送的用于指示所述一个或多个预定窄带位置的指示信息，根据所述指示信息确定所述一个或多个预定窄带位置；

第二确定单元，设置为根据预配置的用于标识所述一个或多个预定窄带位置的协议确定所述位置。

Setting/determining method and device of subcarrier spacing of reference numerology, base station and terminal

Abstract

The invention provides a setting/determining method and device of subcarrier spacing of reference numerology, a base station and a terminal. The setting method of the subcarrier spacing of reference numerology comprises the steps of setting the subcarrier spacing of the reference numerology to be 2n times of 15 KHz, and informing a terminal device to indicate that the subcarrier spacing of the reference numerology of the terminal device who can have synchronous communication with the base station is 2n times of 15 KHz, wherein n is an integer greater than or equal to -2. Through the technical scheme, the terminal device can determine synchronous signals, reference signals and time-frequency resource granularity of to-be-transmitted resources, particularly, the subcarrier spacing, subframe time units and the like of the reference numerology, on the basis of obtaining the reference numerology, and reliability and accuracy of synchronous communication between the terminal device and a base station device are further improved.

reference numerology的子载波间隔的设置/确定方法、装置、基站和终端

(57)摘要

本发明提供了一种reference numerology的子载波间隔的设置/确定方法、装置、基站和终端，其中，所述reference numerology的子载波间隔的设置方法包括：设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，n为大于或等于-2的整数。通过本发明的技术方案，使得终端设备在获取reference numerology的基础上确定同步信号、参考信号和待传输资源为时频资源粒度，尤其是reference numerology的子载波间隔和子帧(subframe)时间单元等，进一步地提升了终端设备和基站设备之间同步通信的可靠性和准确性。

CN 106376050 A

1.一种reference numerology的子载波间隔的设置/确定方法，其特征在于，所述方法包括：

设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示所述终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15Klz的2^n倍，

其中，所述n为大于或等于-2的整数。

2.根据权利要求1所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

给所有所述终端设备在同一个载波上配置相同的reference numerology的子载波间隔。

3.根据权利要求2所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

设置特定下行信号占用的子载波间隔为reference numerology，并设置发送所述特定下行信号的第一参考子帧，在所述第一参考子帧内以指定的子载波间隔发送所述特定下行信号，以指示终端设备能够与所述基站设备进行同步通信的reference numerology的子载波间隔即为所述特定下行信号传输的子载波间隔。

4.根据权利要求2所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

向所述终端设备发送承载reference numerology的子载波间隔的系统信息，以指示所述终端设备能够与所述基站设备进行同步通信的reference numerology的子载波间隔即为所述系统信息中设置的子载波间隔。

5.根据权利要求2所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

根据载波的特征信息设置reference numerology的子载波间隔，并在所述载波上发送特定下行信号，以供所述终端设备根据检测到的所述载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔，

其中，所述载波的特征信息包括载波频点和/或载波带宽。

6.根据权利要求3或5所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，

所述特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

7.根据权利要求1所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

给所有所述终端设备在同一个载波上配置不同的reference numerology的子载波间隔。

8.根据权利要求7所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

根据所述终端设备的设备类型和/或需要传输的业务类型向所述终端设备发送无线资

源控制信令或下行控制信令，以通过所述无线资源控制信令或下行控制信令半静态地或动态地通知所述终端设备reference numerology的子载波间隔。

9.根据权利要求1或2所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

在所述终端设备确定能够与所述基站设备进行同步通信的reference numerology的子载波间隔后，设置所述终端设备的专用numerology的子载波间隔，并根据所述专用numerology的子载波间隔设置第二参考子帧，以供所述终端设备根据所述专用numerology的子载波间隔和所述第二参考子帧进行上下行数据收发。

10.根据权利要求9所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

所述专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔与终端的reference numerology的子载波间隔之间的相对比值，以供所述终端设备根据所述相对比值以及reference numerology的子载波间隔确定所述专用numerology的子载波间隔；

或所述专用numerology的子载波间隔的设置信息为所述专用numerology的子载波间隔的绝对值。

11.根据权利要求9所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

根据所述专用numerology的子载波间隔以及所述第二参考子帧，对所述终端设备进行上下行时频资源分配并向所述终端设备发送相应的下行控制信令，

其中，所述下行控制信令用于设置所述终端设备通过物理下行共享信道和/或物理上行共享信道进行数据发送的第一发送时间起点位置和发送时间长度。

12.根据权利要求11所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，

所述第二参考子帧为包含的下行数据的发送子帧时，所述下行控制信令还用于设置所述终端设备接收到的所述下行数据所对应的混合自动重传业务的反馈信息的第二发送时间起点位置。

13.根据权利要求11所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，

所述下行控制信令所在子帧位置加上位置偏移量确定第一偏移子帧，所述下行控制信令所在符号位置加上偏移量确定第一偏移符号，所述第一偏移子帧内的第一偏移符号即为所述第一发送时间起点位置。

14.根据权利要求12所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，

发送所述下行数据的起始位置子帧或结束位置子帧加上偏移量确定所述第二偏移子帧，发送所述下行数据的起始位置符号或结束位置符号加上偏移量确定所述第二偏移符号，所述第二偏移子帧内的第二偏移符号即为所述第二发送时间起点位置。

15.根据权利要求3至5中任一项所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，还包括：

在所述终端设备确定reference numerology的子载波间隔基于所述子载波间隔发送

随机接入前导码后，接收并解析所述终端设备发送的随机接入前导码以实现所述终端设备的随机接入。

16.一种reference numerology的子载波间隔的设置/确定装置，其特征在于，所述装置包括：

设置单元，用于设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示所述终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，

其中，所述n为大于或等于-2的整数。

17.根据权利要求16所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述设置单元还用于：给所有所述终端设备在同一个载波上配置相同的reference numerology的子载波间隔。

18.根据权利要求17所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述设置单元还用于：设置特定下行信号占用的子载波间隔为reference numerology，并设置发送所述特定下行信号的第一参考子帧，在所述第一参考子帧内以指定的子载波间隔发送所述特定下行信号，以指示终端设备能够与所述基站设备进行同步通信的reference numerology的子载波间隔即为所述特定下行信号传输的子载波间隔。

19.根据权利要求17所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，还包括：

第一发送单元，用于向所述终端设备发送承载reference numerology的子载波间隔的系统信息，以指示所述终端设备能够与所述基站设备进行同步通信的reference numerology的子载波间隔即为所述系统信息中设置的子载波间隔。

20.根据权利要求17所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述设置单元还用于：根据载波的特征信息设置reference numerology的子载波间隔，并在该载波上发送特定下行信号，以供所述终端设备根据检测到的所述载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔，

其中，所述载波的特征信息包括载波频点和/或载波带宽。

21.根据权利要求18或20所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

22.根据权利要求16所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述设置单元还用于：给所有所述终端设备在同一个载波上配置不同的reference numerology的子载波间隔。

23.根据权利要求22所述的reference numerology的子载波间隔的设置/确定装置，其

特征在于，还包括：

第二发送单元，用于根据所述终端设备的设备类型和/或需要传输的业务类型向所述终端设备发送无线资源控制信令或下行控制信令，以通过所述无线资源控制信令或下行控制信令半静态地或动态地通知所述终端设备reference numerology的子载波间隔。

24.根据权利要求16或17所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述设置单元还用于：在所述终端设备确定能够与所述基站设备进行同步通信的reference numerology的子载波间隔后，设置所述终端设备的专用numerology的子载波间隔，并根据所述专用numerology的子载波间隔设置第二参考子帧，以供所述终端设备根据所述专用numerology的子载波间隔和所述第二参考子帧进行上下行数据收发。

25.根据权利要求24所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔与终端的reference numerology的子载波间隔之间的相对比值，以供所述终端设备根据所述相对比值以及reference numerology的子载波间隔确定所述专用numerology的子载波间隔；

或所述专用numerology的子载波间隔的设置信息为所述专用numerology的子载波间隔的绝对值。

26.根据权利要求24所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，还包括：

第二发送单元，用于根据所述专用numerology的子载波间隔以及所述第二参考子帧，对所述终端设备进行上下行时频资源分配并向所述终端设备发送相应的下行控制信令，

其中，所述下行控制信令用于设置所述终端设备通过物理下行共享信道和/或物理上行共享信道进行数据发送的第一发送时间起点位置和发送时间长度。

27.根据权利要求26所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述第二参考子帧为已包含的下行数据的发送子帧时，所述下行控制信令还用于设置所述终端设备接收到的所述下行数据所对应的混合自动重传业务的反馈信息的第二发送时间起点位置。

28.根据权利要求26所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述下行控制信令所在子帧位置加上位置偏移量确定第一偏移子帧，所述下行控制信令所在符号位置加上偏移量确定第一偏移符号，所述第一偏移子帧内的第一偏移符号即为所述第一发送时间起点位置。

29.根据权利要求27所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

发送所述下行数据的起始位置子帧或结束位置子帧加上偏移量确定所述第二偏移子帧，发送所述下行数据的起始位置符号或结束位置符号加上偏移量确定所述第二偏移符号，所述第二偏移子帧内的第二偏移符号即为所述第二发送时间起点位置。

30.根据权利要求18至20中任一项所述的reference numerology的子载波间隔的设

置/确定装置，其特征在于，还包括：

接入单元，用于在所述终端设备确定reference numerology的子载波间隔基于所述子载波间隔发送随机接入前导码后，接收并解析所述终端设备发送的随机接入前导码以实现所述终端设备的随机接入。

31.一种基站设备，其特征在于，包括：

如权利要求16至30中任一项所述的reference numerology的子载波间隔的设置/确定装置。

32.一种reference numerology的子载波间隔的设置/确定方法，其特征在于，包括：

获取基站在第一参考子帧内以指定的子载波间隔发送的特定下行信号；

确定用于传输所述特定下行信号的传输带宽，以及所述传输带宽对应的预存的参数M和N，其中，所述M为所述特定下行信号占用的资源块个数，所述N为每个所述资源块包含的子载波个数数据；

确定所述传输带宽除以所述M再除以所述N之后的商值，所述商值即为所述特定下行信号传输的子载波间隔，也即能够与所述基站设备进行同步通信的reference numerology的子载波间隔。

33.根据权利要求32所述的reference numerology的子载波间隔的设置/确定方法，其特征在于，

所述特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

34.一种reference numerology的子载波间隔的设置/确定装置，其特征在于，包括：

获取单元，用于获取基站在第一参考子帧内以指定的子载波间隔发送的特定下行信号；

确定单元，用于确定用于传输所述特定下行信号的传输带宽，以及所述传输带宽对应的预存的参数M和N，其中，所述M为所述特定下行信号占用的资源块个数，所述N为每个所述资源块包含的子载波个数数据；

所述确定单元还用于：确定所述传输带宽除以所述M再除以所述N之后的商值，所述商值即为所述特定下行信号传输的子载波间隔，也即能够与所述基站设备进行同步通信的reference numerology的子载波间隔。

35.根据权利要求34所述的reference numerology的子载波间隔的设置/确定装置，其特征在于，

所述特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

36.一种终端设备，其特征在于，包括：

如权利要求34或35所述的reference numerology的子载波间隔的设置/确定装置，

其中，所述终端设备与如权利要求16至30中任一项所述的reference numerology的子载波间隔的设置/确定装置进行同步通信，以确定与如权利要求31所述的基站设备进行同步通信的reference numerology的子载波间隔。

reference numerology的子载波间隔的设置/确定方法、装置、基站和终端

技术领域

[0001] 本发明涉及通信技术领域，具体而言，涉及一种reference numerology的子载波间隔的设置/确定方法、一种reference numerology的子载波间隔的设置/确定装置、一种基站和一种终端。

背景技术

[0002] 未来5G通信主要场景包括以下三种：eMBB、mMTC和URLLC。而这三种场景所针对的业务类型不一样，其需求也不一样。

[0003] 比如eMBB(Enhanced Mobile BroadBand，增强的移动宽带)业务，两个主要的指标是高带宽和低时延(要求4ms)。在未来的高频通信上，可能支持100MHz的大带宽，而且很可能某个时刻整个带宽都直接分配给一个用户，而上行调度时延和HARQ(Hybird Automatic Repeat Request，混合自动重传)技术的反馈时延也会带来时延影响，所以eMBB业务需要较大的子载波间隔和较小的时间粒度。

[0004] 又如mMTC(Massive Machine Type Communications，大量机器类通信)业务，需要的是窄带服务，需要电池寿命很长，这种业务就需要更小粒度的子载波间隔和更宽粒度的时域资源。

[0005] 对于URLLC(Ultra-Reliable and Low Latency Communications，高可靠低时延)业务，时延要求是0.5ms，也需要减少时域调度粒度，上行调度时延和HARQ反馈时延带来的时延影响。

[0006] 在上述5G通信场景中，为了适配多种通信业务的传输需求，例如增大带宽和减少时延，NR(New radio，新无线通信)系统中需要引入多个numerology，比如对于eMBB业务和URLLC业务的numerology子载波间隔需要增大，最小传输单元需要减小。

[0007] 相关技术的LTE方法中，只有一个固定的子载波间隔为15KHz，在这个子载波间隔的前提下，subframe子帧的长度即为1ms。那么用户根据默认的子载波间隔和子帧长度就能根据同步信号比如PSS/SSS，和/或参考信号CRS/CSI-RS/DRS来获得下行时间的同步，即帧同步、子帧同步和符号同步。

[0008] 而在5G NR中，不同的业务可能使用不同的子载波间隔，即在上下行数据发送的时候每个用户使用的子载波间隔和传输时间粒度可能不一样。但是在初始的下行时间同步的过程中，需要所有用户能有一个reference numerology的子载波间隔来获取帧同步和子帧同步等。

[0009] 因此，如何在统一的空口框架下，针对不同的用户设置和/或确定reference numerology的子载波间隔是实现终端设备与基站设备之间的同步通信的核心技术问题。

发明内容

[0010] 本发明正是基于上述技术问题至少之一，提出了一种reference numerology的子

载波间隔的设置/确定方案，通过设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以供终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，同步通信是指终端设备获得的数据帧的同步、子帧同步和符号同步。

[0011] 有鉴于此，根据本发明的第一方面的实施例，提出了一种reference numerology的子载波间隔的设置/确定方法，包括：设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，n为大于或等于-2的整数。

[0012] 在该技术方案中，通过设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以供终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，同步通信是指终端设备获得的数据帧的同步、子帧同步和符号同步。

[0013] 其中，NR系统中子载波间隔的理论范围为3.75KHz～480KHz，而为了适应不同的通信业务的传输需求，基站设备可以根据通信业务的传输需求确定相应的子载波间隔，设置reference numerology的子载波间隔为15KHz的2^n倍，在执行通信业务的同时，告知终端设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，以保证终端设备和基站设备之间实现数据帧的同步、子帧同步和符号同步。

[0014] 在上述技术方案中，优选地，还包括：给所有终端设备在同一个载波上配置相同的reference numerology的子载波间隔。

[0015] 在该技术方案中，同一个载波是指频点相同且带宽相同的一个载波。

[0016] 在上述技术方案中，优选地，还包括：设置特定下行信号占用的子载波间隔为reference numerology，并设置发送特定下行信号的第一参考子帧，在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0017] 在该技术方案中，通过在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0018] 具体地，基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^n)$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0019] 具体地，可以采用隐式指示的方式实现reference numerology的子载波间隔的设置/确定，比如LTE网络的小区搜索过程中，PSS(Primary Synchronization Signal，主同步信号)/SSS(Secondary Synchronization Signal，辅同步信号)信令的numerology的子载波间隔为15KHz，子帧时长为1ms。这时候基站设备设置PSS/SSS信令占用的带宽为72(M×N即6×12，每个RB包含12个子载波，PSS/SSS传输带宽为中心6个RB)个子载波的带宽，即1.08MHz，占用的时长为1个符号即1/14ms。那么当numerology为30KHz时，PSS/SSS信令还是占有带宽为72个子载波，带宽为2.16MHz，占用的时长为1个符号为0.5/14ms。

[0020] 依次类推，PSS/SSS信令占用的带宽为LTE中1.08MHz带宽的2^n倍时，reference

numerology的子载波间隔即为15KHz的2^n倍。

[0021] 另外，NR系统中一个RB(Resource Block，资源块)可能会变成16个子载波，也就是说带宽是reference numerology的子载波间隔为15KHz的PSS/SSS信令的占用带宽(16/12)×2^n倍，reference numerology的子载波间隔即为15KHz的2^n倍，终端设备在确定循环前缀部分占用的时长和/或PSS/SSS信令占用的时长为LTE网络中1/14ms的1/(2^n)时，确定reference numerology的子载波间隔即为15KHz的2^n倍。

[0022] 其中，特定下行信号为主同步信号/辅同步信号、参考信号(包括CRS-Cell Specific Signal，CSI-RS:Channel State Information-Reference Signal，DRS-Discovery Reference Signal以及可能设计的新的参考信号)、寻呼信号和系统信息(包括MIB:Master Information Block和SIB:System Information Block)中的一个或多个的任意组合。

[0023] 在上述技术方案中，优选地，还包括：向终端设备发送承载reference numerology的子载波间隔的系统信息，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为系统信息中设置的子载波间隔。

[0024] 在该技术方案中，终端设备解析系统信息以确定通过系统信息显式指示的reference numerology的子载波间隔。

[0025] 其中，系统信息包括一个Master Information Block(MIB)和多个System Information Blocks(SIBs)。MIB使用一种固定的、具有40ms周期的调度方式，其中40ms周期内发送四次，第一次传输是安排在满足系统帧号SFN mod 4＝0的无线帧的子帧#0中，后面三次是在其他无线帧的子帧#0中重复发送。

[0026] System Information Block Type1应用一种固定的具有80ms周期的调度方式，其中80ms时间内发送四次。第一次传输是安排在满足系统帧号SFN mod 8＝0的无线帧的子帧#5中，后面三次是在满足系统帧号SFN mod 2＝0的其他无线帧的子帧#5中重复发送。

[0027] 值得特别指出的是，如果系统信息指示reference numerology的子载波间隔时，那么特定下行信号比如PSS/SSS的带宽就不一定必须是LTE中1.08MHz的2^r或(16/12)×2^n倍，PSS/SSS的发送时长也不一定是LTE中1/14ms的1/(2^n)了。

[0028] 在上述技术方案中，优选地，还包括：根据载波的特征信息设置reference numerology的子载波间隔，并在载波上发送特定下行信号，以供终端设备根据检测到的载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔，其中，载波的特征信息包括载波频点和/或载波带宽。

[0029] 在该技术方案中，终端设备在检测到承载有特定下行信号的载波时，对载波的特征信息如载波频点和/或载波带宽进行解析，终端设备根据载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔。

[0030] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0031] 在上述技术方案中，优选地，还包括：给所有终端设备在同一个载波上配置不同的reference numerology的子载波间隔。

[0032] 在上述技术方案中，优选地，还包括：根据终端设备的设备类型和/或需要传输的业务类型向终端设备发送无线资源控制信令或下行控制信令，以通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔。

[0033] 在该技术方案中，通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔，例如：

[0034] (1)基站设备向特定的UE(User Equipment，终端设备)发送RRC(Radio Resource Control，无线资源控制)信令单独通知特定的UE可进行同步通信的reference numerology的子载波间隔，该reference numerology的子载波间隔可以是特定UE处于连接状态时第一个业务需要使用的reference numerology的子载波间隔。这个reference numerology的子载波间隔可以是半静态变化的，比如第一个业务还没结束时，又有第二个业务到达特定UE，那么特定UE继续使用第一个业务的numerology为第二个业务的reference numerology。但是如果第一个业务结束了之后，第二个业务才到达特定UE，那么基站设备可以再次发送用于指示reference numerology的子载波间隔的RRC信令，以定义第二个业务的numerology为该用户的reference numerology，也可以使用随机接入反馈信令来指示reference numerology。

[0035] (2)根据UE的通信能力或UE类型来定义reference numerology的子载波间隔，比如有些UE就是MTC终端，那么这些终端的reference numerology就直接将执行MTC业务时的numerology写入到这些终端的芯片中，比如3.75KHz。又如其它支持eMBB业务和URLLC业务的终端，使用LTE的15KHz为reference numerology或者更高的30KHz或60KHz为reference numerology。reference numerology的子载波间隔的指示方法可以直接是写入UE的硬件芯片，不需要信令通知，或者系统信息通知。

[0036] 在上述技术方案中，优选地，还包括：在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，并根据专用numerology的子载波间隔设置第二参考子帧，以供终端设备根据专用numerology的子载波间隔和第二参考子帧进行上下行数据收发。

[0037] 在该技术方案中，通过在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，以供终端设备发送或接收SRS(Sounding Reference Signals，探测参考信号)，或基于专用numerology的子载波间隔接入于各个通信信道，如PRACH(Physical Random Access Channel，随机接入信道)、PDCCH(Physical Downlink Control Channel，下行物理控制信道)、PDSCH(Physical Downlink Shared Channel，下行物理共享信道)、PUCCH(Physical Uplink Control Channel，上行物理控制信道)和PUSCH(Physical Uplink Control Channel，上行物理共享信道)等。

[0038] 其中，专用numerology的子载波间隔可以是基于用户业务类型来配置的。

[0039] 在上述技术方案中，优选地，还包括：专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔与终端的reference numerology的子载波间隔之间的相对比值，以供终端设备根据相对比值以及reference numerology的子载波间隔确定专用numerology的子载波间隔；或专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔的绝对值。

[0040] 在该技术方案中，终端设备在确定Reference numerology的子载波间隔后，基站设备再给终端设备根据业务类型配置装用numerology时，RRC信令或下行控制信令只需给出当前专用numerology的子载波间隔与reference numerology的子载波间隔的比值，该比值为2^m，m为负整数，0和正整数。

[0041] 专用numerology的子载波间隔和子帧长度也可以在随机接入过程Msg.4中或者其它时候的RRC信令中给出。

[0042] 在上述技术方案中，优选地，还包括：根据专用numerology的子载波间隔以及第二参考子帧，对终端设备进行上下行时频资源分配并向终端设备发送相应的下行控制信令，其中，下行控制信令用于设置终端设备通过物理下行共享信道和/或物理上行共享信道进行数据发送的第一发送时间起点位置和发送时间长度。

[0043] 在上述技术方案中，优选地，第二参考子帧为自包含的下行数据的发送子帧时，下行控制信令还用于设置终端设备接收到的下行数据所对应的混合自动重传业务的反馈信息的第二发送时间起点位置。

[0044] 在上述技术方案中，优选地，下行控制信令所在子帧位置加上位置偏移量确定第一偏移子帧，下行控制信令所在符号位置加上偏移量确定第一偏移符号，第一偏移子帧内的第一偏移符号即为第一发送时间起点位置。

[0045] 在该技术方案中，基站设备在指示终端设备确定专用numerology的子帧长度后，DCI(Downlink Control Information，下行控制信令)调度上下行信道发送资源时，需要给出发送资源的时间位置起点和时间长度，时间位置起点给出以DCI信令当前子帧位置为f的话，时间起点位置的子帧位置为f+k，DCI信令当前符号位置为z的话，时间起点位置的符号位置为z+l，同时给出发送时间长度：比如是一个子帧中的14个符号(或者要去除DCI信令占用的符号和gap(间隙)时间以及HARQ反馈时间)，或一个slot即半个子帧的5个或6个符号，或一个mini-slot即2个符号左右，上述f、k和z均为整数。另外，上述f、k和z的指示也可以是使用bit序列来指示，但是bit序列与上述f、k和z的值的映射表必须预先存储在终端设备。

[0046] 其中，发送时间长度的取值为整数个符号，和/或整数个slot(每个slot包含多个符号)和/或整数个mini-slot(每个mini-slot包含多个符号)和/或整数个子帧。

[0047] 在上述技术方案中，优选地，发送下行数据的起始位置子帧或结束位置子帧加上偏移量确定第二偏移子帧，发送下行数据的起始位置符号或结束位置符号加上偏移量确定第二偏移符号，第二偏移子帧内的第二偏移符号即为第二发送时间起点位置。

[0048] 在该技术方案中，自包含的下行数据的发送子帧或者slot，需要给出相应的下行数据发送的HARQ反馈时间，同样给出子帧的偏移值，符号的偏移值，发送时长一般是默认值，不需要额外信令通知。

[0049] 在上述技术方案中，优选地，还包括：在终端设备确定reference numerology的子载波间隔并基于子载波间隔发送随机接入前导码后，接收并解析终端设备发送的随机接入前导码以实现终端设备的随机接入。

[0050] 根据本发明的第二方面的实施例，提出了一种reference numerology的子载波间隔的设置/确定装置，包括：设置单元，用于设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，n为大于或等于-2的整数。

[0051] 在该技术方案中，通过设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以供终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，同步通信是指终端设备获得的数据帧的同步、子帧同步和符号同步。

[0052] 其中，NR系统中子载波间隔的理论范围为3.75KHz～480KHz，而为了适应不同的通信业务的传输需求，基站设备可以根据通信业务的传输需求确定相应的子载波间隔，设置reference numerology的子载波间隔为15KHz的2^n倍，在执行通信业务的同时，告知终端设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，以保证终端设备和基站设备之间实现数据帧的同步、子帧同步和符号同步。

[0053] 在上述技术方案中，优选地，设置单元还用于：给所有终端设备在同一个载波上配置相同的reference numerology的子载波间隔。

[0054] 在该技术方案中，同一个载波是指频点相同且带宽相同的一个载波。

[0055] 在上述技术方案中，优选地，设置单元还用于：设置特定下行信号占用的子载波间隔为reference numerology，并设置发送特定下行信号的第一参考子帧，在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0056] 在该技术方案中，通过在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0057] 具体地，基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^n)$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0058] 具体地，可以采用隐式指示的方式实现reference numerology的子载波间隔的设置/确定，比如LTE网络的小区搜索过程中，PSS(Primary Synchronization Signal，主同步信号)/SSS(Secondary Synchronization Signal，辅同步信号)信令的numerology的子载波间隔为15KHz，子帧时长为1ms。这时候基站设备设置PSS/SSS信令占用的带宽为72($M\times N$即6×12，每个RB包含12个子载波，PSS/SSS传输带宽为中心6个RB)个子载波的带宽，即1.08MHz，占用的时长为1个符号即1/14ms。那么当numerology为30KHz时，PSS/SSS信令还是占有带宽为72个子载波，带宽为2.16MHz，占用的时长为1个符号为0.5/14ms。

[0059] 依次类推，PSS/SSS信令占用的带宽为LTE中1.08MHz带宽的2^n倍时，reference numerology的子载波间隔即为15KHz的2^n倍。

[0060] 另外，NR系统中一个RB(Resource Block，资源块)可能会变成16个子载波，也就是说带宽是reference numerology的子载波间隔为15KHz的PSS/SSS信令的占用带宽$(16/12)\times 2^n$倍，reference numerology的子载波间隔即为15KHz的2^n倍，终端设备在确定循环前缀部分占用的时长和/或PSS/SSS信令占用的时长为LTE网络中1/14ms的$1/(2^n)$时，确定reference numerology的子载波间隔即为15KHz的2^n倍。

[0061] 其中，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0062] 在上述技术方案中，优选地，还包括：第一发送单元，用于向终端设备发送承载reference numerology的子载波间隔的系统信息，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为系统信息中设置的子载波间隔。

[0063] 在该技术方案中，终端设备解析系统信息以确定通过系统信息显式指示的reference numerology的子载波间隔。

[0064] 其中，系统信息包括一个Master Information Block(MIB)和多个System Information Blocks(SIBs)。MIB使用一种固定的、具有40ms周期的调度方式，其中40ms周期内发送四次，第一次传输是安排在满足系统帧号SFN mod 4＝0的无线帧的子帧#0中，后面三次是在其他无线帧的子帧#0中重复发送。

[0065] System Information Block Type1应用一种固定的具有80ms周期的调度方式，其中80ms时间内发送四次。第一次传输是安排在满足系统帧号SFN mod 8＝0的无线帧的子帧#5中，后面三次是在满足系统帧号SFN mod 2＝0的其他无线帧的子帧#5中重复发送。

[0066] 值得特别指出的是，如果系统信息指示reference numerology的子载波间隔时，那么特定下行信号比如PSS/SSS的带宽就不一定必须是LTE中1.08MHz的2^n或$(16/12)\times 2^n$倍，PSS/SSS的发送时长也不一定是LTE中1/14ms的$1/(2^n)$了。

[0067] 在上述技术方案中，优选地，设置单元还用于：根据载波的特征信息设置reference numerology的子载波间隔，并在该载波上发送特定下行信号，以供终端设备根据检测到的载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔，其中，载波的特征信息包括载波频点和/或载波带宽。

[0068] 在该技术方案中，终端设备在检测到承载有特定下行信号的载波时，对载波的特征信息如载波频点和/或载波带宽进行解析，终端设备根据载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔。

[0069] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0070] 在上述技术方案中，优选地，设置单元还用于：给所有终端设备在同一个载波上配置不同的reference numerology的子载波间隔。

[0071] 在上述技术方案中，优选地，还包括：第二发送单元，用于根据终端设备的设备类型和/或需要传输的业务类型向终端设备发送无线资源控制信令或下行控制信令，以通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔。

[0072] 在该技术方案中，通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔，例如：

[0073] (1)基站设备向特定的UE(User Equipment，终端设备)发送RRC(Radio Resource Control，无线资源控制)信令单独通知特定的UE可进行同步通信的reference numerology的子载波间隔，该reference numerology的子载波间隔可以是特定UE处于连接状态时第一个业务需要使用的reference numerology的子载波间隔。这个reference numerology的子载波间隔可以是半静态变化的，比如第一个业务还没结束时，又有第二个业务到达特定UE，

那么特定UE继续使用第一个业务的numerology为第二个业务的reference numerology。但是如果第一个业务结束了之后，第二个业务才到达特定UE，那么基站设备可以再次发送用于指示reference numerology的子载波间隔的RRC信令，以定义第二个业务的numerology为该用户的reference numerology，也可以使用随机接入反馈信令来指示reference numerology。

[0074] (2)根据UE的通信能力或UE类型来定义reference numerology的子载波间隔，比如有些UE就是MTC终端，那么这些终端的reference numerology就直接将执行MTC业务时的numerology写入到这些终端的芯片中，比如3.75KHz。又如其它支持eMBB业务和URLLC业务的终端，使用LTE的15KHz为reference numerology或者更高的30KHz或60KHz为reference numerology。reference numerology的子载波间隔的指示方法可以直接是写入UE的硬件芯片，不需要信令通知，或者系统信息通知。

[0075] 在上述技术方案中，优选地，设置单元还用于：在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，并根据专用numerology的子载波间隔设置第二参考子帧，以供终端设备根据专用numerology的子载波间隔和第二参考子帧进行上下行数据收发。

[0076] 在该技术方案中，通过在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，以供终端设备发送或接收SRS(Sounding Reference Signals，探测参考信号)，或基于专用numerology的子载波间隔接入于各个通信信道，如PRACH(Physical Random Access Channel，随机接入信道)、PDCCH(Physical Downlink Control Channel，下行物理控制信道)、PDSCH(Physical Downlink Shared Channel，下行物理共享信道)、PUCCH(Physical Uplink Control Channel，上行物理控制信道)和PUSCH(Physical Uplink Control Channel，上行物理共享信道)等。

[0077] 其中，专用numerology的子载波间隔可以是基于用户业务类型来配置的。

[0078] 在上述技术方案中，优选地，专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔与终端的reference numerology的子载波间隔之间的相对比值，以供终端设备根据相对比值以及reference numerology的子载波间隔确定专用numerology的子载波间隔；或专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔的绝对值。

[0079] 在该技术方案中，终端设备在确定Reference numerology的子载波间隔后，基站设备再给终端设备配置根据业务类型配置专用numerology时，RRC信令或下行控制信令只需给出当前专用numerology的子载波间隔/reference numerology的子载波间隔的比值，该比值为2^m，m为负整数，0和正整数。

[0080] 专用numerology的子载波间隔和子帧长度也可以在随机接入过程Msg.4中或者其它时候的RRC信令中给出。

[0081] 在上述技术方案中，优选地，还包括：第三发送单元，用于根据专用numerology的子载波间隔以及第二参考子帧，对终端设备进行上下行时频资源分配并向终端设备发送相应的下行控制信令，其中，下行控制信令用于设置终端设备通过物理下行共享信道和/或物理上行共享信道进行数据发送的第一发送时间起点位置和发送时间长度。

[0082] 在上述技术方案中，优选地，第二参考子帧为自包含的下行数据的发送子帧时，下行控制信令还用于设置终端设备接收到的下行数据所对应的混合自动重传业务的反馈信息的第二发送时间起点位置。

[0083] 在上述技术方案中，优选地，下行控制信令所在子帧位置加上位置偏移量确定第一偏移子帧，下行控制信令所在符号位置加上偏移量确定第一偏移符号，第一偏移子帧内的第一偏移符号即为第一发送时间起点位置。

[0084] 在该技术方案中，基站设备在指示终端设备确定专用numerology的子帧长度后，DCI(Downlink Control Information，下行控制信令)调度上下行信道发送资源时，需要给出发送资源的时间位置起点和时间长度，时间位置起点给出以DCI信令当前子帧位置为f的话，时间起点位置的子帧位置为f+k，DCI信令当前符号位置为z的话，时间起点位置的符号位置为z+1，同时给出发送时间长度；比如是一个子帧中的14个符号(或者要去除DCI信令占用的符号和gap时间以及HARQ反馈时间)，或一个slot即半个子帧的5个或6个符号，或一个mini-slot即2个符号左右，上述f、k和z均为整数。另外，当然，上述f、k和z的指示也可以是使用bit序列来指示，但是bit序列与上述f、k和z的值的映射表必须预先存储在终端设备。

[0085] 其中，发送时间长度的取值为整数个符号，和/或整数个slot(每个slot包含多个符号)和/或整数个mini-slot(每个mini-slot包含多个符号)和/或整数个子帧。

[0086] 在上述技术方案中，优选地，发送下行数据的起始位置子帧或结束位置子帧加上偏移量确定第二偏移子帧，发送下行数据的起始位置符号或结束位置符号加上偏移量确定第二偏移符号，第二偏移子帧内的第二偏移符号即为第二发送时间起点位置。

[0087] 在该技术方案中，自包含的下行数据的发送子帧或者slot，需要给出相应的下行数据发送的HARQ反馈时间，同样给出子帧的偏移值，符号的偏移值，发送时长一般是默认值，不需要额外信令通知。

[0088] 在上述技术方案中，优选地，还包括：接入单元，用于在终端设备确定reference numerology的子载波间隔基于子载波间隔发送随机接入前导码后，接收并解析终端设备发送的随机接入前导码以实现终端设备的随机接入。

[0089] 根据本发明的第三方面的实施例，提出了一种基站设备，包括：如上述第二方面中的任一项技术方案所述的reference numerology的子载波间隔的设置/确定装置。

[0090] 根据本发明的第四方面的实施例，提出了一种reference numerology的子载波间隔的设置/确定方法，包括：获取基站在第一参考子帧内以指定的子载波间隔发送的特定下行信号；确定用于传输特定下行信号的传输带宽，以及传输带宽对应的预存的参数M和N，其中，M为特定下行信号占用的资源块个数，N为每个资源块包含的子载波个数数据；确定传输带宽除以M再除以N之后的商值，商值即为特定下行信号传输的子载波间隔，也即能够与基站设备进行同步通信的reference numerology的子载波间隔。

[0091] 在该技术方案中，终端设备基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^n)$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0092] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0093] 根据本发明的第五方面的实施例，提出了一种reference numerology的子载波间隔的设置/确定装置，包括：获取单元，用于获取基站在第一参考子帧内以指定的子载波间隔发送的特定下行信号；确定单元，用于确定用于传输特定下行信号的传输带宽，以及传输带宽对应的预存的参数M和N，其中，M为特定下行信号占用的资源块个数，N为每个资源块包含的子载波个数数据；确定单元还用于：确定传输带宽除以M再除以N之后的商值，商值即为特定下行信号传输的子载波间隔，也即能够与基站设备进行同步通信的reference numerology的子载波间隔。

[0094] 在该技术方案中，终端设备基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^{n})$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0095] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0096] 根据本发明的第六方面的实施例，提出了一种终端设备，包括：如上述第五方面中的任一项技术方案所述的reference numerology的子载波间隔的设置/确定装置，其中，终端设备与第二方面中的任一项技术方案所述的reference numerology的子载波间隔的设置/确定装置进行同步通信，以确定与第二方面的基站设备进行同步通信的reference numerology的子载波间隔。

[0097] 通过以上技术方案，通过特定下行信号占用的子载波间隔或显式指示信息、或载波的特征信息、或专用numerology、或终端设备的设备类型和/或需要传输的业务类型来指示终端设备reference numerology的子载波间隔，使得终端设备可以获知上下行信道、上下行信号和数据的时频资源粒度，以提高与基站设备的同步通信的准确度和可靠度。

具体实施方式

[0112] 为了能够更清楚地理解本发明的上述目的、特征和优点，下面结合附图和具体实施方式对本发明进行进一步的详细描述。需要说明的是，在不冲突的情况下，本申请的实施例及实施例中的特征可以相互组合。

[0113] 在下面的描述中阐述了很多具体细节以便于充分理解本发明，但是，本发明还可以采用其他不同于在此描述的其他方式来实施，因此，本发明的保护范围并不受下面公开的具体实施例的限制。

[0114] 下面结合图1至图14对根据本发明的reference numerology的子载波间隔的设置/确定方案的多种实施方式进行具体说明。

[0115] 实施例一：

[0116] 如图1所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，包括：步骤102，设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，n为大于或等于-2的整数。

[0117] 在该技术方案中，通过设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以供终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，同步通信是指终端设备获得的数据帧的同步、子帧同步和符号同步。

[0118] 其中，NR系统中子载波间隔的理论范围为3.75KHz~480KHz，而为了适应不同的通信业务的传输需求，基站设备可以根据通信业务的传输需求确定相应的子载波间隔，设置reference numerology的子载波间隔为15KHz的2^n倍，在执行通信业务的同时，告知终端设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，以保证终端设备和基站设备之间实现数据帧的同步、子帧同步和符号同步。

[0119] 在上述技术方案中，优选地，还包括：给所有终端设备在同一个载波上配置相同的reference numerology的子载波间隔。

[0120] 在该技术方案中，同一个载波是指频点相同且带宽相同的一个载波。

[0121] 实施例二：

[0122] 如图2所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，在实施例一的基础上还包括：步骤202，设置特定下行信号占用的子载波间隔为reference numerology，并设置发送特定下行信号的第一参考子帧，在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0123] 在该技术方案中，通过在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0124] 具体地，基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^n)$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0125] 具体地，可以采用隐式指示的方式实现reference numerology的子载波间隔的设置/确定，比如LTE网络的小区搜索过程中，PSS(Primary Synchronization Signal，主同步信号)/SSS(Secondary Synchronization Signal，辅同步信号)信令的numerology的子载波间隔为15KHz，子帧时长为1ms。这时候基站设备设置PSS/SSS信令占用的带宽为72(M×N即6×12，每个RB包含12个子载波，PSS/SSS传输带宽为中心6个RB)个子载波的带宽，即1.08MHz，占用的时长为1个符号即1/14ms。那么当numerology为30KHz时，PSS/SSS信令还是占有带宽为72个子载波，带宽为2.16MHz，占用的时长为1个符号为0.5/14ms。

[0126] 依次类推，PSS/SSS信令占用的带宽为LTE中1.08MHz带宽的2^n倍时，reference numerology的子载波间隔即为15KHz的2^n倍。

[0127] 另外，NR系统中一个RB(Resource Block，资源块)可能会变成16个子载波，也就是说带宽是reference numerology的子载波间隔为15KHz的PSS/SSS信令的占用带宽(16/12)$\times 2^n$倍，reference numerology的子载波间隔即为15KHz的2^n倍，终端设备在确定循环前缀部分占用的时长和/或PSS/SSS信令占用的时长为LTE网络中1/14ms的$1/(2^n)$时，确定reference numerology的子载波间隔即为15KHz的2^n倍。

[0128] 其中，特定下行信号为主同步信号/辅同步信号、参考信号(包括CRS-Cell Specific Signal，CSI-RS:Channel State Information-Reference Signal，DRS-Discovery Reference Signal以及可能设计的新的参考信号)、寻呼信号和系统信息(包括MIB:Master Information Block和SIB:System Information Block)中的一个或多个的任意组合。

[0129] 实施例三：

[0130] 如图3所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，在实施例一和二的基础上还包括：步骤302，向终端设备发送承载reference numerology的子载波间隔的系统信息，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为系统信息中设置的子载波间隔。

[0131] 在该技术方案中，终端设备解析系统信息以确定通过系统信息显式指示的reference numerology的子载波间隔。

[0132] 其中，系统信息包括一个Master Information Block(MIB)和多个System

Information Blocks(SIBs)。MIB使用一种固定的、具有40ms周期的调度方式，其中40ms周期内发送四次，第一次传输是安排在满足系统帧号SFN mod 4=0的无线帧的子帧#0中，后面三次是在其他无线帧的子帧#0中重复发送。

[0133] System Information Block Type1应用一种固定的具有80ms周期的调度方式，以及在80ms时间内重传方式。其中80ms时间内发送四次。第一次传输是安排在满足系统帧号SFN mod 8=0的无线帧的子帧#5中，后面三次是在满足系统帧号SFN mod2=0的其他无线帧的子帧#5中重复发送。

[0134] 值得特别指出的是，如果系统信息指示reference numerology的子载波间隔时，那么特定下行信号比如PSS/SSS的带宽就不一定必须是LTE中1.08MHz的2^n或$(16/12)\times 2^n$倍，PSS/SSS的发送时长也不一定是LTE中1/14ms的$1/(2^n)$了。

[0135] 实施例四：

[0136] 如图4所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，在实施例一至三的基础上还包括：步骤402根据载波的特征信息设置reference numerology的子载波间隔，并在载波上发送特定下行信号，以供终端设备根据检测到的载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔，其中，载波的特征信息包括载波频点和/或载波带宽。

[0137] 在该技术方案中，终端设备在检测到承载有特定下行信号的载波时，对载波的特征信息如载波频点和/或载波带宽进行解析，终端设备根据载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔。

[0138] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0139] 在上述技术方案中，优选地，还包括：给所有终端设备在同一个载波上配置不同的reference numerology的子载波间隔。

[0140] 实施例五：

[0141] 如图5所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，在实施例一至四的基础上还包括：步骤502，根据终端设备的设备类型和/或需要传输的业务类型向终端设备发送无线资源控制信令或下行控制信令，以通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔。

[0142] 在该技术方案中，通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔，例如：

[0143] (1)基站设备向特定的UE(User Equipment，终端设备)发送RRC(Radio Resource Control，无线资源控制)信令单独通知特定的UE可进行同步通信的reference numerology的子载波间隔，该reference numerology的子载波间隔可以是特定UE处于连接状态时第一个业务需要使用的reference numerology的子载波间隔。这个reference numerology的子载波间隔可以是半静态变化的，比如第一个业务还没结束时，又有第二个业务到达特定UE，那么特定UE继续使用第一个业务的numerology为第二个业务的reference numerology。但

是如果第一个业务结束了之后，第二个业务才到达特定UE，那么基站设备可以再次发送用于指示reference numerology的子载波间隔的RRC信令，以定义第二个业务的numerology为该用户的reference numerology，也可以使用随机接入反馈信令来指示reference numerology。

[0144] (2)根据UE的通信能力或UE类型来定义reference numerology的子载波间隔，比如有些UE就是MTC终端，那么这些终端的reference numerology就直接将执行MTC业务时的numerology写入到这些终端的芯片中，比如3.75KHz。又如其它支持eMBB业务和URLLC业务的终端，使用LTE的15KHz为reference numerology或者更高的30KHz或60KHz为reference numerology。reference numerology的子载波间隔的指示方法可以直接是写入UE的硬件芯片，不需要信令通知，或者系统信息通知。

[0145] 实施例六：

[0146] 如图6所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，在实施例一至五的基础上还包括：步骤602，在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，并根据专用numerology的子载波间隔设置第二参考子帧，以供终端设备根据专用numerology的子载波间隔和第二参考子帧进行上下行数据收发。

[0147] 在该技术方案中，通过在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，以供终端设备发送或接收SRS(Sounding Reference Signals，探测参考信号)，或基于专用numerology的子载波间隔接入于各个通信信道，如PRACH(Physical Random Access Channel，随机接入信道)、PDCCH(Physical Downlink Control Channel，下行物理控制信道)、PDSCH(Physical Downlink Shared Channel，下行物理共享信道)、PUCCH(Physical Uplink Control Channel，上行物理控制信道)和PUSCH(Physical Uplink Control Channel，上行物理共享信道)等。

[0148] 其中，专用numerology的子载波间隔可以是基于用户业务类型来配置的。

[0149] 在上述技术方案中，优选地，还包括：专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔与终端的reference numerology的子载波间隔之间的相对比值，以供终端设备根据相对比值以及reference numerology的子载波间隔确定专用numerology的子载波间隔；或专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔的绝对值。

[0150] 在该技术方案中，终端设备在确定Reference numerology的子载波间隔后，基站设备再给终端设备根据业务类型配置专用numerology时，RRC信令或下行控制信令只需给出当前专用numerology子载波间隔/reference numerology子载波间隔的值，该值为2^m，m为负整数，0和正整数。

[0151] 专用numerology的子载波间隔和子帧长度也可以在随机接入过程Msg.4中或者其它时候的RRC信令中给出。

[0152] 在上述技术方案中，优选地，还包括：根据专用numerology的子载波间隔以及第二参考子帧，对终端设备进行上下行时频资源分配并向终端设备发送相应的下行控制信令，其中，下行控制信令用于设置终端设备通过物理下行共享信道和/或物理上行共享信道进

行数据发送的第一发送时间起点位置和发送时间长度。

[0153] 在上述技术方案中，优选地，第二参考子帧为自包含的下行数据的发送子帧时，下行控制信令还用于设置终端设备接收到的下行数据所对应的混合自动重传业务的反馈信息的第二发送时间起点位置。

[0154] 在上述技术方案中，优选地，下行控制信令所在子帧位置加上位置偏移量确定第一偏移子帧，下行控制信令所在符号位置加上偏移量确定第一偏移符号，第一偏移子帧内的第一偏移符号即为第一发送时间起点位置。

[0155] 在该技术方案中，基站设备在指示终端设备确定专用numerology的子帧长度后，DCI(Downlink Control Information，下行控制信令)调度上下行信道发送资源时，需要给出发送资源的时间位置起点和时间长度，时间位置起点给出以DCI信令当前子帧位置为f的话，时间起点位置的子帧位置为f+k，DCI信令当前符号位置为z的话，时间起点位置的符号位置为z+1，同时给出发送时间长度：比如是一个子帧中的14个符号(或者要去除DCI信令占用的符号和gap时间以及HARQ反馈时间)，或一个slot即半个子帧的5个或6个符号，或一个mini-slot即2个符号左右，上述f、k和z均为整数。其中，上述f、k和z的指示也可以是使用bit序列来指示，但是bit序列与上述f、k和z的值的映射表必须预先存储在终端设备。

[0156] 其中，发送时间长度的取值为整数个符号，和/或整数个slot(每个slot包含多个符号)和/或整数个mini-slot(每个mini-slot包含多个符号)和/或整数个子帧。

[0157] 在上述技术方案中，优选地，发送下行数据的起始位置子帧或结束位置子帧加上偏移量确定第二偏移子帧，发送下行数据的起始位置符号或结束位置符号加上偏移量确定第二偏移符号，第二偏移子帧内的第二偏移符号即为第二发送时间起点位置。

[0158] 在该技术方案中，自包含的下行数据的发送子帧或者slot，需要给出相应的下行数据发送的HARQ反馈时间，同样给出子帧的偏移值，符号的偏移值，发送时长一般是默认值，不需要额外信令通知。

[0159] 在上述技术方案中，优选地，还包括：在终端设备确定reference numerology的子载波间隔并基于子载波间隔发送随机接入前导码后，接收并解析终端设备发送的随机接入前导码以实现终端设备的随机接入。

[0160] 如图7所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定装置700，包括：设置单元702，用于设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，n为大于或等于-2的整数。

[0161] 在该技术方案中，通过设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以供终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，同步通信是指终端设备获得的数据帧的同步了帧同步和符号同步。

[0162] 其中，NR系统中子载波间隔的理论范围为3.75KHz～480KHz，而为了适应不同的通信业务的传输需求，基站设备可以根据通信业务的传输需求确定相应的子载波间隔，设置reference numerology的子载波间隔为15KHz的2^n倍，在执行通信业务的同时，告知终端设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，以保证终端设备和基站设备之间实现数据帧的同步、子帧同步和符号同步。

[0163] 在上述技术方案中，优选地，设置单元702还用于：给所有终端设备在同一个载波上配置相同的reference numerology的子载波间隔。

[0164] 在该技术方案中，同一个载波是指频点相同且带宽相同的一个载波。

[0165] 在上述技术方案中，优选地，设置单元702还用于：设置特定下行信号占用的子载波间隔为reference numerology，并设置发送特定下行信号的第一参考子帧，在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0166] 在该技术方案中，通过在第一参考子帧内以指定的子载波间隔发送特定下行信号，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为特定下行信号传输的子载波间隔。

[0167] 具体地，基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^{n})$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0168] 具体地，可以采用隐式指示的方式实现reference numerology的子载波间隔的设置/确定，比如LTE网络的小区搜索过程中，PSS(Primary Synchronization Signal，主同步信号)/SSS(Secondary Synchronization Signal，辅同步信号)信令的numerology的子载波间隔为15KHz，子帧时长为1ms。这时候基站设备设置PSS/SSS信令占用的带宽为72(M×N即6×12，每个RB包含12个子载波，PSS/SSS传输带宽为中心6个RB)个子载波的带宽，即1.08MHz，占用的时长为1个符号即1/14ms。那么当numerology为30KHz时，PSS/SSS信令还是占有带宽为72个子载波，带宽为2.16MHz，占用的时长为1个符号为0.5/14ms。

[0169] 依次类推，PSS/SSS信令占用的带宽为LTE中1.08MHz带宽的2^{n}倍时，reference numerology的子载波间隔即为15KHz的2^{n}倍。

[0170] 另外，NR系统中一个RB(Resource Block，资源块)可能会变成16个子载波，也就是说带宽是reference numerology的子载波间隔为15KHz的PSS/SSS信令的占用带宽(16/12)$\times 2^{n}$倍，reference numerology的子载波间隔即为15KHz的2^{n}倍，终端设备在确定循环前缀部分占用的时长和/或PSS/SSS信令占用的时长为LTE网络中1/14ms的$1/(2^{n})$时，确定reference numerology的子载波间隔即为15KHz的2^{n}倍。

[0171] 其中，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0172] 在上述技术方案中，优选地，还包括：第一发送单元704，用于向终端设备发送承载reference numerology的子载波间隔的系统信息，以指示终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔即为系统信息中设置的子载波间隔。

[0173] 在该技术方案中，终端设备解析系统信息以确定通过系统信息显式指示的reference numerology的子载波间隔。

[0174] 其中，系统信息包括一个Master Information Block(MIB)和多个System Information Blocks(SIBs)。MIB使用一种固定的、具有40ms周期的调度方式，其中40ms周期内发送四次，第一次传输是安排在满足系统帧号SFN mod 4＝0的无线帧的子帧#0中，后面三次是在其他无线帧的子帧#0中重复发送。System Information Block Type1应用一种

固定的具有80ms周期的调度方式，其中80ms时间内发送四次。第一次传输是安排在满足系统帧号SFN mod 8=0的无线帧的子帧#5中，后面三次是在满足系统帧号SFN mod 2=0的其他无线帧的子帧#5中重复发送。

[0175] 值得特别指出的是，如果系统信息指示reference numerology的子载波间隔时，那么特定下行信号比如PSS/SSS的带宽就不一定必须是LTE中1.08MHz的2^n或$(16/12)\times 2^n$倍，PSS/SSS的发送时长也不一定是LTE中1/14ms的$1/(2^n)$了。

[0176] 在上述技术方案中，优选地，设置单元702还用于：根据载波的特征信息设置reference numerology的子载波间隔，并在该载波上发送特定下行信号，以供终端设备根据检测到的载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔，其中，载波的特征信息包括载波频点和/或载波带宽。

[0177] 在该技术方案中，终端设备在检测到承载有特定下行信号的载波时，对载波的特征信息如载波频点和/或载波带宽进行解析，终端设备根据载波的特征信息、以及预存的载波特征信息与reference numerology的子载波间隔映射表来确定reference numerology的子载波间隔。

[0178] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0179] 在上述技术方案中，优选地，设置单元702还用于：给所有终端设备在同一个载波上配置不同的reference numerology的子载波间隔。

[0180] 在上述技术方案中，优选地，还包括：第二发送单元706，用于根据终端设备的设备类型和/或需要传输的业务类型向终端设备发送无线资源控制信令或下行控制信令，以通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔。

[0181] 在该技术方案中，通过无线资源控制信令或下行控制信令半静态地或动态地通知终端设备reference numerology的子载波间隔，例如：

[0182] (1)基站设备向特定的UE(User Equipment，终端设备)发送RRC(Radio Resource Control，无线资源控制)信令单独通知特定的UE可进行同步通信的reference numerology的子载波间隔，该reference numerology的子载波间隔可以是特定UE处于连接状态时第一个业务需要使用的reference numerology的子载波间隔。这个reference numerology的子载波间隔可以是半静态变化的，比如第一个业务还没结束时，又有第二个业务到达特定UE，那么特定UE继续使用第一个业务的numerology为第二个业务的reference numerology。但是如果第一个业务结束了之后，第二个业务才到达特定UE，那么基站设备可以再次发送用于指示reference numerology的子载波间隔的RRC信令，以定义第二个业务的numerology为该用户的reference numerology，也可以使用随机接入反馈信令来指示reference numerology。

[0183] (2)根据UE的通信能力或UE类型来定义reference numerology的子载波间隔，比如有些UE就是MTC终端，那么这些终端的reference numerology就直接将执行MTC业务时的numerology写入到这些终端的芯片中，比如3.75KHz。又如其它支持eMBB业务和URLLC业务的终端，使用LTE的15KHz为reference numerology或者更高的30KHz或60KHz为reference

numerology，reference numerology的子载波间隔的指示方法可以直接是写入UE的硬件芯片，不需要信令通知，或者系统信息通知。

[0184] 在上述技术方案中，优选地，设置单元702还用于：在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，并根据专用numerology的子载波间隔设置第二参考子帧，以供终端设备根据专用numerology的子载波间隔和第二参考子帧进行上下行数据收发。

[0185] 在该技术方案中，通过在终端设备确定能够与基站设备进行同步通信的reference numerology的子载波间隔后，设置终端设备的专用numerology的子载波间隔，以供终端设备发送或接收SRS(Sounding Reference Signals，探测参考信号)，或基于专用numerology的子载波间隔接入于各个通信信道，如PRACH(Physical Random Access Channel，随机接入信道)、PDCCH(Physical Downlink Control Channel，下行物理控制信道)、PDSCH(Physical Downlink Shared Channel，下行物理共享信道)、PUCCH(Physical Uplink Control Channel，上行物理控制信道)和PUSCH(Physical Uplink Control Channel，上行物理共享信道)等。

[0186] 其中，专用numerology的子载波间隔可以是基于用户业务类型来配置的。

[0187] 在上述技术方案中，优选地，专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔与终端的reference numerology的子载波间隔之间的相对比值，以供终端设备根据相对比值以及reference numerology的子载波间隔确定专用numerology的子载波间隔；或专用numerology的子载波间隔的设置信息为专用numerology的子载波间隔的绝对值。

[0188] 在该技术方案中，终端设备在确定Reference numerology的子载波间隔后，基站设备再给终端设备根据业务类型配置专用numerology时，RRC信令或下行控制信令只需给出当前专用numerology子载波间隔/reference numerology子载波间隔的值，该值为2^m，m为负整数，0和正整数。

[0189] 专用numerology的子载波间隔和子帧长度也可以在随机接入过程Msg.4中或者其它时候的RRC信令中给出。

[0190] 在上述技术方案中，优选地，还包括：第三发送单元708，用于根据专用numerology的子载波间隔以及第二参考子帧，对终端设备进行上下行时频资源分配并向终端设备发送相应的下行控制信令，其中，下行控制信令用于设置终端设备通过物理下行共享信道和/或物理上行共享信道进行数据发送的第一发送时间起点位置和发送时间长度。

[0191] 在上述技术方案中，优选地，第二参考子帧为自包含的下行数据的发送子帧时，下行控制信令还用于设置终端设备接收到的下行数据所对应的混合自动重传业务的反馈信息的第二发送时间起点位置。

[0192] 在上述技术方案中，优选地，下行控制信令所在子帧位置加上位置偏移量确定第一偏移子帧，下行控制信令所在符号位置加上偏移量确定第一偏移符号，第一偏移子帧内的第一偏移符号即为第一发送时间起点位置。

[0193] 在该技术方案中，基站设备在指示终端设备确定专用numerology的子帧长度后，DCI(Downlink Control Information，下行控制信令)调度上下行信道发送资源时，需要给出发送资源的时间位置起点和时间长度，时间位置起点给出以DCI信令当前子帧位置为f的

话，时间起点位置的子帧位置为f+k，DCI信令当前符号位置为z的话，时间起点位置的符号位置为z+1，同时给出发送时间长度：如图11和图12所示，比如是一个子帧中的14个符号（或者要去除DCI信令占用的符号和gap时间以及HARQ反馈时间），如图13和图14所示，或一个slot即半个子帧的5个或6个符号，或一个mini-slot即2个符号左右，上述f、k和z均为整数。另外，上述f、k和z的指示也可以是使用bit序列来指示，但是bit序列与上述f、k和z的值的映射表必须预先存储在终端设备。

[0194] 其中，发送时间长度的取值为整数个符号，和/或整数个slot（每个slot包含多个符号）和/或整数个mini-slot（每个mini-slot包含多个符号）和/或整数个子帧。

[0195] 在上述技术方案中，优选地，发送下行数据的起始位置子帧或结束位置子帧加上偏移量确定第二偏移子帧，发送下行数据的起始位置符号或结束位置符号加上偏移量确定第二偏移符号，第二偏移子帧内的第二偏移符号即为第二发送时间起点位置。

[0196] 在该技术方案中，包含的下行数据的发送子帧或者slot，需要给出相应的下行数据发送的HARQ反馈时间，同样给出子帧的偏移值，符号的偏移值，发送时长一般是默认值，不需要额外信令通知。

[0197] 在上述技术方案中，优选地，还包括：接入单元710，用于在终端设备确定reference numerology的子载波间隔基于子载波间隔发送随机接入前导码后，接收并解析终端设备发送的随机接入前导码以实现终端设备的随机接入。

[0198] 如图8所示，根据本发明的实施例的基站设备800，包括：如上述第二方面中的任一项技术方案所述的reference numerology的子载波间隔的设置/确定装置700。

[0199] 适用于终端设备侧的实施例：

[0200] 根据本发明的实施例的reference numerology的子载波间隔的设置/确定方法，包括：获取基站在第一参考子帧内以指定的子载波间隔发送的特定下行信号；确定用于传输特定下行信号的传输带宽，以及传输带宽对应的预存的参数M和N，其中，M为特定下行信号占用的资源块个数，N为每个资源块包含的子载波个数数据；确定传输带宽除以M再除以N之后的商值，商值即为特定下行信号传输的子载波间隔，也即能够与基站设备进行同步通信的reference numerology的子载波间隔。

[0201] 在该技术方案中，终端设备基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^{n})$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0202] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0203] 如图9所示，根据本发明的实施例的reference numerology的子载波间隔的设置/确定装置900，包括：获取单元902，用于获取基站在第一参考子帧内以指定的子载波间隔发送的特定下行信号；确定单元904，用于确定用于传输特定下行信号的传输带宽，以及传输带宽对应的预存的参数M和N，其中，M为特定下行信号占用的资源块个数，N为每个资源块包含的子载波个数数据；确定单元904还用于：确定传输带宽除以M再除以N之后的商值，商值即为特定下行信号传输的子载波间隔，也即能够与基站设备进行同步通信的reference numerology的子载波间隔。

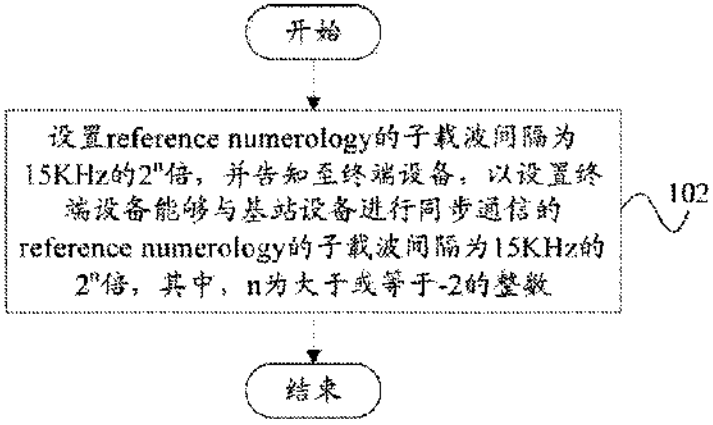
[0204] 在该技术方案中，终端设备基于reference numerology的子载波间隔的隐式指示的方法，检测到特定下行信号的传输带宽为$(M\times N\times 15\times 2^{m})$KHz，其中，M为特定下行信号占用的RB的个数，N为每个RB包含的子载波的个数，这个M和N是终端设备的芯片中预存的，所以根据特定下行信号的传输带宽、M和N能获得reference numerology的子载波间隔。

[0205] 在上述技术方案中，优选地，特定下行信号为主同步信号/辅同步信号、参考信号、寻呼信号和系统信息中的一个或多个的任意组合。

[0206] 如图10所示，根据本发明的实施例的终端设备1000，包括：如上述第五方面中的任一项技术方案所述的reference numerology的子载波间隔的设置/确定装置900，其中，终端设备1000与第二方面中的任一项技术方案所述的reference numerology的子载波间隔的设置/确定装置700进行同步通信，以确定与第三方面的基站设备800进行同步通信的reference numerology的子载波间隔。

[0207] 以上结合附图详细说明了本发明的技术方案，考虑到如何在统一的空口框架下针对不同的用户设置和/或确定reference numerology的子载波间隔的核心技术问题。因此，本发明提出了一种reference numerology的子载波间隔的设置/确定方案，通过特定下行信号占用的子载波间隔或显式指示信息、或载波的特征信息、或专用numerology、或终端设备的设备类型和/或需要传输的业务类型来指示终端设备reference numerology的子载波间隔，使得终端设备可以获知上下行信道、上下行信号和数据的时频资源粒度，以提高与基站设备的同步通信的准确度和可靠度。

[0208] 以上所述仅为本发明的优选实施例而已，并不用于限制本发明，对于本领域的技术人员来说，本发明可以有各种更改和变化。凡在本发明的精神和原则之内，所作的任何修改、等同替换、改进等，均应包含在本发明的保护范围之内。



开始
设置reference numerology的子载波间隔为15KHz的2^n倍，并告知至终端设备，以设置终端设备能够与基站设备进行同步通信的reference numerology的子载波间隔为15KHz的2^n倍，其中，n为大于或等于-2的整数

Communication resource distribution method, communication resource distribution device, base station and terminal

Abstract

The invention provides a communication resource distribution method, a communication resource distribution device, a base station and a terminal, wherein the communication resource distribution method comprises the following steps of determining the service type of a current service when service loading is established; according to the service type of the current service, determining granularity information of time-frequency resources and a frequency domain resource range for the service type; and sending the granularity information of the time-frequency resource and the frequency domain resource range for the service type to the terminal requesting for establishing the service loading. By means of the technical scheme, for different types of services, the granularity of the time-frequency resources and the frequency domain resource range are adjusted flexibly and correspondingly; resource scheduling can be flexibly suitable for different service types; and the resource use rate is increased easily.

通信资源的分配方法、分配装置、基站和终端

(57)摘要

本发明提供了一种通信资源的分配方法、分配装置、基站和终端，其中，通信资源的分配方法，包括：在业务发起建立时，确定当前业务的业务类型；根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围；将针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务的终端。本发明的技术方案使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

1.一种通信资源的分配方法，其特征在于，包括：

在业务承载建立时，确定当前业务的业务类型；

根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和域域资源范围；

将针对所述业务类型的时频资源的粒度信息和域域资源范围发送至请求建立所述业务承载的终端。

2.根据权利要求1所述的通信资源的分配方法，其特征在于，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和域域资源范围的步骤，具体包括：

在所述当前业务为LTE业务时，确定时域资源的粒度为1ms、频域资源的粒度为15KHz，频域资源范围为整个带宽的全部或部分范围。

3.根据权利要求1所述的通信资源的分配方法，其特征在于，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和域域资源范围的步骤，具体包括：

在所述当前业务为eMBB业务时，确定时域资源的粒度为T_1、频域资源的粒度为F_1、频域资源范围为整个带宽的全部或部分范围。

其中，$T_1<1ms$，$F_1\geq 15KHz$。

4.根据权利要求1所述的通信资源的分配方法，其特征在于，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和域域资源范围的步骤，具体包括：

在所述当前业务为mMTC业务时，确定时域资源的粒度为T_2、频域资源的粒度为F_2、频域资源范围为整个带宽的部分范围。

其中，$T_2\geq 1ms$，$F_2<15KHz$。

5.根据权利要求1所述的通信资源的分配方法，其特征在于，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和域域资源范围的步骤，具体包括：

在所述当前业务为URLLC业务时，确定时域资源的粒度为T_3、频域资源的粒度为F_3、频域资源范围为整个带宽的部分范围。

其中，$T_3<1ms$，$F_3\geq 15KHz$。

6.根据权利要求1所述的通信资源的分配方法，其特征在于，将针对所述业务类型的时频资源的粒度信息和域域资源范围发送至请求建立所述业务承载的终端的步骤，具体包括：

将整个带宽划分为带宽相等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点；或

将整个带宽划分为带宽不等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和带宽大小，或向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和终点。

7.根据权利要求6所述的通信资源的分配方法，其特征在于，所述多个频域资源范围不重叠或部分重叠。

8.根据权利要求1所述的通信资源的分配方法，其特征在于，所述域域资源范围包括用于传输参考信号的第一频域范围和用于传输数据的第二频域范围，其中，所述第一频域范围和所述第二频域范围不重叠、部分重叠或全部重叠。

9.根据权利要求1至8中任一项所述的通信资源的分配方法，其特征在于，通过RRC信令

将针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

10.根据权利要求1至8中任一项所述的通信资源的分配方法，其特征在于，还包括：

通过DCI信令指示所述终端在处理所述当前业务时被调度分配使用的资源块信息，所述资源块信息中包含有在针对所述业务类型的频域资源范围中选取的频域资源。

11.一种通信资源的分配方法，其特征在于，包括：

接收基站发送的第一信令和第二信令；

根据所述第一信令获取所述基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，并根据所述第二信令获取所述基站在所述频域资源范围内选取且分配的频域资源；

根据所述时频资源的粒度信息和所述频域资源，确定所述基站分配的用于处理所述当前业务的资源块信息；

基于所述资源块信息处理所述当前业务。

12.根据权利要求11所述的通信资源的分配方法，其特征在于，所述第一信令为RRC信令，所述第二信令为DCI信令

13.一种通信资源的分配装置，其特征在于，包括：

第一确定单元，用于在业务承载建立时，确定当前业务的业务类型；

第二确定单元，用于根据所述第一确定单元确定的所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围；

发送单元，用于将所述第二确定单元确定的针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

14.根据权利要求13所述的通信资源的分配装置，其特征在于，所述第二确定单元具体用于：

在所述当前业务为LTE业务时，确定时域资源的粒度为1ms、频域资源的粒度为15KHz、频域资源范围为整个带宽的全部或部分范围；

在所述当前业务为eMBB业务时，确定时域资源的粒度为T_1、频域资源的粒度为F_1、频域资源范围为整个带宽的全部或部分范围，其中，$T_1 \leq 1ms$，$F_1 \geq 15KHz$；

在所述当前业务为mMTC业务时，确定时域资源的粒度为T_2、频域资源的粒度为F_2、频域资源范围为整个带宽的部分范围，其中，$T_2 \geq 1ms$，$F_2 \leq 15KHz$；

在所述当前业务为URLLC业务时，确定时域资源的粒度为T_3、频域资源的粒度为F_3、频域资源范围为整个带宽的部分范围，其中，$T_3 \leq 1ms$，$F_3 \geq 15KHz$。

15.根据权利要求13所述的通信资源的分配装置，其特征在于，所述发送单元具体用于：

将整个带宽划分为带宽相等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点；或

将整个带宽划分为带宽不等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和带宽大小；或向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和终点。

16.根据权利要求15所述的通信资源的分配装置，其特征在于，所述多个频域资源范围

不重合或部分重合。

17.根据权利要求13所述的通信资源的分配装置，其特征在于，所述频域资源范围包括用于传输参考信号的第一频域范围和用于传输数据的第二频域范围，其中，所述第一频域范围和所述第二频域范围不重合、部分重合或全部重合。

18.根据权利要求13至17中任一项所述的通信资源的分配装置，其特征在于，所述发送单元还用于：

通过DCI信令指示所述终端在处理所述当前业务时被调度分配使用的资源块信息，所述资源块信息中包含有在针对所述业务类型的频域资源范围中选取的频域资源。

19.一种通信资源的分配装置，其特征在于，包括：

接收单元，用于接收基站发送的第一信令和第二信令；

获取单元，用于根据所述第一信令获取所述基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，并根据所述第二信令获取所述基站在所述频域资源范围内选取并分配的频域资源；

确定单元，用于根据所述时频资源的粒度信息和所述频域资源，确定所述基站分配的用于处理所述当前业务的资源块信息；

处理单元，用于基于所述资源块信息处理所述当前业务。

20.根据权利要求19所述的通信资源的分配装置，其特征在于，所述第一信令为RRC信令，所述第二信令为DCI信令。

21.一种基站，其特征在于，包括：如权利要求13至18中任一项所述的通信资源的分配装置。

22.一种终端，其特征在于，包括：如权利要求19或20所述的通信资源的分配装置。

通信资源的分配方法、分配装置、基站和终端

技术领域

[0001] 本发明涉及通信技术领域，具体而言，涉及一种通信资源的分配方法、一种通信资源的分配装置、一种基站和一种终端。

背景技术

[0002] 现有的4G以及1.5G移动通信技术，都是基于LTE(Long Term Evolution，长期演进)及LTE-A(LTE-Advanced)的无线接入技术、时频资源粒度和帧结构等，比如目前LTE系统能支持的最大单载波带宽为20MHz，暂未支持更大带宽，只能依靠载波聚合(Carrier Aggregation，简称CA)的使用。另外，目前的帧结构主要包括：FDD(Frequency Division Duplexing，频分双工)帧结构、TDD(Time Division Duplexing，时分双工)帧结构和LAA(LTE Assisted Access，LTE辅助接入)非授权载波使用的动态帧结构。不管是哪种帧结构，都包含10个子帧，每个子帧为1ms，每个子帧包含两个slot(时隙)，一个slot为0.5ms，每个slot又包含7个symbol(符号)。频域方面，在LTE系统中，子载波间距主要是15KHz，一个RB(Resource Block，资源块)包含了12个子载波。而在NB-IoT(Narrow Band Internet of Things，基于蜂窝的窄带物联网)R13又提出一种新的3.75KHz的子载波间隔，而且NB-IoT的载波带宽仅有180KHz。

[0003] 在资源分配方面，FDD帧结构和TDD帧结构都是以1ms子帧为时域调度粒度，除了TDD帧结构中的特殊子帧内的DwPTS(Down Link Pilot Time Slot，下行导频时隙)用于传输数据时，时域调度粒度是小于1ms的，同样在LAA非授权载波使用的帧结构中也出现了复用DwPTS作为partial subframe的下行调度时域粒度，同时也使用了1ms整子帧的调度粒度。而在FDD帧结构和TDD帧结构中，除了TDD帧结构中的特殊子帧既有下行发送和上行发送外，其它的子帧都是上行或下行要么时域分开要么频域分开。在LAA非授权载波使用的帧结构中的partial subframe内也会出现同一个子帧前半部分用于下行传输后半部分用于上行传输。

[0004] 另外，在上行调度方面，LTE系统上行发送的UL grant(上行调度指令)和它所传输上行数据的子帧之间的时间间隔一般在4ms，而HARQ(Hybrid Automatic Repeat Request，混合自动重传请求)ACK/NACK反馈一般是在相应的数据发送之后的4ms及以上时间才能发送。

[0005] 可见，目前的帧结构和频域资源的粒度都会使得资源分配不够灵活，而上行调度机制与HARQ反馈机制等的时间间隔又使得时延较大，20MHz带宽很不满足高带宽需求。

[0006] 未来5G通信主要场景包括以下三种：eMBB(Enhanced Mobile Broadband，增强的移动宽带网络)，mMTC(Massive Machine Type Communication，大规模机器类通讯)和URLLC(Ultra Reliable and Low Latency Communications，高可靠低时延通信)。而这三种场景所针对的业务类型不一样，其需求也不一样，比如：eMBB业务的两个主要指标是高带宽和低时延，在未来的5G通信中，eMBB业务可能支持100MHz的大带宽，而且要可能某个时刻整个带宽都直接分配给一个用户使用，而上行调度时延和HARQ反馈时延也会带来时延影响；

mMTC业务需要的是窄带服务，需要电池寿命很长，这种业务就需要更小粒度的频域和更宽粒度的时域资源；对于URLLC业务，也需要减少上行调度时延和HARQ反馈时延带来的时延影响。

[0007] 也就是说由于业务的多样化，使得目前固定的帧结构、固定的频域资源粒度和时域资源粒度会造成较大的上行调度时延和较长的HARQ反馈时延，并且较小的载波带宽也无法满足业务的多样化需求，上述这些都是亟待解决的技术问题。

发明内容

[0008] 本发明正是基于上述技术问题至少之一，提出了一种新的通信资源的分配方案，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

[0009] 有鉴于此，根据本发明的第一方面，提出了一种通信资源的分配方法，包括：在业务承载建立时，确定当前业务的业务类型；根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围；将针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0010] 在该技术方案中，通过确定当前业务的业务类型，并确定针对该业务类型的时频资源的粒度信息和频域资源范围，并将确定的时频资源的粒度信息和频域资源范围发送至请求建立业务承载的终端，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的上行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

[0011] 其中，时频资源的粒度信息包括频域资源的粒度和时域资源的粒度，频域资源的粒度用为子载波间隔(subcarrier spacing)，时域资源的粒度用为传输时间间隔(Transmission Time Interval，简称TTI)。

[0012] 在上述技术方案中，优选地，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围的步骤，具体包括：在所述当前业务为URLLC业务时，确定时域资源的粒度为1ms、频域资源的粒度为15KHz、频域资源范围为整个带宽的全部或部分范围。

[0013] 在上述任一技术方案中，优选地，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围的步骤，具体包括：在所述当前业务为eMBB业务时，确定时域资源的粒度为T_1、频域资源的粒度为F_1、频域资源范围为整个带宽的全部或部分范围，其中，$T_1 \leq 1ms$，$F_1 \geq 15KHz$。

[0014] 在该技术方案中，由于eMBB业务的主要指标是高带宽和低时延，为了满足eMBB业务的需求，其频域资源的粒度要大于URLLC业务的时域资源的粒度，即大于15KHz，其时域资源的粒度要小于或等于URLLC业务的时域资源的粒度，即小于或等于1ms。

[0015] 在上述任一技术方案中，优选地，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围的步骤，具体包括：在所述当前业务为mMTC业务时，确定时域资源的粒度为T_2、频域资源的粒度为F_2、频域资源范围为整个带宽的部分

范围，其中，T_1≥1ms，F_1≥15KHz。

[0016] 在该技术方案中，由于mMTC业务需要的是窄带服务，需要电池寿命很长，这种业务就需要更小粒度的频域和更宽粒度的时域资源，因此其频域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于15KHz，其时域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于1ms。

[0017] 在上述任一技术方案中，优选地，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围的步骤，具体包括：在所述当前业务为URLLC业务时，确定时域资源的粒度为T_2，频域资源的粒度为F_2，频域资源范围为整个带宽的部分范围，其中，T_2<1ms，F_2≥15KHz。

[0018] 在该技术方案中，由于URLLC业务是高可靠低时延业务，需要减少上行调度时延和HARQ反馈时延带来的时延影响，因此为了满足URLLC业务的需求，其频域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于15KHz，其时域资源的粒度要远小于LTE业务的时域资源的粒度，即远小于1ms。

[0019] 在本发明的一个实施例中，还针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端的步骤，具体包括：将整个带宽划分为带宽相等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点，其中，所述多个频域资源范围不重叠或部分重叠。

[0020] 在该实施例中，由于整个带宽已经被划分为带宽相等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时仅需指示起始点即可，进而终端能够根据起始点和在整个带宽上划分的每个频域资源范围的带宽来确定针对业务类型的频域资源范围。

[0021] 在本发明的另一个实施例中，还针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端的步骤，具体包括：将整个带宽划分为带宽不等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和带宽大小，或向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和终点，其中，所述多个频域资源范围不重叠或部分重叠。

[0022] 在该实施例中，由于整个带宽被划分为带宽不等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时需要指示该频域范围在整个带宽上的起始点和带宽大小，或指示其在整个带宽上的起始点和终点。其中，当向终端指示针对业务类型的频域资源范围在整个带宽上的起始点和终点时，既可以向终端指示整个带宽上连续的多个资源块，也可以指示不连续的多个资源块。

[0023] 在上述任一技术方案中，优选地，所述频域资源范围包括用于传输参考信号的第一频域范围和用于传输数据的第二频域范围，其中，所述第一频域范围和所述第二频域范围全重叠、部分重叠或全部重叠。

[0024] 在该技术方案中，基站向终端指示的针对业务类型的频域资源范围包含了用于传输参考信号的频域范围(即第一频域范围)和用于传输数据的频域范围(即第二频域范围)，这两个频域范围既可以不重叠，也可以部分重叠，还可以全部重叠。其中，所述的参考信号主要是用于同步和RRM(Radio Resource Management，无线资源管理)测量的参考信号。

[0025] 在上述任一技术方案中，优选地，通过RRC(Radio Resource Control，无线资源控

息)信令或针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0026] 在上述技术方案中，优选地，还包括：通过DCI(Downlink Control Information，下行控制信息)信令指示所述终端在处理所述当前业务时被调度分配使用的资源块信息，所述资源块信息中包含有在针对所述业务类型的频域资源范围中选取的频域资源。

[0027] 根据本发明的第二方面，还提出了一种通信资源的分配方法，包括：接收基站发送的第一信令和第二信令；根据所述第一信令获取所述基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，并根据所述第二信令获取所述基站在所述频域资源范围内选取并分配的频域资源；根据所述时频资源的粒度信息和所述频域资源，确定所述基站分配的用于处理所述当前业务的资源块信息；基于所述资源块信息处理所述当前业务。

[0028] 在该技术方案中，通过根据第一信令获取基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的下行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率，而通过根据第二信令获取基站在频域资源范围内选取并分配的频域资源，使得能够调度终端来对当前业务进行处理。

[0029] 在上述技术方案中，优选地，所述第一信令为RRC信令，所述第二信令为DCI信令。

[0030] 根据本发明的第三方面，提出了一种通信资源的分配装置，包括：第一确定单元，用于在业务承载建立时，确定当前业务的业务类型；第二确定单元，用于根据所述第一确定单元确定的所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围；发送单元，用于将所述第二确定单元确定的针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0031] 在该技术方案中，通过确定当前的业务的业务类型，并确定针对该业务类型的时频资源的粒度信息和频域资源范围，并将确定的时频资源的粒度信息和频域资源范围发送至请求建立业务承载的终端，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的下行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

[0032] 其中，时频资源的粒度信息包括频域资源的粒度和时域资源的粒度，频域资源的粒度即为子载波间隔，时域资源的粒度即为传输时间间隔。

[0033] 在上述技术方案中，优选地，所述第二确定单元具体用于：在所述当前业务为LTE业务时，确定时域资源的粒度为1ms、频域资源的粒度为15KHz、频域资源范围为整个带宽的全部或部分范围。

[0034] 在上述任一技术方案中，优选地，所述第二确定单元具体用于：在所述当前业务为eMBB业务时，确定时域资源的粒度为T1、频域资源的粒度为F1、频域资源范围为整个带宽的

个部或部分范围，其中，$T_a \leq 1ms$，$F_b \geq 15KHz$。

[0035] 在该技术方案中，由于eMBB业务的主要指标是高带宽和低时延，为了满足eMBB业务的需求，其频域资源的粒度要大于LTE业务的时域资源的粒度，即大于15KHz，其时域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于1ms。

[0036] 在上述任一技术方案中，优选地，所述第二确定单元具体用于：在所述当前业务为mMTC业务时，确定时域资源的粒度为T_a、频域资源的粒度为F_b、频域资源范围为整个带宽的部分范围，其中，$T_a \geq 1ms$，$F_b \leq 15KHz$。

[0037] 在该技术方案中，由于mMTC业务需要的是窄带服务，需要电池寿命很长，这种业务就需要更小粒度的频域和更高粒度的时域资源，因此其频域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于15KHz，其时域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于1ms。

[0038] 在上述任一技术方案中，优选地，所述第二确定单元具体用于：在所述当前业务为URLLC业务时，确定时域资源的粒度为T_a、频域资源的粒度为F_b、频域资源范围为整个带宽的部分范围，其中，$T_a \leq 1ms$，$F_b \geq 15KHz$。

[0039] 在该技术方案中，由于URLLC业务是超可靠低时延业务，需要减少上行调度时延和HARQ反馈时延带来的时延影响，因此为了满足URLLC业务的需求，其频域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于15KHz，其时域资源的粒度要远小于LTE业务的时域资源的粒度，即远小于1ms。

[0040] 在本发明的一个实施例中，所述发送单元具体用于：将整个带宽划分为带宽相等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点，其中，所述多个频域资源范围不重叠或部分重叠。

[0041] 在该实施例中，由于整个带宽已经被划分为带宽相等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时仅需指示起始点即可，进而终端即能根据起始点和在整个带宽上划分的每个频域资源范围的带宽来确定针对业务类型的频域资源范围。

[0042] 在本发明的另一个实施例中，所述发送单元具体用于：将整个带宽划分为带宽不等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和带宽大小，或向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和终点，其中，所述多个频域资源范围不重叠或部分重叠。

[0043] 在该实施例中，由于整个带宽被划分为带宽不等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时需要指示该频域范围在整个带宽上的起始点和带宽大小，或指示其在整个带宽上的起始点和终点。其中，当向终端指示针对业务类型的频域资源范围在整个带宽上的起始点和终点时，既可以向终端指示整个带宽上连续的多个资源块，也可以指示不连续的多个资源块。

[0044] 在上述任一技术方案中，优选地，所述频域资源范围包括用于传输参考信号的第一频域范围和用于传输数据的第二频域范围，其中，所述第一频域范围和所述第二频域范围不重叠、部分重叠或全部重叠。

[0045] 在该技术方案中，基站向终端指示的针对业务类型的频域资源范围包含了用于传输参考信号的频域范围(即第一频域范围)和用于传输数据的频域范围(即第二频域范围)，

这两个频域范围既可以不重叠，也可以部分重叠，还可以全部重叠。其中，所述的参考信号为用于同步和RRM测量的参考信号。在上述任一技术方案中，优选地，通过RRC信令进行对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0046] 在上述任一技术方案中，优选地，所述发送单元还用于：通过DCI信令指示所述终端在处理所述当前业务时被调度分配使用的资源块信息，所述资源块信息中包含有在针对所述业务类型的频域资源范围中选取的频域资源。

[0047] 根据本发明的第四方面，还提出了一种通信资源的分配装置，包括：接收单元，用于接收基站发送的第一信令和第二信令；获取单元，用于根据所述第一信令获取所述基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，并根据所述第二信令获取所述基站在所述频域资源范围内选取并分配的频域资源；确定单元，用于根据所述时频资源的粒度信息和所述频域资源，确定所述基站分配的用于处理所述当前业务的资源块信息；处理单元，用于基于所述资源块信息处理所述当前业务。

[0048] 在该技术方案中，通过根据第一信令获取基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的上行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率，而通过根据第二信令获取基站在频域资源范围内选取并分配的频域资源，使得能够调度终端来对当前业务进行处理。

[0049] 在上述技术方案中，优选地，所述第一信令为RRC信令，所述第二信令为DCI信令。

[0050] 根据本发明的第五方面，还提出了一种基站，包括：如上述第二方面所述的通信资源的分配装置。

[0051] 根据本发明的第六方面，还提出了一种终端，包括：如上述第四方面所述的通信资源的分配装置。

[0052] 通过以上技术方案，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

具体实施方式

[0060] 为了能够更清楚地理解本发明的上述目的、特征和优点，下面结合附图和具体实

施方式对本发明进行进一步的详细描述，需要说明的是，在不冲突的情况下，本申请的实施例及实施例中的特征可以相互组合。

[0061] 在下面的描述中阐述了很多具体细节以便于充分理解本发明，但是，本发明还可以采用其他不同于在此描述的其他方式来实施，因此，本发明的保护范围并不受下面公开的具体实施例的限制。

[0062] 图1示出了根据本发明的第一个实施例的通信资源的分配方法的示意流程图，该通信资源的分配方法的执行主体可以是基站。

[0063] 如图1所示，根据本发明的第一个实施例的通信资源的分配方法，包括：

[0064] 步骤S10，在业务承载建立时，确定当前业务的业务类型。

[0065] 在该步骤中，当前业务的业务类型包括但不限于：LTE业务、eMBB业务、mMTC业务和URLLC业务。

[0066] 步骤S12，根据所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围。

[0067] 其中，时频资源的粒度信息包括频域资源的粒度和时域资源的粒度，频域资源的粒度即为子载波间隔，时域资源的粒度即为传输时间间隔。

[0068] 步骤S14，将针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0069] 在本发明的一个实施例中，步骤S12具体包括：在所述当前业务为LTE业务时，确定时域资源的粒度为1ms、频域资源的粒度为15KHz、频域资源范围为整个带宽的全部或部分范围。

[0070] 在本发明的一个实施例中，步骤S12具体包括：在所述当前业务为eMBB业务时，确定时域资源的粒度为T_1、频域资源的粒度为F_1、频域资源范围为整个带宽的全部或部分范围，其中，$T_1 \leq 1ms$，$F_1 > 15KHz$。

[0071] 在该实施例中，由于eMBB业务的主要指标是高带宽和低时延，为了满足eMBB业务的需求，其频域资源的粒度要大于LTE业务的时域资源的粒度，即大于15KHz，其时域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于1ms。

[0072] 在本发明的一个实施例中，步骤S12具体包括：在所述当前业务为mMTC业务时，确定时域资源的粒度为T_2、频域资源的粒度为F_2、频域资源范围为整个带宽的部分范围，其中，$T_2 \geq 1ms$，$F_2 \leq 15KHz$。

[0073] 在该实施例中，由于mMTC业务需要的是零星服务，需要电池寿命很长，这种业务就需要更小粒度的频域和更宽粒度的时域资源，因此其频域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于15KHz，其时域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于1ms。

[0074] 在本发明的一个实施例中，步骤S12具体包括：在所述当前业务为URLLC业务时，确定时域资源的粒度为T_3、频域资源的粒度为F_3、频域资源范围为整个带宽的部分范围，其中，$T_3 < 1ms$，$F_3 \geq 15KHz$。

[0075] 在该实施例中，由于URLLC业务是高可靠低时延业务，需要减少上行调度时延和HARQ反馈时延带来的时延影响，因此为了满足URLLC业务的需求，其频域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于15KHz，其时域资源的粒度要远小于LTE业

务的时域资源的粒度，即远小于1ms。

[0076] 在本发明的一个实施例中，步骤S11具体包括：将整个带宽划分为带宽相等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点。其中，所述多个频域资源范围不重叠或部分重叠。

[0077] 在该实施例中，由于整个带宽已经被划分为带宽相等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时仅需指示起始点即可，进而终端能够根据起始点和在整个带宽上划分的每个频域资源范围的带宽来确定针对业务类型的频域资源范围。当然，也可以指示起始点和终点，当向终端指示针对业务类型的频域资源范围在整个带宽上的起始点和终点时，既可以向终端指示整个带宽上连续的多个资源块，也可以指示不连续的多个资源块。

[0078] 在本发明的另一个实施例中，步骤S11具体包括：将整个带宽划分为带宽不等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和带宽大小，或向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和终点。其中，所述多个频域资源范围不重叠或部分重叠。

[0079] 在该实施例中，由于整个带宽被划分为带宽不等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时需要指示该频域范围在整个带宽上的起始点和带宽大小，或指示其在整个带宽上的起始点和终点。其中，当向终端指示针对业务类型的频域资源范围在整个带宽上的起始点和终点时，既可以向终端指示整个带宽上连续的多个资源块，也可以指示不连续的多个资源块。

[0080] 在上述任一技术方案中，优选地，所述频域资源范围包括用于传输参考信号的第一频域范围和用于传输数据的第二频域范围，其中，所述第一频域范围和所述第二频域范围不重叠、部分重叠或全部重叠。

[0081] 在该技术方案中，基站向终端指示的针对业务类型的频域资源范围包含了用于传输参考信号的频域范围(即第一频域范围)和用于传输数据的频域范围(即第二频域范围)，这两个频域范围既可以不重叠，也可以部分重叠，还可以全部重叠。其中，所述的参考信号指用于同步和RRM测量的参考信号。

[0082] 在上述任一技术方案中，优选地，通过RRC信令将针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0083] 在上述任一技术方案中，优选地，还包括：通过DCI信令指示所述终端在处理所述当前业务时被调度分配使用的资源块信息，所述资源块信息中包含有在针对所述业务类型的频域资源范围中选取的频域资源。

[0084] 在图1所示的技术方案中，通过确定当前业务的业务类型，并确定针对该业务类型的时频资源的粒度信息和频域资源范围，并将确定的时频资源的粒度信息和频域资源范围发送至请求建立业务承载的终端，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的上行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

[0085] 图2示出了根据本发明的第一个实施例的通信资源的分配装置的示意框图。

[0086] 如图2所示，根据本发明的第一个实施例的通信资源的分配装置200，包括：第一确定单元202、第二确定单元204和发送单元206。

[0087] 其中，第一确定单元202用于在业务承载建立时，确定当前业务的业务类型；第二确定单元204用于根据所述第一确定单元202确定的所述当前业务的业务类型，确定针对所述业务类型的时频资源的粒度信息和频域资源范围；发送单元206用于将所述第二确定单元204确定的针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0088] 在该技术方案中，通过确定当前业务的业务类型，并确定针对该业务类型的时频资源的粒度信息和频域资源范围，并将确定的时频资源的粒度信息和频域资源范围发送至请求建立业务承载的终端，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的下行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。

[0089] 其中，时频资源的粒度信息包括频域资源的粒度和时域资源的粒度，频域资源的粒度即为子载波间隔，时域资源的粒度即为传输时间间隔。

[0090] 在上述技术方案中，优选地，所述第二确定单元204具体用于：在所述当前业务为LTE业务时，确定时域资源的粒度为1ms、频域资源的粒度为15KHz、频域资源范围为整个带宽的全部或部分范围。

[0091] 在上述任一技术方案中，优选地，所述第二确定单元204具体用于：在所述当前业务为eMBB业务时，确定时域资源的粒度为T_1、频域资源的粒度为F_1、频域资源范围为整个带宽的全部或部分范围，其中，$T_1 \leq 1ms$，$F_1 \geq 15KHz$。

[0092] 在该技术方案中，由于eMBB业务的主要指标是高带宽和低时延，为了满足eMBB业务的需求，其频域资源的粒度要大于LTE业务的时域资源的粒度，即大于15KHz，其时域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于1ms。

[0093] 在上述任一技术方案中，优选地，所述第二确定单元204具体用于：在所述当前业务为mMTC业务时，确定时域资源的粒度为T_2、频域资源的粒度为F_2、频域资源范围为整个带宽的部分范围，其中，$T_2 > 1ms$，$F_2 \leq 15KHz$。

[0094] 在该技术方案中，由于mMTC业务需要的是窄带服务，需要电池寿命很长，这种业务就需要更小粒度的频域和更宽粒度的时域资源，因此其频域资源的粒度要小于或等于LTE业务的时域资源的粒度，即小于或等于15KHz，其时域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于1ms。

[0095] 在上述任一技术方案中，优选地，所述第二确定单元204具体用于：在所述当前业务为URLLC业务时，确定时域资源的粒度为T_3、频域资源的粒度为F_3、频域资源范围为整个带宽的部分范围，其中，$T_3 < 1ms$，$F_3 \geq 15KHz$。

[0096] 在该技术方案中，由于URLLC业务是超可靠低时延业务，需要减少上行调度时延和HARQ反馈时延带来的时延影响，因此为了满足URLLC业务的需求，其频域资源的粒度要大于或等于LTE业务的时域资源的粒度，即大于或等于15KHz，其时域资源的粒度要远小于LTE业务的时域资源的粒度，即远小于1ms。

[0097] 在本发明的一个实施例中，所述发送单元206具体用于：将整个带宽划分为带宽相等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点。其中，所述多个频域资源范围不重叠或部分重叠。

[0098] 在该实施例中，由于整个带宽已经被划分为带宽相等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时仅需指示起始点即可，进而终端能够根据起始点和在整个带宽上划分的每个频域资源范围的带宽来确定针对业务类型的频域资源范围。当然，也可以指示起始点和终点，当向终端指示针对业务类型的频域资源范围在整个带宽上的起始点和终点时，既可以向终端指示整个带宽上连续的多个资源块，也可以指示不连续的多个资源块。

[0099] 在本发明的另一个实施例中，所述发送单元206具体用于：将整个带宽划分为带宽不等的多个频域资源范围，并向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和带宽大小，或向所述终端指示针对所述业务类型的频域资源范围在所述整个带宽上的起始点和终点。其中，所述多个频域资源范围不重叠或部分重叠。

[0100] 在该实施例中，由于整个带宽被划分为带宽不等的多个频域资源范围，因此基站在向终端指示针对业务类型的频域资源范围时需要指示该频域范围在整个带宽上的起始点和带宽大小，或指示其在整个带宽上的起始点和终点。其中，当向终端指示针对业务类型的频域资源范围在整个带宽上的起始点和终点时，既可以向终端指示整个带宽上连续的多个资源块，也可以指示不连续的多个资源块。

[0101] 在上述任一技术方案中，优选地，所述频域资源范围包括用于传输参考信号的第一频域范围和用于传输数据的第二频域范围，其中，所述第一频域范围和所述第二频域范围不重叠、部分重叠或全部重叠。

[0102] 在该技术方案中，基站向终端指示的针对业务类型的频域资源范围包含了用于传输参考信号的频域范围(即第一频域范围)和用于传输数据的频域范围(即第二频域范围)，这两个频域范围既可以不重叠，也可以部分重叠，还可以全部重叠。其中，所述的参考信号指用于同步和RRM测量的参考信号。

[0103] 在上述任一技术方案中，优选地，通过RRC信令将针对所述业务类型的时频资源的粒度信息和频域资源范围发送至请求建立所述业务承载的终端。

[0104] 在上述任一技术方案中，优选地，所述发送单元206还用于：通过DCI信令指示所述终端在处理所述当前业务时被调度分配使用的资源块信息，所述资源块信息中包含有在针对所述业务类型的频域资源范围中选取的频域资源。

[0105] 图3示出了根据本发明的实施例的基站的示意框图。

[0106] 如图3所示，根据本发明的实施例的基站300，包括：如图2中所示的通信资源的分配装置200。

[0107] 图4示出了根据本发明的第一个实施例的通信资源的分配方法的示意流程图，该通信资源的分配方法的执行主体可以是终端。

[0108] 如图4所示，根据本发明的第一个实施例的通信资源的分配方法，包括：

[0109] 步骤S10，接收基站发送的第一信令和第二信令。

[0110] 步骤S12，根据所述第一信令获取所述基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，并根据所述第二信令获取所述基站在所述频域资源范围

内选取并分配的频域资源。

[0111] 步骤S11，根据所述时频资源的粒度信息和所述频域资源，确定所述基站分配的用于处理所述当前业务的资源块信息。

[0112] 步骤S16，基于所述资源块信息处理所述当前业务。

[0113] 其中，所述第一信令为RRC信令，所述第二信令为DCI信令。

[0114] 在图1所示的技术方案中，通过根据第一信令获取基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的上行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。而通过根据第二信令获取基站在频域资源范围内选取并分配的频域资源，使得能够调度终端来对当前业务进行处理。

[0115] 图5示出了根据本发明的第二个实施例的通信资源的分配装置的示意框图

[0116] 如图5所示，根据本发明的第二个实施例的通信资源的分配装置500，包括：接收单元502，获取单元501，确定单元506和处理单元508。

[0117] 其中，接收单元502用于接收基站发送的第一信令和第二信令；获取单元501用于根据所述第一信令获取所述基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，并根据所述第二信令获取所述基站在所述频域资源范围内选取并分配的频域资源；确定单元506用于根据所述时频资源的粒度信息和所述频域资源，确定所述基站分配的用于处理所述当前业务的资源块信息；处理单元508用于基于所述资源块信息处理所述当前业务。

[0118] 其中，所述第一信令为RRC信令，所述第二信令为DCI信令。

[0119] 在该技术方案中，通过根据第一信令获取基站根据当前业务的业务类型确定的时频资源的粒度信息和频域资源范围，使得能够针对不同类型的业务，灵活地对时频资源的粒度和频域资源范围进行相应的调整，进而能够避免采用固定的时频资源粒度而造成较大的上行调度时延和较长的HARQ反馈时延，同时也能够避免采用较小的频域资源范围(载波带宽)而无法满足5G通信场景中的业务需求，实现了资源调度能够灵活地适应不同的业务类型，有利于提高资源使用率。而通过根据第二信令获取基站在频域资源范围内选取并分配的频域资源，使得能够调度终端来对当前业务进行处理。

[0120] 图6示出了根据本发明的实施例的终端的示意框图

[0121] 如图6所示，根据本发明的实施例的终端600，包括：如图5中所示的通信资源的分配装置500。

[0122] 综上所述，本发明的技术方案主要是提出了一种新的通信资源的分配方案，可以针对不同的业务类型，采用相应的时频资源粒度和频域资源范围，以适应于5G通信的需求。

[0123] 具体包括以下几个方面：

[0124] 一、在终端的每个业务承载建立时，基站通过RRC信令向该终端发送关于该业务承载的信息，这些信息包含的内容如下：

[0125] 1、Subcarrier spacing，子载波间隔，也就是频域资源粒度；

[0126] 2、Transmission Time Interval，传输时间间隔，也就是时域资源粒度。其中，LTE

系统中的传输时间间隔一般是1ms；

[0127] 3、可分配的RB范围，此处RB范围主要指的是频域资源的范围。

[0128] 由于5G通信中一个载波的带宽可能很大，比如80MHz或者100MHz，因此如果在RRC信令中限定一个RB范围，那么后续向终端指示具体RB分配时的DCI信令的开销将比较大。对于可分配的RB范围的指示还有一个含义，即该无线业务承载相关的系统信息、参考信号、同步信号等也都在该RB范围内发送，也就是说只需要在该RB范围内进行检测，就能正确处理该无线业务承载。当然用于参考信号和数据发送的RB范围可以不一样。

[0129] 在RRC信令向终端通知的以上三种信息中，Subcarrier spacing和Transmission Time Interval是针对无线业务承载的，也就是说只要是一个业务承载，这两个参数就不会变，而每后一个RB范围，可能根据整体业务情况进行变化，但也可以通过RRC信令进行半静态的调整。

[0130] 1、针对不同的业务类型，上述三个参数的取值具体如下：

[0131] 1、对于传统的LTE业务，上述三个参数的取值依次如下：

[0132] LTE_Subcarrier Spacee=15KHz；

[0133] LTE_tti=1ms；

[0134] LTE_RB为整个带宽的全部或部分范围。

[0135] 2、对于eMBB业务，其三个参数与LTE业务的三个参数比较如下：

[0136] eMBB Subcarrier Spacee≥LTE Subcarrier Spacee；

[0137] eMBB tti≤LTE tti；

[0138] eMBB RB可能是整个带宽也可能是整个带宽的一部分。

[0139] 3、对于mMTC业务，其三个参数与LTE的三个参数比较如下：

[0140] mMTC Subcarrier Spacee≤LTE Subcarrier Spacee；

[0141] mMTC_tti≥LTE_tti；

[0142] mMTC_RB是整个带宽的很小一部分，比如只有180KHz。

[0143] 4、对于URLLC业务，其三个参数与LTE的三个参数比较如下：

[0144] URLLC_Subcarrier Spacee≥LTE_Subcarrier Spacee；

[0145] URLLC_tti≤LTE_tti，即URLLC的tti通常小于LTE的tti；

[0146] URLLC_RB是整个带宽的很小一部分。

[0147] 2、基站在通过RRC信令向终端发送关于该业务承载的信息时，对于RB范围的指示方法具体如下：

[0148] 基站可以先通过RRC信令指示出RB范围在整个带宽上的大致位置，为了后向兼容和同时支持MTC业务(窄带业务)，在整个带宽上RB的大小值是要统一的。因此可以选择一个RB_baseline(RB基准)，其值可能与LTE的RB值一样，即可以是180KHz。那么在RRC信令指示RB范围时，可以以RB_baseline为粒度来进行指示。具体的指示方法如下：

[0149] 1、当整个带宽上划分的多个频域范围的带宽都相同时，比如每个频域范围的带宽都是20MHz，这时只需要指示RB范围的起点即可；

[0150] 2、当整个带宽上划分的多个频域范围的带宽不定时，需要同时指示RB范围的起点和带宽大小，或者指示RB范围的起点和终点。

[0151] 针对以上两种指示方法，若RRC信令针对的业务不同，即对一个终端有多个业务的

话，则可能RRC信令指示的频域资源区域是独立的。另外，上述的多个频域范围可能是完全不重叠的，也可能是有部分重叠的，并且，指示的RB范围可以是一段连续的带宽(如图7所示)，也可能是多段不连续的带宽。

[0152] 2、基站在通过RRC信令向终端指示完RB范围后，通过DCI信令向终端指示具体的RB分配。

[0153] 具体地，比如对于LTE业务，若基站通过RRC信令指示的RB范围包含了110个RB(即20MHz)，则DCI信令可以指示该110个RB中的其中N个RB分配给终端。

[0154] 对于eMBB业务，若RB范围指示了整个带宽为80MHz，那么DCI信令可以指示该80MHz中的其中M个eMBB RB分配给终端。其中，eMBB RB由eMBB的sub-carrier spacing和CP决定，eMBB RB的大小可能是RB base Inc 180KHz的很多倍。

[0155] 对于mMTC业务，若RB范围指示了其中P个RB，那么DCI信令要指示其中的哪些个mMTC RB分配给终端。其中，mMTC RB由mMTC的sub carrier spacing和CP决定，比如类似NB-IoT中，指示的就是哪些个15KHz分配给终端。

[0156] 上述所述的RB范围是针对参考信号和数据发送的。其中，针对参考信号和针对数据发送的RB范围可以是一样的，也可以是不一样的。如果不一样，则需要分成针对参考信号的RB范围和针对数据发送的RB范围。针对参考信号的RB范围主要用来上下行同步和RRM(Radio Resource Management，无线资源管理)测量等，针对数据发送的RB范围主要用来发送和接收数据。对于同一终端来说，针对参考信号的RB范围和针对数据发送的RB范围可以不重叠、部分重叠或完全重叠，也可以是一个范围包含另一个范围。

[0157] 同时，对于不在上述两个范围(即针对参考信号的RB范围和针对数据发送的RB范围)内的频域资源，终端不需要去测量也不需要监听PDCCH(Physical Downlink Control Channel，物理下行控制信道)。

[0158] 此外，对于不同业务类型来说，DCI信令在指示时所使用的bit数和指示方法可以不一样。

[0159] 四、终端的处理过程：

[0160] 1、接收基站发送的RRC信令和DCI信令；

[0161] 2、从RRC信令中获得基站指示的RB范围、当前业务的sub-carrier spacing和CP，比如若是eMBB业务，那么其使用eMBB RB为粒度。

[0162] 3、根据DCI信令中的指示，确定RB范围内具体的频域资源是分配给自己使用的。比如确定哪些个eMBB RB值是分配给自己的

[0163] 4、基于确定的时频资源来处理当前业务。

[0164] 可见，本发明的技术方案通过设计新的RRC信令，以指示不同业务对应的子载波间隔、传输时间间隔，以及使用的RB范围，从而能够更好的为该业务调度资源，并且能够减少DCI信令的开销。

[0165] 以上结合附图详细说明了本发明的技术方案，本发明提出了一种新的通信资源的分配方案，使得能够针对不同类型的业务，灵活且时频资源的粒度和频域资源范围进行相应的调整，实现了资源调度能够更灵活地适应不同的业务类型，有利于提高资源使用率。

[0166] 以上所述仅为本发明的优选实施例而已，并不用于限制本发明，对于本领域的技术人员来说，本发明可以有各种更改和变化。凡在本发明的精神和原则之内，所作的任何修

改、等同替换、改进等，均应包含在本发明的保护范围之内。

Signal transmission method and related network element

Abstract

The embodiment of the invention discloses a signal transmission method and a related network element. The method includes steps: when a new radio (NR) business is transmitted on a unauthorized frequency band, a base station performs a listen before talk (LBT) mechanism and determines whether remaining subframes exit in a resource block (RB); if yes, the base station selects the signal type applicable to the NR business on the remaining subframes according to the NR business type; and the base station sends a control signaling of the NR business to a terminal by employing the signal type of the NR business on the remaining subframes. According to the method and the related network element, the control signaling of the NR business is sent by employing the remaining subframes so that the utilization rate of channel resources can be increased.

一种信号传输方法及相关网元

(57)摘要

本发明实施例公开了一种信号传输方法及相关网元，其中的方法包括：当新无线NR业务在非授权频段上传输时，基站执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；若存在，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；所述基站在所述剩余子帧上采用所述NR业务的信号类型的终端发送所述NR业务的控制信令。本发明实施例中，采用剩余子帧发送所述NR业务的控制信令，有利于提高信道资源利用率。

CN 105323611 A

1.一种信号传输方法，其特征在于，所述方法包括：

当新无线NR业务在非授权频段上传输时，基站执行先听后说LBT机制并判断用于执行所述LBT机制所在的资源块RB中是否存在剩余子帧；

若存在，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；

所述基站在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。

2.根据权利要求1所述的方法，其特征在于，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型，包括：

若所述NR业务类型为增强型移动宽带应用eMBB业务，则所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述eMBB业务的信号类型。

3.根据权利要求1所述的方法，其特征在于，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型，包括：

若所述NR业务类型为超可靠及低时延通信URLLC业务，则所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述URLLC业务的信号类型。

4.根据权利要求1所述的方法，其特征在于，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型，包括：

若所述NR业务类型为大量物联网通信mMTC业务，则所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述mMTC业务的信号类型。

5.根据权利要求1所述的方法，其特征在于，所述用于执行LBT机制的占用资源可以配置在模设子帧位置上。

6.根据权利要求1所述的方法，其特征在于，所述执行LBT机制的信号类型与适用于所述NR业务的信号类型不同。

7.根据权利要求1所述的方法，其特征在于，所述适用于所述NR业务的信号类型是指所述基站根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔，循环前缀长度和传输时间间隔TTI长度上的至少一种相匹配的NR业务的信号类型。

8.根据权利要求1-7任一项所述的方法，其特征在于，所述控制信令包括探测信号、信道探测的参考信号或同步信号。

9.一种信号传输方法，其特征在于，所述方法包括：

当新无线NR业务在非授权频段上传输时，终端执行先听后说LBT机制并判断用于执行所述LBT机制所在的资源块RB中是否存在剩余子帧；

若存在，所述终端向基站发送所述RB中存在剩余子帧的指示消息；

所述终端接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择。

10.根据权利要求9所述的方法，其特征在于，所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，包括：

若所述NR业务类型为增强型移动宽带应用eMBB业务，则所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述eMBB业务的控制信令。

11.根据权利要求9所述的方法，其特征在于，所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，包括：

若所述NR业务类型为超可靠及低时延通信URLLC业务，则所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述URLLC业务的控制信令。

12.根据权利要求9所述的方法，其特征在于，所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的适用于所述NR业务的控制信令，包括：

若所述NR业务类型为大规物联网通信mMTC业务，则所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述mMTC业务的控制信令。

13.根据权利要求9所述的方法，其特征在于，所述用于执行LBT机制的占用资源可以配置在预设子帧位置上。

14.根据权利要求9所述的方法，其特征在于，所述执行LBT机制的信号类型与适用于所述NR业务的信号类型不同。

15.根据权利要求9所述的方法，其特征在于，所述适用于所述NR业务的信号类型是指所述基站根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔、循环前缀长度和传输时间间隔TTI长度中的至少一种相匹配的NR业务的信号类型。

16.根据权利要求9-15任一项所述的方法，其特征在于，所述控制信令包括保留信号、信道探测的参考信号或同步信号。

17.一种基站，其特征在于，所述基站包括：

判断单元，用于当新无线NR业务在上授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

选择单元，用于若存在所述剩余子帧，在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；

发送单元，用于在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。

18.根据权利要求17所述的基站，其特征在于，所述选择单元具体用于：

若所述NR业务类型为增强型移动宽带应用eMBB业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述eMBB业务的信号类型。

19.根据权利要求17所述的基站，其特征在于，所述选择单元具体用于：

若所述NR业务类型为超可靠及低时延通信URLLC业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述URLLC业务的信号类型。

20.根据权利要求17所述的基站，其特征在于，所述选择单元具体用于：

若所述NR业务类型为大规物联网通信mMTC业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述mMTC业务的信号类型。

21.根据权利要求17所述的方法，其特征在于，所述用于执行LBT机制的占用资源可以配置在预设子帧位置上。

22.根据权利要求17所述的方法，其特征在于，所述执行LBT机制的信号类型与适用于所述NR业务的信号类型不同。

23.根据权利要求17所述的基站，其特征在于，所述适用于所述NR业务的信号类型是指根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔、循环前缀长度和传输时间间

隙TTI长度中的至少一种相匹配的NR业务的信号类型。

21.根据权利要求17-23任一项所述的方法，其特征在于，所述控制信令包括保留信号、信道探测的参考信号或同步信号。

25.一种终端，其特征在于，所述终端包括：

判断单元，用于当新无线NR业务在上授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

发送单元，若存在所述剩余子帧，向基站发送所述RB中存在剩余子帧的指示消息；

接收单元，用于接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择。

26.根据权利要求25所述的终端，其特征在于，所述接收单元具体用于：

若所述NR业务类型为增强型移动宽带应用eMBB业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述eMBB业务的控制信令。

27.根据权利要求25所述的终端，其特征在于，所述接收单元具体用于：

若所述NR业务类型为超可靠及低时延通信URLLC业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述URLLC业务的控制信令。

28.根据权利要求25所述的终端，其特征在于，所述接收单元具体用于：

若所述NR业务类型为大量物联网通信mMTC业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述mMTC业务的控制信令。

29.根据权利要求25所述的方法，其特征在于，所述用于执行LBT机制的与用资源可以配置在预设子帧位置上。

30.根据权利要求25所述的方法，其特征在于，所述执行LBT机制的信号类型与适用于所述NR业务的信号类型不同。

31.根据权利要求25所述的终端，其特征在于，所述适用于所述NR业务的信号类型是指根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔，循环前缀长度和传输时间间隙TTI长度中的至少一种的NR业务的信号类型。

32.根据权利要求25-31任一项所述的终端，其特征在于，所述控制信令包括保留信号、信道探测的参考信号或同步信号。

一种信号传输方法及相关网元

技术领域

[0001] 本发明涉及通信技术领域，尤其涉及一种信号传输方法及相关网元。

背景技术

[0002] 无线通信网络的广泛部署可为用户提供各种通信服务，例如语音、视频、分组数据、消息传送、广播等。这些无线网络可以是能够通过共享可用的网络资源来支持多个用户的多址网络。这些多址网络的示例包括码分多址(Code Division Multiple Access,CDMA)网络、时分多址(Time Division Multiple Access,TDMA)网络、频分多址(Frequency Division Multiple Access,FDMA)网络、正交频分多址(Orthogonal Frequency Division Multiple Access,OFDMA)网络和单载波频分多址(Single-carrier Frequency Division Multiple Access,SC-FDMA)网络、以及下一代新无线(New Radio,NR)网络(例如5G)。

[0003] NR的提出带来了新的机遇和挑战，未来NR业务的三大主要应用场景和需求主要包括增强型移动宽带应用(Enhanced mobile broadband,eMBB)、超可靠及低时延通信(Ultra-reliable and low latency communications,URLLC)以及大规物联网通信(Massive machine type communications,mMTC)。针对增强型的移动宽带eMBB这种应用场景下，智能终端用户上网峰值速率要达到10Gbps甚至20Gbps，为虚拟现实、无处不在的视频直播和分享、随时随地的云接入等大带宽应用提供支持。针对大连接物联网mMTC这种场景下，5G网络需要支持100万一平方公里规模的人和物的连接。针对低时延、超可靠通信uRLLC这种场景要求5G网络的时延达到1毫秒，为智能制造、远程机械控制、辅助驾驶和自动驾驶等低时延业务提供强有力的支持。

[0004] 为进一步提高频谱资源的利用，第三代合作伙伴计划(3rd Generation Partnership Project,3GPP)引入了授权频谱辅助接入(Licensed Assisted Access,LAA)的概念，其可以借助长期演进(Long Term Evolution,LTE)甚至NR的授权频谱的帮助来处理非授权频段。同时，为确保LAA能够友好地与现有的接入技术共存，提出了一种先听后说(Listen Before Talk,LBT)机制来避免碰撞。若在非授权频谱上检测到信道处于空闲状态，才能占用该信道进行信号发送。在正常循环前缀(Cyclic Prefix,CP)情况下，一个资源块(Resource Block,RB)在时域上的最小长度是7个正交频分复用(Orthogonal Frequency Division Multiplexing,OFDM)符号，也就是0.5ms。非授权频段上，无线系统(包括后来的NR系统)在使用信道(或者使用RB)之前可以执行LBT机制，用以判断信道是否可用，而执行LBT的时间一般都是微秒级。非LBT事件的引入会产生新的频谱资源利用率的问题。

发明内容

[0005] 本发明实施例提供一种信号传输方法及相关网元，可提高频谱利用率。

[0006] 在第一方面，本发明实施例提供了一种信号传输方法，包括：

[0007] 当新无线NR业务在非授权频段上传输时，终端执行先听后说LBT机制，并判断资源块RB中是否存在剩余子帧；

[0008] 若存在，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；

[0009] 所述基站在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。

[0010] 在第二方面，本发明实施例提供了一种信号传输方法，包括：

[0011] 当新无线NR业务在非授权频段上传输时，终端执行先听后说LBT机制，并判断用于执行所述LBT机制所在的资源块RB中是否存在剩余子帧；

[0012] 若存在，所述终端向基站发送所述RB中存在剩余子帧的指示消息；

[0013] 所述终端接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择。

[0014] 在第三方面，本发明实施例提供了一种基站，包括：

[0015] 判断单元，用于当新无线NR业务在非授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

[0016] 选择单元，用于若存在所述剩余子帧，在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；

[0017] 发送单元，用于在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制指令。

[0018] 在第四方面，本发明实施例提供了一种终端，包括：

[0019] 判断单元，用于当新无线NR业务在非授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

[0020] 发送单元，用于若存在所述剩余子帧，向基站发送所述RB中存在剩余子帧的指示消息；

[0021] 接收单元，用于接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择。

[0022] 在NR系统中，因为FAA的引入，从而使得在非授权频段上的LBT机制可能只是占用了RB的部分时频位置，从而会出现RB中的OFDM符号的剩余的现象，此剩余的OFDM符号的利用率成为当前亟需讨论的问题。

[0023] 而本发明实施例，当新无线NR业务在非授权频段上传输时，基站执行先听后说LBT机制并判断是否存在剩余子帧，若存在，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型，并在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令，本发明实施例采用剩余子帧发送所述NR业务的控制信令，合理地使用了剩余子帧，提高了频谱利用率。

附图说明

[0024] 为了更清楚地说明本发明实施例技术方案，下面将对实施例描述中所需要使用的附图作简单地介绍，显而易见地，下面描述中的附图是本发明的一些实施例，对于本领域普通技术人员来讲，在不付出创造性劳动的前提下，还可以根据这些附图获得其他的附图。

[0025] 图1是本发明实施例提供的信号传输方法的第一实施例流程示意图；

[0026] 图1a是本发明实施例提供的发送NR业务的RB的结构示意图；

具体实施方式

[0037] 下面将结合本发明实施例中的附图，对本发明实施例中的技术方案进行清楚、完整地描述。显然，所描述的实施例是本发明一部分实施例，而不是全部的实施例。基于本发明中的实施例，本领域普通技术人员在没有做出创造性劳动前提下所获得的所有其他实施例，都属于本发明保护的范围。

[0038] 需要说明的是，在本发明实施例中使用的术语是仅仅出于描述特定实施例的目的，而非旨在限制本发明。在本发明实施例和所附权利要求书中所使用的单数形式的"一种"、"所述"和"该"也旨在包括多数形式，除非上下文清楚地表示其他含义。还应当理解，本文中使用的术语"和/或"是指并包含一个或多个相关联的列出项目的任何或所有可能组合。

[0039] 需要说明的是，在没有明示的特别说明的情况下，本发明各实施例中的各项技术特征可视为能够进行相互组合或者结合，只要该种组合或者结合不是因为技术的原因而无法实施，为了较为简分的说明本发明，一些示例性的、可选的、或者优选的特征在本发明各实施例中与其他技术特征结合在一起进行描述，但这种结合不是必须的，而应该理解该示例性的、可选的、或者优选的特征与其他的技术特征都是彼此可分离的或者独立的，只要该种可分离或者独立不是因为技术的原因而无法实施。方法实施例中的技术特征的一些功能性描述可以理解为执行该功能、方法或者步骤，装置实施例中的技术特征的一些功能性描述可以理解为使用该种装置来执行该功能、方法或者步骤。

[0040] 无线通信网络可以包括能够支持多个无线用户装置的通信的多个基站。无线用户装置可以通过下行链路和上行链路与基站进行通信。下行链路(或前向链路)是指从基站到无线用户装置的通信链路，而上行链路(或反向链路)是指从无线用户装置到基站的通信链路。

[0041] 无线用户设备(例如，蜂窝电话或者智能电话)可以利用无线通信系统来发射和接收数据以用于双路通信。无线用户设备可以包括用于数据发射的发射机以及用于数据接收的接收机。对于数据发射，发射机可以利用将数据对发射本地振荡器(Local Oscillator，LO)信号进行调制以获得经过调制的射频(Radio Frequency，RF)信号，对经过调制的RF信号进行放

从以获得具有恰当发射功率级别的输出RF信号，并且经由天线来输出RF信号发射给基站。对于数据接收，接收机可以经由天线来获得所接收的RF信号，放大并利用接收IQ信号来将所接收的RF信号下变频，并且处理经下变频的信号以恢复由基站发送的数据。

[0042] 无线用户设备可以支持与不同无线电接入技术(Radio Access Technology,RAT)的多个无线系统的通信(例如LTE、LTE-A和NR)。每个无线系统可能具有某些特性和要求，能够高效地支持利用不同RAT的无线系统的同时通信。无线用户设备还可以被称为用户设备(User Equipment,UE)、移动台、终端、接入终端、用户单元、站点、等等。无线用户设备可以是蜂窝电话、智能电话、平板计算机、无线调制解调器、个人数字助理(Personal Digital Assistant,PDA)、手持式设备、膝上型计算机、智能本、上网本、无绳电话、无线本地回路(wireless local loop,WLL)站点、蓝牙设备、等等。无线用户设备可以能够与无线系统进行通信，还可以能够从广播站、一个或多个全球导航卫星系统(Global Navigation Satellite System,GNSS)中的卫星等接收信号。无线用户设备可以支持用于无线通信的一个或多个RAT，诸如GSM、WCDMA、cdma2000、LTE、LTE-A、802.11、等等。术语"无线电接入技术"、"RAT"、"无线电技术"、"空中接口"和"标准"经常可互换地被使用。

[0043] 需要说明的是，在LTE/LTE-A系统中，上、下行载波分别采用单载波频分多址(Single-carrier Frequency-Division Multiple Access,SC-FDMA)/OFDM以及循环前缀(Cyclic Prefix,CP)。在5G标准中，示例性的，可以对上下行载波进行统一，即上行链路与下行链路均采用OFDM以及CP。另外示例性的，5G中的RB可以被如下配置，1个资源块包含12个子载波，子载波间隔以15kHz为基准，子载波间隔可以是15kHz的N(N=2^n)倍，或者也可以固定为子载波间隔为75kHz。具体而言，传统LTE小区工作在频段上的带宽是由RB构成，RB分别具有固定的子载波间隔和符号长度，比如正常CP下，频域上的大小为180KHz(即：12个15KHz子载波间隔)，时域上，包括7个符号，一个符号的长度约等于71.3us。而在下一代移动通信技术中(例如NR系统中)，不同子载波可以基于业务类型不再具有固定的子载波间隔和固定的符号长度(可以动态变化)。为区别于传统LTE系统中的RB概念，NR系统新定义了"numerology"(参考数值)的概念，它主要包括子载波间隔、CP长度和TTI长度等。目前，NR系统共定义了三种业务类型，分别是eMBB、URLLC和mMTC，不同业务类型的"numerology"类型是可以不同，意味不同类型的子载波间隔、CP长度或TTI长度可能有所不同。示例性的，可以定义下一代移动通信将会支持最大为100MHz的单载波带宽。一个资源块RB在频域上的大小变为900KHz(即：12个75kHz子载波间隔)，而在时域上支持0.1ms。一个无线帧的长度是10ms，但是由50个子帧构成，每个子帧的长度为0.2ms。需要说明的是，本文通信所述的适用于所述NR业务的信号类型，可以是指包括载波间隔、CP长度和TTI长度等相关参数中的至少一种参数的配置。

[0044] 请参照图1和图1a，图1是本发明实施例提供的信号传输方法的第一实施例流程示意图，图1a是本发明实施例提供的发送NR业务的RB句结构示意图。本实施例中所描述的一种信号传输方法，包括步骤S101～S103：

[0045] S101，当新无线NR业务在非授权频段上传输时，基站执行先听后说LBT机制，并判断用于执行所述LBT机制所在的资源块RB中是否存在剩余子帧。

[0046] 具体实现中，当新无线NR业务在非授权频段上传输时，NR业务在占用信道之前都要执行LBT机制，通过能量感知的方式获取目标信道是否空闲。当信道处于空闲状态时，才

能使用该信道进行NR业务传输。由于LBT机制的时间一般微秒级的如LBT机制最短的执行时间是25us，而一个RB是0.5ms，基站一般以两个RB为单位即1ms来调度终端，LBT机制只是占用了RB的部分时频位置，所以，在执行完LBT机制之后，可能会出现剩余子帧。本发明实施例中，当基站需要采用非授权频段上向终端传输NR业务时，基站首先需要执行LBT机制，并在执行LBT机制之后判断RB中是否存在剩余子帧，如图1a所示为发送NR业务的RB的结构示意图，LBT机制的执行占用了1st部分的时频位置，其余的n2为剩余部分子帧，可以用于传输适用于所述NR业务的信号。本发明实施例中，若出现剩余子帧，则可以根据NR业务类型利用剩余子帧来发送与业务类型相匹配的相关控制信令或者是相匹配的数据业务相关指令。在上行链路中，上述LBT机制的执行过程和剩余子帧的判断过程也可以由终端来执行。

[0047] 作为检测目标信道是否处于空闲状态的一种示例性的方式，具体的，当有新无线NR业务需要在非授权频段上传输时，基站检测时间是否有其它设备正在目标信道发送数据，如果该目标载信道已被其它设备占用，可以在下一监听周期到来时继续监听，也可以不再监听；若监听到信道资源空闲，该基站可以立即占用该目标信道。信道占用时间可以是一个固定值，也可以在下一个信道检测位置前设定一个静默时间。优选的，若监听到信道资源繁忙，可以生成一个竞机数1作为退避时间，在这个退避时间内，继续监听目标信道，若检测到1次目标信道处于空闲状态，则退避时间结束，同时该基站就可以占几该目标信道。如果基站检测到信道状态为繁忙（例如已被其它设备占用），则在这个周期内设备不能占用信道，则该基站可以等到下一个周期的固定位置继续检测。

[0048] 作为检测目标信道是否处于空闲状态的另一种示例性的方式，具体的，当有新无线NR业务需要在非授权频段上传输时，触发初始检测，若基站初始检测到目标信道处于空闲状态，即可占用该目标信道，并在基站预先配置一个信道占用时间T；若基站初始检测到目标信道状态为非空闲，则可生成一个推迟周期(defer period)时间，如果在推迟周期时间还是检测到目标信道忙，则继续生成一个推迟周期时间，UE在此次检测时间检测到信道状态为空闲之后可以占用目标信道，占用目标信道时间为T。

[0049] S102，若存在，所述基站在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型。

[0050] S103，所述基站在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。

[0051] 具体实现中，NR业务类型可以包括eMBB、URLLC、mMTC等，基站可以根据上述业务类型选择与所述剩余子帧的子载波间隔、循环前缀长度和传输时间间隔(Transmission time interval，TTI)长度中至少一种相匹配的NR业务的信号，例如当NR业务类型为eMBB业务时，基站可以选择适用于eMBB业务所支持的参数取值如numerology类型或者频域资源组(Frequency resource group，FRG)类型的信号类型。FRG是指在一个NR载波上连续的或者非连续的频域资源上使用一个numerology类型的频域资源，而numerology类型主要与子载波间隔、循环前缀(Cyclic Prefix，CP)长度和TTI长度相关。所以，FRG的配置也理解为是包括子载波间隔、CP长度和TTI长度等相关参数中的至少一种参数的配置。

[0052] 基站可以在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。本发明实施例中，控制信令可以包括保留信号，信道探测的参考信号或同步信号，其中，保留信号可以是未携带任何信息的信号，主要用于防止其它无线接入设备在此期

间占用该信道；参考信号主要用于对当前信道的信计以及信道质量的获取，也可在一定程度上防止其它无线接入设备在此期间占用该信道，它可以通过预设的序列生成，也可以以触发方式由基站发送；同步信号则可以防止终端与基站出现业务中断现象。

[0053] 本发明实施例，当NR业务在非授权频段上传输时，基站执行先听后说LBT机制并判断是否存在剩余子帧，若存在，所述基站根据所述NR业务类型选择适用于所述NR业务的信号类型，并在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令，本发明实施例采用剩余子帧发送所述NR业务的控制信令，合理使用了剩余子帧，有利于提高频谱利用率。

[0054] 请参照图2，图2是本发明实施例提供的信号传输方法的第一实施例流程示意图，本实施例中所描述的一种信号传输方法，包括步骤S201～S203。

[0055] S201，当新无线NR业务在非授权频段上传输时，基站执行先听后说LBT机制并判断用于执行所述LBT机制所在的资源块RB中是否存在剩余子帧。

[0056] 具体实现中，当新无线NR业务在非授权频段上传输时，NR业务在占用信道之前都要执行LBT机制，通过能量感知的方式获取目标信道是否空闲。当信道处于空闲状态时，才能使用该信道进行NR业务传输。由于LBT机制的时间一般微秒级的如LBT机制最短的执行时间是25us，而一个RB是0.5ms，基站一般以两个RB为单位即1ms来调度终端，LBT机制只是占用了RB的部分时频位置。所以，在执行完LBT机制之后，RB中可能会出现剩余子帧。在上行链路中，上述LBT机制的执行过程和剩余子帧的判断过程也可以由终端来执行。

[0057] 可选的，所述用于执行LBT机制的占用资源可以配置在预设子帧位置上。

[0058] 需要说明的是，下一代移动通信工作的频段可以包括非授权频段，也就是说，在无线通信系统的通信链路可以包括用于携带上行链路(UL)传输(例如，从UE116到eNB105)的上行链路和/或用于携带下行链路(DL)传输(例如，从基站到UE)的下行链路。UL传输还可以称为反向链路传输，而DL传输还可以称为前向链路传输。可以使用授权的频段(例如，LTE/LTE-A)、非授权的频段或两者来进行下行链路传输。类似地，可以使用授权的频段(例如，LTE/LTE-A)、非授权的频段或两者来进行上行链路传输。但是在非授权频段上，需要考虑到其它无线接入设备的存在，为了更好的与它们实现合理共存，LTE/LTE-A以及NR(例如，5G)系统需要遵守一些规则。比如LBT，即系统在使用非授权频段之前需要通过执行LBT机制用以判断目标信道是否可用。但是考虑到下一代移动通信系统中三种业务类型的特点，即为提高频谱利用率，三种业务类型所对应的"numerology"(数值参数)类型应有所不同。而对于非授权频段，在保证与其它异系统(诸如WiFi、蓝牙等)实现合理共存的同时，还要保证5G系统与LTE系统的兼容性。所以，针对这种情况，非授权频段会出现一种划分频段的情况，其示意图如图2a所示。可以看出，在子帧上被划分出一部分区域作为LBT区域，而另一部分区域作为不同NR类型业务(eMBB、URLLC、mMTC)的承载区域。考虑到LBT机制的执行时间处于微秒级别，所以，针对划分出来的LBT执行区域，可以以多子帧聚合的方式出现，即类似于LBT机制中基于帧结构设计的LBT机制(Frame Based Equipment，FBE)，基站或者终端会在预设若干个，每个无线帧中固定子帧的开头执行FBE；或者在每个无线帧中的一些固定子帧的开头执行FBE。所以，为提高非授权频段的频谱利用率，将划分出来用于执行LBT机制的占用资源，执行LBT机制的占用资源可以配置在预设子帧位置上，也可放在每个无线帧中固定子帧位置上，比如每个无线帧的第0号子帧和第5号子帧上。

[0059] 可选的，所述执行LBT机制的信号类型与适用于所述NR业务的信号类型不同。需要说明的是，考虑到尽可能保证LBT机制在适用于LTE/LTE-A业务的信号和适用于NR业务的信号两者中的兼容性，因此执行LBT机制的信号类型可以与传统的适用于LTE/LTE-A业务的信号保持一致，而与适用于NR业务的信号的类型不相同，此种设计被证明是有益的，可以在向前兼容的情形下同时考虑到新特性的引入，有利于提高频谱的利用效率。

[0060] S202，若存在上所述NR业务类型为增强型移动宽带应用eMBB业务，则从所述基础选择适用于所述eMBB业务的信号类型。

[0061] 具体实现中，为了使NR系统能够支持灵活和多种部署场景，不同"numerology(数值参数)"类型的子载波间隔和CP长度有所不同。同时，不同的"numerology(数值参数)"类型需具有可扩展性，以适应未来系统新增业务的需求，且不同的NR业务对于子帧结构的设计要求也不同。例如对于时延比较敏感的业务采用小数据包的发送或短周期TTI会比较适合。另外，同载波上不同频域范围内的"numerology(数值参数)"类型也可能不同。针对NR系统支持eMBB、URLLC、mMTC三大不同业务场景，业务具体分析如下：

[0062] eMBB主要工作在较宽的频段上，包括中高速的物联网通信(machine type communications,MTC)服务。该业务主要用于热点区域，以为终端用户提供较好的视频服务，通过设定合适的"numerology(数值参数)"类型以更好地适应该业务场景。例如可将该部分频段子载波间隔设置相对较大，以保证能够传输大带宽数业务。从频段特点来看，小于40GHz的频段上，最适合密集的城市宏小区场景中，高于40GHz以上的频段，比较适合室内或者微基站小区部署的城市密集场景。

[0063] URLLC场景主要面向车联网、工业控制等应用需求，其对时延要求和业务的可靠性要求较高。所以，可以适用于一些诸如室内和城市热点的微基站小区之中，例如部署大量小小区的场景中。不同于另外两种业务场景，可以将该场景的"numerology(数值参数)"类型中的TTI长度设置成短周期TTI最为适合。可以通过如下两种方式设置成短周期TTI：一种是在维持当前子载波间隔宽度的情况下，减少一个TTI内的符号数；一种是在维持相同TTI长度的情况下，增加每个符号的子载波间隔。

[0064] mMTC场景主要适用于以传感器和数据采集为主要的应用场景，例如环境监测、智能农业等。目前，它主要用于传输小流量数据包，其具有低功耗和低成本的特点，所以该业务场景的传输信道相对于前面两种业务场景而言，对频段宽度要求不是太高。因此，低于1GHz(如700MHz)的农村场景比较适合。其最佳典型场景和频谱设计可参见如下表1：

[0065]

使用场景	典型部属场景	典型频谱
eMBB	城市宏小区 密集城市场景（包括小小区）	<~40GHz， >~40GHz
URLLC	小小区/室内场景	<~40GHz
mMTC	农村场景	<1GHz（如700MHz）

[0066] 表1

[0067] 若所述NR业务类型为超可靠及低时延通信URLLC业务，则可以根据eMBB业务选择与所述剩余子帧的子载波间隔、循环前缀长度和TTI长度中至少一种相匹配的eMBB业务

的信号类型。

[0068] 可选的，若所述NR业务类型为超可靠及低时延通信URLLC业务，则所述基站可以选择适用于所述URLLC业务的信号类型。若存在剩余子帧且传输业务为URLLC业务，所述基站可以根据URLLC业务选择与所述剩余子帧的子载波间隔、循环前缀长度和TTI长度或者中至少一种相匹配的eMBB业务的信号类型。

[0069] 可选的，若所述NR业务类型为大量物联网通信mMTC业务，则所述基站选择适用于所述mMTC业务的信号类型。若存在剩余子帧且传输业务为mMTC业务时，可以根据mMTC业务选择与所述剩余子帧的子载波间隔、循环前缀长度和TTI长度中至少一种相匹配的mMTC业务的信号。

[0070] 其中，保留信号可以是未携带任何信息的信号，主要用于防止其它无线接入设备在此期间占用该信道；参考信号主要用于对当前信道的估计以及信道质量的获取，也可在一定程度上防止其它无线接入设备在此期间占用该信道，它可以通过预设的序列生成，也可以以触发方式由基站发送；同步信号则可以防止终端与基站出现业务中断现象。

[0071] S203、所述基站在所述剩余子帧上向终端发送适用于所述NR业务的控制信令。

[0072] 具体实现中，若已选择适用于所述NR业务的信号类型，可以在所述剩余子帧上发送适用于所述NR业务的信号。如图2b～2d所示，图2b是本发明实施例提供的发送eMBB业务的RB的结构示意图，图2c是本发明实施例提供的发送URLLC业务的RB的结构示意图，图2d是本发明实施例提供的发送mMTC业务的RB的结构示意图。RB一部分用于LBT机制的执行，另一部分根据不同的NR业务类型发送不同的信号，如eMBB业务的信号、URLLC业务的信号、mMTC业务的信号。其中，上述控制信令可以包括保留信号、信道探测的参考信号或同步信号。

[0073] 本发明实施例，当NR业务在非授权频段上传输时，执行先听后说LBT机制并判断是否存在剩余子帧，若存在且所述NR业务类型为增强型移动宽带应用eMBB业务，则选择适用于所述eMBB业务的信号类型，并在所述剩余子帧上采用所述NR业务的信号类型向终端发送适用于所述NR业务的控制信令，实现了NR业务和LAA共存，并通过合理使用剩余子帧发送NR业务的控制信令，提高了频谱利用率。

[0074] 请参照图3，图3是本发明实施例提供的信号传输方法的第一实施例流程示意图。本实施例中所描述的一种信号传输方法，包括步骤S301～S303。

[0075] S301、当新无线NR业务在非授权频段上传输时，终端执行先听后说LBT机制方法判断用于执行所述LBT机制所在的资源块RB中是否存在剩余子帧。

[0076] 具体实现请参考图1对应的方法实施例的步骤S101以及图2对应的方法实施例的步骤S201的具体解释，在此不再赘述。

[0077] 作为检测目标信道是否处于空闲状态的一种示例性的方式，具体的，当有新无线NR业务需要在非授权频段上传输时，终端检测周围是否有其它设备正在目标信道发送物理上行共享信道(Physical Uplink Shared Channel，PUSCH)数据。如果该目标某信道已被其它设备占用，可以在下一监听周期到来时继续监听，也可以根据指示不再监听；若监听到信道资源空闲，该终端也以立即占用该目标信道。信道占用时间是一个固定值，也可以在下一信道检测位置前设定一个等候时间。优选的，若监听到信道资源繁忙，可以生成一个随机数N作为退避时间，在这个退避时间内，继续监听目标信道，若检测到N次目标信道处于空闲状态，则退避时间结束，同时该终端就可以占用该目标信道。如果终端检测到信道状态为繁忙

(例如已被其它终端占用)，则在这个周期内设备不能占用信道，则该终端可以等到下一个周期的时间点位置继续检测。

[0078] 作为检测目标信道是否处于空闲状态的另一种示例性的方式，具体的，当有新无线NR业务需要在非授权频段上传输时，触发初始检测。若终端初始检测到目标信道处于空闲状态，即可占用该目标信道，并在基站预先配置一个信道占用时间T；若终端初始检测到目标信道状态为非空闲，则可生成一个推迟周期(defer period)时间，如果在推迟周期时间还是检测到目标信道忙，则继续生成一个推迟周期时间。终端在T次检测时间检测到信道状态为空闲之后可以占用目标信道，占用目标信道时间为T。

[0079] S302、若存在，所述终端向基站发送所述RB中存在剩余子帧的指示消息。

[0080] 具体实现中，若所在的RB中存在剩余子帧，则所述终端会向基站发送一个指示消息，该指示消息可以用于告知基站RB中存在剩余子帧，进一步的，该指示消息还可以触发基站在该剩余子帧上发送适用于所述NR业务的信号。

[0081] S303、所述终端接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择。

[0082] 具体实现中，基站获知RB中存在剩余子帧后，会根据NR业务类型选择适用于所述NR业务的信号类型，并在所述剩余子帧上采用NR业务的信号类型向终端发送所述NR业务的控制信令，具体过程请参见图1对应实施例的步骤S102～S103以及图2对应实施例的步骤S202～S203，在此不再赘述。所述终端可以接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令。

[0083] 可选的，若所述NR业务类型为增强型移动宽带应用eMBB业务，则所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述eMBB业务的控制信令

[0084] 可选的，若所述NR业务类型为超可靠及低时延通信URLLC业务，则所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述URLLC业务的控制信令。

[0085] 可选的，若所述NR业务类型为大量物联网通信mMTC业务，则所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述mMTC业务的控制信令。

[0086] 可选的，所述适用于所述NR业务的信号类型是指所述基站根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔，循环前缀长度和传输时间间隔TTI长度中的至少一种相匹配的NR业务的信号类型。

[0087] 可选的，所述控制信令包括保留信号、信道探测的参考信号或同步信号。

[0088] 上述可选步骤的具体实现请参考图2对应的方法实施例的具体解释，在此不再赘述。

[0089] 本发明实施例中，当新无线NR业务在非授权频段上传输时，终端执行先听后说LBT机制并判断用于执行所述LBT机制的所在的资源集RB中是否存在剩余子帧，若存在，所述终端接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择，实现了NR业务和LAA共存，并可以使基站在该剩余子帧上发送NR业务的控制信令，提高了频谱利用率。

[0090] 请参照图4，为本发明实施例提供的基站的第一实施例结构示意图。本发明实施例的基站包括：判断单元101、选择单元102和发送单元103

[0091] 判断单元101，用于当新无线NR业务在非授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

[0092] 选择单元102，用于若存在所述剩余子帧，在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；

[0093] 可选的，所述选择单元102具体用于若所述NR业务类型为增强型移动宽带应用eMBB业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述eMBB业务的信号类型。

[0094] 可选的，所述选择单元102具体用于若所述NR业务类型为超可靠及低时延通信URLLC业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述URLLC业务的信号类型。

[0095] 可选的，所述选择单元102具体用于若所述NR业务类型为大量物联网通信mMTC业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述mMTC业务的信号类型。

[0096] 发送单元103，用于在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。

[0097] 可选的，所述适用于所述NR业务的信号类型是指根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔，循环前缀长度和传输时间间隔TTI长度中的至少一种相匹配的NR业务的信号类型。

[0098] 可选的，所述控制信令包括保留信号，信道探测的参考信号或同步信号。

[0099] 上述实施例各个单元的具体解释请参见图一-图2所对应的方法实施例，在此不再赘述。

[0100] 请参照图5，是本发明实施例提供的基站的第二实施例结构示意图。本实施例中所描述的基站主要包括：至少一个输入设备1000和输出设备1001；至少一个处理器1002，例如CPU；可选的存储器1003，上述输入设备1000、输出设备1001、处理器1002和可选的存储器1003通过总线1004连接。

[0101] 上述存储器1003可以是高速RAM存储器，也可为非易失性存储器(non-volatile memory，NVM)，例如磁盘存储器。上述存储器1003可用于存储程序代码，上述处理器1002用于调用存储器1003中存储的程序代码，执行如下操作：

[0102] 上述处理器1002，用于当新无线NR业务在非授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

[0103] 上述处理器1002，还用于若存在，在所述剩余子帧上根据所述NR业务类型选择适用于所述NR业务的信号类型；

[0104] 上述处理器1002，还用于在所述剩余子帧上采用所述NR业务的信号类型向终端发送所述NR业务的控制信令。

[0105] 可选的，上述处理器1002，具体用于若所述NR业务类型为增强型移动宽带应用eMBB业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述eMBB业务的信号类型。

[0106] 上述处理器1002，具体用于若所述NR业务类型为超可靠及低时延通信URLLC业务，则在所述剩余子帧上根据所述NR业务类型选择适用于所述URLLC业务的信号类型。

[0107] 上述处理器1002，具体用于若所述NR业务类型为大量物联网通信mMTC业务，则在

所述剩余子帧上根据所述NR业务类型选择适用于所述mMTC业务的信号类型。

[0108] 其中，所述适用于所述NR业务的信号类型是指根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔、循环前缀长度和传输时间间隔TTI长度中的至少一种相匹配的NR业务的信号类型。所述控制信令包括保留信号、信道探测的参考信号或同步信号。

[0109] 具体实现中，本发明实施例中所描述的输入设备1000、输出设备1001和处理器1002可执行本发明实施例提供的信号传输方法的第一实施例、第二实施例中所描述的实现方式，也可执行本发明实施例提供的基站中所描述的终实现方式，在此不再赘述。

[0110] 请参照图6，为本发明实施例提供的终端的第一实施例结构示意图。本发明实施例的终端包括：判断单元201、发送单元202和接收单元203。

[0111] 所述判断单元201，用于当新无线NR业务在非授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

[0112] 所述发送单元202，用于若存在所述剩余子帧，向基站发送所述RB中存在剩余子帧的指示消息；

[0113] 所述接收单元203，接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择。

[0114] 可选的，所述接收单元203具体用于若所述NR业务类型为增强型移动宽带应用eMBB业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述eMBB业务的控制信令。

[0115] 可选的，所述接收单元203具体用于若所述NR业务类型为超可靠及低时延通信URLLC业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述URLLC业务的控制信令。

[0116] 可选的，所述接收单元203具体用于若所述NR业务类型为大规物联网通信mMTC业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述mMTC业务的控制信令。

[0117] 可选的，所述适用于所述NR业务的信号类型是指根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔、循环前缀长度和传输时间间隔TTI长度中的至少一种相匹配的NR业务的信号类型。所述控制信令包括保留信号、信道探测的参考信号或同步信号。

[0118] 上述实施例各个单元的具体解释请参见图2所对应的方法实施例，在此不再赘述。

[0119] 请参照图7，是本发明实施例提供的终端的第二实施例结构示意图。本实施例中所描述的终端主要包括：至少一个输入设备2000和输出设备2001；至少一个处理器2002，例如CPU；可选的存储器2003。上述输入设备2000、输出设备2001、处理器2002和可选的存储器2003通过总线2004连接。

[0120] 上述存储器2003可以是高速RAM存储器，也可为NVM，例如磁盘存储器。上述存储器2003可用于存储程序代码，上述处理器2002用于调用存储器2003中存储的程序代码，执行如下操作：

[0121] 上述处理器2002，用于当新无线NR业务在非授权频段上传输时，执行先听后说LBT机制并判断资源块RB中是否存在剩余子帧；

[0122] 上述处理器2002，用于若存在所述剩余子帧，向基站发送所述RB中存在剩余子帧

的指示消息；

[0123] 上述处理器2002，还用于若存在所述剩余子帧，接收所述基站在所述剩余子帧上采用NR业务的信号类型发送的所述NR业务的控制信令，所述NR业务的信号类型由所述基站在所述剩余子帧上根据所述NR业务类型所选择；

[0124] 可选的，上述处理器2002，具体用于若所述NR业务类型为增强型移动宽带应用eMBB业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述eMBB业务的控制信令。

[0125] 上述处理器2002，具体用于若所述NR业务类型为超可靠及低时延通信URLLC业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述URLLC业务的控制信令。

[0126] 上述处理器2002，具体用于若所述NR业务类型为大量物联网通信mMTC业务，则接收基站在所述剩余子帧上采用NR业务的信号类型发送的所述mMTC业务的控制信令。

[0127] 其中，所述适用于所述NR业务的信号类型是指根据所述NR业务类型所选择的与所述剩余子帧的子载波间隔、循环前缀长度和传输时间间隔TTI长度中的至少一种相匹配的NR业务的信号类型，所述控制信令包括参考信号、信道探测的参考信号或同步信号。

[0128] 具体实现中，本发明实施例中所描述的输入设备2000、输出设备2001和处理器2002可执行本发明实施例提供的信号传输方法的第二实施例中所描述的实现方式，也可执行本发明实施例提供的终端中所描述的终实现方式，在此不再赘述。

[0129] 本发明实施例方法中的步骤可以根据实际需要进行顺序调整、合并和删减。

[0130] 本发明实施例装置中的单元可以根据实际需要进行合并、划分和删减。

[0131] 本领域普通技术人员可以理解实现上述实施例方法中的全部或部分流程，是可以通过计算机程序来指令相关的硬件来完成，所述的程序可存储于一计算机可读取存储介质中，该程序在执行时，可包括如上述各方法的实施例的流程。其中，所述的存储介质可为磁碟、光盘、只读存储记忆体(Read-Only Memory，ROM)或随机存储记忆体(Random access Memory，RAM)等。

[0132] 以上所揭露的仅为本发明较佳实施例而已，当然不能以此来限定本发明之权利范围，因此依本发明权利要求所作的等同变化，仍属本发明所涵盖的范围。

(54) Title: METHOD FOR RECEIVING/SENDING PAGING MESSAGE AND RELATED NETWORK AND USER EQUIPMENT

(54) 发明名称: 寻呼消息的接收/发送方法及相关网络节点和用户设备

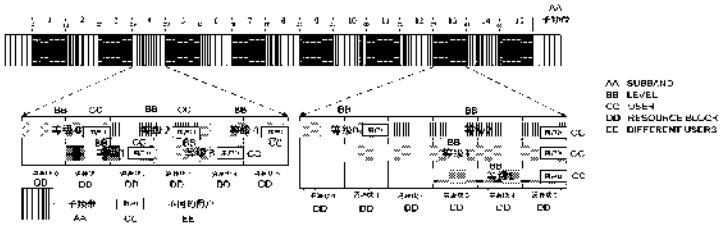

图10 / FIG. 10

(57) Abstract: The present invention provides a method for receiving/sending a paging message and a corresponding network node/user equipment. The method comprises: receiving an indication of a physical resource block set used to send a paging message, an index of the physical resource block set in a subframe being determined according to the level of the paging message; and receiving the paging message on the indicated physical resource block set. According to the technical solution, a paging message transmission mechanism for a coverage enhanced MTC user equipment and/or a low-complexity or low-cost MTC user equipment can be provided.

(57) 摘要: 本发明提供了寻呼消息接收/发送方法以及相应网络节点/用户设备。该方法包括: 接收对用于发送所述寻呼消息的物理资源块集的指示, 其中, 所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的; 以及在所指示的物理资源块集上接收所述寻呼消息。根据该技术方案, 可提供同时针对覆盖增强 MTC 用户设备和/或低复杂度或低成本的 MTC 用户设备的寻呼消息传输机制。

寻呼消息的接收/发送方法及相关网络节点和用户设备

技术领域

本发明涉及无线通信技术领域。更具体地，本发明涉及寻呼消息的接收/发送方法以及相关网络节点/用户设备。

背景技术

第三代移动通信合作计划组织（3GPP）部署的长期演进项目（LTE）旨在提供日益多样化的未来移动通信服务，无线蜂窝通信日益成为大众生活和工作中不可或缺的一部分。在 3GPP LTE 的第一版（即 Release 8）中，引入了正交频分多址（OFDMA）和多天线（MIMO）技术。3GPP 的 Release 10 版本经国际电信联盟的评估和测试，正式成为了第四代全球移动通信标准 LTE-Advanced。在 LTE-Advanced 标准中，引入了载波聚合（CA）和中继技术，增强了上行/下行 MIMO 技术，同时支持异构网络（HetNet）的部署。

为了满足未来家庭设备通信的市场需求和规模庞大的物联网(IOT)部署，3GPP 决定在 LTE 及其升级版本中引入低成本机器间通信技术（MTC: Machine Type Communication），将 MTC 服务由目前的 GSM 网络支持迁移至 LTE 网络支持，并定义了若干种新的 LTE 用户设备(UE: User Equipment)的类型，其一称之为低成本 MTC 用户设备（Low-cost MTC UE），该 MTC 用户设备在现有 LTE 网络的所有双工模式中支持 MTC 服务，并具有这样的性能：1）单接收天线；2）下行和上行最大的传输模块大小（TBS: Transport Block Size）为 1000 比特；3a）下行链路数据信道的基带带宽降低为 1.4MHz，下行链路控制信道的带宽与网络侧系统带宽保持一致，上行链路信道带宽以及下行链路的射频部分与现有 LTE 网络中的用户设备保持一致；3b）下行/上行链路控制信道和数据信道的基带带宽降低为 1.4MHz。

MTC 是一种不需要人为参与的数据通信服务。大规模的 MTC 用户设备部署，可以用于安全、跟踪、付账、测量以及消费电子等领域，具体涉及的应用包括视频监控、供货链跟踪、智能电表，远程监控等。MTC 用户设备要求较低的功率消耗，支持较低的数据传输速率和较低的移动性。

目前 LTE 系统主要是针对人与人（H2H）的通信服务。因此，实现 MTC 服务的规模竞争优势及应用前景，关键环节在于 LTE 网络支持低成本的 MTC 设备能够低成本，低复杂性的工作。

一些 MTC 用户设备需要安装在居民楼地下室或者由绝缘箔片、金属护窗或者传统建筑物的厚墙保护的位置，相比较 LTE 网络中常规设备终端（如手机，平板电脑等），这些设备的空中接口将明显遭受更严重的穿透损失。3GPP 决定研究 LTE 网络提供 MTC 用户设备附加 20dB/15dB 覆盖增强服务的方案设计与性能评估，值得注意的是，位于糟糕网络覆盖区域的 MTC 用户设备具有这样的特点：非常低的数据传输速率，非常宽松的延时要求，以及有限的移动性。针对 MTC 用户设备特点，LTE 网络可以进一步优化一些信令和/或信道用以支持 MTC 用户设备。3GPP 要求为新定义的MTC用户设备以及其他运行MTC服务(如，非常宽松的延迟要求）的用户设备提供一定的 LTE 网络覆盖增强，其中，对于 LTE 频分双工（FDD）网络提供 15dB 的网络覆盖增强。另外，并不是所有的运用 MTC 服务的用户设备都需要相同网络覆盖增强。

在 2014 年 6 月举行的 3GPP RAN#64 次全会上，提出了一个新的面向 Rel-13 的低复杂性和覆盖增强的 MTC 的工作项目（参见非专利文献：RP-140990 New Work Item on Even Lower Complexity and Enhanced Coverage LTE UE for MTC，Ericsson，NSN）。在该工作项目的描述中，LTE Rel-13 系统需要支持上下行 1.4MHz 射频带宽的 MTC 用户设备（User Equipment，UE，以下称为窄带 MTC UE）工作在任意的系统带宽（例如 1.4MHz、3 MHz、5 MHz、10 MHz、15 MHz、20 MHz 等等）下，并且为该类 MTC 用户提供覆盖增强功能。在系统设计时，低成本 MTC 用户和覆盖增强 MTC 用户要采用统一的设计方案。降低 MTC 用户设备的能耗是该工作项目的主要目标之一。

针对 3GPP LTE 用户设备运行 MTC 业务并处于覆盖增强模式下，物理层信道如(E)PDCCH/PDSCH/PUCCH/PUSCH 的覆盖增强设计与配置是一个需要标准化的工作，根据 3GPP RAN1 #74 会议的讨论，在完成初始接入过后，任何一个需要重复传输的物理信道，其配置模式取决于基站端。而 MTC 用户设备合并解调大量重复数据会引入 2 至 10 秒的延迟。这样的延迟会增加MTC用户设备的耗电量。根据 3GPP RAN1 #74b 会议的决定，

对于需要覆盖增强的 MTC 用户设备数据信道的传输应在控制信道传输完成之后。因此为了减少用户设备的耗电量，对于需要覆盖增强的 MTC 用户设备的寻呼消息传输可以不需要控制信道。同时由于低复杂度 MTC 用户设备（Low complexity MTC UE）与覆盖增强的 MTC 用户设备具有相似的信息传输机制，需要设计一种同时针对覆盖增强 MTC 用户设备和/或低复杂度或低成本的 MTC 用户设备的寻呼消息传输机制。因此在 Rel-12 及其之后版本中，针对覆盖增强模式下 MTC 用户设备和/或低复杂度或低成本的 MTC 用户设备的寻呼消息传输需要重新标准化。

发明内容

本发明旨在提供同时针对例如覆盖增强 MTC 用户设备和/或低复杂度或低成本的 MTC 用户设备的寻呼消息传输机制。

根据本发明的一个方案，提供了一种用户设备接收寻呼消息的方法。该方法包括：接收对用于发送所述寻呼消息的物理资源块集的指示，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的；以及在所指示的物理资源块集上接收所述寻呼消息。

根据本发明的另一个方案，提供了一种网络节点发送寻呼消息的方法。该方法包括：根据所述寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；向作为所述寻呼消息的接收方的用户设备通知对所述物理资源块集的指示，以及在所确定的物理资源块集上发送所述寻呼消息。

根据本发明的另一个方案，提供了一种用户设备。该用户设备包括：接收单元，用于接收对用于发送所述寻呼消息的物理资源块集的指示，以及用于在所指示的物理资源块集上接收所述寻呼消息，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的。

根据本发明的另一个方案，提供了一种网络节点。该基站包括：块集索引确定单元，用于根据寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引，以及发送单元，用于向作为所述寻呼消息的接收方的用户设备通知对所述块集索引确定单元确定的物理资源块集的指示，以及用于在所述确定的物理资源块集上发送所述寻呼消息。

本发明的上述方案简单易行，并且由于用于发送寻呼消息的物理资源块的参数（例如索引）取决于寻呼消息的等级，而该寻呼消息等级同样可用于对 MTC 用户设备进行覆盖增强，因此该方案同时适用于覆盖增强 MTC 用户设备和/或低复杂度或低成本的 MTC 用户设备的寻呼消息传输。

附图说明

通过下文结合附图的详细描述，本发明的上述和其它特征将会变得更加明显，其中：

图 1 示出了根据本发明的接收寻呼消息的方法的流程图；

图 2 示出了根据本发明的发送寻呼消息的方法的流程图；

图 3 示出了根据本发明的用于接收寻呼消息的用户设备的示意性框图；

图 10 示出了将系统频带划分为多个子频带的示意图。

具体实施方式

以下将结合附图和具体实施例，对本发明所提出的针对需要额外覆盖增强的 MTC 用户设备或者低复杂度/低成本 MTC 用户设备的寻呼消息在频域资源上的发送/接收方法、网络节点和用户设备（UE）进行详细阐述。应当注意的是，虽然本发明是针对需要额外覆盖增强或者低复杂度/低成本 MTC 用户设备来阐述的，但其同样也适用于其他支持延迟容忍服务和/或需要一定覆盖增强的用户设备。应当注意的是，本发明不应局限于下文所述的具体实施例。另外，为了简便起见，省略了对与本发明没有直接关联的公知技术的详细描述，以防止对本发明的理解造成混淆。

下文以 LTE 移动通信系统及其后续的演进版本作为示例应用环境，具体描述了根据本发明的多个实施例。然而，需要指出的是，本发明不限于以下实施例，而是可适用于更多其它的无线通信系统，例如今后的 5G 蜂窝通信系统或现有的其他通信系统，只要其要求提供同时针对覆盖增强 MTC 用户设备和/或低复杂度或低成本的 MTC 用户设备的寻呼消息传输机制。

图 1 示出了根据本发明的一个实施例的寻呼消息接收方法。在图 1 的步骤 110 中，用户设备接收对用于发送寻呼消息的物理资源块集的指示，其中，物理资源块集在子帧中的索引是根据寻呼消息的等级确定的。在步骤 120 中，用户设备在所指示的物理资源块集上接收寻呼消息。

在本发明的一些实施例中，寻呼消息的等级是通过以下方式之一获得的：由基站通过广播系统信息和/或用户设备专用无线电资源控制信令配置；由网络侧通过 NAS 信令配置；以及由用户设备根据其测量结果确定。

在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

在本发明的另一些实施例中，物理资源块集的大小根据寻呼消息的等级确定。

在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

在本发明的一些实施例中，接收对用于发送寻呼消息的物理资源块集的指示包括：通过广播系统信息和/或用户设备专用的无线电资源控制(UE dedicated Radio Resource Control)信令从基站接收物理资源块集在子帧中的索引和/或物理资源块集的大小；或通过非接入层（NAS）信令从网络侧设备接收物理资源块集在子帧中的索引和/或物理资源块集的大小。

在本发明的一些实施例中，该用户设备使用的系统带宽包括 6 个物理资源块。在该情况下，物理资源块集是系统带宽的子集

然而，也可能存在系统带宽大于 6 个物理资源块的情况。在本发明的一些实施例中，当系统带宽大于 6 个物理资源块时，系统带宽可包括多个子频带。该多个子频带中的每一个包含不多于 6 个的物理资源块。例如，在系统带宽中包含的物理资源块的数目能够被 6 整除时，该多个子频带中的每一个包含 6 个物理资源块。然而当系统带宽中包含的物理资源块的数目不能够被 6 整除时，该多个子频带中的一个子频带包含的物理资源块可以小于 6 个，而其他子频带可以均包含 6 个物理资源块。也可以存在其他的子频带分配方式，例如在其他通信系统中可以使用除 6 之外的其他物理资源块数目。只要寻呼消息对应的物理资源块的数目小于该子频带具有的资源块的总数目，便可以使用本文上述的方案确定该子频带中用于该寻呼消息的资源块集的起始位置索引和大小，本发明不受限于系统带宽/子频带中包含的具体资源块的数目。

在上述任一情况下，寻呼消息在多个子频带中由网络节点（例如基站或网络侧）确定的一个子频带上接收。

图 2 示出了根据本发明的一个实施例的网络节点侧的寻呼消息发送方法。在图 2 所示的流程图中，该方法包括：步骤 210，根据寻呼消息的等级确定用于发送寻呼消息的物理资源块集在子帧中的索引；步骤 220，向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示；以及步骤 230，在所确定的物理资源块集上发送寻呼消息。

在本发明的一些实施例中，寻呼消息的等级是通过以下方式之一获得的：由网络节点预先存储，由上级网络节点通知（例如，在网络节点是基站的情况下，由网络侧通过 S1 寻呼消息指示）；以及用户设备根据其测量结果确定并通知网络节点。

在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

在本发明的一些实施例中，物理资源块集的大小根据寻呼消息的等级确定。

在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

在本发明的一些实施例中，寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

在本发明的一些实施例中，向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示包括：如果网络节点是基站，通过广播系统信息和/或用户设备专用的无线电资源控制信令向用户设备发送物理资源块集在子帧中的索引和/或物理资源块集的大小；或如果网络节点是网络侧设备，通过非接入层信令向用户设备发送物理资源块集在子帧中的索引和/或物理资源块集的大小。然而本发明不限于此，例如基站也可以使用其他的群发机制（例如，多播机制等）来发送物理资源块集在子帧中的索引。

在本发明的一些实施例中，网络节点为用户设备分配的系统带宽包括 6 个物理资源块。在该情况下，物理资源块集是所述系统带宽的子集。

在本发明的一些实施例中，当网络节点为用户设备分配的系统带宽大于 6 个物理资源块时，将所述系统带宽划分为包含不多于 6 个物理资源块的多个子频带，以及确定所述多个子频带中要在其上向用户设备发送寻呼消息的一个子频带。

图 3 示出了用于根据本发明的实施例发送寻呼消息的用户设备。该用户设备至少包括：接收单元 310，用于接收对用于发送寻呼消息的物理资源块集的指示，且用于在所指示的物理资源块集上接收寻呼消息，其中，物理资源块集在子帧中的索引是根据寻呼消息的等级确定的。

在本发明的一些实施例中，寻呼消息的等级是由基站通过广播系统信息和/或用户设备专用无线电资源控制信令配置或由网络侧通过 NAS 信令配置，并通过接收单元 310 接收的。在本发明的另一些实施例中，用户设

备还包括用于测量信道状态的测量单元 320，以及用于根据测量单元的测量结果确定寻呼消息的等级的等级确定单元 330。

在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

在本发明的一些实施例中，物理资源块集的大小由网络节点（根据不同的实现，可以是基站或网络侧设备，如移动性管理实体（MME））根据寻呼消息的等级确定，并通过广播系统信息和/或用户设备专用无线电资源控制信令由接收单元 310 接收。

对物理资源块集的指示可以包括物理资源块集在子帧中的索引以及物理资源块集的大小。在本发明的一些实施例中，接收单元 310 还用于通过广播系统信息和/或用户设备专用的无线电资源控制(UE dedicated RRC)信令从基站接收物理资源块集在子帧中的索引和/或物理资源块集的大小。或者在其他一些实施例中，接收单元 310 还用于通过非接入层信令从网络侧设备接收物理资源块集在子帧中的索引和/或物理资源块集的大小。

在本发明的一些实施例中，用户设备使用的系统带宽包括 6 个物理资源块，以及物理资源块集是所述系统带宽的子集。

在本发明的一些实施例中，当用户设备使用的系统带宽大于 6 个物理资源块时，系统带宽包括多个子频带，该多个子频带中的每一个包含不多于 6 个的物理资源块。在该情况下，寻呼消息由接收单元 310 在所述多个子频带中由网络节点（基站或网络侧）确定的一个子频带上接收。

在本发明的一些实施例中，用户设备还包括存储器 340，用于存储接收单元 310 接收到的各种信息，例如寻呼消息、物理资源块集的大小、物理资源块集在子帧中的索引以及其他用户设备接收到的信息等。存储器 350 还可以存储测量单元 320、等级确定单元 330 所使用或输出的信息，例如测量单元 320 的测量结果，在该情况下，等级确定单元 330 可从存储器 350 获得该测量结果。存储器 350 还可以存储发送单元 340 要发送的信息，例如等级确定单元 330 确定的寻呼消息的等级。

图 4 示出了根据本发明的实施例发送寻呼消息的网络节点。图 4 示出

的网络节点至少包括：块集索引确定单元 410，用于根据寻呼消息的等级确定用于发送寻呼消息的物理资源块集在子帧中的索引；以及发送单元 420，用于向作为寻呼消息的接收方的用户设备通知对块集索引确定单元 410 确定的物理资源块集的指示，以及用于在所确定的物理资源块集上发送寻呼消息。

在本发明的一些实施例中，网络节点还包括接收单元 430。其中，寻呼消息的等级由网络节点预先存储，或者由上级网络节点通知，或由用户设备根据其测量结果确定并通知网络节点，并由接收单元 430 接收。

在本发明的一些实施例中，物理资源块集在子帧中的索引是指物理资源块集的起始资源块在子帧中的索引。

在本发明的一些实施例中，物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

在本发明的一些实施例中，网络节点还包括：块集大小确定单元 440，用于根据寻呼消息的等级确定物理资源块集的大小。

在本发明的一些实施例中，网络节点还包括：重复次数确定单元 450，用于根据寻呼消息的等级确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

在本发明的一些实施例中，网络节点还包括：捆绑大小确定单元 460，用于根据寻呼消息的等级确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和、或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

在本发明的一些实施例中，如果网络节点是基站，发送单元 420 通过广播系统信息和/或用户设备专用的无线电资源控制(UE dedicated RRC)信令向用户设备发送物理资源块集在子帧中的索引和/或物理资源块集的大小；或者如果网络节点是网络侧设备，发送单元 420 通过非接入层信令向用户设备发送物理资源块集在子帧中的索引和/或物理资源块集的大小。

在本发明的一些实施例中，网络节点为用户设备分配的系统带宽包括 6 个物理资源块。在该情况下所述物理资源块集是系统带宽的子集。

在本发明的一些实施例中，网络节点还包括：子频带划分单元 470，用于当网络节点为用户设备分配的系统带宽大于 6 个物理资源块时，将所述系统带宽划分为包含不多于 6 个物理资源块的多个子频带；以及子频带确定单元 480，用于确定所述子频带划分单元 470 划分的所述多个子频带中要在其上向用户设备发送寻呼消息的一个子频带。

在本发明的一些实施例中，网络节点还包括存储器 490。存储器 490 可存储发送单元 420 要发送的信息，如寻呼消息，也可以存储接收单元 430 接收到的信息，例如接收单元 430 从网络侧（例如 MME）或用户设备接收到的寻呼消息的等级。存储器 490 还可以存储块集索引确定单元 410、块集大小确定单元 440、重复次数确定单元 450、捆绑大小确定单元 460、子频带划分单元 470、子频带确定单元 480 等单元所需的信息或输出的信息。

本发明的上述网络节点可以是基站，也可以是网络侧设备，例如网络侧的移动性管理实体（MME），当然，也可以是本领域技术人员通常使用来配置传输/移动性参数的任何网络侧设备。本发明不对此进行限制。

需要注意的是，在图 3 和图 4 中描述的用户设备和网络节点仅是为了使本领域技术人员更清楚地理解本发明而作的图，其中省略了一些对理解本发明不必要的模块/组件，本发明的保护范围不应受这些附图的具体细节所限制。此外，实际的设备中可以包括更多的模块/组件，如显示器、操作维护接口（对于图 4 中的网络节点）、输入输出接口等等。本发明不对这些进行限制。

下面将参考图 5 至图 10 来对图 1 和图 2 中示出的方法以及图 3 和图 4 中示出的设备进行更详细地阐述。需要注意的是，本发明中多数信息的确定和发送既可以由基站完成，也可以由网络侧设备完成。因此，除非特别说明，在本说明书中可以将术语基站、网络侧设备（如 MME）以及网络节点交换使用。此外，如上所述，虽然本发明主要针对需要额外覆盖增强或者低复杂度/低成本 MTC 用户设备来阐述的，但其同样也适用于其他支持延迟容忍服务和/或需要一定覆盖增强的用户设备。

对覆盖增强 MTC UE 而言，其上、下行物理信道需要多次重复发送，以满足信道的覆盖增强要求。处于不同地理位置的 UE 所需的信道覆盖增强程度不一样，导致处于不同地理位置的 UE 的物理信道所需重复发送的

次数不同。因此，可以将物理信道的覆盖增强程度分为若干个不同的覆盖增强等级。而不同覆盖增强等级的物理信道，其所需重复发送的次数不同。例如，可以将物理信道分为四个覆盖增强等级（CE0, CE1, CE2 和 CE3），每个覆盖增强等级对应物理信道所需的不同覆盖增强补偿，例如，CE0 指代的是覆盖增强等级 0，即不需要覆盖增强；CE1 指代的是覆盖增强等级 1，即需要例如 1~5dB 覆盖增强，其物理信道大致需要数次重复传输；CE2 指代的是覆盖增强等级 2，即需要例如 6~10dB 覆盖增强，其物理信道大致需要十数次重复传输；CE3 指代的是覆盖增强等级 3，即需要例如 11~15dB 覆盖增强，其物理信道大致需要数十次重复传输。然而，需要注意的是，本发明的技术方案不限于四个覆盖增强等级，而是可以根据需要采用更多或更少的覆盖增强等级。还需要注意的是，上述物理信道的重复次数仅是为了使本领域技术人员理解本发明而给出的示例，具体系统中使用的重复次数不限于上述次数，而是可以根据系统需求/限制（例如系统资源限制）选择更多或更少的次数。

由于寻呼消息对应的控制信道不传输，因此需要给出 MTC 用户设备的寻呼消息在频域上的位置。在本发明的技术方案中，网络节点（例如基站）将不同等级的寻呼消息映射到不同的资源块集（RBgroup）来指示寻呼消息在频域上的位置。在本文中，资源块集指的是寻呼消息在子帧上占用的物理资源块的集合。资源块集的大小是指寻呼消息在子帧上占用的资源块的数目。此处资源块集可以是物理资源块集（PRB group），也可以是虚拟资源块集（VRB group），物理资源块与虚拟资源块间的映射关系可参考 3GPP TS36.211 6.2.3.1，本发明不再进行赘述。在本发明的技术方案中，可以对多个资源块进行虚拟连续分配，即虚拟资源块集的集中式分配（virtual resource blocks of localized type）。此处虚拟资源块集的集中式分配指的是将虚拟资源块 n_{VRB} 直接映射到物理资源块 n_{PRB}。而虚拟资源块的大小与物理资源块的大小一致。

寻呼消息可以占用多个子帧，不同等级的寻呼消息占用的子帧数目可以不同。不同的用户设备占用的子帧也可以不同。例如，用户设备可根据用户 ID 在不同的子帧上接收寻呼消息，或通过 3GPP 协议中用于寻呼消息的时域复用的方法来进行子帧分配。在本发明的一些实施例中，需要确定确定两个参数，承载寻呼消息的物理资源块集的起始位置及连续分配的

资源块数目。然而在另一些实施例中，由于承载寻呼消息的物理资源块集的大小（即，连续分配的资源块数目）被预先确定，且对于不同等级的寻呼消息而言是相同的，仅需要确定物理资源块集的起始位置。

再次返回图 2，在图 2 的步骤 210 中，根据寻呼消息的等级确定用于发送寻呼消息的物理资源块集在子帧中的索引。该步骤由图 4 中的块集索引确定单元 410 执行。在本发明中，物理资源块集的起始位置与物理资源块集在子帧中的索引表达相同的概念，可相互交换使用。基于承载不同等级的寻呼消息的资源块集的大小是否一致，本发明提出了两种方案。网络节点和用户设备可同时支持两种方式或其中的一种。

图 5 示出了承载不同等级的寻呼消息的资源块集的大小一致的情况。如图 5 所示，系统带宽为 6 个物理资源块大小，且承载不同等级的寻呼消息的资源块集的大小是一样的，相应的资源块集的起始位置由基站和/或网络侧（例如 MME）配置，其原则可以是尽量利用子帧中的物理资源块，也可以是本领域技术人员可想到或通常使用的其他原则。在图 5 所示的示例中，资源块集的起始位置与不同等级的寻呼消息的关系可以是：覆盖增强等级 0 的寻呼消息对应的资源块集的起始位置索引为 0 或 4；覆盖增强等级 1 的寻呼消息对应的资源块集的起始位置索引为 1；覆盖增强等级 2 的寻呼消息对应的资源块集的起始位置索引为 2；覆盖增强等级 3 的寻呼消息对应的资源块集的起始位置索引为 3。在图 5 的示例中，相应的承载寻呼消息的资源块集的大小为例如 2 个资源块，然而在其他示例中也可以是更大或更小的其他数目，且可以采用与图 5 不同的索引分配模式。

寻呼消息的等级可以由基站通过广播信息和/或用户设备专用 RRC 信令配置给用户设备，或者可以由网络侧（例如 MME）通过 NAS 信令配置给用户设备。在一些示例中，寻呼消息的等级可以由用户设备根据自己的下行链路测量结果确定。例如，用户设备通过测量单元 320 执行信道测量，并使用等级确定单元 330 根据测量得到的下行信道的参考信号接收功率（RSRP）值与特定阈值比较。该特定阈值可以是在 3GPP 技术规范 TS36.104 中规定的阈值，可由用户设备通过接收单元 310 从基站/网络侧先行接收到的，并预先存储在用户设备的存储单元 350 中。如果大于或等于该阈值，则等级确定单元 330 确定寻呼消息等级为 0；小于该阈值 1~5dB，则确定寻呼消息等级为 1；小于该阈值 6~10dB，则确定寻呼消息等级为 2；

小于该阈值 11~15dB，则确定寻呼消息等级为 3。

可选地，在确定寻呼消息等级之后，用户设备/基站/网络侧可存储该寻呼消息等级，以用于下一次的资源块集起始位置确定或用于其他用途。

在块集索引确定单元 410 确定用于发送寻呼消息的物理资源块集在子帧中的索引之后，在步骤 220 中，网络节点向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示。在一些实施例中，该对物理资源块集的指示可包括块集索引确定单元 410 确定的物理资源块集在子帧中的索引，并可选地包括物理资源块集的大小。然而在另一些实施例中，物理资源块集的大小已由被预先通知给了用户设备。

承载不同等级的寻呼消息的资源块的数目可以是预定的，并例如可由基站通过广播信息和/或用户设备专用 RRC 信令配置给用户设备。在其他一些示例中，承载不同等级的寻呼消息的资源块的数目可以由网络侧（例如，MME）通过 NAS 信令配置。此外，基站可通过广播系统信息和/或用户设备专用 RRC 信令通知物理资源块集在子帧中的索引；或网络侧（例如，MME）可通过 NAS 信令通知该索引。在本发明中，子帧中承载寻呼消息的资源块集的索引与这些资源块中起始资源块的索引表达相同的含义，可以互换使用。

在一些示例中，寻呼消息的等级可被基站的重复次数确定单元 450 用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

在一些示例中，寻呼消息的等级可被基站的捆绑大小确定单元 460 用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道，物理上行控制信道和物理随机接入信道的 TTI bundle（Transmission Time Interval bundle: 传输时间间隔捆绑）大小。

图 6 示出了不同等级的寻呼消息与相应的资源块起始位置索引的对应关系的另一示意图。然而该图仅是为说明本发明而做出的示例，本发明不应被其所限制。例如，寻呼消息等级也可以对应于两个资源块起始位置，如索引 0 和 4，而不仅限于索引 0。

图 7 示出了承载不同等级的寻呼消息的资源块集的大小不一致的情况。如图 7 所示，系统带宽为 6 个物理资源块大小，且承载不同等级的寻呼消息的资源块集的大小是不一样的，相应的资源块集的起始位置由基站和/

或网络侧（例如，MME）配置，其原则可以是尽量利用子帧中的物理资源块，也可以是本领域技术人员可想到或通常使用的其他原则。在图 7 所示的示例中，资源块集的起始位置与不同等级的寻呼消息的关系可以是：覆盖增强等级 0 的寻呼消息对应的资源块集的起始位置索引为 0；覆盖增强等级 1 的寻呼消息对应的资源块集的起始位置索引为 3；覆盖增强等级 2 的寻呼消息对应的资源块集的起始位置索引为 2；覆盖增强等级 3 的寻呼消息对应的物理资源块集的起始位置索引为 1。

在图 7 示出的示例中，承载不同等级的寻呼消息的资源块集的大小不一致，因此需要对资源块集的大小进行确定。该操作可以由图 4 中的块集大小确定单元 440 执行。在一些示例中，承载不同等级的寻呼消息的资源块的数目可以是：覆盖增强等级 0 的寻呼消息对应的资源块的数目为 2；覆盖增强等级 1 的寻呼消息对应的资源块的数目为 3；覆盖增强等级 2 的寻呼消息对应的资源块的数目为 4；覆盖增强等级 3 的寻呼消息对应的资源块的数目为 5。当然，本领域技术人员也可以根据实际需求（例如系统资源限制等）选择不同的资源块集大小分配方案，理论上只要覆盖增强等级较高的寻呼消息对应更多数目的资源块即可。

图 7 所示情形的其他技术特征与图 5 所示情形相同，在此不再赘述。

图 8 示出了在承载不同等级的寻呼消息的资源块集的大小不一致的情况下，寻呼消息等级与资源块集大小的映射关系。图 9 示出了在承载不同等级的寻呼消息的资源块集的大小不一致的情况下，寻呼消息等级与资源块起始位置的映射关系。如上所述，这些映射关系都仅是为了说明本发明而做出的示例，本发明不应被其所限制。

在块集索引确定单元 410 确定用于发送寻呼消息的物理资源块集在子帧中的索引以及块集大小确定单元 440 确定该物理资源块集的大小之后，在步骤 220 中，网络节点向作为寻呼消息的接收方的用户设备通知对物理资源块集的指示。在一些实施例中，该对物理资源块集的指示可包括块集索引确定单元 410 确定的物理资源块集在子帧中的索引以及块集大小确定单元 440 确定的该物理资源块集的大小。

在步骤 230 中，网络单元的发送单元 420 在所确定的物理资源块集上发送寻呼消息。

然而，在 3GPP LTE 中，也可能存在系统带宽大于 6 个物理资源块的

情况。图 10 示出了在该情形下根据本发明的处理。如图 10 所示，当系统带宽大于 6 个物理资源块时，可将系统带宽分成多个子频带。在每一个子频带中依然可执行图 1-9 中所示的技术方案。在图 10 所示情况下，网络节点还需要通过发送单元 430 向用户设备通知子频带的划分。子频带可以是连续的 6 个物理资源块。同样地，子频带的划分可以由基站通过广播系统信息和/或用户设备专用无线电资源控制信令配置给用户设备，或者由网络侧（例如，MME）通过 NAS 信令配置给用户设备。

作为一般性的示例，可以假设系统带宽包含 M 个 PRB，并可被划分成 N 个子频带，其中 M 和 N 需满足 N = floor（M，6），即 N 是小于 M 除与 6 的最大自然数。这样整个系统带宽可划分为 N 个带宽大小为 6 个物理资源块的子频带和一个带宽大小为（M-6*N）个物理资源块的子频带。从上式可以看出，在 M 不是 6 的整倍数的情况下，可能包括子频带具有小于 6 个物理资源的情况。在这种情况下，只要寻呼消息对应的物理资源块的数目小于该子频带具有的资源块的总数目，依然可以使用本文上述的方案确定该子频带中用于该寻呼消息的资源块集的起始位置索引和大小，本发明不受限于系统带宽/子频带中包含的具体资源块的数目。

用户设备需要在一个子频带上接收寻呼消息，该子频带是在配置/确定物理资源块集在子帧中的索引和/或物理资源块的大小之前确定的。在本发明的一些实施例中，可以根据寻呼消息的等级来确定用户设备所使用的子频带。例如可通过以下公式：**[*index of sub-band*] = [*UE ID*] mod [*the number of sub-band*]**来确定用户设备所使用的子频带。其中 UE ID 可以是国际移动用户标识（IMSI，International Mobile Subscriber Identity），用于在核心网中唯一标识一个用户。该标识存储在 SIM 卡中。当然，在本发明的其他实施例中，本领域技术人员也可以使用唯一标识用户的其他可能的标识符，并对上式进行适应性修改，本发明不对此进行限制。

在用户设备侧，用户设备的接收单元 310 在步骤 110 中接收对用于发送寻呼消息的物理资源块集的指示。该指示可以包括其用于接收寻呼消息的物理资源块集在子帧中的索引。在一些情况下，该指示还可以包括物理资源块集的大小。而在另一些情况下，物理资源块集的大小已由网络节点确定并在之前发送给用户设备（例如，物理资源块集的大小对不同寻呼消息等级而言固定的情况下）。

然后，在步骤 120 中，用户设备可通过接收单元 310 在所指示的物理资源块集上接收寻呼消息。

当用户设备处于 RRC CONNECT 状态时，基站和/或网络侧（例如，MME）已经配置用户设备工作在一个子频带上接收数据。此时，当用户设备需要被寻呼时，该寻呼消息可在当前的子频带上传输，用于发送该寻呼消息的物理资源块集可通过根据本发明附图 1 至 9 中所述的方法来确定。

应该理解，本发明的上述实施例可以通过软件、硬件或者软件和硬件两者的结合来实现。例如，上述实施例中的基站和用户设备内部的各种组件可以通过多种器件来实现，这些器件包括但不限于：模拟电路器件、数字电路器件、数字信号处理（DSP）电路、可编程处理器、专用集成电路（ASIC）、现场可编程门阵列（FPGA）、可编程逻辑器件（CPLD），等等。

在本申请中，“基站”是指具有较大发射功率和较广覆盖面积的移动通信数据和控制交换中心，包括资源分配调度、数据接收发送等功能。“用户设备”是指用户移动终端，例如包括移动电话、笔记本等可以与基站或者微基站进行无线通信的终端设备。

此外，这里所公开的本发明的实施例可以在计算机程序产品上实现。更具体地，该计算机程序产品是如下的一种产品：具有计算机可读介质，计算机可读介质上编码有计算机程序逻辑，当在计算设备上执行时，该计算机程序逻辑提供相关的操作以实现本发明的上述技术方案。当在计算系统的至少一个处理器上执行时，计算机程序逻辑使得处理器执行本发明实施例所述的操作（方法）。本发明的这种设置典型地提供为设置或编码在例如光介质（例如 CD-ROM）、软盘或硬盘等的计算机可读介质上的软件、代码和/或其他数据结构、或者诸如一个或多个 ROM 或 RAM 或 PROM 芯片上的固件或微代码的其他介质、或一个或多个模块中的可下载的软件图像、共享数据库等。软件或固件或这种配置可安装在计算设备上，以使得计算设备中的一个或多个处理器执行本发明实施例所描述的技术方案。

尽管以上已经结合本发明的优选实施例示出了本发明，但是本领域的技术人员将会理解，在不脱离本发明的精神和范围的情况下，可以对本发明进行各种修改、替换和改变。因此，本发明不应由上述实施例来限定，而应由所附权利要求及其等价物来限定。

权 利 要 求

1. 一种用户设备接收寻呼消息的方法，包括：

接收对用于发送所述寻呼消息的物理资源块集的指示，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的；以及

在所指示的物理资源块集上接收所述寻呼消息。

2. 根据权利要求1所述的方法，其中，所述寻呼消息的等级是通过以下方式之一获得的：

由基站通过广播信息和/或用户设备专用无线电资源控制信令配置；

由网络侧通过NAS信令配置；以及

由所述用户设备根据其测量结果确定。

3. 根据权利要求1所述的方法，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

4. 根据权利要求1所述的方法，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

5. 根据权利要求1所述的方法，其中，所述物理资源块集的大小根据所述寻呼消息的等级确定。

6. 根据权利要求1所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

7. 根据权利要求1所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

8. 根据权利要求1所述的方法，其中，接收对用于发送所述寻呼消息的物理资源块集的指示包括：

通过广播系统信息和/或用户设备专用无线电资源控制信令从基站接收所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小；或

通过非接入层信令从网络侧设备接收所述物理资源块集在子帧中的

索引和/或所述物理资源块集的大小。

9. 根据权利要求1所述的方法，其中，所述用户设备使用的系统带宽包括6个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

10. 根据权利要求1所述的方法，其中，当所述用户设备使用的系统带宽大于6个物理资源块时，所述系统带宽包括多个子频带，所述多个子频带中的每一个包含不多于6个的物理资源块，所述寻呼消息在所述多个子频带中由网络节点确定的一个子频带上接收。

11. 一种网络节点发送寻呼消息的方法，包括：

根据所述寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；

向作为所述寻呼消息的接收方的用户设备通知对所述物理资源块集的指示，以及

在所确定的物理资源块集上发送所述寻呼消息。

12. 根据权利要求11所述的方法，其中，所述寻呼消息的等级是通过以下方式之一获得的：

由所述网络节点预先存储；

由上级网络节点通知；或

用户设备根据其测量结果确定并通知所述网络节点。

13. 根据权利要求11所述的方法，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

14. 根据权利要求11所述的方法，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

15. 根据权利要求11所述的方法，其中，所述物理资源块集的大小根据所述寻呼消息的等级确定。

16. 根据权利要求11所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

17. 根据权利要求11所述的方法，其中，所述寻呼消息的等级还用于确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信

道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

18. 根据权利要求11所述的方法，其中，向作为所述寻呼消息的接收方的用户设备通知对所述物理资源块集的指示包括：

如果所述网络节点是基站，通过广播系统信息和/或用户设备专用无线电资源控制信令向所述用户设备发送所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小；或

如果所述网络节点是网络侧设备，通过非接入层信令向所述用户设备发送所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小。

19. 根据权利要求11所述的方法，其中，所述网络节点为用户设备分配的系统带宽包括6个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

20. 根据权利要求11所述的方法，还包括：当所述网络节点为用户设备分配的系统带宽大于6个物理资源块时，将所述系统带宽划分为包含不多于6个物理资源块的多个子频带，以及确定所述多个子频带中要在其上向所述用户设备发送寻呼消息的一个子频带。

21. 一种用户设备，包括：

接收单元，用于接收对用于发送所述寻呼消息的物理资源块集的指示，以及用于在所指示的物理资源块集上接收所述寻呼消息，其中，所述物理资源块集在子帧中的索引是根据所述寻呼消息的等级确定的。

22. 根据权利要求21所述的用户设备，其中，所述寻呼消息的等级是由基站通过广播信息和/或用户设备专用无线电资源控制信令配置或由网络侧通过NAS信令配置，并通过所述接收单元接收的；或者

所述用户设备还包括：

测量单元，用于测量信道状态；以及

等级确定单元，用于根据所述测量单元的测量结果确定所述寻呼消息的等级。

23. 根据权利要求21所述的用户设备，其中，所述物理资源块集在子帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

24. 根据权利要求21所述的用户设备，其中，所述物理资源块集的大

小对于不同等级的寻呼消息而言是相同的。

25. 根据权利要求21所述的用户设备，其中，所述物理资源块集的大小由网络节点根据所述寻呼消息的等级确定，并通过广播信息和/或用户设备专用无线电资源控制信令由所述接收单元接收。

26. 根据权利要求21所述的用户设备，其中，对所述物理资源块集的指示包括所述物理资源块集在子帧中的索引以及所述物理资源块集的大小；以及

所述接收单元还用于通过广播系统信息和/或用户设备专用无线电资源控制信令从基站接收所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小；或

所述接收单元还用于通过非接入层信令从网络侧设备接收所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小。

27. 根据权利要求21所述的用户设备，其中，所述用户设备使用的系统带宽包括6个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

28. 根据权利要求21所述的用户设备，其中，当所述用户设备使用的系统带宽大于6个物理资源块时，所述系统带宽包括多个子频带，所述多个子频带中的每一个包含不多于6个的物理资源块，所述寻呼消息由所述接收单元310在所述多个子频带中由网络节点确定的一个子频带上接收。

29. 一种网络节点，包括：

块集索引确定单元，用于根据寻呼消息的等级确定用于发送所述寻呼消息的物理资源块集在子帧中的索引；以及

发送单元，用于向作为所述寻呼消息的接收方的用户设备通知对所述块集索引确定单元确定的物理资源块集的指示，以及用于在所述确定的物理资源块集上发送所述寻呼消息。

30. 根据权利要求29所述的网络节点，还包括接收单元，

其中，所述寻呼消息的等级由所述网络节点预先存储，或者由上级网络节点通知，或者由用户设备根据其测量结果确定并通知所述网络节点，并由所述接收单元接收。

31. 根据权利要求29所述的网络节点，其中，所述物理资源块集在子

帧中的索引是指所述物理资源块集的起始资源块在子帧中的索引。

32 根据权利要求29所述的网络节点，其中，所述物理资源块集的大小对于不同等级的寻呼消息而言是相同的。

33. 根据权利要求29所述的网络节点，还包括：块集大小确定单元，用于根据所述寻呼消息的等级确定所述物理资源块集的大小。

34. 根据权利要求29所述的网络节点，还包括：重复次数确定单元，用于根据所述寻呼消息的等级确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的重复次数。

35. 根据权利要求29所述的网络节点，还包括：捆绑大小确定单元，用于根据所述寻呼消息的等级确定一个或多个物理下行共享信道，物理上行共享信道，物理下行控制信道和/或增强型物理下行控制信道，物理上行控制信道和物理随机接入信道的传输时间间隔捆绑大小。

36. 根据权利要求29所述的网络节点，其中，对所述物理资源块集的指示包括所述物理资源块集在子帧中的索引以及所述物理资源块集的大小；以及

如果所述网络节点是基站，所述发送单元通过广播系统信息和/或用户设备专用无线电资源控制信令向用户设备发送所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小；或

如果所述网络节点是网络侧设备，所述发送单元通过非接入层信令向用户设备发送所述物理资源块集在子帧中的索引和/或所述物理资源块集的大小。

37. 根据权利要求29所述的网络节点，其中，所述网络节点为用户设备分配的系统带宽包括6个物理资源块，以及所述物理资源块集是所述系统带宽的子集。

38. 根据权利要求29所述的网络节点，还包括：

子频带划分单元，用于当所述网络节点为用户设备分配的系统带宽大于6个物理资源块时，将所述系统带宽划分为包含不多于6个物理资源块的多个子频带；以及

子频带确定单元，用于确定所述子频带划分单元划分的所述多个子频

带中要在其上向用户设备发送寻呼消息的一个子频带。

(54) Title: PERFORMING MISSION CRITICAL COMMUNICATIONS AT A USER EQUIPMENT (UE)

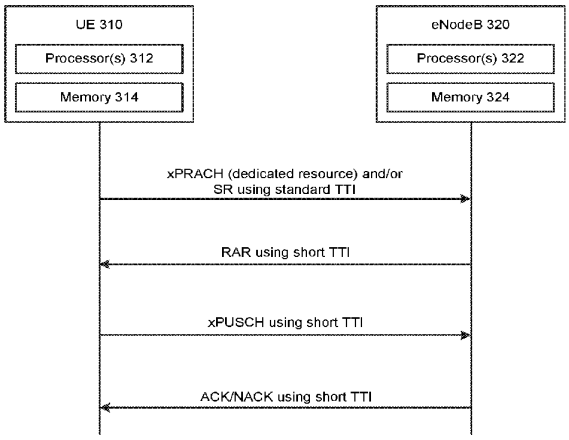

FIG. 3

(57) Abstract: Technology for a user equipment (UE) operable to perform mission critical communications with an eNodeB is disclosed. The UE can transmit a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB. The PRACH signal can be transmitted in accordance with a first transmission time interval (TTI). The UE can receive a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication. The RAR message can be transmitted from the eNodeB using a second TTI. The UE can perform the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message. The mission critical communication can be performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

PERFORMING MISSION CRITICAL COMMUNICATIONS AT A USER EQUIPMENT (UE)

BACKGROUND

[0001] Wireless mobile communication technology uses various standards and protocols to transmit data between a node (e.g., a transmission station) and a wireless device (e.g., a mobile device). Some wireless devices communicate using orthogonal frequency-division multiple access (OFDMA) in a downlink (DL) transmission and single carrier frequency division multiple access (SC-FDMA) in uplink (UL). Standards and protocols that use orthogonal frequency-division multiplexing (OFDM) for signal transmission include the third generation partnership project (3GPP) long term evolution (LTE), the Institute of Electrical and Electronics Engineers (IEEE) 1202.16 standard (e.g., 1202.16e, 1202.16m), which is commonly known to industry groups as WiMAX (Worldwide interoperability for Microwave Access), and the IEEE 1202.11 standard, which is commonly known to industry groups as WiFi.

[0002] In 3GPP radio access network (RAN) LTE systems, the node can be a combination of Evolved Universal Terrestrial Radio Access Network (E-UTRAN) Node Bs (also commonly denoted as evolved Node Bs, enhanced Node Bs, eNodeBs, or eNBs) and Radio Network Controllers (RNCs), which communicates with the wireless device, known as a user equipment (UE). The downlink (DL) transmission can be a communication from the node (e.g., eNodeB) to the wireless device (e.g., UE), and the uplink (UL) transmission can be a communication from the wireless device to the node.

BRIEF DESCRIPTION OF THE DRAWINGS

[0003] Features and advantages of the disclosure will be apparent from the detailed description which follows, taken in conjunction with the accompanying drawings, which together illustrate, by way of example, features of the disclosure; and, wherein:

[0004] FIG. 1 illustrates a flexible radio access technology (RAT) in accordance with an example;

[0005] FIG. 2 illustrates a subframe structure for low latency applications in accordance

with an example;

[0006] FIG. 3 illustrates a mission critical communication between a user equipment (UE) and an eNodeB in accordance with an example;

[0007] FIG. 4 illustrates a partition of a physical random access channel (PRACH) preamble resource in accordance with an example;

[0008] FIG. 5 illustrates a multiplexing of a physical random access channel (PRACH) signal and a scheduling request (SR) message in a repeated transmission in accordance with an example;

[0009] FIG. 6 illustrates a random access response (RAR) window for repeated transmissions between a user equipment (UE) and an eNodeB in accordance with an example;

[0010] FIGS. 7A to 7C illustrates a resource allocation of a primary partition and a secondary partition within a transmission time interval (TTI) in accordance with an example;

[0011] FIG. 8 illustrates a repeated transmission of a random access response (RAR) message using a short transmission time interval (TTI) in accordance with an example;

[0012] FIG. 9 depicts functionality of a user equipment (UE) operable to perform mission critical communications with an eNodeB in accordance with an example;

[0013] FIG. 10 depicts functionality of a base station operable to receive mission critical communications from a user equipment (UE) in accordance with an example;

[0014] FIG. 11 depicts a flowchart of a machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB in accordance with an example;

[0015] FIG. 12 illustrates a diagram of a wireless device (e.g., UE) in accordance with an example; and

[0016] FIG. 13 illustrates a diagram of a wireless device (e.g., UE) in accordance with an example.

[0017] Reference will now be made to the exemplary embodiments illustrated, and specific language will be used herein to describe the same. It will nevertheless be

understood that no limitation of the scope of the technology is thereby intended.

DETAILED DESCRIPTION

[0018] Before the present technology is disclosed and described, it is to be understood that this technology is not limited to the particular structures, process actions, or materials disclosed herein, but is extended to equivalents thereof as would be recognized by those ordinarily skilled in the relevant arts. It should also be understood that terminology employed herein is used for the purpose of describing particular examples only and is not intended to be limiting. The same reference numerals in different drawings represent the same element. Numbers provided in flow charts and processes are provided for clarity in illustrating actions and operations and do not necessarily indicate a particular order or sequence.

EXAMPLE EMBODIMENTS

[0019] An initial overview of technology embodiments is provided below and then specific technology embodiments are described in further detail later. This initial summary is intended to aid readers in understanding the technology more quickly but is not intended to identify key features or essential features of the technology nor is it intended to limit the scope of the claimed subject matter.

[0020] The field of mobile communications has evolved significantly from early voice systems to today's highly sophisticated integrated communication platform. 4G Long Term Evolution (LTE) networks are deployed in more than 100 countries to provide services in various spectrum band allocations depending on spectrum regime. Recently, significant momentum has started to build around the idea of a next generation, i.e., fifth generation (5G) wireless communications technology.

[0021] A wide range of potential applications and services have been identified for the 5G system. Some examples include (1) enhanced mobile broadband, (2) massive machine type communications (MTC), and (3) ultra-reliable and low latency or mission critical communications. In enhanced mobile broadband, increased data rates is expected to be a key driver in network development and evolution for the 5G system. A peak data rate of more than 10 gigabits per second (Gbps) and a minimum guaranteed user data rate of at

least 100 megabits per second (Mbps) are envisioned for the 5G system. With respect to massive MTC, the support of a massive number of Internet of Things (IoT) or MTC devices is expected to be a key feature for the 5G system. MTC devices can be used for a wide variety of applications. MTC devices use low operational power consumption and are expected to communicate with infrequent small burst transmissions. Finally, with respect to ultra-reliable and low latency or mission critical communications, the support of mission critical MTC applications for the 5G system can necessitate a high level of reliable connectivity with guaranteed low latency, availability and reliability-of-service.

[0022] FIG. 1 illustrates an exemplary flexible radio access technology (RAT). The flexible RAT, also referred to as a 5G xRAT, can function to address the diverse features of the 5G system, such as the enhanced mobile broadband, massive MTC, and ultra-reliable and low latency or mission critical communications. The flexible RAT can define a unified framework that supports these diverse applications and services. In addition, the flexible RAT can support multiple frequency bands, multiple application/services, licensed/unlicensed frequency, and multiple RATs.

[0023] As shown in FIG. 1, the flexible RAT can be represented in two dimensions – frequency and time. Multiple RATs/sub-RATs/partitions or applications in the same frequency resources or frequency bands (or different frequency resources or frequency bands) can be multiplexed using time-division multiplexing (TDM), frequency-division multiplexing (FDM), code-division multiplexing (CDM), or a combination of the above.

[0024] In one example, the flexible RAT can include a medium/high frequency band, as well as a low frequency band. In the low frequency band, there can be a primary partition. The primary partition can be in accordance with a standard transmission time interval (TTI). As an example, the standard TTI can be for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure. The standard TTI can be approximately one millisecond (ms) in duration. Furthermore, in the low frequency band, there can be a first secondary partition and a second secondary partition. The primary partition and the secondary partition can be in both time and frequency. The first secondary partition can be in accordance with a short TTI and the second secondary partition can be in accordance with a long TTI. In general, the short TTI can have a duration that is less than

the standard TTI, and the long TTI can have a duration that is greater than the standard TTI. As non-limiting examples, the short TTI can be approximately 0.1 to 0.2 ms in duration, and the long TTI can be approximately 5 ms in duration. In one example, the primary partition in the flexible RAT can be utilized for non-mission critical communications (e.g., voice, data), and the secondary partition in the flexible RAT can be utilized for mission critical communications.

[0025] In one example, for a carrier frequency below 6 Gigahertz (GHz), the primary partition can reuse existing LTE numerology, while the secondary partition can be designed to support low latency or mission critical MTC applications. In particular, the short TTI can enable the low latency for mission critical MTC communications. In addition, increased subcarrier spacing, e.g., 75 kilohertz (kHz), can be adopted for the secondary partition. In contrast, a 15 KHz subcarrier spacing can be utilized for the primary partition.

[0026] FIG. 2 illustrates an exemplary subframe structure for low latency applications. The subframe structure can be for a secondary partition in a low frequency band, and the secondary partition can be associated with a short TTI of approximately 0.1 to 0.2 ms in duration. In one example, the subframe structure for the secondary partition can be based on an orthogonal frequency division multiplexing (OFDM) waveform.

[0027] In the example shown in FIG. 2, a 0.2ms TTI can be achieved. Within one TTI, 12 OFDM symbols can be grouped together (e.g., symbol 0 to symbol 11). Each OFDM symbol can have a duration of 13.3 micro seconds (us). A cyclic prefix (CP) can be inserted between each OFDM symbol. A CP length can be approximately 3.3 us or 512 samples if a sampling rate is 153.6MHz.

[0028] As described in further detail below, a system and method for mission critical communications in a 5G system is described. The mission critical communication can be performed at a user equipment (UE) in a radio resource control (RRC) idle mode. In one example, the procedure can involve a "keep trying" mechanism in which transmissions are repeated to ensure robust communication. The repeated transmissions can provide the ultra-reliability for the mission critical communication. The procedure can involve using a short transmission time interval (TTI) for signaling between the UE and an eNodeB, thereby providing the low latency for the mission critical communication. In one

example, dedicated resources can be used for a 5G physical random access channel (xPRACH) transmission that triggers or indicates the mission critical communication. The xPRACH transmission can be combined with a contention based scheduling request (SR). In addition, the procedure can involve information content, resource allocation and transmission schemes for random access response (RAR) messages with respect to the mission critical communication.

[0029] FIG. 3 illustrates an exemplary mission critical communication between a user equipment (UE) 310 and an eNodeB 320. In one example, the UE 310 can be a mission critical machine type communication (MTC) device. The UE 310 can initially be in a radio resource control (RRC) idle mode. The UE can include one or more processors 312 and memory 314, and the eNodeB 320 can include one or more processors 322 and memory 324. The mission critical communication between the UE 310 and the eNodeB 320 can include four distinct actions. In a first action, the UE 310 can transmit a fifth generation (5G) physical random access channel (xPRACH) signal to the eNodeB 320 using a dedicated resource to indicate or trigger the mission critical communication. To enable faster uplink access and transmission, the xPRACH signal can be combined together with a scheduling request (SR) message. The xPRACH signal and/or SR message can be transmitted using a standard transmission time interval (TTI) in a primary partition. The standard TTI can be approximately one millisecond (ms) in duration. In addition, the dedicated resource can be represented in the form of an xPRACH preamble signature/sequence, time and frequency resource. In a second action, after successful detection of the xPRACH signal and/or decoding of the SR message, the eNodeB 320 can transmit a random access response (RAR) message using a short TTI in a secondary partition. The short TTI can be approximately 0.1 to 0.2 ms in duration. In general, the short TTI is associated with a time interval that is less than the standard TTI. In one example, the standard TTI can be referred to as a first TTI and the short TTI can be referred to as a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI. The RAR message may include a timing advance (TA), a resource allocation for an uplink transmission, etc. In a third action, after successfully decoding the RAR message, the UE 310 can transmit uplink data (i.e., the mission critical data) to the eNodeB 320 in a 5G physical uplink shared channel (xPUSCH) using the short TTI in the secondary partition. In other words, the mission critical communication

from the UE 310 to the eNodeB 320 is performed using the 5G xPUSCH and the short TTI. The uplink data in the xPUSCH can be transmitted on the allocated resource in the RAR message. In a fourth action, the eNodeB 320 can transmit acknowledgement (ACK) or negative acknowledgement (NACK) information to the UE 310. The ACK/NACK information can be transmitted in a 5G physical downlink control channel (xPDCCH) or a 5G physical hybrid-ARQ indicator channel (xPHICH) using the short TTI in the secondary partition. The four actions involved in performing the mission critical communication are described in further detail below.

[0030] In one configuration, a transmitter (e.g., the UE 310 or the eNodeB 320) can keep transmitting the signal until a response is received from a receiver (e.g., the eNodeB 320 or the UE 310). This "keep trying" mechanism can ensure high robustness of the reception, which is essential for the mission critical communication. For instance, in the first action, the UE 310 can continue transmitting the xPRACH signal on the dedicated resource until the UE 310 receives the RAR message from the eNodeB 320. The "keep trying" mechanism can be viewed as an early termination of a repeated transmission. In other words, the transmitter can terminate the repeated transmission when the transmitter receives a response/feedback from the receiver. In addition, a maximum repetition number for each action (e.g., actions 1-4 as described above) can be predefined or configured by higher layers via a 5G master information block (xMIB), a 5G system information block (xSIB) or dedicated RRC signaling. When the transmission reaches the maximum repetition number, the UE 310 can perform a random back-off on the xPRACH signal to re-initiate the mission critical communication.

[0031] In one configuration, for each action (e.g., actions 1-4 as described above), the transmitter can repeat the transmission using a fixed number of repetitions (K repetitions). The number of repetitions can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling. In one example, the value of K can be configured as 1, which indicates that no repetition is used for the transmission. When the transmission reaches the fixed repetition number, the UE 310 can perform a random back-off on the xPRACH signal to re-initiate the mission critical communication, or the UE 310 can indicate a random access problem to upper layers in order to trigger corresponding procedure(s).

[0032] In one example, a combination of the above options can be considered for the transmission of channels and signals in each action (e.g., actions 1-4 as described above). In particular, the transmitter can keep sending the signal until the transmitter receives the response from the receiver, wherein each transmission occupies K repetitions. Similar to the above option, the number of repetitions (K) in each transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0033] In one configuration, a set of dedicated resources can be allocated for the transmission of the xPRACH signal from the UE to indicate or trigger the mission critical communication. The dedicated xPRACH resources can be multiplexed with resources for other applications (i.e., non-mission critical applications) using TDM or FDM or CDM, or a combination of the above. In addition, the partition of the set of dedicated resources for mission critical communications and the resources for other applications can be predefined or configured by higher layer via the xMIB, the xSIB or dedicated RRC signaling.

[0034] In one example, the xPRACH signal can be transmitted using the standard TTI (e.g., 1 ms duration) on the primary partition. Several options can be utilized to allocate the dedicated resource for the transmission of the xPRACH signal. For example, one or a plurality of signatures can be reserved for the xPRACH signal to indicate or trigger the mission critical communication. In addition, to handle the mission critical communication with different applications/services, one or a plurality of dedicated preamble signatures can be reserved for each specific event.

[0035] FIG. 4 illustrates an exemplary partition of a physical random access channel (PRACH) preamble resource. The PRACH preamble resource can include a fifth generation (5G) xPRACH preamble resource. The partition of the xPRACH preamble resource can be for mission critical applications, as well as other applications (i.e., non-mission critical applications). In other words, the xPRACH preamble resource can include a first resource for other applications and a second resource for mission critical applications. In addition, the partition of the xPRACH preamble resource can be associated with different applications and/or events. For example, the xPRACH preamble resource size or the number of reserved sequences for each event can be different. For instance, event #1 in the resource for mission critical applications can correspond to a

mission critical application for earthquake event, and one preamble signature can be reserved for event #1. Event #2 in the resource for mission critical applications can correspond to a mission-critical Vehicular to Vehicular (V2V) application, and five preamble signatures can be reserved for event #2.

[0036] In one example, one or a plurality of frequency resources can be allocated for the xPRACH signal to trigger the mission critical communication. When the UE transmits the xPRACH signal in the dedicated frequency resource, the eNodeB can transmit the corresponding RAR message using the short TTI on the secondary partition. The eNodeB can transmit the corresponding RAR message upon successful detection of xPRACH signal.

[0037] In one example, one or a plurality of time resources can be allocated for the xPRACH signal to trigger the mission critical communication. For example, the xPRACH signal for other applications (i.e., non-mission critical applications) can be transmitted in subframe 0, 2, 4, 6, 8 within one frame, while the xPRACH signal used to trigger the mission critical communication can be transmitted in subframe 1, 3, 5, 7, 9 within one frame.

[0038] In one example, a combination of TDM and/or FDM and/or CDM based multiplexed schemes can be used to separate the resource for mission critical applications and other applications (i.e., non-mission critical applications). For example, a combination of FDM and CDM multiplexing schemes can be utilized, i.e., one additional frequency resource can be reserved for mission critical applications, and within this dedicated frequency resource, different mission critical applications/services can be separated using different xPRACH preamble signatures.

[0039] In another example, a combination of TDM and CDM multiplexing schemes can be utilized. The xPRACH signal for the other application (i.e., a non-mission critical application) can be transmitted in subframe 0, 2, 4, 6, 8 within one frame, while the xPRACH signal used to trigger the mission critical communication can be transmitted in subframe 1, 3, 5, 7, 9 within one frame. Further, different mission critical applications/services can be separated using different xPRACH preamble signatures.

[0040] In one example, with respect to ultra-reliable and low latency communications, multiple mission critical devices can operate as a "single frequency network" (SFN),

which can improve a link level performance for mission critical communication. In this case, the eNodeB can treat multiple mission critical devices as a single mission critical device. For example, the eNodeB can transmit a single RAR message to multiple UEs, and in response, multiple UEs can transmit uplink data (i.e., mission critical data) simultaneously to the eNodeB on the same time and frequency resource.

[0041] In one example, in order to differentiate a typical operation from a "single frequency network" type of operation, different xPRACH resources can be allocated. For example, one event ID or dedicated xPRACH signature can be allocated for the "single frequency network" type of operation. In addition, when repeated transmissions of the xPRACH preamble are used, a starting subframe of the repeated xPRACH transmission can be predefined or configured by higher layers, thereby causing the eNodeB to perform efficient detection of the repeated xPRACH signal.

[0042] A more detailed description is now provided with respect to the first action shown in FIG. 3, in which the UE can transmit the 5G xPRACH signal and/or SR message to the eNodeB using dedicated resources to indicate or trigger the machine critical communication. The xPRACH signal transmission can be combined with a contention based scheduling request (SR) message to allow uplink access in a reduced amount of time, thereby fulfilling the latency constraints for mission critical communications. The contention based SR message can include the UE ID and buffer status report to enable uplink access in the reduced amount of time.

[0043] For mission critical applications, the SR message can be transmitted from the UE to the eNodeB as part of a random access channel (RACH) procedure, which allows for a reduction in connection establishment delay as compared to existing LTE systems. The SR message can be a fixed size and can include several parameters/fields. The SR message can include a mission critical MTC device ID, which can be the same as the UE ID or a different ID. The SR message can include an event ID to indicate an access cause when a same set of xPRACH sequences are allocated for multiple applications/services. The event ID can be included in the SR message to expedite access for the UE. The SR message can include a mission critical MTC device capability, which can include mission critical specific UE radio access capability information, such as carrier aggregation (CA) capability, i.e., component carrier (CC) index(s) that are supported by the UE (e.g., the

mission critical MTC device), supported multiple input multiple output (MIMO) capability, etc. The SR message can include a resource request and modulation and coding scheme (MCS) for an uplink transmission (e.g., mission critical data) from the UE. For example, the SR message can include the resource request in the time and frequency domain, e.g., physical resource block (PRB) index or numbers within one band, or symbol/slot/subframe/frame index or CC index(s) used for the uplink transmission. Alternatively, the UE can indicate the total amount of data for mission critical application and/or channel state information (CSI)/reference signaling measurements, which can subsequently be used for downlink MCS selection and open loop power control calculation.

[0044] In one example, when the resource request of PRB index and MCS are included in the SR message, the eNodeB can feedback 1 bit ACK/NACK information to the UE (or mission critical MTC device). Upon successful ACK detection, the UE can use the resource indicated in the SR message for uplink data transmission based on a predefined timing following a subframe in which the ACK/NACK information is detected.

[0045] In one example, the "keep trying" mechanism or repeated transmission can be employed when transmitting the xPRACH signal and/or SR message to the eNodeB. The same xPRACH preamble signature and the same SR information can be used for the transmission of the xPRACH signal and the SR message during the repetition, respectively. In addition, the SR message can occupy the resource allocated for the SR transmission to further enhance the link level performance.

[0046] In one example, UEs may not have the xPRACH/SR repetition capability, or the function may not be configured at the UE by the eNodeB. In this case, different xPRACH and/or SR resources can be used with respect to (1) an initial transmission that is shared among all UEs and (2) subsequent repeated transmission that is dedicated for UEs enabled with the xPRACH/SR repetition capability. In one example, the resource for the initial transmission of the xPRACH signal and SR message can be selected by the UE within a contention-based resource region, while the resources for subsequent repeated transmissions can be configured by higher-layers (e.g., broadcasted in the xSIB) within a contention-free resource region on the same partition or a different partition.

[0047] In one example, available sets of xPRACH or SR resources reserved for the UE

(e.g., a mission critical MTC device) can be divided into two different regions – a first region can be used for the xPRACH/SR transmission repetition and the second region can be reserved for the xPRACH/SR transmission without repetition. More specifically, an xPRACH signal or SR message can be repeatedly transmitted on a configurable or fixed consecutive xPRACH or SR resources within the first region according to a known pattern (e.g., TDM, CDM or FDM). The number of repetition times can be predefined or configured by higher layers for an individual UE. In addition, one-to-one mapping between the xPRACH repetition level and the xPRACH/SR resource set can be utilized. The UE can select an xPRACH/SR repetition level based on a measurement, such as a reference signal received power (RSRP), and the UE can transmit the xPRACH/SR using the xPRACH/SR resources set according to the selected xPRACH/SR repetition level.

[0048] FIG. 5 illustrates an exemplary multiplexing of a physical random access channel (PRACH) signal and a scheduling request (SR) message in a repeated transmission. The PRACH signal can include a fifth generation (5G) xPRACH signal. Various multiplexing mechanisms, such as time division multiplexing (TDM) or frequency division multiplexing (FDM), can be applied to the xPRACH signal and the SR message. As shown in FIG. 5, TDM multiplexing can be used for repeated transmissions of the xPRACH signal and the SR message, or FDM multiplexing can be used for repeated transmissions of the xPRACH signal and the SR message. In other words, TDM and FDM based multiplexing mechanisms can be applied to the "keep trying" mechanism for repeated transmissions. In addition, the SR message can be transmitted using all the available resource to achieve ultra-reliable communication.

[0049] In one example, with respect to transmission power control mechanism for the transmission of the xPRACH signal and/or the SR message, several options can be used. In one example, when (re)transmitting the xPRACH signal and/or SR message, a maximum transmit power can be used to ensure robust detection at the eNodeB. In another example, an existing power control mechanism can be applied for the transmission and retransmission of the xPRACH signal and/or SR message. In particular, for an initial transmission, the xPRACH transmission power can be set to an initial PRACH power, while for the retransmission, power ramping can be used to increase the actual transmission power.

[0050] In yet another example with respect to transmission power control, repetition level ramping can be applied for the transmission and retransmission of the xPRACH signal and/or SR message. Further, the repetition level ramping mechanism can be combined in conjunction with power ramping to further improve the performance. In one example, the repetition level can be doubled for each retransmission. In the initial transmission, the repetition level can be defined as K, while in the first retransmission, the repetition level can be set to 2K, etc. Additionally, if power ramping is applied on top of the repetition level ramping, the power ramping can be defined so as to account for an increase in the repetition level. Specifically, the power level for the first attempt at a subsequent repetition level can be reduced by a factor of 10*log(numRepL/numRepL-1), wherein numRepL and numRepL-1 are the number of repetitions configured for repetition levels L and L-1, respectively.

[0051] A more detailed description is now provided with respect to the second action shown in FIG. 3, in which the eNodeB can transmit the RAR message to the UE using the short TTI. After identifying the mission critical event based on detection of the xPRACH signal, the eNodeB can dynamically allocate the resource in a secondary partition, and the eNodeB can transmit the corresponding RAR message using the short TTI.

[0052] For mission critical MTC applications, a fixed relationship can be defined between the time (e.g., a last repetition/retransmission) of the xPRACH transmission and a time of the first transmission of the xPDCCH/xPDSCH signal (either scheduling or carrying the RAR message). Additionally, the frequency resource for the xPDCCH (if xPDCCH is not wideband) or xPDSCH can be determined as a function of at least the preamble sequence of the detected xPRACH signal, and possibly also the frequency location of the detected xPRACH signal. If additional flexibility is desired at the eNodeB, then for time-domain scheduling of the RAR message, a short RAR window can be defined in which the UE monitors for the first transmission of the xPDCCH/xPDSCH signal with the RAR message.

[0053] FIG. 6 illustrates an exemplary random access response (RAR) window for repeated transmissions between a user equipment (UE) and an eNodeB. When repeated transmissions are used for the xPRACH signal and/or SR message, the RAR window can be defined such that the UE (e.g., a mission critical MTC device) can monitor for the

RAR message within the RAR window. As shown in FIG. 6, the xPRACH signal and SR message can be transmitted in an uplink in accordance with a standard TTI (e.g., 1 ms in duration). After transmission of the xPRACH signal and SR message, the RAR window can be defined. During the RAR window, the UE can monitor a downlink for the RAR message. The UE can detect the RAR message during the RAR message, wherein the RAR message is transmitted in accordance with a short TTI. In one example, the position of the RAR window can be predefined or configured by higher layer via the xMIB, the xSIB or dedicated RRC signaling. In addition, the starting position of the RAR window can be defined relative to the starting of the last subframe of the repeated xPRACH signal and/or SR message transmission.

[0054] FIGS. 7A to 7C illustrates exemplary resource allocations of a primary partition and a secondary partition within a transmission time interval (TTI). The TTI can be a standard TTI with a duration of one millisecond (ms). Guard bands can be inserted between the primary and secondary partitions in a frequency domain in order to reduce inter-carrier interference.

[0055] As shown in FIG. 7A, a secondary partition using a short TTI (e.g., 0.1 to 0.2 ms) can be allocated after an xPDCCH region. The xPDCCH region can be in the primary partition using the standard TTI. When different numerologies, e.g., subcarrier spacing, are used for the primary and secondary partitions, a guard time may be inserted between the xPDCCH region using the standard TTI and the secondary partition using the short TTI. This option may avoid traffic interruption for the primary partition, as the eNodeB can schedule the downlink and uplink transmission via the xPDCCH within the primary partition.

[0056] As shown in FIG. 7B, a secondary partition using a short TTI (e.g., 0.1 to 0.2 ms) can be allocated after an xPDCCH region. The xPDCCH region can be in the primary partition using the standard TTI. Further, the secondary partition can occupy a full system bandwidth to enhance the link level performance. In this approach, guard times may not be inserted between the xPDCCH region using the standard TTI and the secondary partition using the short TTI.

[0057] As shown in FIG. 7C, a secondary partition using a short TTI (e.g., 0.1 to 0.2 ms) can span a standard TTI (e.g., 1 ms). In this approach, the secondary partition can occupy

a full system bandwidth to enhance the link level performance. In addition, a guard time may be inserted to reduce interference in a primary partition.

[0058] In one example, the resource allocation for the secondary partition can be predefined, or broadcasted in a mission critical specific xSIB message, or indicated in a downlink control information (DCI) format in the xPDCCH using the standard TTI in the primary partition. In the latter case, the UE (e.g., a mission critical MTC device) can monitor the xPDCCH with a cyclic redundancy check (CRC) scrambled by an existing random-access radio network temporary identifier (RA-RNTI) or a newly defined RA-RNTI for mission critical applications. The RA-RNTI can be predefined in the specification or defined as a function of at least one of: the time index, frequency index, preamble sequence, and repetition level used for the detected xPRACH transmission. Upon successful decoding of the xPDCCH signal, the UE can switch to a short TTI mode and decode the RAR message within the secondary partition.

[0059] FIG. 8 illustrates an exemplary repeated transmission of a random access response (RAR) message using a short transmission time interval (TTI). The "keep trying" mechanism or repeated transmissions of the RAR message can be used to improve the link level performance. The repeated RAR transmissions using the short TTI can occur within a secondary partition used for mission critical communication. As shown in FIG. 8, a preamble can be inserted before each transmission of the RAR message to improve a downlink synchronization accuracy, which is useful in view of the higher sampling rate used for the short TTI with large subcarrier spacing (e.g., 15 KHz). The preamble can utilize similar principles as compared to the 5G downlink synchronization channel (xSCH). To differentiate the preamble from the xSCH, independent root sequences can be employed when Zadoff-Chu (ZC) sequences are used for the xSCH.

[0060] In one example, the RAR message can include various parameters. For example, the RAR message can include a timing advance (TA). The eNodeB can estimate an initial TA from the xPRACH signal sent by the UE. The RAR message can include an UL grant for a subsequent uplink transmission. In addition, the UL grant can include a resource allocation of the secondary partition used for the subsequent uplink transmission. When the UE (e.g., a mission critical MTC device) supports carrier aggregation (CA), the resource allocation for multiple component carriers (CCs) can be included in the uplink

grant. The UL grant can include a modulation and coding scheme (MCS) and a power control parameter for the subsequent uplink transmission, as well as the number of repetitions used for the RAR transmission. In one example, the RAR message can include a mission critical MTC device ID, which can be used for contention resolution. The RAR message can include an event ID, which can be obtained from the SR message and used for contention resolution. In addition, the RAR message can include a random access preamble ID that is useful for contention resolution. The random access preamble ID can include a preamble index for the xPRACH transmission.

[0061] In one example, the RAR message can be transmitted in the secondary partition using the short TTI either: (1) on the xPDSCH scheduled by the xPDCCH, or (2) using the xPDCCH directly, or (3) using the xPDSCH directly. With respect to the first option, the xPDCCH can indicate the resource allocation and MCS for the transmission of the xPDSCH signal, while the xPDSCH carries the RAR message. With respect to the second option, the RAR message can be transmitted via the xPDCCH. In this case, the UE (e.g., a mission critical MTC device) can monitor the xPDCCH with the CRC scrambled by the RA-RNTI. With respect to the third option, the RAR message can be transmitted via the xPDSCH using the short TTI. When repeated transmissions or the "keep trying" mechanism is employed for the RAR message, TTI bundling and a predefined redundancy version (RV) pattern (e.g., [0 2 3 1]) can be used when turbo coding is adopted. Further, a scrambling seed for the transmission of the xPDSCH signal can be defined as a function of the RA-RNTI or a group ID with respect to a "single frequency network" (SFN) type of operation. In one example, the group ID can be specified as the event ID.

[0062] In one example, the UE (e.g., a mission critical MTC device) can monitor for the xPDSCH signal using fixed and known values of the MCS and a transport block size (TBS). If a UE processing complexity increase can be accommodated for mission critical devices, then a limited number of options for MCS and TBS for the xPDSCH can be configured, from which the UE can perform blind detection.

[0063] A more detailed description is now provided with respect to the third action shown in FIG. 3, in which the UE can transmit uplink data (i.e., mission critical data) to the eNodeB using the short TTI. A resource allocation for the uplink data transmission can be

indicated in the RAR message. In particular, the resource allocation can be associated with a secondary partition to be used for the uplink data transmission. Further, a scrambling seed for a transmission of the xPUSCH signal can be defined as a function of a mission critical MTC device ID or a group ID with respect to a "single frequency network" type of operation. In one example, the group ID can be specified as the event ID.

[0064] When the repeated transmission is used for the uplink transmission, a gap between the end of a last RAR transmission and a starting subframe of the uplink transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling. Alternatively, to allow additional flexibility, a delay parameter can be indicated in the UL grant of the RAR message, wherein the delay parameter can be of the order of one or more standard or short TTI(s).

[0065] In one example, to improve the robustness of the uplink transmission, the same information can be transmitted on multiple component carriers (CC) simultaneously, or transmitted repeatedly within a CC to fulfil the reliability constraint of the mission critical communication. Further, TTI bundling with a predefined redundancy version (RV) pattern can be employed for performance enhancement. For mission critical applications with small data packet transmissions, tail biting convolution coding (TBCC) can be used as a forward error correction (FEC) scheme as opposed to turbo coding.

[0066] A more detailed description is now provided with respect to the fourth action shown in FIG. 3, in which the eNodeB can transmit ACK/NACK information to the UE using the short TTI. The ACK/NACK can be transmitted via the xPDCCH or the xPHICH using the short TTI on the secondary partition. When repeated transmission are used for the ACK/NACK transmission, a gap between the end of a last uplink data transmission and a starting subframe of the ACK/NACK transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0067] In one example, when a NACK is received or an ACK is not received, the UE (e.g., a mission critical MTC device) can perform a retransmission of the uplink data. When a maximum number of retransmission is reached, the UE can perform a random back-off and re-initiate the procedure for mission critical communication. Alternatively, assuming that an uplink synchronization has been established via a mission critical

random access procedure, the UE can transmit a scheduling request (SR) using the short TTI on the secondary partition at a next available SR opportunity. In one example, periodically occurring SR opportunities can be defined in the secondary partition. The SR transmission can be based on a physical structure of the xPUSCH or xPUCCH, which are adapted for transmissions using short TTIs. The configuration of the SR opportunities in the secondary partition can be pre-defined or broadcasted using the xSIB. Alternatively, the configuration of the SR opportunities can be indicated via a combination of broadcasted information of system level configurations and UE-specific signaling of the actual configured SR resource periodicity carried in the RAR message.

[0068] In one example, with respect to the "single frequency network (SFN)" type of operation, multiple UEs that are closely co-located (i.e., located within a defined distance from each other) can transmit the xPRACH signal on the same xPRACH resource using the same xPRACH preamble, which can improve the xPRACH detection performance. In response to receiving the xPRACH signal from multiple UEs, the eNodeB can transmit a single RAR message that targets the multiple UEs. In addition, when one or more UEs successfully receive the RAR message, the UEs can transmit the xPUSCH signal simultaneously on the same resource, which can achieve SFN gain.

[0069] In one configuration, a system and method of ultra-reliable and low latency communications for a fifth generation (5G) system is described. A user equipment (UE) can transmit, to an eNodeB, a 5G Physical Random Access Channel (xPRACH) and/or a scheduling request (SR) message to trigger a mission critical communication. The xPRACH and/or SR can be transmitted on a dedicated resource using a standard transmission time interval (TTI) in a primary partition. The UE can receive a random access response (RAR) using a short TTI in a secondary partition. The UE can transmit uplink data to the eNodeB in a 5G physical uplink shared channel (xPUSCH) using the short TTI in the secondary partition. The UE can receive, from the eNodeB, acknowledgement (ACK) or negative acknowledgement (NACK) information in a 5G physical downlink control channel (xPDCCH) or a 5G Physical Hybrid-ARQ Indicator Channel (xPHICH) using the short TTI in the secondary partition.

[0070] In one configuration, a keep trying mechanism is employed between the UE and the eNodeB for ultra-reliable and low latency communication. A transmitter (e.g., the UE

or eNodeB) can keep sending a signal until a response is received from a receiver (e.g., the eNodeB or UE). A maximum repetition number for each transmission can be predefined or configured by higher layers via a 5G master information block (xMIB), a 5G system information block (xSIB) or dedicated RRC signaling.

[0071] In one configuration, a transmitter (e.g., the UE or eNodeB) can repeat the transmission using a fixed number of repetitions. The fixed number of repetitions can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0072] In one configuration, a transmitter (e.g., the UE or eNodeB) can keep sending the signal until a response is received from a receiver (e.g., the eNodeB or UE). In addition, each transmission can occupy K repetitions, and K is predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0073] In one configuration, a set of dedicated xPRACH resources for mission critical communications can be multiplexed with resources for non-mission critical applications using time division multiplexing (TDM) or frequency division multiplexing (FDM) or code division multiplexing (CDM) or a combination of above. In addition, a partition configuration can be predefined or configured by higher layer via the xMIB, the xSIB or dedicated RRC signaling.

[0074] In one configuration, one or more signatures can be reserved for the xPRACH to trigger the mission critical communication.

[0075] In one configuration, one or more time resources can be reserved for the xPRACH to trigger the mission critical communication.

[0076] In one configuration, one or more frequency resources can be reserved for the xPRACH to trigger the mission critical communication.

[0077] In one configuration, one or more xPRACH signatures or time resources or frequency resources can be reserved for "single frequency network" type of operations.

[0078] In one configuration, the SR message can have a fixed size, and the SR can include at least the following parameters or fields: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, a resource request, and a modulation and coding scheme (MCS) for

transmission of the uplink data from the UE to the eNodeB. In addition, the resource request can include a physical resource block (PRB) index or numbers within one band, or symbol/slot/subframe/frame index or component carrier (CC) index(s) used for the transmission of the uplink data.

[0079] In one configuration, a resource for an initial transmission of the xPRACH and SR is selected by a given UE within a contention-based resource region, and resources for subsequent repeated transmissions can be configured by higher-layers (e.g.. broadcasted in the xSIB) within a contention-free resource region on a same partition or a different partition.

[0080] In one configuration, a maximum transmit power can be utilized for the transmission and retransmission of the xPRACH signal and/or SR message.

[0081] In one configuration, existing power control mechanisms can be applied for the transmission and retransmission of the xPRACH signal and/or SR message.

[0082] In one configuration, repetition level ramping can be applied for the transmission and retransmission of the xPRACH signal and/or SR message.

[0083] In one configuration, the UE (e.g., a mission critical MTC device) can monitor a random access response (RAR) message within a RAR window. A position of the RAR window can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0084] In one configuration, a resource allocation of a secondary partition or a RAR transmission is predefined, or broadcasted in a xSIB message, or indicated in a downlink control information (DCI) format in the xPDCCH using a standard TTI in the primary partition.

[0085] In one configuration, the secondary partition can be allocated after the xPDCCH region in the primary partition using the standard TTI (e.g., 1 ms). In addition, the secondary partition can occupy a full system bandwidth.

[0086] In one configuration, the secondary partition can span a standard TTI (e.g., 1 ms). In addition, the secondary partition can occupy a full system bandwidth.

[0087] In one configuration, a preamble can be inserted prior to the transmission of the RAR message. The preamble can be based on a 5G downlink synchronization channel

(xSCH).

[0088] In one configuration, the RAR message can include the following parameters or fields: a timing advance command (TA), an uplink grant, a mission critical MTC device ID, an event ID and a random access preamble ID. The uplink grant can further include a resource allocation of the secondary partition used for a subsequent uplink transmission.

[0089] In one configuration, the RAR message can be transmitted via the xPDSCH using a short TTI. When a repeated transmission mechanism (or "keep trying" mechanism) is employed, TTI bundling and a predefined redundancy version (RV) pattern can be used for the transmission of the RAR message when turbo coding is adopted. In addition, with respect to a "single frequency network" type of operation, a scrambling seed for the transmission of the xPDSCH can be defined as a function of a random access radio network temporary identifier (RA-RNTI), a group ID or an event ID.

[0090] In one configuration, the RAR message can be transmitted via the xPDCCH. The UE (e.g., a mission critical MTC device) can monitor the xPDCCH with a cyclic redundancy check (CRC) scrambled by an RA-RNTI.

[0091] In one configuration, the RAR message can be transmitted via the xPDSCH scheduled by the xPDCCH.

[0092] In one configuration, a gap between an end of a last RAR transmission and a starting subframe of the uplink transmission can be predefined or configured by higher layers via the xMIB, the xSIB or dedicated RRC signaling. In addition, a delay parameter in the order of standard or short TTI can indicated in the UL grant of the RAR message.

[0093] In one configuration, for the uplink transmission, the same information can be transmitted on multiple component carriers (CC) simultaneously or transmitted repeatedly over multiple sets of PRBs within a CC. In one example, TTI bundling with a predefined redundancy version (RV) pattern can be employed for the uplink transmission. In another example, a scrambling seed for the transmission of the xPUSCH can be defined as a function of a mission critical MTC device ID or a group ID for a "single frequency network" type of operation.

[0094] In one configuration, a gap between an end of the uplink data transmission and a starting subframe of the ACK/NACK transmission can be predefined or configured by

higher layers via the xMIB, the xSIB or dedicated RRC signaling.

[0095] In one configuration, when a negative acknowledgement (NACK) is received or an acknowledgement (ACK) is not received, the UE (e.g., a mission critical MTC device) can perform a retransmission of the uplink data. When a maximum number of retransmission is reached, the UE can perform a random back-off and re-initiate the procedure for mission critical communication.

[0096] Another example provides functionality 900 of a user equipment (UE) operable to perform mission critical communications with an eNodeB, as shown in the flow chart in FIG. 9. The UE can comprise one or more processors and memory configured to: transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI), as in block 910. The UE can comprise one or more processors and memory configured to: receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI, as in block 920. The UE can comprise one or more processors and memory configured to: decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication, as in block 930. The UE can comprise one or more processors and memory configured to: perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI, as in block 940.

[0097] Another example provides functionality 1000 of a base station operable to receive mission critical communications from a user equipment (UE), as shown in the flow chart in FIG. 10. The base station can comprise one or more processors and memory configured to: receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in

accordance with a first transmission time interval (TTI), as in block 1010. The base station can comprise one or more processors and memory configured to: transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI, as in block 1020. The base station can comprise one or more processors and memory configured to: receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message, as in block 1030. The base station can comprise one or more processors and memory configured to: transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI, as in block 1040.

[0098] Another example provides at least one machine readable storage medium having instructions 1100 embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, as shown in the flow chart in FIG. 11. The instructions can be executed on a machine, where the instructions are included on at least one computer readable medium or one non-transitory machine readable storage medium. The instructions when executed perform: transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI), as in block 1110. The instructions when executed perform: receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI, as in block 1120. The instructions when executed perform: performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation

indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI, as in block 1130. The instructions when executed perform: receiving, using the at least one processor of the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI, as in block 1140.

[0099] FIG. 12 provides an example illustration of a user equipment (UE) device 1200, such as a wireless device, a mobile station (MS), a mobile wireless device, a mobile communication device, a tablet, a handset, or other type of wireless device. The UE device 1200 can include one or more antennas configured to communicate with a node or transmission station, such as a base station (BS), an evolved Node B (eNB), a baseband unit (BBU), a remote radio head (RRH), a remote radio equipment (RRE), a relay station (RS), a radio equipment (RE), a remote radio unit (RRU), a central processing module (CPM), or other type of wireless wide area network (WWAN) access point. The UE device 1200 can be configured to communicate using at least one wireless communication standard including 3GPP LTE, WiMAX, High Speed Packet Access (HSPA), Bluetooth, and WiFi. The UE device 1200 can communicate using separate antennas for each wireless communication standard or shared antennas for multiple wireless communication standards. The UE device 1200 can communicate in a wireless local area network (WLAN), a wireless personal area network (WPAN), and/or a WWAN.

[00100] In some embodiments, the UE device 1200 may include application circuitry 1202, baseband circuitry 1204, Radio Frequency (RF) circuitry 1206, front-end module (FEM) circuitry 1208 and one or more antennas 1210, coupled together at least as shown.

[00101] The application circuitry 1202 may include one or more application processors. For example, the application circuitry 1202 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The processor(s) may include any combination of general-purpose processors and dedicated processors (e.g., graphics processors, application processors, etc.). The processors may be coupled with and/or may include a storage medium 1212, and may be configured to execute instructions stored in the storage medium 1212 to enable various applications and/or operating systems to run on the system.

[00102] The baseband circuitry 1204 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry 1204 may include one or more baseband processors and/or control logic to process baseband signals received from a receive signal path of the RF circuitry 1206 and to generate baseband signals for a transmit signal path of the RF circuitry 1206. Baseband processing circuity 1204 may interface with the application circuitry 1202 for generation and processing of the baseband signals and for controlling operations of the RF circuitry 1206. For example, in some embodiments, the baseband circuitry 1204 may include a second generation (2G) baseband processor 1204a, third generation (3G) baseband processor 1204b, fourth generation (4G) baseband processor 1204c, and/or other baseband processor(s) 1204d for other existing generations, generations in development or to be developed in the future (e.g., fifth generation (5G), 6G, etc.). The baseband circuitry 1204 (e.g., one or more of baseband processors 1204a-d) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry 1206. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some embodiments, modulation/demodulation circuitry of the baseband circuitry 1204 may include Fast-Fourier Transform (FFT), precoding, and/or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry 1204 may include convolution, tail-biting convolution, turbo, Viterbi, and/or Low Density Parity Check (LDPC) encoder/decoder functionality. Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments.

[00103] In some embodiments, the baseband circuitry 1204 may include elements of a protocol stack such as, for example, elements of an evolved universal terrestrial radio access network (EUTRAN) protocol including, for example, physical (PHY), media access control (MAC), radio link control (RLC), packet data convergence protocol (PDCP), and/or radio resource control (RRC) elements. A central processing unit (CPU) 1204e of the baseband circuitry 1204 may be configured to run elements of the protocol stack for signaling of the PHY, MAC, RLC, PDCP and/or RRC layers. In some embodiments, the baseband circuitry may include one or more audio digital signal

processor(s) (DSP) 1204f. The audio DSP(s) 104f may be include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments. Components of the baseband circuitry may be suitably combined in a single chip, a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry 1204 and the application circuitry 1202 may be implemented together such as, for example, on a system on a chip (SOC).

[00104] In some embodiments, the baseband circuitry 1204 may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry 1204 may support communication with an evolved universal terrestrial radio access network (EUTRAN) and/or other wireless metropolitan area networks (WMAN), a wireless local area network (WLAN), a wireless personal area network (WPAN). Embodiments in which the baseband circuitry 1204 is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

[00105] The RF circuitry 1206 may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry 1206 may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry 1206 may include a receive signal path which may include circuitry to down-convert RF signals received from the FEM circuitry 1208 and provide baseband signals to the baseband circuitry 1204. RF circuitry 1206 may also include a transmit signal path which may include circuitry to up-convert baseband signals provided by the baseband circuitry 1204 and provide RF output signals to the FEM circuitry 1208 for transmission.

[00106] In some embodiments, the RF circuitry 1206 may include a receive signal path and a transmit signal path. The receive signal path of the RF circuitry 1206 may include mixer circuitry 1206a, amplifier circuitry 1206b and filter circuitry 1206c. The transmit signal path of the RF circuitry 1206 may include filter circuitry 1206c and mixer circuitry 1206a. RF circuitry 1206 may also include synthesizer circuitry 1206d for synthesizing a frequency for use by the mixer circuitry 1206a of the receive signal path and the transmit signal path. In some embodiments, the mixer circuitry 1206a of the receive signal path

may be configured to down-convert RF signals received from the FEM circuitry 1208 based on the synthesized frequency provided by synthesizer circuitry 1206d. The amplifier circuitry 1206b may be configured to amplify the down-converted signals and the filter circuitry 1206c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals. Output baseband signals may be provided to the baseband circuitry 1204 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals, although this is not a requirement. In some embodiments, mixer circuitry 1206a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

[00107] In some embodiments, the mixer circuitry 1206a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 1206d to generate RF output signals for the FEM circuitry 1208. The baseband signals may be provided by the baseband circuitry 1204 and may be filtered by filter circuitry 1206c. The filter circuitry 1206c may include a low-pass filter (LPF), although the scope of the embodiments is not limited in this respect.

[00108] In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a of the transmit signal path may include two or more mixers and may be arranged for quadrature down-conversion and/or up-conversion respectively. In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a may be arranged for direct down-conversion and/or direct up-conversion, respectively. In some embodiments, the mixer circuitry 1206a of the receive signal path and the mixer circuitry 1206a of the transmit signal path may be configured for super-heterodyne operation.

[00109] In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 1206 may include analog-to-digital converter (ADC) and digital-to-analog

converter (DAC) circuitry and the baseband circuitry 1204 may include a digital baseband interface to communicate with the RF circuitry 1206.

[00110] In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

[00111] In some embodiments, the synthesizer circuitry 1206d may be a fractional-N synthesizer or a fractional N/N+1 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 1206d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

[00112] The synthesizer circuitry 1206d may be configured to synthesize an output frequency for use by the mixer circuitry 1206a of the RF circuitry 1206 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 1206d may be a fractional N/N+1 synthesizer.

[00113] In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO), although that is not a requirement. Divider control input may be provided by either the baseband circuitry 1204 or the applications processor 1202 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the applications processor 1202.

[00114] Synthesizer circuitry 1206d of the RF circuitry 1206 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or N+1 (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into Nd equal packets of phase, where Nd is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

[00115] In some embodiments, synthesizer circuitry 1206d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 1206 may include an IQ/polar converter.

[00116] FEM circuitry 1208 may include a receive signal path which may include circuitry configured to operate on RF signals received from one or more antennas 1210, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 1206 for further processing. FEM circuitry 1208 may also include a transmit signal path which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 1206 for transmission by one or more of the one or more antennas 1210.

[00117] In some embodiments, the FEM circuitry 1208 may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry may include a low-noise amplifier (LNA) to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry 1206). The transmit signal path of the FEM circuitry 1208 may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry 1206), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas 1210.

[00118] FIG. 13 provides an example illustration of the wireless device, such as a user equipment (UE), a mobile station (MS), a mobile wireless device, a mobile communication device, a tablet, a handset, or other type of wireless device. The wireless device can include one or more antennas configured to communicate with a node, macro node, low power node (LPN), or, transmission station, such as a base station (BS), an evolved Node B (eNB), a baseband processing unit (BBU), a remote radio head (RRH), a remote radio equipment (RRE), a relay station (RS), a radio equipment (RE), or other

type of wireless wide area network (WWAN) access point. The wireless device can be configured to communicate using at least one wireless communication standard such as, but not limited to, 3GPP LTE, WiMAX, High Speed Packet Access (HSPA), Bluetooth, and WiFi. The wireless device can communicate using separate antennas for each wireless communication standard or shared antennas for multiple wireless communication standards. The wireless device can communicate in a wireless local area network (WLAN), a wireless personal area network (WPAN), and/or a WWAN. The wireless device can also comprise a wireless modem. The wireless modem can comprise, for example, a wireless radio transceiver and baseband circuitry (e.g., a baseband processor). The wireless modem can, in one example, modulate signals that the wireless device transmits via the one or more antennas and demodulate signals that the wireless device receives via the one or more antennas.

[00119] FIG. 13 also provides an illustration of a microphone and one or more speakers that can be used for audio input and output from the wireless device. The display screen can be a liquid crystal display (LCD) screen, or other type of display screen such as an organic light emitting diode (OLED) display. The display screen can be configured as a touch screen. The touch screen can use capacitive, resistive, or another type of touch screen technology. An application processor and a graphics processor can be coupled to internal memory to provide processing and display capabilities. A non-volatile memory port can also be used to provide data input/output options to a user. The non-volatile memory port can also be used to expand the memory capabilities of the wireless device. A keyboard can be integrated with the wireless device or wirelessly connected to the wireless device to provide additional user input. A virtual keyboard can also be provided using the touch screen.

Examples

[00120] The following examples pertain to specific technology embodiments and point out specific features, elements, or actions that can be used or otherwise combined in achieving such embodiments.

[00121] Example 1 includes an apparatus of a user equipment (UE) operable to perform mission critical communications with an eNodeB, the apparatus comprising one or more processors and memory configured to: transmit, from the UE to the eNodeB, a physical

random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI); receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication; and perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

[00122] Example 2 includes the apparatus of Example 1, further configured to receive, from the eNodeB, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00123] Example 3 includes the apparatus of any of Examples 1-2, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and the second TTI is approximately 0.1 to 0.2 ms.

[00124] Example 4 includes the apparatus of any of Examples 1-3, wherein the first TTI is associated with a first partition of a low band and the second TTI is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00125] Example 5 includes the apparatus of any of Examples 1-4, wherein the UE is configured to: perform repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and perform repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative

acknowledgement (NACK) is received from the eNodeB, wherein a maximum number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling, wherein the UE performs a random back off and reinitiates a procedure for performing the mission critical communication when the maximum number of repetitions for a defined transmission is reached.

[00126] Example 6 includes the apparatus of any of Examples 1-5, wherein the UE is configured to: repeatedly transmit the PRACH signal to the eNodeB in accordance with a fixed number of repetitions; and repeatedly perform the mission critical communication with the eNodeB in accordance with a fixed number of repetitions, wherein the fixed number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

[00127] Example 7 includes the apparatus of any of Examples 1-6, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

[00128] Example 8 includes the apparatus of any of Examples 1-7, wherein a plurality of signatures, time resources and frequency resources are reserved for transmitting the PRACH signal from the UE to trigger the mission critical communication.

[00129] Example 9 includes the apparatus of any of Examples 1-8, wherein the PRACH signal is communicated to the eNodeB with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE.

[00130] Example 10 includes the apparatus of any of Examples 1-9, wherein the PRACH signal is transmitted from the UE to the eNodeB in accordance with a maximum transmit power.

[00131] Example 11 includes the apparatus of any of Examples 1-10, wherein the UE is

configured to receive the RAR message from the eNodeB by monitoring a RAR message window, wherein a position of the RAR message window is configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

[00132] Example 12 includes the apparatus of any of Examples 1-11, further configured to receive a preamble from the eNodeB prior to receiving the RAR message, wherein the preamble functions to improve a downlink synchronization accuracy.

[00133] Example 13 includes the apparatus of any of Examples 1-12, wherein the RAR message received at the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

[00134] Example 14 includes the apparatus of any of Examples 1-13, wherein: the RAR message is received at the UE via a physical downlink control channel (PDCCH), wherein the UE is configured to monitor the PDCCH using a cyclic redundancy check (CRC) scrambled by a random-access radio network temporary identifier (RA-RNTI); or the RAR message is received at the UE via a physical downlink shared channel (PDSCH) that is scheduled by the PDCCH.

[00135] Example 15 includes the apparatus of any of Examples 1-14, wherein: a gap between a last subframe for a RAR message transmission and a starting subframe of the mission critical communication in uplink is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling; and a gap between a last subframe of the mission critical communication in uplink and a starting subframe of an acknowledgement (ACK) or a negative acknowledgement (NACK) transmission is predefined or configured by higher layers via one of: the MIB, the SIB, or dedicated RRC signaling.

[00136] Example 16 includes the apparatus of any of Examples 1-15, wherein the UE includes at least one of an antenna, a touch sensitive display screen, a speaker, a microphone, a graphics processor, an application processor, a baseband processor, an internal memory, a non-volatile memory port, and combinations thereof.

[00137] Example 17 includes an apparatus of a base station operable to receive mission

critical communications from a user equipment (UE), the apparatus comprising one or more processors and memory configured to: receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI); transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message; and transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00138] Example 18 includes the apparatus of Example 17, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00139] Example 19 includes the apparatus of any of Examples 17-18, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

[00140] Example 20 includes the apparatus of any of Examples 17-19, wherein: the PRACH signal is received from the UE with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device

identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE; and the RAR message transmitted to the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

[00141] Example 21 includes the apparatus of any of Examples 17-20, wherein the RAR message is transmitted to the UE via a physical downlink control channel (PDCCH) or a physical downlink shared channel (PDSCH).

[00142] Example 22 includes at least one machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, the instructions when executed perform the following: transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI); receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI; performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI; and receiving, using the at least one processor of the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

[00143] Example 23 includes the at least one machine readable storage medium of Example 22, wherein the UE is configured to initiate performance of the mission critical

communication when in a radio resource control (RRC) idle mode.

[00144] Example 24 includes the at least one machine readable storage medium of any of Examples 22-23, wherein the first TTI is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

[00145] Example 25 includes the at least one machine readable storage medium of any of Examples 22-24, further comprising instructions which when executed perform the following: performing repeated transmissions of the repeatedly transmit the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and performing repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB.

[00146] Various techniques, or certain aspects or portions thereof, may take the form of program code (i.e., instructions) embodied in tangible media, such as floppy diskettes, compact disc-read-only memory (CD-ROMs), hard drives, non-transitory computer readable storage medium, or any other machine-readable storage medium wherein, when the program code is loaded into and executed by a machine, such as a computer, the machine becomes an apparatus for practicing the various techniques. A non-transitory computer readable storage medium can be a computer readable storage medium that does not include signal. In the case of program code execution on programmable computers, the computing device may include a processor, a storage medium readable by the processor (including volatile and non-volatile memory and/or storage elements), at least one input device, and at least one output device. The volatile and non-volatile memory and/or storage elements may be a random-access memory (RAM), erasable programmable read only memory (EPROM), flash drive, optical drive, magnetic hard drive, solid state drive, or other medium for storing electronic data. The node and wireless device may also include a transceiver module (i.e., transceiver), a counter module (i.e., counter), a processing module (i.e., processor), and/or a clock module (i.e., clock) or timer module (i.e., timer). One or more programs that may implement or utilize

the various techniques described herein may use an application programming interface (API), reusable controls, and the like. Such programs may be implemented in a high level procedural or object oriented programming language to communicate with a computer system. However, the program(s) may be implemented in assembly or machine language, if desired. In any case, the language may be a compiled or interpreted language, and combined with hardware implementations.

[00147] As used herein, the term "circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

[00148] It should be understood that many of the functional units described in this specification have been labeled as modules, in order to more particularly emphasize their implementation independence. For example, a module may be implemented as a hardware circuit comprising custom very-large-scale integration (VLSI) circuits or gate arrays, off-the-shelf semiconductors such as logic chips, transistors, or other discrete components. A module may also be implemented in programmable hardware devices such as field programmable gate arrays, programmable array logic, programmable logic devices or the like.

[00149] Modules may also be implemented in software for execution by various types of processors. An identified module of executable code may, for instance, comprise one or more physical or logical blocks of computer instructions, which may, for instance, be organized as an object, procedure, or function. Nevertheless, the executables of an identified module may not be physically located together, but may comprise disparate instructions stored in different locations which, when joined logically together, comprise the module and achieve the stated purpose for the module.

[00150] Indeed, a module of executable code may be a single instruction, or many instructions, and may even be distributed over several different code segments, among

different programs, and across several memory devices. Similarly, operational data may be identified and illustrated herein within modules, and may be embodied in any suitable form and organized within any suitable type of data structure. The operational data may be collected as a single data set, or may be distributed over different locations including over different storage devices, and may exist, at least partially, merely as electronic signals on a system or network. The modules may be passive or active, including agents operable to perform desired functions.

[00151] Reference throughout this specification to "an example" or “exemplary” means that a particular feature, structure, or characteristic described in connection with the example is included in at least one embodiment of the present technology. Thus, appearances of the phrases "in an example" or the word “exemplary” in various places throughout this specification are not necessarily all referring to the same embodiment.

[00152] As used herein, a plurality of items, structural elements, compositional elements, and/or materials may be presented in a common list for convenience. However, these lists should be construed as though each member of the list is individually identified as a separate and unique member. Thus, no individual member of such list should be construed as a de facto equivalent of any other member of the same list solely based on their presentation in a common group without indications to the contrary. In addition, various embodiments and example of the present technology may be referred to herein along with alternatives for the various components thereof. It is understood that such embodiments, examples, and alternatives are not to be construed as defacto equivalents of one another, but are to be considered as separate and autonomous representations of the present technology.

[00153] Furthermore, the described features, structures, or characteristics may be combined in any suitable manner in one or more embodiments. In the following description, numerous specific details are provided, such as examples of layouts, distances, network examples, etc., to provide a thorough understanding of embodiments of the technology. One skilled in the relevant art will recognize, however, that the technology can be practiced without one or more of the specific details, or with other methods, components, layouts, etc. In other instances, well-known structures, materials, or operations are not shown or described in detail to avoid obscuring aspects of the

technology.

[00154] While the forgoing examples are illustrative of the principles of the present technology in one or more particular applications, it will be apparent to those of ordinary skill in the art that numerous modifications in form, usage and details of implementation can be made without the exercise of inventive faculty, and without departing from the principles and concepts of the technology. Accordingly, it is not intended that the technology be limited, except as by the claims set forth below.

CLAIMS

What is claimed is:

1. An apparatus of a user equipment (UE) operable to perform mission critical communications with an eNodeB, the apparatus comprising one or more processors and memory configured to:

transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI);

receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication; and

perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI.

2. The apparatus of claim 1, further configured to receive, from the eNodeB, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

3. The apparatus of claim 1, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and the second TTI is approximately 0.1 to

0.2 ms.

4. The apparatus of claim 1, wherein the first TTI is associated with a first partition of a low band and the second TTI is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

5. The apparatus of any of claims 1 to 4, wherein the UE is configured to:

perform repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and

perform repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB,

wherein a maximum number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling,

wherein the UE performs a random back off and reinitiates a procedure for performing the mission critical communication when the maximum number of repetitions for a defined transmission is reached.

6. The apparatus of claim 1, wherein the UE is configured to:

repeatedly transmit the PRACH signal to the eNodeB in accordance with a fixed number of repetitions; and

repeatedly perform the mission critical communication with the eNodeB in accordance with a fixed number of repetitions,

wherein the fixed number of repetitions for each transmission from the UE is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

7. The apparatus of claim 1, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

8. The apparatus of claim 1, wherein a plurality of signatures, time resources and frequency resources are reserved for transmitting the PRACH signal from the UE to trigger the mission critical communication.

9. The apparatus of claim 1, wherein the PRACH signal is communicated to the eNodeB with a scheduling request (SR), wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE.

10. The apparatus of claim 1, wherein the PRACH signal is transmitted from the UE to the eNodeB in accordance with a maximum transmit power.

11. The apparatus of claim 1, wherein the UE is configured to receive the RAR message from the eNodeB by monitoring a RAR message window, wherein a position of the RAR message window is configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling.

12. The apparatus of claim 1, further configured to receive a preamble from the eNodeB prior to receiving the RAR message, wherein the preamble functions to improve a downlink synchronization accuracy.

13. The apparatus of claim 1, wherein the RAR message received at the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type

communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

14. The apparatus of claim 1, wherein:

the RAR message is received at the UE via a physical downlink control channel (PDCCH), wherein the UE is configured to monitor the PDCCH using a cyclic redundancy check (CRC) scrambled by a random-access radio network temporary identifier (RA-RNTI); or

the RAR message is received at the UE via a physical downlink shared channel (PDSCH) that is scheduled by the PDCCH.

15. The apparatus of any of claims 6 to 14, wherein:

a gap between a last subframe for a RAR message transmission and a starting subframe of the mission critical communication in uplink is predefined or configured by higher layers via one of: a master information block (MIB), a system information block (SIB) or dedicated radio resource control (RRC) signaling; and

a gap between a last subframe of the mission critical communication in uplink and a starting subframe of an acknowledgement (ACK) or a negative acknowledgement (NACK) transmission is predefined or configured by higher layers via one of: the MIB, the SIB, or dedicated RRC signaling.

16. The apparatus of claim 1, wherein the UE includes at least one of an antenna, a touch sensitive display screen, a speaker, a microphone, a graphics processor, an application processor, a baseband processor, an internal memory, a non-volatile memory port, and combinations thereof.

17. An apparatus of a base station operable to receive mission critical communications from a user equipment (UE), the apparatus comprising one or more processors and memory configured to:

receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the

eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI);

transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message; and

transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

18. The apparatus of claim 17, wherein the first TTI is for a Third Generation Partnership Project (3GPP) Long Term Evolution (LTE) Release 8 orthogonal frequency division multiple access (OFDMA) frame structure and is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

19. The apparatus of claim 17, wherein the dedicated PRACH resources for mission critical communications are multiplexed with PRACH resources for non-mission critical application using at least one of: time division multiplexing (TDM), frequency division multiplexing (FDM) and code division multiplexing (CDM).

20. The apparatus of any of claims 17 to 19, wherein:

the PRACH signal is received from the UE with a scheduling request (SR),

wherein the SR includes at least one of: a mission critical machine type communication (MTC) device identifier (ID), an event ID, a mission critical MTC device capability, and a resource request and a modulation and coding scheme (MCS) for the mission critical communication in uplink from the UE; and

the RAR message transmitted to the UE includes at least one of: the timing advance (TA), an uplink grant that contains the resource allocation for the mission critical communication, a mission critical machine type communication (MTC) device identifier (ID), an event ID, and a random access preamble ID.

21. The apparatus of claim 17, wherein the RAR message is transmitted to the UE via a physical downlink control channel (PDCCH) or a physical downlink shared channel (PDSCH).

22. At least one machine readable storage medium having instructions embodied thereon for performing mission critical communications between a user equipment (UE) and an eNodeB, the instructions when executed perform the following:

transmitting, using at least one processor of the UE, a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI);

receiving, using the at least one processor of the UE, a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI;

performing, using the at least one processor of the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI; and

receiving, using the at least one processor of the UE, an acknowledgement

(ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI.

23. The at least one machine readable storage medium of claim 22, wherein the UE is configured to initiate performance of the mission critical communication when in a radio resource control (RRC) idle mode.

24. The at least one machine readable storage medium of claim 22, wherein the first TTI is approximately one millisecond (ms) and is associated with a first partition of a low band, wherein the second TTI is approximately 0.1 to 0.2 ms and is associated with a second partition of a low band, wherein the first partition is utilized for non-mission critical communications and the second partition is utilized for mission critical communications.

25. The at least one machine readable storage medium of any of claims 22 to 24, further comprising instructions which when executed perform the following:

performing repeated transmissions of the PRACH signal to the eNodeB until the RAR message is received from the eNodeB; and

performing repeated mission critical communications with the eNodeB until an acknowledgement (ACK) or a negative acknowledgement (NACK) is received from the eNodeB.

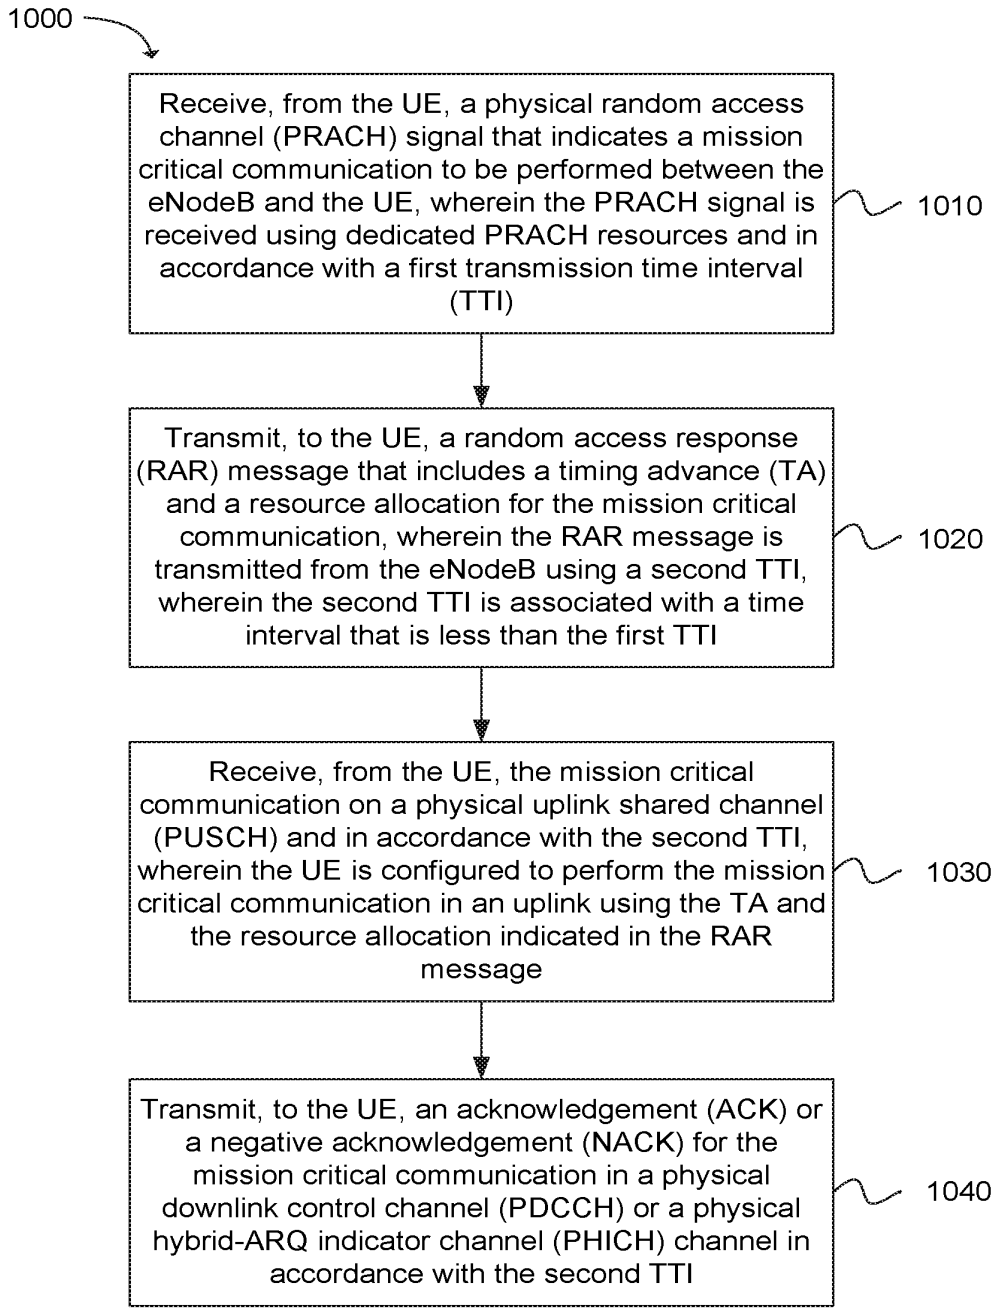
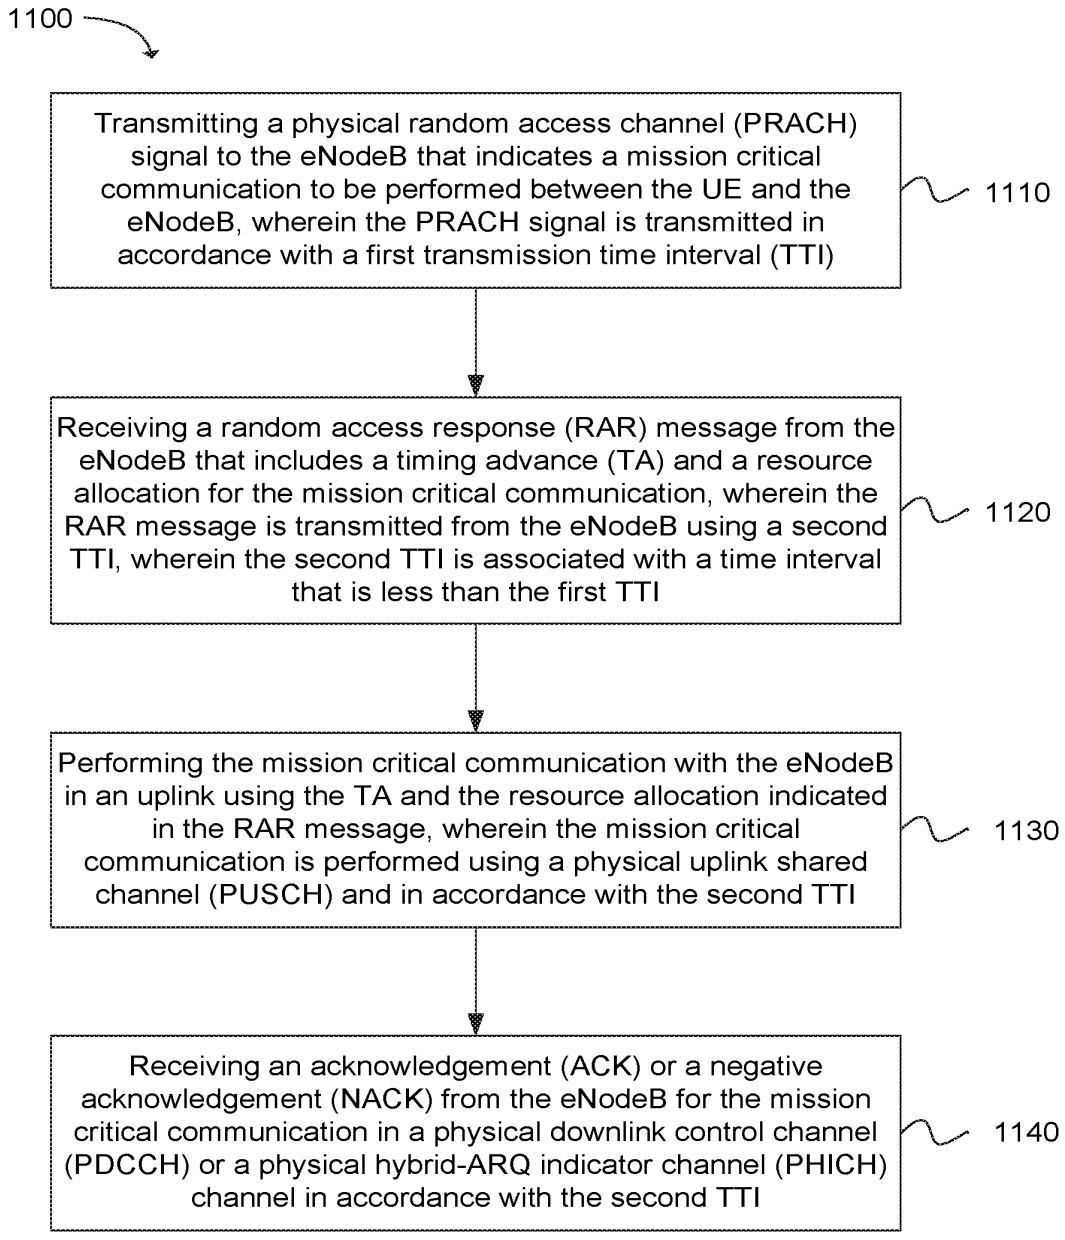
900
Transmit, from the UE to the eNodeB, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted using dedicated PRACH resources and in accordance with a first transmission time interval (TTI)
910
Receive, from the eNodeB, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
920
Decode, at the UE, the RAR message to determine the TA and the resource allocation for the mission critical communication
930
Perform, at the UE, the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI
940

FIG. 9



1000
Receive, from the UE, a physical random access channel (PRACH) signal that indicates a mission critical communication to be performed between the eNodeB and the UE, wherein the PRACH signal is received using dedicated PRACH resources and in accordance with a first transmission time interval (TTI)
1010
Transmit, to the UE, a random access response (RAR) message that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
1020
Receive, from the UE, the mission critical communication on a physical uplink shared channel (PUSCH) and in accordance with the second TTI, wherein the UE is configured to perform the mission critical communication in an uplink using the TA and the resource allocation indicated in the RAR message
1030
Transmit, to the UE, an acknowledgement (ACK) or a negative acknowledgement (NACK) for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI
1040

FIG. 10



1100
Transmitting a physical random access channel (PRACH) signal to the eNodeB that indicates a mission critical communication to be performed between the UE and the eNodeB, wherein the PRACH signal is transmitted in accordance with a first transmission time interval (TTI)
1110
Receiving a random access response (RAR) message from the eNodeB that includes a timing advance (TA) and a resource allocation for the mission critical communication, wherein the RAR message is transmitted from the eNodeB using a second TTI, wherein the second TTI is associated with a time interval that is less than the first TTI
1120
Performing the mission critical communication with the eNodeB in an uplink using the TA and the resource allocation indicated in the RAR message, wherein the mission critical communication is performed using a physical uplink shared channel (PUSCH) and in accordance with the second TTI
1130
Receiving an acknowledgement (ACK) or a negative acknowledgement (NACK) from the eNodeB for the mission critical communication in a physical downlink control channel (PDCCH) or a physical hybrid-ARQ indicator channel (PHICH) channel in accordance with the second TTI

(54) Title: DEVICE AND METHODS FOR MULTIPLEXING TRANSMISSIONS WITH DIFFERENT TTI DURATION

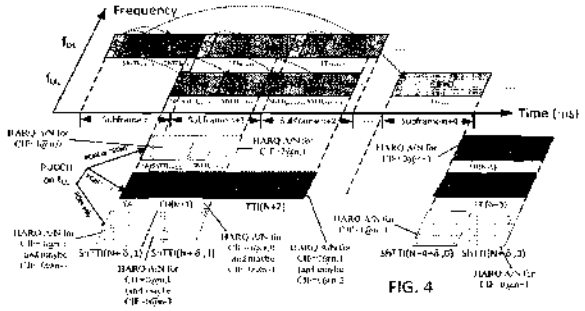

FIG. 4

(57) Abstract: A wireless transmit/receive unit, WTRU and methods of using a WTRU within a wireless communications network include communicating with a serving cell in the wireless communications network and determining, based on downlink control information whether the WTRU shall transmit with a first transmission time interval, TTI, length, using a first set of transmission resources, or a second TTI length, using a second set of transmission resources. Alternatively, determining based on said DCI, that the serving cell has indicated that the WTRU should use a first TTI on a physical uplink channel to communicate with the serving cell, or whether said DCI indicates that the WTRU should use a second TTI that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation.

WO 2017/079530 A1

DEVICE AND METHODS FOR MULTIPLEXING TRANSMISSIONS WITH DIFFERENT TTI DURATION

BACKGROUND

[0001] In a wireless communication network, such as a Long Term Evolution (LTE) system or New Radio (NR), a wireless transmit/receive unit (WTRU) device may access resources of the communication system. Latency associated with transmission of data in a communication system may have one or more latency components. A latency component may be the time to perform the transmission of a transport block, which time may be referred to as a Transmission Time Interval (TTI). Such TTI may be tied to a specific numerology associated with the transmission method and to a specific number of transmission symbols associated with the transmission. Other latency components may include processing time at a receiver, e.g., time decoding a transmission, transmission of feedback (e.g. ACK or NACK) and/or one or more retransmissions with one or more latency components.

SUMMARY

[0002] Systems, methods, and instrumentalities are disclosed for multiplexing transmissions with different durations, for example transmissions that are associated with different TTI lengths. Latency may be reduced (e.g., in an LTE system and/or in a NR system), for example, by multiplexing transmissions with different TTI durations or associated with different transmission numerologies. TTI duration may be modeled based on defining one or more cell(s) for a given carrier frequency, for example that may be associated with different TTI lengths and/or transmission durations. For example, the different transmission durations may be achieved by time-shifting one or more of the cells. In order to support signaling techniques that allow for concurrent and/or complementary scheduling of transmissions associated with different duration, a logical structure for the physical layer resources (e.g., a cell, a spectrum block, etc.) may configured to correspond to a secondary cell ("SCell"). A primary cell ("PCell") may logically maintain a first transmission duration (e.g., a first TTI length such as a legacy TTI length). The SCell may be configured with a second transmission duration (e.g., a second TTI length or a shortened TTI length). One or more of a PCell or an SCell may be configured with either the legacy or shortened TTI length (e.g., a shorter duration TTI (ShTTI).

[0003] By associating different TTI lengths with different cells, the LTE carrier aggregation framework can be utilized to support multiplexing of transmissions of different durations. For example, carrier aggregation signaling, including cross-carrier scheduling mechanisms, can be used to different scheduling grants and assignments of varying length. For example, a WTRU may determine a TTI duration (e.g., first or second TTI length) applicable to a transmission. For example, a WTRU may determine a TTI duration using cross-carrier scheduling. A WTRU may be configured to associate a given cell identity (e.g., servCellID) with a given transmission duration. Different cell identities (e.g., different servCellIDs) may be associated with different transmission durations/different TTI lengths. When a WTRU receives scheduling information applicable to a given cell identity, the WTRU may determine the associated TTI length based on the configuration received for that cell identity.

[0004] A WTRU may determine a TTI length and/or transmission duration based on one or more parameters and/or received fields. For example, a WTRU may associate a given TTI duration with a given transmission mode (TM). A TTI duration may be indicated by a Carrier Indicator Field (CIF), for example where certain values of the CIF are associated with SCells configured with a given TTI durations such as a ShTTI. The CIF may also be referred to as a Carrier Indicator Field (CIF). The TTI duration may be indicated by a field that indicates a set of resources such as a set of PRBs, a carrier, a serving cell of the WTRU's configuration, and/or a spectrum block. A TTI duration may be determined from an identity of a PRB subset associated with the transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using a medium access control (MAC) Activation/Deactivation control element. MAC Activation/Deactivation CE may be used to toggle between first and second TTIs (e.g. legacy TTI and ShTTIs) or between slot-based ShTTIs and/or may be used to determine zero, one or more TTI (e.g. ShTTI) period(s) within a subframe.

[0005] HARQ processing may be performed according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. An exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA) formats and/or (e.g. legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g. legacy) format, although, for example, interpretation of fields such as the CIF and/or fields that indicate the PRBs applicable for the transmission may be different than the interpretations of the first

(e.g. legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. Physical random access channel (PRACH) resources and/or physical downlink control channel (PDCCH) order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g. a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0006] A method of using a wireless transmit/receive unit within a wireless communications network that is capable of aggregating different sets of physical layer resources (e.g., such as carrier aggregation, for example) may include communicating with a serving cell in the wireless communications network and determining that the serving cell has indicated that the WTRU should use a first transmission time interval on a physical uplink channel to communicate with the serving cell. The method may also include determining whether downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel). The method may further include communicating with the wireless communications network using the second transmission time interval.

[0007] The method may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g, on the physical uplink channel) comprises determining based on a carrier indicator field in received downlink control information.

[0008] The method may include communicating with the wireless communications network using the second transmission time interval comprises communicating with the serving cell using the second transmission time interval.

[0009] The method may include wherein communicating with the wireless communications network using the second transmission time interval includes communicating with a secondary cell using the second transmission time interval.

[0010] The method may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a third

transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network. The shorten transmission time interval may correspond to at least one of at least one symbol or at least one resource block. The first transmission time interval may be one millisecond.

[0011] The method may include determining a time to transmit with the second transmission time interval based on the downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment). The time to transmit may defined by a time partition (e.g., a slot in a subframe and/or one or more time symbols, (e.g., OFDM symbols), an arrangement of symbols, a min-slot, or other time for a sub-carrier spacing).

[0012] The method may include determining whether a first downlink control information (e.g., using carrier aggregation fields such as the CIF) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel) or whether the WTRU should transmit using carrier aggregation comprises determining with cross-carrier scheduling.

[0013] A wireless transmit/receive unit (WTRU) for use within a wireless communications network that is capable of carrier aggregation may have a processor having executable instructions that communicate with a serving cell in the wireless communications network and determine that the serving cell has indicated that the WTRU should use a first transmission time interval on an uplink channel (e.g., physical uplink channel) to communicate with the serving cell. The processor instructions may include determining whether a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel). The WTRU processor instructions may include communicating with the wireless communications network using the second transmission time interval.

[0014] The WTRU processor instructions that determine that a first downlink control information (e.g, carrier aggregation field such as the CIF) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel) may comprise determining based on a carrier indicator field in received downlink control information.

[0015] The WTRU processor executable instructions that communicate with the wireless communications network using the second transmission time interval may comprise communicating with the serving cell using the second transmission time interval.

[0016] The WTRU processor executable instructions that communicate with the wireless communications network using the second transmission time interval may comprise communicating with a secondary cell using the second transmission time interval.

[0017] The WTRU processor executable instructions may include determining that a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network. The shorten transmission time interval may correspond to at least one of at least one symbol or at least one resource block. The first transmission time interval may be one millisecond.

[0018] The WTRU processor executable instructions may include determining a time to transmit with the second transmission time interval based on the downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment). The time to transmit may be defined by a slot in a subframe.

[0019] The WTRU processor executable instructions that determine whether a downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network (e.g., on the physical uplink channel).

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] FIG. 1A is a system diagram of an example communications system in which disclosed subject matter may be implemented.

[0021] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used in a communications system.

[0022] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0023] FIG. 1D is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0024] FIG. 1E is a system diagram of an example radio access network and an example core network that may be used in a communications system.

[0025] FIG. 2 shows an example of DL physical layer channels.

[0026] FIG. 3 shows an example of UL physical layer channels.

[0027] FIG. 4 is an example of scheduling with time-shifted cells.

DETAILED DESCRIPTION

[0028] A detailed description of illustrative embodiments will now be described with reference to the various figures. Although this description provides a detailed example of possible implementations, it should be noted that the details are intended to be exemplary and in no way limit the scope of the application.

[0029] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, for example voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, for example code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0030] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, and/or 102d (which generally or collectively may be referred to as WTRU 102), a radio access network (RAN) 103/104/105, a core network 106/107/109, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include a user equipment (WTRU), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0031] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to

one or more communication networks, for example the core network 106/107/109, the Internet 110, and/or the networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0032] The base station 114a may be part of the RAN 103/104/105, which may also include other base stations and/or network elements (not shown), for example a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In an embodiment, the base station 114a may employ multiple-input multiple output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0033] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 115/116/117, which may be any suitable wireless communication link (e.g. radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 115/116/117 may be established using any suitable radio access technology (RAT).

[0034] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, for example CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 103/104/105 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 115/116/117 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0035] In an embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 115/116/117 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0036] In an embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), New Radio (NR) and the like. The descriptions and example provided herein apply to any of the air interface and communications standards that have been implemented although the terminology may differ among them for the functional components.

[0037] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, for example a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In an embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet an embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (e.g. WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106/107/109.

[0038] The RAN 103/104/105 may be in communication with the core network 106/107/109, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106/107/109 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, for example user authentication. Although not shown in FIG. 1A, it will be appreciated that the RAN 103/104/105 and/or the core network 106/107/109 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 103/104/105 or a different RAT. For example, in addition to being connected to the RAN 103/104/105, which may be utilizing an E-UTRA radio technology, the core network 106/107/109 may also be in communication with a RAN (not shown) employing a GSM radio technology.

[0039] The core network 106/107/109 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The

PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, for example the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include a core network connected to one or more RANs, which may employ the same RAT as the RAN 103/104/105 or a different RAT.

[0040] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0041] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment. Also, embodiments contemplate that the base stations 114a and 114b, and/or the nodes that base stations 114a and 114b may represent, for example but not limited to transceiver station (BTS), a Node-B, a site controller, an access point (AP), a home node-B, an evolved home node-B (eNodeB), a home evolved node-B (HeNB), a home evolved node-B gateway, and proxy nodes, among others, may include some or each of the elements depicted in FIG. 1B and described herein.

[0042] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the

transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0043] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (e.g. the base station 114a) over the air interface 115/116/117. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In an embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet an embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0044] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (e.g. multiple antennas) for transmitting and receiving wireless signals over the air interface 115/116/117.

[0045] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, for example UTRA and IEEE 802.11, for example.

[0046] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (e.g. a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, for example the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In an embodiment, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, for example on a server or a home computer (not shown).

[0047] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (e.g. nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0048] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (e.g. longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 115/116/117 from a base station (e.g. base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0049] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0050] FIG. 1C is a system diagram of the RAN 103 and the core network 106 according to an embodiment. As noted above, the RAN 103 may employ a UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 115. The RAN 103 may also be in communication with the core network 106. As shown in FIG. 1C, the RAN 103 may include Node-Bs 140a, 140b, 140c, which may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 115. The Node-Bs 140a, 140b, 140c may each be associated with a particular cell (not shown) within the RAN 103. The RAN 103 may also include RNCs 142a, 142b. It will be appreciated that the RAN 103 may include any number of Node-Bs and RNCs while remaining consistent with an embodiment.

[0051] As shown in FIG. 1C, the Node-Bs 140a, 140b may be in communication with the RNC 142a. Additionally, the Node-B 140c may be in communication with the RNC142b. The Node-Bs 140a, 140b, 140c may communicate with the respective RNCs 142a, 142b via an Iub interface. The RNCs 142a, 142b may be in communication with one another via an Iur interface.

Each of the RNCs 142a, 142b may be configured to control the respective Node-Bs 140a, 140b, 140c to which it is connected. In addition, each of the RNCs 142a, 142b may be configured to carry out or support other functionality, for example outer loop power control, load control, admission control, packet scheduling, handover control, macro diversity, security functions, data encryption, and the like.

[0052] The core network 106 shown in FIG. 1C may include a media gateway (MGW) 144, a mobile switching center (MSC) 146, a serving GPRS support node (SGSN) 148, and/or a gateway GPRS support node (GGSN) 150. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0053] The RNC 142a in the RAN 103 may be connected to the MSC 146 in the core network 106 via an IuCS interface. The MSC 146 may be connected to the MGW 144. The MSC 146 and the MGW 144 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices.

[0054] The RNC 142a in the RAN 103 may also be connected to the SGSN 148 in the core network 106 via an IuPS interface. The SGSN 148 may be connected to the GGSN 150. The SGSN 148 and the GGSN 150 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between and the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0055] As noted above, the core network 106 may also be connected to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0056] FIG. 1D is a system diagram of the RAN 104 and the core network 107 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 107.

[0057] The RAN 104 may include eNode-Bs 160a, 160b, 160c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 160a, 160b, 160c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 160a, 160b, 160c may implement MIMO technology. Thus, the eNode-B 160a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0058] Each of the eNode-Bs 160a, 160b, 160c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1D, the eNode-Bs 160a, 160b, 160c may communicate with one another over an X2 interface.

[0059] The core network 107 shown in FIG. 1D may include a mobility management gateway (MME) 162, a serving gateway 164, and a packet data network (PDN) gateway 166. While each of the foregoing elements are depicted as part of the core network 107, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0060] The MME 162 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 162 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 162 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, for example GSM or WCDMA.

[0061] The serving gateway 164 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via the S1 interface. The serving gateway 164 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 164 may also perform other functions, for example anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0062] The serving gateway 164 may also be connected to the PDN gateway 166, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0063] The core network 107 may facilitate communications with other networks. For example, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 107 may include, or may communicate with, an IP gateway (e.g. an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 107 and the PSTN 108. In addition, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to

the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0064] FIG. 1E is a system diagram of the RAN 105 and the core network 109 according to an embodiment. The RAN 105 may be an access service network (ASN) that employs IEEE 802.16 radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 117. As will be further discussed below, the communication links between the different functional entities of the WTRUs 102a, 102b, 102c, the RAN 105, and the core network 109 may be defined as reference points.

[0065] As shown in FIG. 1E, the RAN 105 may include base stations 180a, 180b, 180c, and an ASN gateway 182, though it will be appreciated that the RAN 105 may include any number of base stations and ASN gateways while remaining consistent with an embodiment. The base stations 180a, 180b, 180c may each be associated with a particular cell (not shown) in the RAN 105 and may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 117. In one embodiment, the base stations 180a, 180b, 180c may implement MIMO technology. Thus, the base station 180a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a. The base stations 180a, 180b, 180c may also provide mobility management functions, for example handoff triggering, tunnel establishment, radio resource management, traffic classification, quality of service (QoS) policy enforcement, and the like. The ASN gateway 182 may serve as a traffic aggregation point and may be responsible for paging, caching of subscriber profiles, routing to the core network 109, and the like.

[0066] The air interface 117 between the WTRUs 102a, 102b, 102c and the RAN 105 may be defined as an R1 reference point that implements the IEEE 802.16 specification. In addition, each of the WTRUs 102a, 102b, 102c may establish a logical interface (not shown) with the core network 109. The logical interface between the WTRUs 102a, 102b, 102c and the core network 109 may be defined as an R2 reference point, which may be used for authentication, authorization, IP host configuration management, and/or mobility management.

[0067] The communication link between each of the base stations 180a, 180b, 180c may be defined as an R8 reference point that includes protocols for facilitating WTRU handovers and the transfer of data between base stations. The communication link between the base stations 180a, 180b, 180c and the ASN gateway 182 may be defined as an R6 reference point. The R6 reference point may include protocols for facilitating mobility management based on mobility events associated with each of the WTRUs 102a, 102b, 102c.

[0068] As shown in FIG. 1E, the RAN 105 may be connected to the core network 109. The communication link between the RAN 105 and the core network 109 may defined as an R3 reference point that includes protocols for facilitating data transfer and mobility management capabilities, for example. The core network 109 may include a mobile IP home agent (MIP-HA) 184, an authentication, authorization, accounting (AAA) server 186, and a gateway 188. While each of the foregoing elements are depicted as part of the core network 109, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0069] The MIP-HA may be responsible for IP address management, and may enable the WTRUs 102a, 102b, 102c to roam between different ASNs and/or different core networks. The MIP-HA 184 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, for example the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices. The AAA server 186 may be responsible for user authentication and for supporting user services. The gateway 188 may facilitate interworking with other networks. For example, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, for example the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. In addition, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0070] Although not shown in FIG. 1E, it will be appreciated that the RAN 105 may be connected to other ASNs and the core network 109 may be connected to other core networks. The communication link between the RAN 105 the other ASNs may be defined as an R4 reference point, which may include protocols for coordinating the mobility of the WTRUs 102a, 102b, 102c between the RAN 105 and the other ASNs. The communication link between the core network 109 and the other core networks may be defined as an R5 reference, which may include protocols for facilitating interworking between home core networks and visited core networks.

[0071] Systems, methods, and instrumentalities are disclosed for multiplexing transmissions with different durations, for example such as transmission that utilize different TTI lengths. Latency reduction for some transmissions may achieved, for example, by multiplexing transmissions with different TTI durations. Although examples may be described with respect to multiplexing of an LTE legacy TTI (e.g., 1 ms) with a shortened TTI length (e.g., less than 1 ms), the techniques described herein may be generally applicable to the multiplexing of other

types of transmissions that are of different/varying lengths. For example, the examples may be described with respect to transmissions that contain one transport block (TB), but the examples may be equally applicable to transmissions that include a portion of a TB, transmissions that contain multiple TBs, etc. Thus, as may be appreciated, although specific examples herein may be described with respect to multiplexing transmissions associated with a "legacy" 1 ms TTI with transmissions that are less than 1 ms, these examples are not limited to the specific embodiments described and may be applied to transmissions of varying length that include varying amounts of data. Additionally, although examples may be described with respect to multiplexing shorter than 1 ms transmissions into a legacy LTE system that utilizes a legacy TTI length of 1 ms, the techniques may be applied to other types of transmission configurations, for example such as the NR system that may be utilized for 5G cellular communications.

[0072] Transmissions of different length may be realized in multiple ways and be consistent with this disclosure. For example, multiple TTI lengths may be defined, and the system may be configured to multiplex transmissions associated with the different TTI lengths over a common set of transmission resources. In example, rather than or in addition to defining different TTI lengths, transmissions of different durations may be supported, for example where one or more of the transmissions durations may or may not correspond to a TTI. Transmission duration may be defined in a number of ways, for example an amount of time over which the transmission occurs, (e.g., a specific duration or a time partition), a number of symbols over which the transmission occurs (e.g., 14 OFDM symbols, 12 OFDM symbols, 1 OFDM symbol, etc.), a slot, a minislot, a time partition for a sub-carrier spacing, and/or in terms of a specific numerology associated with the transmissions. For example, the numerology may be defined based on one or more of a sub-carrier spacing (e.g., different sub-carrier spacing may lead to different time durations for a symbol), a symbol length, a waveform type, etc.

[0073] Examples may also be described with respect to one or more cells. However, the techniques described herein may be equally applicable to other types of resource partitions. For example, in LTE cells may be defined based on certain OFDM time-frequency resources that are defined for a certain operating band for the cell. However, the multiplexing techniques described herein may be applied to physical resources that may or may not be defined using the cell construct. For example, the techniques described herein may apply of a subset of the physical resources in a cell and/or to physical resources that are not defined using the cell construct.

[0074] In order to TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency, e.g. in an LTE system such as a legacy LTE system. A "logical" cell structure may correspond to an SCell (e.g., a legacy SCell). A PCell may logically maintain

a TTI (e.g., a first TTI such as a legacy TTI that may be 1 ms) or may be (e.g. also) configured with a second duration TTI (e.g., a shorter duration TTI (ShTTI) that may be less than 1 ms).

[0075] In an example, a WTRU may determine a TTI duration (e.g. first or second TTI) applicable to a transmission. A determination may be, for example, a function of one or more facts, factors, and/or parameters. For example, a WTRU may determine a TTI duration using cross-carrier scheduling information. A WTRU may associate a certain TTI duration with a certain cell identity (e.g. servCellID). A WTRU may associate a certain TTI duration with certain a transmission mode (TM). A TTI duration may be indicated by a CIF included in DCI. For example, a first cell identity (e.g., servCellID = 1) may be associated with a first TTI duration and a second cell identity (e.g., servCellID = 2) may be associated with a second TTI duration. When the CIF field indicates that the received DCI is applicable to the first cell identity (e.g., CIF = '001' - servCellID = 1), the WTRU may determine that the scheduled transmission is associated with the first TTI duration. When the CIF field indicates that the received DCI is applicable to the second cell identity (e.g., CIF = '010' - servCellID = 2), the WTRU may determine that the scheduled transmission is associated with the second TTI duration. In this matter, carrier aggregation signaling methods may be reused/reinterpreted in order to support multiple TTI length.

[0076] A TTI duration may be determined from an identity of a PRB subset associated with the transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using MAC Activation/Deactivation. MAC Activation/Deactivation may be used to toggle between first and second TTIs (e.g. between a legacy TTI and one or more ShTTIs). For example, a WTRU may utilize a first TTI length for a first cell prior to receiving MAC Activation/Deactivation control element. Upon receiving the MAC Activation/Deactivation control element for the first cell, the WTRU may toggle to a second TTI length. In an example, the MAC Activation/Deactivation control element may be used to toggle between different slots used for a ShTTI transmission in a legacy suframe. For example, the MAC Activation/Deactivation control element may be used to switch between the first and second slots for the shortened TTI transmission. MAC Activation/Deactivation may be used to determine zero, one or more ShTTIs period(s) within a subframe.

[0077] HARQ processing may remain according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. In an example, an exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA)

formats and/or (e.g., legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g., legacy) format, although, for example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different than the first (e.g., legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. PRACH resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g., a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0078] A device may access resources of a communication system. Latency associated with transmission of data may have one or more latency components. A latency component may be the time to perform the transmission of a transport block, which time may be referred to as a Transmission Time Interval (TTI). A latency component may be processing time at a receiver, e.g., time decoding a transmission. Receiver processing time may be tied to implementation complexity and may be accounted for using a fixed timing relationship between different events associated with the transmission of a data unit. A timing relationship may be fixed, for example, when time-division duplex (TDD) is used for a carrier and/or synchronous Hybrid ARQ (HARQ) operation (e.g., such as for LTE in the uplink).

[0079] There may be additional latency components, for example, when a transmission is not successfully decoded. For example, additional components may include transmission of feedback (e.g. HARQ ACK or NACK), processing time at the receiver and/or one or more retransmissions with one or more latency components.

[0080] Latency components may be measured in integer multiples of a basic time interval (BTI). For example, latency components may be measured in TTIs, e.g., in LTE.

[0081] Latency in wireless networks may be caused by multiple factors. Latency may be affected, e.g., at lower layers, by a need for highly reliable transmissions, which may be obtained using HARQ. One or more retransmissions may affect the latency of a transmission, for example, given that retransmissions may not be performed in adjacent time periods.

[0082] A WTRU may incur processing time, for example, for downlink (DL) transmission, to determine whether a transmission was decoded properly, which may lead to a time interval between reception of a DL transmission and transmission of an ACK or NACK. An eNB may

incur processing time, for example, to determine whether an ACK or NACK was transmitted by the WTRU and/or whether a retransmission is required. A similar consumption of processing time may occur for uplink (UL) transmissions. Processing times may be cumulative. There may be a tradeoff between latency and implementation complexity.

[0083] A system (e.g. LTE) may accommodate processing times in a timing relationship between a first transmission for a transport block and its corresponding ACK-NACK HARQ response for downlink and/or uplink operation and possible retransmission.

[0084] Time Division Duplex (TDD) and Frequency Division Duplex (FDD) DL scheduling timing may be the same, such that a WTRU may receive a scheduling grant for a DL transmission in the same subframe or transmission time interval (TTI).

[0085] A WTRU may transmit a corresponding Physical UL Shared Channel (PUSCH), e.g., in subframe n+4, for example, upon detection of a Physical DL Control Channel PDCCH or enhanced PDCCH (EPDCCH) with UL Downlink Control Information (DCI) format and/or Physical Hybrid ARQ Indicator Channel (PHICH) transmission in subframe n, e.g., in an FDD UL transmission intended for the WTRU. A HARQ ACK/NACK response for a DL or UL transmission in subframe n may be provided in subframe n+4.

[0086] A WTRU may transmit a corresponding PUSCH in subframe n+k, for example, upon detection of a (E)PDCCH with UL DCI format and/or PHICH transmission in subframe n, e.g., for a UL transmission in a TDD system intended for the WTRU. The value of k may depend on the TDD UL/DL configuration, the subframe where the UL DCI and/or PHICH was transmitted and/or the PHICH resource and the MSB or LSB of the UL index in the (E)PDCCH, e.g., in TDD UL/DL configuration 0. A HARQ ACK/NACK response for a DL or UL transmission in subframe n may be provided in subframe n+k, where k may depend on the value of n and the TDD UL/DL configuration. Bundling may be used to provide HARQ for multiple transmissions in one instance.

[0087] Processing time available to a WTRU may depend, for example, on the value of the timing advance or on the distance between the WTRU and the eNB. In an example, an LTE system may have a distance of 100km between a WTRU and an eNB, which may correspond to a (e.g. a maximum) timing advance of 0.67ms. In an example, there may be approximately 2.3 ms left for terminal processing. An eNB may have, for example, 3 ms processing time available, which may be on the same order as that of the terminal.

[0088] FIG. 2 shows an example of DL physical layer channels. In a DL example with reference to the example shown in FIG. 2, there may be three channel areas in a subframe to support DL Shared Channel (DL-SCH) and UL-SCH. Three channel areas may comprise a PDCCH (which may include Physical Control Format Indicator Channel (PCFICH) and PHICH),

a Physical DL Shared Channel (PDSCH) and an EPDCCH. An EPDCCH may include scheduling information for a WTRU while taking advantage of the benefits of the PDSCH region, such as beamforming gain and frequency domain Inter-Cell Interference Coordination (ICIC) and/or improving PDCCH capacity.

[0089] FIG. 3 shows an example of UL physical layer channels. In a UL example with reference to the example shown in FIG. 3, there may be two channel areas in a subframe to support DL-SCH and UL-SCH. Two channel areas may comprise a PUSCH and a PDSCH. These channel areas may be transmitted in different RBs in each time slot (e.g. frequency hopping of PUSCH), for example, to increase robustness in frequency selective channels.

[0090] A transmission time interval (TTI) duration may be based on and/or defined by one or more symbols. A TTI duration may be defined in terms of a number of OFDM symbols. For example, a TTI duration may be defined as an entire (legacy) subframe and/or a pair of physical resource blocks (PRBs). In the legacy 1 ms TTI length, there may be 14 OFDM symbols for normal cyclic prefix and 12 OFDM symbols for extended cyclic prefix. For example when multiplexing ShTTI transmissions with legacy TTI transmissions of 1 ms, a ShTTI may be made as short as a single ODFM symbol. Symbol-based categorization may be referred to as symbol-based TTI durations.

[0091] A TTI duration may be based on time-varying symbol duration. TTI durations may have a fixed number of symbols (e.g., 14 symbols) while symbol duration may vary in time. For example, variable time symbol-based TTI duration may be achieved by modifying subcarrier spacing. In an example, a first TTI duration may be achieved with a first subcarrier spacing and a second TTI duration may be achieved with a second subcarrier spacing. Different bandwidth portions (e.g. PRBs) of a carrier may support different subcarrier spacing, thus enabling different TTI duration for different bandwidth portions (e.g. PRBs). Multiplexing transmissions associated with different sub-carrier spacing and/or symbol duration may be applicable to 5G systems such as NR. Such techniques may also be used in LTE-Advanced.

[0092] A TTI duration may be based on a time slot. A TTI duration may be defined in terms of a time slot (e.g. 7 OFDM symbols for normal cyclic prefix and 6 OFDM symbols for extended cyclic prefix). For example, if a ShTTI is defined as the length of one slot, two ShTTI transmissions may be time multiplexed into a legacy 1 ms TTI length.

[0093] A TTI duration may be based on time. A TTI duration may be defined in terms of a time value (e.g. 1ms legacy TTI or a 100ms ShTTI).

[0094] A TTI duration may be based on a hybrid, such as a combination of forgoing TTI duration bases. In an example of a hybrid method of achieving variable TTI durations, a different number of symbols and different symbol durations may be used.

[0095] Latency may be improved. It may be beneficial to decrease the TTI duration of different channels. A decrease in TTI duration may enable a decrease in WTRU processing time and may permit a WTRU to begin processing data sooner. Such a scenario may enable a shorter HARQ timeline. Different channels may have different TTI durations. A TTI duration shorter than one subframe for one or more of the EPDCCH, PDSCH, PUCCH, PDSCH, etc. may be provided. Effective HARQ feedback for PDSCH and PUSCH transmissions using shorter than (e.g., legacy 1ms) subframe TTI durations may be provided. Shorter TTIs may be referred to as ShTTI.

[0096] ShTTI and/or a combination of TTI and ShTTI may be supported for a given WTRU, for example, to minimize the impact of other aspects related to WTRU transmissions, such as scheduling (e.g., formats of DCIs), HARQ (e.g., related processing/process identities), feedback formats and determination of an applicable TTI duration. For example, the configuration of ShTTIs and/or the signaling of DCI for ShTTIs may utilize certain signaling originally defined for purposes of carrier aggregation in order to limit the amount of complexity at the WTRU and/or facilitated TTI length multiplexing in a backwards compatible manner. One or more latency components may be reduced, for example, to minimize the impact on WTRU implementations.

[0097] A WTRU may (e.g., based on a determination) operate with a one or more TTI durations, such as subframe TTI duration (e.g., 1 ms), a timeslot TTI duration (e.g., 0.5 ms), a symbol-based TTI duration (e.g., one or more OFDM symbols in duration), and/or other shorter than 1 ms TTI durations. In an example, a WTRU may be configured to operate with specific but different TTI duration configuration in downlink and uplink. In an example, a WTRU may be configured to permit the same TTI duration configuration to be used in downlink and uplink for applicable transmissions. For example, if the WTRU receives a configuration that indicates a first cell is associated with a first TTI duration in the downlink, the WTRU may determine that the uplink TTI duration is also the first TTI duration unless the configuration indicates otherwise.

[0098] A TTI duration may be WTRU specific. A WTRU may operate with a TTI duration during a given period. A WTRU may be configured to operate according to one or more of a plurality of possible TTI durations and may operate with the one or more TTI durations for a specific period of time, e.g., based on an L3 (e.g., radio resource control (RRC)) reconfiguration. A TTI duration may be fixed (e.g. statically, semi-statically or dynamically) for a (e.g. every) transmission to and from a WTRU.

[0099] Multiple TTI durations may be concurrently configured and/or used. A WTRU may be configured to operate for transmissions of different TTI durations concurrently. Different TTI durations may be based on, for example, semi-static allocation (e.g. configuration of a subset of frames/subframes dedicated to different TTI durations based on a semi-persistent grant or assignment) and/or dynamic allocation (e.g. based on detection and/or reception of downlink control signaling).

[0100] A TTI duration may be cell/cell group (CG)-specific. Configuration may be applicable per cell of a WTRU's configuration, for a subset of cells of a WTRU's configuration, and/or for all cells of the same timing advance group (TAG) and/or all cells of the same cell group (CG). For example, upon adding a new cell, the TTI duration may be defined for the new cell. As an example, if the WTRU adds an SCell, the SCell configuration may indicated that the WTRU is to utilize a shortened TTI duration for the SCell. The HARQ instances associated with a specific MAC entity may be configured with a similar configuration for TTI duration. A similar or same configuration for TTI duration may be used, for example, for cells associated with the same channel(s) (e.g. PUCCH, PUSCH) for uplink control signaling.

[0101] TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency. Modeling may enable co-existence between WTRUs operating according to different TTI durations, e.g. in legacy LTE systems. A "logical" cell structure may correspond to the use of one or more serving cell(s). Serving cells may include secondary cells, such as an SCell type or a PSCell type defined for LTE CA. A PCell may logically maintain a first (e.g., legacy) TTI such as 1 ms or may be (e.g., also) configured as a ShTTI.

[0102] Multiple serving cells may be associated with a specific TTI duration. A WTRU may support multiple TTI durations based on one or more functions and/or characteristic associated to a serving cell.

[0103] A WTRU may determine the duration of a downlink control region, e.g., according to a first (e.g., legacy) behavior for LTE. A reception of PDCCH may be a first (e.g., legacy) behavior for downlink subframes. In an example, the first ShTTI in a subframe may include a control region, e.g., in case of slot-based operation, such as two slots of 7 symbols where the first slot include 1-3 symbols for PDCCH. In an example, the ShTTI duration may exclude the control region, e.g., in case of symbol-based ShTTIs. In an example, an offset in time or in symbol from the start of a subframe may be used to indicate the start of an ShTTI (e.g., in the DCI).

[0104] In an example, a WTRU may operate on a given carrier frequency (e.g., for downlink and/or uplink) according to at least one of the following: TTI duration per Transmission

Mode (TM), TTI duration per Serving Cell Identity (servCellID), and/or TTI duration per Serving Cell.

[0105] In an example of TTI duration per Transmission Mode (TM), a WTRU may be configured with multiple transmission modes (TM), e.g., one for each applicable TTI duration.

[0106] In an example of TTI duration per Serving Cell Identity (servCellID), a WTRU may be configured with multiple serving cell identities (e.g., servCellIDs), e.g., one for each applicable TTI duration.

[0107] In an example of TTI duration per Serving Cell, a WTRU may be configured with multiple serving cells for a given carrier frequency, e.g. one for each applicable TTI duration.

[0108] Combinations may be made using different types of serving cells. For example, a WTRU may be configured according to any of the following examples or other examples.

[0109] In a first case or example, a WTRU may be configured with one PCell and one SCell (or PSCell). A WTRU may perform a transmission associated with a PCell using a first ShTTI and a transmission associated with the SCell/PSCell using a second ShTTI. A WTRU may transmit Uplink Control Information (UCI) for a transmission associated with a specific cell using the uplink resources associated with the concerned cell (e.g., according to a first (e.g. legacy) behavior or processing time associated with the ShTTI), for example, when an SCell is configured with PUCCH resources or when the WTRU is configured with PSCell. A WTRU may perform the transmission of UCI using resources of the PCell (e.g., according to a first (e.g., legacy) behavior), for example, otherwise. In either case or other cases, a WTRU may transmit UCI using the TTI applicable to the uplink configuration of the concerned cell or according to the ShTTI applicable the received transmission.

[0110] In a second case or example, a WTRU may be configured with one PCell and two SCells. A WTRU may perform a transmissions associated with a PCell using a first TTI (e.g., a legacy 1ms TTI) and a transmission associated with an SCell using a second TTI (e.g., an ShTTI). A WTRU may transmit UCI for a transmission associated with a specific cell using the uplink resources associated with the concerned cell (e.g., according to a first (e.g., legacy) behavior or processing time associated with the ShTTI), for example, when an SCell is configured with PUCCH resources. A WTRU may perform the transmission of UCI using resources of the PCell (e.g., according to a first (e.g., legacy) behavior), for example, otherwise. In either case or other cases, a WTRU may transmit UCI using the TTI applicable to the uplink configuration of the concerned cell or according to the ShTTI applicable to the received transmission.

[0111] In a third case or example, a WTRU may be configured with one PCell and multiple SCells. A configuration may be a generalization of either of the first and second examples,

whereby more than two TTI durations may be supported (e.g., within a first (e.g., legacy) subframe).

[0112] In an example involving a PSCell, a different Cell Radio Network Temporary Identifier (C-RNTI) than that applicable for a PCell may indicate the duration of the TTI. Examples presented and other examples may be used separately or in combination. Other realizations and/or combinations are possible.

[0113] Examples for handling of downlink control region for case 1 with slot-based operation are described.

[0114] A WTRU may be configured with a (e.g., DL) control region of zero symbols for a serving cell used for the purpose of ShTTI, e.g., for the serving cell that corresponds to a second slot in case of slot-based operation. A WTRU may determine that a serving cell is configured for the purpose of ShTTI, for example, based on reception of signaling that indicates such value for the duration of the control region. A WTRU may determine that a serving cell is configured as an ShTTI for the second slot, for example, based on reception of signaling that indicates such value for the duration of the control region. A WTRU may determine that a PCell configuration is used for ShTTI for the first slot.

[0115] Different procedures or algorithms may be used to determine applicable TTI duration, e.g., independent of modeling. For example, a WTRU may determine the TTI duration (e.g. legacy duration such as 1ms or shorter (e.g., ShTTI)) applicable to a transmission as a function of one or more of the following: (a) a WTRU may determine TTI duration using cross-carrier scheduling; (b) a WTRU may associate a TTI duration with a serving cell identity; (c) a TTI duration may be indicated by a Carrier Indicator Field (CIF); (d) a TTI duration may be indicated by C-RNTI applicable to control signaling associated with the allocation of resources; (e) a TTI duration may be determined from the identity of a PRB subset applicable to the transmissions and/or to the time-shifted cell within the entire subset of PRBs for the carrier frequency; (f) a MAC Activation/Deactivation may be used to determine the applicable TTI duration and/or the identity of the slot/period applicable to a transmission within a subframe. A MAC Activation/Deactivation may be used, for example, to toggle between multiple TTIs (e.g. a legacy TTI and one or more ShTTIs), toggle between slot-based ShTTIs and/or to determine zero, one or more ShTTIs period(s) within a subframe.

[0116] HARQ processing may be used (e.g., according to a first (e.g., legacy) behavior) for time-shifted cell(s), although, in an example, timing-relationships may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may reuse LTE CA formats, first (e.g., legacy) subframe-based timing relationships and/or timing relationship associated with the HARQ

process. DCI signaling may reuse a first (e.g., legacy) format, although, in an example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with the HARQ process. Physical Random Access Channel (PRACH) resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted according to the shift applied to the TTI associated with a cell, for example, when such time shift is relative to the PCell timing (e.g., the PCell remains the DL timing reference for such SCell with the additional offset corresponding to the start of the ShTTI for those cells).

[0117] Any procedure or algorithm that may operate with or indicate a TTI duration may be applicable as a procedure or algorithm to operate with or to indicate a subcarrier spacing.

[0118] Support may be provided for transmissions with different TTI duration. A WTRU may be configured for operation with the LTE physical layer. A WTRU may be configured, for example, for operation according to a first (e.g., legacy) LTE behavior or for operation together with a 5gFLEX configuration, e.g., a configuration that supports a physical layer operating with other variants of potentially filtered OFDM transmissions, such as Universal Filtered OFDM (UF-OFDM), Filtered Based OFDM (FB-OFDM), etc.

[0119] In an example of LTE FDD, a radio frame may consist of 10 subframes of 1ms each with a TTI of 1ms. Each TTI may consist of two 0.5ms slots of 7 symbols for a configuration with a normal cyclic prefix. In the downlink, there may be 8 asynchronous HARQ processes numbered 0-7 that may be addressed by means of downlink DCI. In the uplink, there may be 8 synchronous HARQ processes per RTT, which identity may be tied to the subframe timing. A WTRU may be configured for 1 to 3 symbols at the beginning of the first slot used for control signaling (PDCCH). Control signaling may span the entire bandwidth for a given cell. A TTI duration may be fixed, e.g., at 1ms, as an aspect of the LTE physical layer.

[0120] Different cells of a WTRU's configuration may be (e.g. explicitly) associated with a TTI duration/offset shift. Support for different TTI durations may be realized, for example, by maintaining a unique association between a cell and a TTI duration in a WTRU's configuration. Timing associated with the cell (e.g. a cell of the LTE CA SCell type) may be shifted and/or offset in time with respect to the timing of a reference cell. A reference cell may be the PCell of the WTRU's configuration. The PCell may be considered to have a zero time shift, e.g., by default. In an example of dual connectivity, a PSCell may be considered to have a zero time shift (e.g., by

default), for example, when a secondary group of cells is configured and when the PSCell is used as the timing reference.

[0121] In an example, a time-shifted/TTI duration/offset shift may be associated with an identity. For example, a time-shifted cell may be configured with a serving cell identity, with an offset in time relative to the start of a cell-specific subframe (e.g. where timing may be based on the PCell used as a downlink timing reference) and with a TTI duration (e.g. shorter than a first (e.g. legacy) timing that may be referred to as a shorter TTI or ShTTI).

[0122] TTI duration may be a configuration aspect of a WTRU, such as part of a configured transmission mode associated with the physical layer configuration for the cell.

[0123] Cells using a timing relationship may be configured as part of the same timing advance group (TAG). Cells (e.g., SCells) in a secondary TAG (STAG) supporting ShTTIs may use one of the cells in the same TAG as a timing reference (e.g., a cell used may be a configuration aspect of a WTRU) or may use the PCell as the timing reference (e.g., otherwise).

[0124] Support may be provided for multiplexing transmissions in a cell and/or for a specific WTRU. Support for transmissions using different TTI duration may be for concurrent transmissions in the same cell. For example, transmission may correspond to a single TTI duration for each WTRU at any given time while some WTRUs may have different TTI duration than other WTRUs. Support may be for transmissions for a given WTRU within the same subframe (e.g., within a first (e.g., legacy) subframe such as 1 ms) where different transmissions may be performed according to different TTI durations by the concerned WTRU.

[0125] Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0126] An ShTTI-based transmission mode (TM) and cell timing configuration may be provided. For example, a WTRU may be configured with a PCell (e.g., according to first (e.g., legacy) behavior). For example, a WTRU may operate on a PCell carrier frequency using a first TM (e.g., a TM in the range of 1-10) associated with a first TTI duration (e.g., legacy 1ms). The WTRU may receive a RRC Connection Reconfiguration message that may reconfigure the WTRU according to at least one of the following: the WTRU may reconfigure the PCell and/or may configure at least one SCell.

[0127] In an example of reconfiguring a PCell, the WTRU may reconfigure the PCell such that a second TTI (e.g., ShTTI) of a duration shorter than previously used by the WTRU for the PCell is supported. For example, the WTRU may reconfigure (or add) a TM associated to the PCell. For example, a TM (e.g., TM = 11) may be associated with a TTI duration different than previously used by the WTRU for the PCell.

[0128] For example, a WTRU may configure a TTI duration according to one of the following. In an example, an ShTTI duration may be equal to 1 slot (0.5ms). This may be applicable, for example, to the first case. In another example, an ShTTI may be a duration expressed as an integer multiple of 1 symbol. A duration may include the control region, for example, when the configuration includes a start offset for the ShTTI and such offset is equal to zero. In another example, an ShTTI may be a duration expressed as an integer value in time, e.g. 100 μs or 125μs. Whether an ShTTI duration may include the control region may be determined as a function the value of a start offset for the ShTTI when applicable. A control region may be a separate aspect of a WTRU's configuration for a cell when an offset is equal to a non-zero value.

[0129] For example, a TM may support transmissions in (e.g., only in) the first slot of a first (e.g., legacy) subframe for the concerned ShTTI duration. A WTRU may determine an aspect as a function of the type of cell (e.g., PCell) associated with the TM. A TM may support WTRU-specific demodulation reference signals (e.g., DM-RS) such that their location and density may be better suited for ShTTI operation.

[0130] In an example of reconfiguring a PCell, transmissions on the PCell using a first (e.g., legacy) TTI such as 1ms may be enabled. This may be applicable, for example, in the second case, e.g., when a WTRU may be configured such that PCell operation supports transmissions using a first (e.g. legacy) 1ms TTI and one or more SCells support operation using ShTTI.

[0131] A WTRU may configure a PCell with an additional cell identity to the PCell in the PCell's configuration such that DCI may indicate, for example, "CIF=0" for a transmission on PCell using a first TTI (e.g., 1ms) and "CIF=1" for a transmission on PCell using a second TTI (e.g. a slot-based ShTTI of 0.5ms or similar). This may be applicable, for example, in the first case.

[0132] In an example of reconfiguring at least one SCell, the WTRU may configure an SCell such that an associated TTI duration (e.g., ShTTI) is less than that of a first (e.g., legacy) subframe duration (e.g., less than 1ms). For example, the WTRU may configure a TM associated with the SCell. For example, a TM (e.g., TM = 11) may be associated with a TTI duration similar to that of the PCell (e.g., ShTTI). For example, a ShTTI duration may be equal to 1 slot (0.5ms). This may be applicable, for example, in the first case. A TM (e.g., TM = 11+x) may be (e.g. alternatively) associated with a TTI duration different than that of the PCell, for example, when the TTI duration of such SCell may differ from that of the PCell.

[0133] Combinations of slot-based TTI (e.g., 0.5ms for a PCell) and non slot-based TTIs (e.g., 5 SCells of 100ms each) may be applicable for a given WTRU. Another example may be of a WTRU configured with symbol-based TTIs such that a different number of symbols may be used for each of the control regions (e.g,. 3 symbols), the TTI duration for the PCell (e.g., 5 symbols)

and for a number of SCells of x symbols in duration (e.g., 3 SCells each 2 symbols in TTI duration). Other combinations and/or other values are possible.

[0134] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0135] TTI duration may be determined as a function of a Carrier Indicator Field (CIF) in a DCI on PDCCH. A TTI duration may be signaled as a function of the indicated cell identity in the DCI (e.g., by CIF or similar for a given carrier frequency of the WTRU's configuration). A determination or indication may be achieved, for example, by associating a second identity with a cell of the WTRU's configuration or by duplication of a serving cell configuration for a given carrier frequency. The WTRU may determine that the DCI of a given transmission (e.g., PDDCH transmission, serving cell transmission, received downlink control information, or scheduling information) has indicated that the WTRU should use a first transmission time interval on a physical uplink channel to communicate with the serving cell. For example, the determination may be based on the CIF field of the DCI, as the CIF may refer to a serving cell identity that has been configured to utilize the first transmission time interval. In this manner, downlink control information (e.g., a DCI field, DCI message, CIF field, PRB assignment) may be re-used for scheduling of transmissions associated with the first TTI length. Similarly, the WTRU may determine that the DCI of a given transmission (e.g., PDDCH transmission, serving cell transmission, received downlink control information, or scheduling information) has indicated that the WTRU should use a second transmission time interval on a physical uplink channel to communicate with a second serving cell. For example, the determination may be based on the CIF field of the DCI, as the CIF may refer to the second serving cell identity and the second serving cell may have been configured to utilize the second transmission time interval. One or more of the first or second transmission time intervals may correspond a shortened TTI that is less than the legacy transmission time interval. The first and second serving cells may configured to utilize the same frequency band and/or carrier frequency.

[0136] In an example using slot-based TTI duration, a WTRU may be configured with a PCell with CIF=0, an SCell with CIF=1 and an SCell with CIF=2 for a given carrier frequency. Both SCells may be configured with carrier aggregation cross-carrier scheduling such that scheduling information for the associated resources may be received on the PDCCH associated with the PCell. A WTRU may receive signaling that schedules a transmission on such PDCCH. A WTRU may determine that a TTI duration is according to first (e.g., legacy) operation (e.g., 1ms), for example, when the WTRU determines that the CIF applicable to the transmission is that

of the PCell. The WTRU may determine that the transmission is applicable to the first slot of the concerned subframe, for example, when the WTRU determines that the CIF=1. The WTRU may determine that the transmission is for the second slot of the concerned subframe, for example, when CIF=2.

[0137] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0138] A start offset for ShTTI may be a function of CIF in the DCI on PDCCH. In an example, determination of the applicable location in time (e.g., slot in the subframe, applicable starting symbol and/or all applicable symbols or similar) may be enabled for a transmission, for example, when a TTI duration shorter than that of the subframe duration is configured for a given cell.

[0139] A start offset or applicable location in time may be based on signaling received by the WTRU. The WTRU may perform such determination as a function of the indicated cell identity in the DCI, e.g., by Carrier Indicator Field (CIF) or similar for a given carrier frequency of the WTRU's configuration. An indication or determination may be achieved, for example, by associating a specific offset in the subframe with an identity of a cell of the WTRU's configuration or by configuring multiple serving cells for a given carrier frequency each with a different identity and a different offset.

[0140] For example, an offset may indicate one of a first slot or a second slot of a cell-specific subframe or it may indicate an offset in terms of a starting symbol in a subframe or an offset in absolute time (e.g. 500ms). An offset may be applied from the start of a cell-specific subframe. An offset may implicitly indicate a TTI duration (or vice-versa).

[0141] Example procedures may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU.

[0142] A TTI duration may be a function of PRB(s) for a transmission. In an example, a WTRU may be configured such that a number of PRBs (e.g. a subset of the total set of system-specific PRBs for the concerned carrier frequency) may be associated with a cell of the WTRU's configuration for which the WTRU is operating with shorter than 1ms TTI duration e.g. configured with ShTTI.

[0143] A WTRU may determine an applicable TTI duration as a function of the PRB(s) indicated by the scheduling information. A PRB may correspond to the starting PRB for the resource allocation for the transmission. A set of PRBs may correspond to a range of PRBs. A

WTRU may use the TTI duration associated with a set of PRB(s), for example, when such range includes (e.g., only includes) PRB(s) associated with the concerned set. A WTRU may (e.g., otherwise) use a different TTI duration (e.g., a first (e.g. legacy) TTI duration, such as 1ms, or a configured duration), for example, when such range includes PRBs associated with different sets of PRBs or when such range does not include PRBs associated with any such sets. Sets of PRBs may be a configuration aspect of a WTRU's configuration. For example, a serving cell may be associated with a set of one or more PRBs, for example, when a serving cell is configured for ShTTI operation for a carrier frequency. A WTRU may use the TTI duration associated with such a cell or associated with the concerned PRBs. Scheduling information may be received dynamically in a DCI on PDCCH. Scheduling information may be semi-statically configured. For example, an entire (e.g., system-specific) set of PRBs for a PCell configured with a first (e.g., legacy) operation may be 110 PRBs. A WTRU may (e.g., alternatively) be configured with one or more subsets of PRBs, where each set may be associated with a specific TTI duration.

[0144] A WTRU may (e.g., first) determine the cell configured with ShTTI applicable to the transmission and/or the duration of the TTI (e.g., determining as described herein) and may determine the set of applicable PRBs therefrom (e.g., determining using a configuration of sets of PRBs as discussed herein).

[0145] Example procedures (e.g., operation) may be applicable to any of the cases described above. Procedures may be applicable for uplink and/or downlink transmission and may be a configuration aspect for a WTRU. For example, a procedure may be associated with a transmission mode for downlink and/or uplink. For example, a procedure may be associated with a serving cell of the WTRU's configuration. For example, a WTRU may determine that a configuration is specific to a serving cell of a WTRU's configuration, e.g., a determination may be made that a TTI configuration applies to both DL and UL frequencies. For example, a WTRU may determine that a configuration is specific to a specific direction of a configuration for a given serving cell of the WTRU's configuration, e.g., a determination may be made that a TTI configuration is provided separately for the DL direction and for the UL direction.

[0146] A determination may be made about the start offset time for a transmission. Cell de-activation may control availability of ShTTI. In an example, a first (e.g., legacy) cell activation-deactivation mechanism (e.g., procedure or algorithm) may control the duration (e.g., first or second TTI such as a legacy TTI or an ShTTI duration) of a transmission, e.g., by activating and deactivating the transmission. A WTRU may associate an activation state with an ShTTI, a slot and/or a resource.

[0147] In an example, a WTRU configured using ShTTI cells may receive a first (e.g., legacy) MAC activation/deactivation control element. A WTRU may use the activation/deactivation element as a mechanism to determine the availability of the ShTTI. For example, a WTRU may use a first (e.g., 1ms) TTI duration, e.g., when the WTRU is configured with a single SCell with ShTTI and when the SCell is in a deactivated state when the WTRU determines that it needs to perform a transmission. A WTRU may (e.g., otherwise) use a second TTI duration (e.g., ShTTI) for a transmission, e.g., when the SCell is active. The WTRU may perform a transmission using the second TTI duration (e.g. ShTTI), for example, according to scheduling information independently of the scheduled slot. This example may be extended to apply to the case where a symbol-based TTI duration is used instead of a time duration such as transmission slots.

[0148] In an example where multiple SCells may be used to indicate slot-based transmissions, a WTRU may determine that a first TTI duration is applicable when all cells configured with ShTTI are in a deactivated state. A WTRU may determine (e.g., otherwise) the applicable slot based on the activation state associated with each SCell and associated with each slot. This example may be extended to apply to the case where a symbol-based TTI duration is used, e.g., instead of using time duration such as transmission slots.

[0149] A WTRU may transmit HARQ feedback and/or other Uplink Control Information (UCI) (e.g. CQI, PMI, RI or similar), for example, taking into consideration the configuration of the TTI duration.

[0150] A TTI duration applicable to the transmission of UCI may be a function of at least one of the following: scheduling information, configuration information, TTI applicable to a serving cell, a default configuration for UCI transmission, etc.

[0151] Scheduling information may indicate whether a WTRU has resources for a PUSCH transmission and (e.g., if so) the TTI duration associated with such transmission, which may be determined according to procedures described herein.

[0152] Configuration information may indicate whether a WTRU is configured for simultaneous PUSCH and PUCCH transmission.

[0153] A TTI may be applicable to a serving cell associated with a UCI transmission in the subframe for the concerned UCI transmission.

[0154] A TTI may be applicable (e.g., in duration and/or offset) to a serving cell associated with a UCI transmission in the subframe for a downlink transmission pertaining to the feedback (e.g., in case of HARQ A/N feedback).

[0155] A default configuration for the transmission of UCI may be, for example, for the transmission of UCI on PUCCH (e.g., always a first TTI such as 1 ms TTI on PCell).

[0156] Further examples are provided below.

[0157] An applicable resource may be a PUSCH or PUCCH resource. A WTRU may determine a physical channel to perform the transmission of UCI using any technique, procedure or algorithm. For example, a WTRU may determine that UCI may be included in a PUSCH transmission when the transmission is scheduled, when simultaneous PUSCH and PUCCH transmissions are not configured or on a PUCCH transmission (e.g., otherwise).

[0158] An applicable resource may be a PUSCH resource. A WTRU may perform the transmission of UCI on a PUSCH transmission according to a TTI duration associated with a PUSCH transmission, which may be determined using procedures described herein.

[0159] An applicable resource may be a PUCCH resource. A WTRU may determine that a PUCCH resource may be used for transmission of UCI according to any technique, procedure or algorithm applicable to LTE CA. For example, selection of a resource may be based on the first CCE of the DCI that scheduled a downlink transmission or based on a configuration (e.g. PUCCH format 3 or similar). Bundling and/or multiplexing may be applied, for example, when configured.

[0160] An applicable TTI may be function of the type of transmissions on the carrier frequency PUSCH or PUCCH. Transmission of UCI may use the principles of LTE CA whereby UCI corresponding to transmission on different cells, e.g., including time-shifted cells, maybe multiplexed on a single transmission using a format that supports the required number of information bits (e.g., PUCCH format 3).

[0161] A PUCCH transmission may be performed on a PCell with a first (e.g., 1 ms TTI), where the first TTI may be a fixed TTI. A WTRU may perform PUCCH transmission on resources of an applicable serving cell (e.g., a PCell) according to a TTI duration associated with a concerned (e.g., pertinent) PCell, which may be determined using procedures described herein. In an example, a WTRU may transmit HARQ feedback using a single PUCCH transmission, which may use resources associated with a PCell (e.g. using a 1ms TTI duration), for example, when a WTRU has HARQ A/N feedback to transmit for two slot-based time-shifted cells using PUCCH on the PCell according to a configuration for a given carrier frequency where the PCell uses a first (e.g., 1ms) TTI.

[0162] A PUCCH transmission may be performed on a PCell with alignment in time with TTI being reported. A WTRU may perform PUCCH transmission on resources of an applicable serving cell (e.g. a PCell) according to a TTI duration associated with transmission(s) for which feedback is transmitted. A WTRU may have, for example, HARQ A/N feedback to transmit for

two slot-based time-shifted cells using PUCCH on the PCell according to a configuration for a given carrier frequency. In an example, a WTRU may transmit in the first slot a HARQ feedback for a transmission associated with the first slot and may transmit the HARQ feedback for the other transmission in the second slot for the concerned subframe.

[0163] A PUCCH transmission may be performed on a PCell with TTI/ShTTI of the PCell. A WTRU may perform a PUCCH transmission on resources of an applicable serving cell (e.g. a PCell) according to a TTI duration associated with the PCell, which may be determined using procedures described herein. A PCell may be (e.g., otherwise) configured with a default TTI, such as a first (e.g., 1 ms) TTI or an ShTTI. A WTRU may have HARQ A/N feedback to transmit for two slot-based time-shifted cells using PUCCH on the PCell, e.g., according to a configuration for a given carrier frequency where the PCell uses ShTTI in the concerned subframe (e.g., based on a configuration aspect and/or an activation state such as ShTTI activated for a time-shifted SCell for the concerned subframe). In an example, a WTRU may transmit HARQ feedback using a single PUCCH transmission, which may use resources associated with the PCell using a ShTTI duration with an offset applicable to the PCell.

[0164] A WTRU may transmit HARQ A/N feedback, for example, based on an applicable WTRU processing time for a concerned (e.g., pertinent) HARQ process in a given subframe.

[0165] Processing time associated with a HARQ process may be specific to a TTI associated with a transmissions for a concerned process. Processing time may be specific to a serving cell, a transmission mode or may be indicated by DCI (e.g., from servCellID or CIF) associated with such transmissions for a concerned HARQ process. In an example, HARQ processing time may be the same for all HARQ processes associated with a serving cell configured with a specific TTI (e.g., an ShTTI). Processing time may be a fixed value (e.g., 1ms), a multiple of an ShTTI, etc. Processing time may be determined for a transmission using ShTTI in subframe, the first available occasion in subframe n+2, where an occasion may correspond to a PUCCH or a PUSCH transmission with duration according to a first TTI or second TTI (e.g., ShTTI).

[0166] Systems, methods, and instrumentalities have been disclosed for multiplexing transmissions with different TTI duration. Latency may be reduced (e.g., in an LTE system), for example, by multiplexing transmissions with different TTI durations. TTI duration may be modeled using one or more time-shifted cell(s) for a given carrier frequency. A "logical" cell structure may correspond to an SCell. A PCell may logically maintain a TTI (e.g,. a first TTI) or may be configured with a second duration TTI (e.g., a shorter duration TTI (ShTTI)).

[0167] In an example, a WTRU may determine a TTI duration (e.g., first or second TTI) applicable to a transmission. For example, a WTRU may determine a TTI duration using cross-

carrier scheduling. A WTRU may associate a TTI duration with a cell identity (e.g. servCellID). A WTRU may associate a TTI duration with a transmission mode (TM). A TTI duration may be indicated by Carrier Indicator Field (CIF). A TTI duration may be determined from an identity of a PRB subset applicable to transmissions and/or to a time-shifted cell within a subset of PRBs for a concerned carrier frequency. An applicable TTI duration and/or the identity of a slot/period applicable to a transmission within a subframe may be determined using MAC Activation/Deactivation. MAC Activation/Deactivation may be used to toggle between first and second TTIs (e.g. legacy TTI and ShTTIs) or between slot-based ShTTIs and/or may be used to determine zero, one or more TTI (e.g. ShTTI) period(s) within a subframe.

[0168] HARQ processing may be performed according to a first behavior (e.g. legacy behavior) for one or more (e.g. each) time-shifted cell(s), although there may be exceptions. An exception may be timing-relationships, which may be scaled according to an applicable TTI duration. HARQ A/N feedback formats may use LTE Carrier Aggregation (CA) formats and/or (e.g., legacy) subframe-based timing relationships or a timing relationship associated with the HARQ process. Downlink Control Information (DCI) signaling may use a first (e.g., legacy) format, although, for example, interpretation of fields such as the CIF and/or PRBs applicable for the transmission may be different than the first (e.g., legacy) format. MAC activation/deactivation signaling may be applicable for time-shifted cells. DRX Timers associated with DRX may scale to HARQ A/N timing according to an applicable TTI duration and/or to the cell associated with an HARQ process. PRACH resources and/or PDCCH order for RACH may or may not be supported for time-shifted SCells. Timing advance for uplink transmission may be time shifted, for example, according to a shift applied to the TTI associated with a cell. Time shift may be relative to PCell timing, e.g. a PCell may remain a DL timing reference for an SCell with the additional offset corresponding to the start of the ShTTI for those cells.

[0169] A different TTI may be used in LTE R14 and NR. Multiple serving cells may be configured on the same carrier for a single WTRU. There may be an association between a serving cell and a TTI duration (or more generally – a numerology-related aspect). A WTRU can be configured with multiple such cells on a given carrier to support (*e.g.*, dynamically) a change in transmission duration. A field in downlink control signaling (DCI), *e.g.*, on a downlink control channel (*e.g.*, PDCCH), such as the CIF field in a DCI, may be used to dynamically schedule specific TTI durations for same or later subframes, for UL or DL transmissions.

[0170] The WTRU may be configured with a plurality of transmission methods, where at least two of the configured transmission methods differ in at least the applicable TTI duration.

[0171] A transmission may be associated with a transmission timing (start offset) relative to a timing reference.

[0172] A WTRU transmission mode may be indicated in downlink control information (DCI) signaling.

[0173] WTRU transmissions may be configured for each of a plurality of PRBs in the WTRU's configuration. Each of a plurality of PRBs may correspond to a serving cell of the WTRU's configuration. Each of a plurality of PRBs may correspond to a given carrier.

[0174] An applicable transmission duration/timing may be determined from a serving cell ID indicated in DCI signaling.

[0175] The WTRU may determine the set of resources, transmission duration, and/or uplink control information for a transmission based on a previous combination of received downlink signaling and received transmission duration.

[0176] A WTRU may determine whether a control region (*e.g.*, single control region) (*e.g.*, single level PDCCH) or multiple control regions (*e.g.*, multi-level PDCCH) are applicable and whether they are a function of the PDCCH configuration applicable to the concerned cell(s). A WTRU can determine the location of CCEs with respect to the timing reference (*e.g.*, in support of either self-scheduling or cross-TTI scheduling).

[0177] A WTRU may support mini-slots (*e.g.*, 125usec), slots (*e.g.*, 0.5ms), subframe (*e.g.*, 1ms) and multi-slots (*e.g.*, Multiples of other durations), and transmission durations and use different (*e.g.*, shortened) TTI's based on these time allocations. This may provide a low latency mode, a throughput mode and/or a coverage mode.

[0178] FIG. 4 depicts a scheduling example with time shifted-cells. As shown, there is a frequency axis and a time axis. In Fig. 4, the time is measured in milliseconds and divided into subframes. Other time units can be used such as slots, minislots, symbols, and PRB lengths. The frequency axis shows downlink (DL) and uplink (UL) transmissions. The time axis shows subframes. N, n+1, N=3, etc.... As shown for the DL frequency, for one or more subframes, the WTRU may receive DCI. For subframe n, the DCI may indicate two allocations, for example two ShTTI allocations (*e.g.*, $ShTTI_{DL(n,0)}$ and $ShTTI_{DL(n,1)}$). As an example, setting the CIF equal to 1 may indicate that the allocation is for $ShTTI_{DL(n,0)}$ and setting the CIF equal to 2 may indicate the allocation is for $ShTTI_{DL(n,1)}$. Other values of the CIF may be used to indicate no ShTTI transmissions and/or different transmission durations. For example, the DCI in Subframe

n+1 may indicate that for DL subframe n+1, the transmission has a duration corresponding to the entire subframe by using the value CIF=0 (*see e.g.*, a $TTI_{DL(N+1)}$).

[0179] A similar signaling mechanism can be used for indicating different durations of uplink transmissions. For example, DCI in DL subframe n may indicate that the WTRU has recieved two uplink grants. For example, a first grant for subframe n+1 may be indicate a CIF=1, which may be configured to correspond to $ShTTI_{(n+an\ offset,0)}$, while a CIF equal to 2 may indicate a grant for $ShTTI_{(n+an\ offset,0)}$. Similarly, a different value of the CIF (*e.g.*, CIF = 0) in this example may indicate that the transmissions duration spans an entire legacy TTI as illustrated in FIG. 4. Thus, by associating different CIF values with different transmission durations, the DCI may be used to indicate different transmission durations by referencing the different CIF values. Although the CIF field is used for purposes of illustration, other DCI fields may be used and may have values mapped to/associated with transmissions of different duration.

[0180] FIG. 4 also shows for an example of the PUCCH on the uplink frequency. For the PCell or SCell there may be a HARQ A/N for CIF = 1 at (n, 0) and a HARQ A/N for CIF = 2 at n, 1. For the PCell, (*e.g.*, PCell only), there may be a HARQ A/N for CIF = 0 at (n, 0) or CIF = 0 at n-3. Also, for the PCell, (*e.g.*, PCell only), there may be a HARQ A/N for CIF = 1 at (n, 0) or CIF = 0 at n-3 for the $ShTTI_{(n+?,\ 0)}$ and HARQ A/N for CIF = 2 at (n, 1) or CIF = 0 at n-3 for the $ShTTI_{(n+?,\ 1)}$.

[0181] FIG. 4 shows an example with time shifted cells with an offset of symbols. In this example, the symbol offset is based on CIF. FIG. 4 shows a single HARQ addressing space per TTI duration and start offset in a given subframe. MAC activation/deactivation may be applied by a HARQ process space or CIF value. FIG. 4 also shows a UCI example with time-shifted cells. The first CCE of the DCI on the example channel, PDCCH, may be used for legacy PUCCH resource allocation at TTI or ShTTI. Configured LTE CA PUCCH, PUCCH on an SCell, and/or ARI may be used for UCI using different TTIs. As shown, the WTRU interprets the DCI TTI indication differently in the FIG. 4 example for SCells and PCells to use ShTTI for the SCells. FIG. 4 also shows an example of the frequency being the same for the PCell and SCell. The FIG. 4 example dynamically varies the scheduled TTI for a WTRU and uses the appropriate HARQ signaling. Also, resource allocation for associated control information is resolved and there is flexibility to adapt different time offsets in a subframe and with different ShTTIs.

[0182] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element may be used alone or in any combination with the other features and elements. In addition, the methods described herein

may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, WTRU, terminal, base station, RNC, or any host computer.

CLAIMS

What Is Claimed:

1. A method implemented by a wireless transmit/receive unit (WTRU) for supporting transmissions of different durations, the method comprising:

receiving a first configuration associated with a first set of transmission resources, the first configuration indicating a first transmission time interval (TTI) length for use with the first set of transmission resources;

receiving a second configuration associated with a second set of transmission resources, the second configuration indicating a second transmission time interval (TTI) length for use with the second set of transmission resources;

receiving downlink control information (DCI), wherein the DCI comprises a field that indicates whether the DCI is applicable to first set of transmission resources or the second set of transmission resources; and

determining that a transmission associated with the DCI utilizes the first TTI length on condition that the field indicates that the DCI is applicable to the first set of transmission resources or that the transmission associated with the DCI utilizes the second TTI length on condition that the field indicates that the DCI is applicable to the second set of transmission resources.

2. The method of claim 1, wherein the first set of transmission resources correspond to a first serving cell and the second set of transmission resources correspond to a second serving cell.

3. The method of claim 2, wherein the field corresponds to a carrier indicator field.

4. The method of claim 2, wherein the first serving cell and the second serving cell are associated with the same carrier frequency.

5. The method of claim 2, wherein each of the first and second serving cells are configured as secondary cells (SCells).

6. The method of claim 2, wherein the first serving cell corresponds to a primary cell (PCell), the second serving cells is configured as a secondary cells (SCell), the first TTI length corresponds to 1 millisecond (ms), and the second TTI length corresponds to less than 1 ms.

7. The method of claim 1, wherein the DCI further comprises a physical resource block (PRB) assignment field, and the PRB assignment field is interpreted differently depending on whether the transmission is associated with the first TTI length or the second TTI length.

8. The method as in claim 1, wherein at least the second configuration is received via a radio resource control (RRC) message, and the DCI is received via a physical downlink control channel.

9. The method as in claim 1, wherein a hybrid automatic repeat request timing used for the transmission is dependent on whether the transmission is associated with the first TTI length or the second TTI length.

10. A method implemented by a wireless transmit/receive unit (WTRU) for supporting transmissions of different durations, the method comprising:

receiving downlink control information from a first serving cell in the wireless communications network;

determining that the received downlink control information indicates that the WTRU should use a first transmission time interval to transmit data information to the first serving cell;

determining whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is different than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation; and

communicating with the wireless communications network using the second transmission time interval.

11. The method of claim 10, wherein determining that the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel comprises determining based on a carrier indicator field in the received downlink control information.

12. The method of claim 10, wherein communicating with the wireless communications network using the second transmission time interval comprises communicating with the first serving cell using the second transmission time interval.

13. The method of claim 10, wherein communicating with the wireless communications network using the second transmission time interval comprises communicating with a secondary cell using the second transmission time interval.

14. The method of claim 10, further comprising determining that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network.

15. The method of claim 10, wherein the shorten transmission time interval corresponds to at least one of at least one symbol or at least one resource block.

16. The method of claim 10, wherein the first transmission time interval is one millisecond.

17. The method of claim 10, wherein the first transmission time interval is greater than the first transmission time interval.

18. The method of claim 10, wherein the first transmission time interval corresponds to a first sub-carrier spacing and the second transmission time interval corresponds to a second subcarrier spacing.

19. The method of claim 10, wherein the first transmission time interval corresponds to a first number of transmission symbols and the second transmission time interval corresponds to a second number of transmission symbols.

20. The method of claim 10, further comprising the WTRU communicating with the first serving cell and a second serving cell using the same carrier frequency.

21. The method of claim 10, further comprising determining a time to transmit with the second transmission time interval based on the received downlink control information.

22. The method of claim 21, wherein the time to transmit is defined by a slot in a subframe.

23. The method of claim 10, wherein determining whether the received downlink control information indicates that the WTRU should use a second transmission time interval that

is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation comprises determining with cross-carrier scheduling.

24. A wireless transmit/receive unit (WTRU) for use within a wireless communications network that is capable of carrier aggregation, comprising:

a processor having executable instructions that:

determine that downlink control information from a first serving cell in the wireless communications network has been received;

determine that the received downlink control information indicates that the WTRU should use a first transmission time interval to transmit data information to the first serving cell;

determine whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is different than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation; and

communicate with the wireless communications network using the second transmission time interval.

25. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine that the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel comprises determining based on a carrier indicator field in the received downlink control information.

26. The WTRU of claim 24, wherein the executable instructions that communicate with the wireless communications network using the second transmission time interval comprise communicating with the first serving cell using the second transmission time interval.

27. The WTRU of claim 24, wherein the executable instructions that communicate with the wireless communications network using the second transmission time interval comprise communicating with a secondary cell using the second transmission time interval.

28. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine that the WTRU should use a third transmission time interval that is less than the first transmission time interval to communicate with a secondary cell in the wireless communications network.

29. The WTRU of claim 24, wherein the shorten transmission time interval corresponds to at least one of at least one symbol or at least one resource block.

30. The WTRU of claim 24, wherein the first transmission time interval is one millisecond.

31. The WTRU of claim 24, wherein the processor further comprises executable instructions that determine a time to transmit with the second transmission time interval based on the received downlink control information.

32. The WTRU of claim 31, wherein the time to transmit is defined by a slot in a subframe.

33. The WTRU of claim 24, wherein the executable instructions that determine whether the received downlink control information indicates that the WTRU should use a second transmission time interval that is less than the first transmission time interval to communicate with the wireless communication network on the physical uplink channel or whether the WTRU should transmit using carrier aggregation comprise determining with cross-carrier scheduling.

34. The WTRU of claim 24, wherein the first transmission time interval is greater than the first transmission time interval.

35. The method of claim 24, wherein the first transmission time interval corresponds to a first sub-carrier spacing and the second transmission time interval corresponds to a second subcarrier spacing.

36. The method of claim 24, wherein the first transmission time interval corresponds to a first number of transmission symbols and the second transmission time interval corresponds to a second number of transmission symbols.

37. The method of claim 24, further comprising the WTRU communicating with the first serving cell and a second serving cell using the same carrier frequency.

(54) Title: METHOD AND DEVICE FOR PAGING A MACHINE TO MACHINE DEVICE

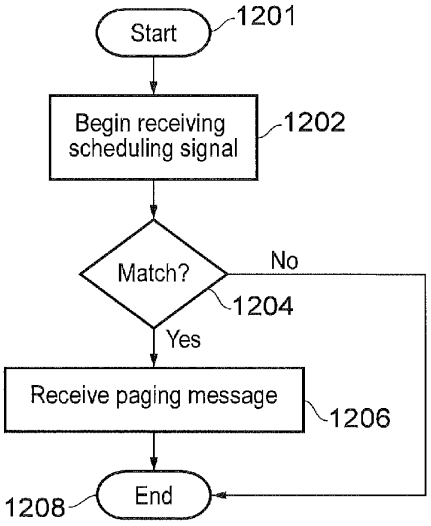

FIG. 12

(57) Abstract: A terminal device for use with a wireless telecommunications network comprising: a transceiver; and a controller. Receiving, during one of a plurality of periodic paging occasions associated with the terminal, a paging scheduling signal for one or more terminal devices, each paging occasion being associated with a value of a characteristic of the scheduling signal which is unique to that paging occasion. Determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the of periodic paging occasions associated with the terminal device; and control the transceiver to receive the paging message scheduled by the received scheduling message.

METHOD AND DEVICE FOR PAGING A MACHINE TO MACHINE DEVICE

BACKGROUND

Field of Disclosure

The present disclosure relates to a terminal device, infrastructure equipment, methods and integrated circuitry for use with a wireless telecommunications network.

Description of Related Art

The "background" description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description which may not otherwise qualify as prior art at the time of filing, are neither expressly or impliedly admitted as prior art against the present disclosure.

Third and fourth generation wireless communications systems, such as those based on the third generation project partnership (3GPP) defined UMTS and Long Term Evolution (LTE) architecture are able to support sophisticated services such as instant messaging, video calls as well as high speed internet access. For example, with the improved radio interface and enhanced data rates provided by LTE systems, a user is able to enjoy high data rate applications such as mobile video streaming and mobile video conferencing that would previously only have been available via a fixed line data connection. The demand to deploy third and fourth generation networks is therefore strong and the coverage area of these networks, i.e. geographic locations where access to the networks is possible, is expected to increase rapidly. However, whilst fourth generation networks can support communications at high data rate and low latencies from devices such as smart phones and tablet computers, it is expected that future wireless communications networks will need to support communications to and from a much wider range of devices, including reduced complexity devices, machine type communication devices, devices which require little or no mobility, high resolution video displays and virtual reality headsets. As such, supporting such a wide range of communications devices can represent a technical challenge for a wireless communications network.

A current technical area of interest to those working in the field of wireless and mobile communications is known as "The Internet of Things" or IoT for short. The 3GPP has proposed to develop technologies for supporting narrow band (NB)-IoT using an LTE or 4G wireless access interface and wireless infrastructure. Such IoT devices are expected to be low complexity and inexpensive devices requiring infrequent communication of relatively low bandwidth data. It is also expected that there will be an extremely large number of IoT devices which would need to be supported in a cell of the wireless

communications network. Furthermore such NB-IoT devices are likely to be deployed indoors and /or in remote locations making radio communications challenging.

SUMMARY OF THE DISCLOSURE

According to a first embodiment, the present technique provides a terminal device for use with a wireless telecommunications network, the terminal device comprising: a transceiver; and a controller operable: to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network; to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

According to the first embodiment, the present technique also provides infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising: a transceiver; and a controller operable: to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

According to a second embodiment, the present technique provides a terminal device for use with a wireless telecommunications network, the terminal device comprising: a transceiver; and a controller operable: to control the transceiver to begin receiving, during one of a plurality of periodic paging

occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

According to the second embodiment, the present technique also provides infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising: a transceiver; and a controller operable: to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

The foregoing paragraphs have been provided by way of general introduction, and are not intended to limit the scope of the following claims. The described embodiments, together with further advantages, will be best understood by reference to the following detailed description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete appreciation of the disclosure and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings wherein like reference numerals designate identical or corresponding parts throughout the several views, and wherein:

Figure 1 is a schematic block diagram illustrating an example of a mobile telecommunication system;

Figure 2 is a schematic representation illustrating a frame structure of a downlink of a wireless access interface according to an LTE standard;

Figure 3 is a schematic representation illustrating a frame structure of an uplink of wireless access interface according to an LTE standard;

DETAILED DESCRIPTION OF THE EMBODIMENTS

Conventional Communications System

Figure 1 provides a schematic diagram illustrating some basic functionality of a mobile telecommunications network / system 100 operating in accordance with LTE principles and which may be adapted to implement embodiments of the disclosure as described further below. Various elements of Figure 1 and their respective modes of operation are well-known and defined in the relevant standards administered by the 3GPP (RTM) body, and also described in many books on the subject, for example, Holma H. and Toskala A [1]. It will be appreciated that operational aspects of the telecommunications network which are not specifically described below may be implemented in accordance with any known techniques, for example according to the relevant standards.

The network 100 includes a plurality of base stations 101 connected to a core network 102. Each base station provides a coverage area 103 (i.e. a cell) within which data can be communicated to and from communications devices 104. Data is transmitted from base stations 101 to communications devices 104 within their respective coverage areas 103 via a radio downlink. Data is transmitted from communications devices 104 to the base stations 101 via a radio uplink. The uplink and downlink

communications are made using radio resources that are licenced for exclusive use by the operator of the network 100. The core network 102 routes data to and from the communications devices 104 via the respective base stations 101 and provides functions such as authentication, mobility management, charging and so on. Communications devices may also be referred to as mobile stations, user equipment (UE), user device, mobile radio, terminal device and so forth. Base stations may also be referred to as transceiver stations / infrastructure equipment / NodeBs / eNodeBs (eNB for short), and so forth.

Wireless communications systems such as those arranged in accordance with the 3GPP defined Long Term Evolution (LTE) architecture use an orthogonal frequency division modulation (OFDM) based interface for the radio downlink (so-called OFDMA) and a single carrier frequency division multiple access scheme (SC-FDMA) on the radio uplink.

Figure 2 provides a simplified schematic diagram of the structure of a downlink of a wireless access interface that may be provided by or in association with the eNB of Figure 1 when the communications system is operating in accordance with the LTE standard. In LTE systems the wireless access interface of the downlink from an eNB to a UE is based upon an orthogonal frequency division multiplexing (OFDM) access radio interface. In an OFDM interface the resources of the available bandwidth are divided in frequency into a plurality of orthogonal subcarriers and data is transmitted in parallel on a plurality of orthogonal subcarriers, where bandwidths between 1.4MHz and 20MHz bandwidth may be divided into 128 to 2048 orthogonal subcarriers for example. Each subcarrier bandwidth may take any value but in LTE it is conventionally fixed at 15kHz. However it has been proposed in the future [2][3] to provide also a reduced subcarrier spacing of 3.75 kHz for certain parts of the LTE wireless access interface for the uplink. As shown in Figure 2, the resources of the wireless access interface are also temporally divided into frames where a frame 200 lasts 10ms and is subdivided into 10 subframes 201 each with a duration of 1ms. Each subframe is formed from 14 OFDM symbols and is divided into two slots each of which comprise six or seven OFDM symbols depending on whether a normal or extended cyclic prefix is being utilised between OFDM symbols for the reduction of inter symbol interference. The resources within a slot may be divided into resources blocks 203 each comprising 12 subcarriers for the duration of one slot and the resources blocks further divided into resource elements 204 which span one subcarrier for one OFDM symbol, where each rectangle 204 represents a resource element. More details of the downlink structure of the LTE wireless access interface are provided in Annex 1.

Figure 3 provides a simplified schematic diagram of the structure of an uplink of an LTE wireless access interface that may be provided by or in association with the eNB of Figure 1. In LTE networks the uplink wireless access interface is based upon a single carrier frequency division multiplexing FDM (SC-FDM) interface and downlink and uplink wireless access interfaces may be provided by frequency division duplexing (FDD) or time division duplexing (TDD), where in TDD implementations subframes switch

between uplink and downlink subframes in accordance with predefined patterns. However, regardless of the form of duplexing used, a common uplink frame structure is utilised. The simplified structure of Figure 3 illustrates such an uplink frame in an FDD implementation. A frame 300 is divided in to 10 subframes 301 of 1ms duration where each subframe 301 comprises two slots 302 of 0.5ms duration. Each slot is then formed from seven OFDM symbols 303 where a cyclic prefix 304 is inserted between each symbol in a manner equivalent to that in downlink subframes. In Figure 3 a normal cyclic prefix is used and therefore there are seven OFDM symbols within a subframe, however, if an extended cyclic prefix were to be used, each slot would contain only six OFDM symbols. The resources of the uplink subframes are also divided into resource blocks and resource elements in a similar manner to downlink subframes. More details of the LTE uplink represented in Figure 3 are provided in Annex 1.

Narrowband Internet of Things

As explained above, it has been proposed to develop an adaptation of a mobile communications network to accommodate narrow band communications within an existing wireless access interface which has been developed to provide broadband wireless communications. For example, in 3GPP a project relating to improvements to LTE wireless access interfaces to provide for a Narrowband Internet of Things (NB-IoT) was agreed [2]. This project is aimed at improved indoor coverage, support for massive number of low throughput devices, low delay sensitivity, ultra-low device cost, low device power consumption and (optimised) network architecture. An example of such a device is a smart meter. It has been proposed that an NB-IoT communications system supports a bandwidth of only 180 kHz and can have three operational modes:

1. 'Stand-alone operation' utilizing for example the spectrum currently being used by GERAN systems as a replacement of one or more GSM carriers
2. 'Guard band operation' utilizing the unused resource blocks within a LTE carrier's guard-band
3. 'In-band operation' utilizing resource blocks within a normal LTE carrier

Figure 4 provides an example schematic block diagram of a terminal device or UE 104 and an infrastructure equipment or eNB 101 according to embodiments of the present technique. As shown in Figure 4, the UE 104 includes a transmitter 401 and a receiver 402 (which together form a transceiver) which are controlled by a controller 403. The UE 104 also comprises a storage medium 420 for storing data. Correspondingly, the eNB 101 includes a transmitter 411 and a receiver 412 (which together form a transceiver) which are controlled by a controller 413 (which can also implement a scheduler function). The eNB 101 also comprises a storage medium 422 for storing data. As explained above, the UE 104 transmits and receives signals to and from the eNB 101 via a wireless access interface provided by the

eNB as part of the wireless communications network. Each of the UE 104 and eNB 101 are configured to exchange signals with each other using NB-IoT.

One of the objectives of NB-IoT is to provide extended coverage of up to 20 dB. The main mechanism to extend coverage is to perform numerous repetitions of a message to be received at a receiving device, such that the receiver can accumulate the signal energy over the repetitive samples in order for it to have an increased signal-to-noise ratio (SNR), which increases the likelihood of successful decoding of the message at the receiving device. Such a mechanism is known as coverage enhancement (CE).

Coverage enhancement (CE) may have several levels. For example, it may provide one of 5 dB, 15 dB and 20 dB additional coverage enhancement. In NB-IoT, the CE levels may be referred to as the targeted MCL (Max Coupling Loss, the achievable coupling loss (accounting for, for example, path loss, feeder losses and/or antenna gains) between transmitter and receiver) of, for example, 144 dB, 154 dB and 164 dB (so that the higher the targeted MCL, the greater the additional coverage enhancement).

As previously mentioned, repetitions of a signal so that a receiver can accumulate energy of the signal over numerous repetitive samples is the basic method used for coverage enhancement. The number of repetitions required is dependent upon the CE level. Thus, a UE at a lower CE level, such as at 144 dB, MCL requires less repetition compared to one at a higher CE level, such as at 154 dB MCL. The power spectral density, PSD (mW/Hz) of a transmission also affects the number of repetitions required, that is, the larger the PSD, the less the required number of repetitions.

The NB-PDCCH (Narrow Band Physical Downlink Control Channel) is a control channel that is used to schedule downlink resources (downlink grant) and uplink resources (uplink grant) for a NB-PDSCH (Narrow Band Physical Downlink Shared Channel) and a NB-PUSCH (Narrow Band Physical Uplink Shared Channel) that carry data traffic. An NB-PDCCH search space consists of multiple NB-PDCCH candidates wherein each candidate has a specific starting time, set of subcarriers, a defined number of repetitions and an aggregation level (the aggregation level relating to the number of frequency resources occupied by the candidate such that when the candidate occupies a higher number of frequency resources, the aggregation level is higher, and when the candidate occupies a lower number of frequency resources, the aggregation level is lower). Candidates that have a larger number of repetitions and a higher aggregation level are more robust and can reach a UE at poorer coverage compared to candidates that have a smaller number of repetitions and a lower aggregation level.

The eNB uses one of the candidates in the search space to carry the NB-PDCCH. The UE is not aware which candidate is used and so it must blind decode all the candidates in the search space in order to find the candidate used by the eNB for the NB-PDCCH. An example of a typical NB-PDCCH search space is

shown in Figure 5. Here, the search space has 4 repetition levels {R1, R2, R3, R4} where R4 = 2×R3 = 4×R2 = 8×R1. It should be appreciated that an NB-PDCCH search space with other repetition levels is also possible. As an example the eNB can use any of the 15 candidates (labelled as C1 to C15) to carry the NB-PDCCH and the UE has to blind decode for all 15 candidates. The max repetition R_{MAX} (in Figure 5, R_{MAX} = R4) of the search space is assigned to the UE based on the UE's radio condition. Thus, for example, if the UE is in a poorer quality radio coverage location, then the eNB can configure a search space with a larger value of R_{MAX}, and if the UE is in a better quality radio coverage location, then the eNB can configure a search space with a smaller value of R_{MAX}. Typically, a set of NB-PDCCH search spaces is predefined in which each NB-PDCCH search space of the set consists of a set of candidates and a value of R_{MAX}. The UE is then assigned one NB-PDCCH search space in the set of NB-PDCCH search spaces. The maximum repetition R_{MAX} of an NB-PDCCH search space can be selected from the set of values {1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048}, for example.

In NB-IoT, paging is performed when a UE is in idle mode. More specifically, when in idle mode, the UE monitors an NB-PDCCH CSS (Common Search Space) which, in the case that a paging message is to be transmitted to the UE, contains an NB-PDCCH that schedules that paging message (the paging message being carried by an NB-PDSCH). In order to reduce power consumption, the UE monitors the NB-PDCCH CSS during each of a plurality of periodic Paging Occasions (PO) rather than constantly monitoring the NB-PDCCH CCS. The PO occurs periodically for a particular UE (or particular group of UEs), wherein the period is configured by the network, for example. In an embodiment, the network can configure multiple POs in which the specific PO that a UE monitors depends on an identifier of that that UE (UE-ID), for example, the UE's International Mobile Subscriber Identifity (IMSI). This enables the network to spread the paging load. For example in Figure 6, the eNB configures four POs where each PO has a period T_{PO}. The UE thus wakes up every T_{PO} ms to monitor for possible paging. The PO is assigned to the UE based on the UE's ID, using a **MOD** function of the number of POs, for example (thus, in the case of Figure 6, the PO assigned to a particular UE is given by UE_ID **MOD** 4).

As described previously, repetition of the paging CSS can reach 2048. A problem with this is that a PO can overlap another PO, causing confusion for UEs reading the PO. For example in Figure 7, two POs are configured. PO 1 begins at time t_1, where UE 1 belonging to this PO will start monitoring for NB-PDCCH in the paging CSS. This paging CSS ends at time t_3. If the repetition of NB-PDCCH is very long (for example, if the paging CSS ending at time t_3 has the structure shown in Figure 5, and the NB-PDDCH is received via the candidate C15 with the largest number of repetitions) , it will overlap into PO 2 at time t_2. At time t_2 UE 2 belonging to PO 2 will start monitoring for NB-PDCCH and will start to accumulate repetition samples from the NB-PDCCH intended for UE 1 (belong to PO 1). If UE 2 is in a better radio condition than UE 1, it may decode the NB-PDCCH and start to accumulate and decode the corresponding NB-PDSCH containing the paging message. UE 2 will not find any paging indication in

this paging message and would waste battery power accumulating and decoding the NB-PDSCH. This is because the paging message contains an identifier of each UE to be paged. If a paging message is not intended for UE 2, then the identifier of UE 2 will not be included in the paging message and thus UE 2 will not be paged. However, since UE 2 has received the NB-PDCCH during its paging occasion, it will still attempt to read the paging message scheduled by the NB-PDCCH by accumulating and decoding the NB-PDSCH, thus wasting battery power. It should be noted that the NB-PDSCH is also repeated.

It should also be appreciated that if the PO period T_{PO} is shorter than the NB-PDCCH repetition, the PO may overlap itself, as shown in an example in Figure 8, in which the NB-PDCCH for PO 1 starts at time t_1 but the repetition doesn't end till time t_4. It overlaps the next PO 1 at time t_3. In this scenario, the UE belonging to PO 1 is confused as to whether to continue accumulating samples from the previous PO 1 (started at time t_1) or start a new accumulation starting at time t_3. Furthermore, in an embodiment, the NB-PDSCH starting subframe is indicated in the downlink control information (DCI) of the NB-PDCCH, this NB-PDSCH starting subframe being defined relative to the end of the NB-PDCCH that schedules this NB-PDSCH. In order to determine the end of an NB-PDCCH transmission, the repetition of the NB-PDCCH is indicated in the DCI of that NB-PDCCH. For example, in Figure 5, if candidate C11 is used to carry the NB-PDCCH (including the DCI), then the NB-PDSCH scheduled by the NB-PDCCH will start at k subframes after time t_6 (t_6 marking the end of the NB-PDCCH carried by candidate C11) where k is indicated in the DCI. Since the UE can decode a message with less repetition when it has a good radio condition, however, the UE may decode C11 at time t_5 and mistake candidate C11 for candidate C5. The UE will thereby use the wrong reference point for the start of the NB-PDSCH. To avoid this, the repetition of the NB-PDCCH is indicated in the DCI so that the UE will not mistake candidate C11 for C5. However, this does not solve the problem shown in Figure 8 in which the search space overlaps itself. In this case, although the UE will know the repetition of the NB-PDCCH from the DCI information, the UE does not know whether the NP-PDCCH repetitions started at time t_1 or at time t_3. This causes confusion at the UE regarding the candidates.

In LTE Release-13 eMTC (enhanced Machine Type Communication), the POs are separated far apart so that they do not overlap. This is possible because the repetition used in this case is not as large as that used in NB-IoT. Furthermore, eMTC can use different narrowbands for different groups of UEs and avoid overlapping. In contrast, only the anchor NB-IoT can contain the paging CSS and paging message, and therefore problem of overlapping of the NB-PDCCH between different POs requires a new solution.

In an embodiment of the present technique, an indicator is used to distinguish one PO from another. The UE belonging to a PO then uses this indicator to determine whether the NB-PDCCH belongs to it or to another PO.

In one embodiment, the said indicator is a PO index in the DCI (carried by the NB-PDCCH). A new field in the DCI would indicate which PO the DCI (that is, the NB-PDCCH) belongs to. The UE, after accumulating the NB-PDCCH, will then decode the DCI and check the PO index to see whether it matches the PO that the UE belongs to.

In another embodiment, different versions of the same PO are also indicated in the DCI. This is to help overcome the issue of uncertainty at the UE regarding when the search space starts when a NB-PDCCH repetition is larger than the PO period T_{PO} (as described in Figure 8). For example, in Figure 8, PO 1 at time t_1 can be version 1 and PO 1 at time t_3 can be version 2, these versions being distinguishable from each other by the PO identifier in the DCI so the UE is clear where the search space starts. This helps to avoid confusion of the candidates in the search space.

In another embodiment the starting time of the CSS is indicated in the DCI. This is similar to indicating the PO index (which indirectly indicates the starting time of the CSS). After decoding the DCI, the UE will determine whether the starting time of the decoded NB-PDCCH belongs to the CSS that starts at its PO or another PO. If the CSS starts at a time belonging to another PO, the UE can discard the decoded DCI.

In another embodiment, a different P-RNTI (Paging Radio Network Temporary Identifier) is used for one or more of each respective PO and each respective PO version. The P-RNTI of each respective PO and/or each respective PO version can be signalled either explicitly or implicitly (that is, derived from a reference P-RNTI). For example, in the case that a different P-RNTI is used for each respective PO, the eNB may signal a single reference P-RNTI and PO 1 will use this P-RNTI, PO 2 will use this reference P-RNTI + 1, PO 3 will use P-RNTI + 2, and so on.

In another embodiment, a scrambling applied to the NB-PDCCH is dependent upon the PO. The UE then applies a descrambler depending upon which PO it belongs to. A different scrambling may be applied to each respective PO (so as to distinguish, for example, PO 1 from PO 2, but not distinguish between different versions of PO 1 or PO 2). Alternatively, or in addition, a different scrambling may be applied to each respective PO version (so that different versions of, for example, PO 1 or PO 2 may be distinguished from each other).

It will be appreciated that various features of these embodiments may be combined as appropriate. For example, it may be the case that each respective PO is distinguished by a different scrambling, but then each version of that PO is further distinguished in the DCI.

In another embodiment of the present technique, two or more different NB-PDCCH search spaces (that is, Common Search Spaces) are configured wherein at least one of these search spaces has max repetition $R1_{MAX}$ greater than the time between two adjacent POs T_S (thus potentially causing the overlapping issue described in Figure 7) whilst the remaining search spaces have max repetition $R2_{MAX}$ smaller than T_S. In this way the search space with $R1_{MAX}$ can be segmented and interleaved with search spaces with $R2_{MAX}$. An example is shown in Figure 9, where each PO is associated with one of two types of NB-PDCCH Common Search Space (CSS) with $R1_{MAX}$ and $R2_{MAX}$, respectively. CSS1 belongs to PO1, starts at time t_1 and has a max repetition of $R1_{MAX}$ where $R1_{MAX} > T_S$, (meaning that, if measures are not taken, then CSS1 will overlap with the adjacent PO (that is, PO2)). Using the method of an embodiment, CSS1 (belonging to the first version of PO1) is segmented into 3 segments, wherein the 1st segment starts at time t_1 and ends at time t_2. The 2nd segment occupies the time t_3 to t_4, which avoids overlapping CSS2 (belonging to the first version of PO2) between time t_2 and t_3. The 3rd segment occupies time t_5 to t_6, which avoids overlapping CSS3 (belonging to the second version of PO1) between time t_4 and t_5. The segments of CSS1 are therefore interleaved with CSS2 and CSS3. CSS3 and CSS4 belong to PO1 (the second and third versions of PO1, respectively) but with a smaller maximum repetition, that is, $R2_{MAX} < T_S$, and therefore do not overlap with any adjacent PO. CSS3 and CSS4 are thus not segmented. CSS5 belongs to PO2 (in particular, the second version of PO2), and since its max repetition is greater that T_S, it is segmented and interleaved in a similar manner as that for CSS1. The example in Figure 9 shows two types of CSS (that is, with two different max repetition values). However, it should be appreciated this method is also applicable for more than two different max repetition CSSs. Also, the segments of CSS1 can be interleaved using a different pattern, for example, interleaved with different CSSs such as CSS3 and CSS4 (as shown in Figure 10).

In an embodiment, different POs have different max CSS repetitions. For example, the CSS for PO1 may have repetition $R1_{MAX} > T_S$ whilst the CSS for PO2 may have max repetition $R2_{MAX} < T_S$. In this embodiment, the CSS for PO1 is segmented and interleaved with the un-segmented CSS for PO2.

In another embodiment, all CSSs have $R1_{MAX} > T_S$. Each CSS (with $R1_{MAX}$) is segmented and the segment occupies multiple POs. That is, the CSS is spread among multiple POs. An example is shown in Figure 11, where CSS1 (belonging to PO1) has $R1_{MAX} > T_S$ and is segmented into two segments. The first segment occupies time t_1 to t_2 and the 2nd segment occupies time t_4 to t_5. Similarly, CSS5 (belonging to PO2) has $R1_{MAX} > T_S$ and is segmented into two segments. The first segment occupies time t_2 to t_3 and the 2nd segment occupies time t_6 to t_7. It should be noted that the 2nd segment length of each of CSS1 and CSS2 is less than T_S in this example.

In another embodiment, the overlapping problem shown in Figure 8 can be overcome by ensuring the Paging Occasion period $T_{PO} >$ R1max. Note that this is easier to achieve than to ensure that $T_S > R1_{MAX}$,

since T_{PO} can be much larger than T_S (for example, up to 2560 subframes) and multiple different POs may fit within the T_{PO}.

In embodiments, the segments of the NB-PDCCH search space can be defined by a predetermined pattern, this pattern being configured by the network and, for example, transmitted to the UE 104 from the eNB 101 as system information (in the System Information Block (SIB), for example). In an embodiment, the pattern may vary depending on the number of repeats of the NB-PDCCH, an identifier of the CSS which is used, or any other parameter which the UE may discern from the CSS or NB-PDCCH. The relationship between the predetermined pattern and the CSS or NB-PDCCH may be determined and transmitted to the UE 104 by the eNB 101 and may be in the form of a lookup table of the like. In another embodiment, the pattern may be fixed for the set of paging occasions associated with the UE (again, information indicative of this fixed pattern may be determined and transmitted to the UE 104 by the eNB 101).

It will thus be appreciated that, in a first embodiment, the present technique provides a terminal device 104 for use with a wireless telecommunications network. The terminal device comprises a transceiver 401, 402 and a controller 403. The controller is operable to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device (for example, the plurality of periodic paging occasions PO1 or PO2), a scheduling signal (carried by the NB-PDCCH, for example) scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network. Each periodic paging occasion associated with the terminal device is associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network. The controller is operable to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, and, if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

In one example, the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal. All periodic paging occasions associated with the terminal device may be associated with the same identifier of the scheduling signal (thus, for example, each paging occasion in the plurality of paging occasions PO1 may have the same index, each paging occasion in the plurality of paging occasions PO2 may have the same index, and so on). Alternatively, each periodic paging occasion

associated with the terminal device may be associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device (thus, for example, each paging occasion in the plurality of paging occasions PO1 may have a version number which distinguishes it from the other paging occasions in the plurality PO1, each paging occasion in the plurality of paging occasions PO2 may have a version number which distinguishes it from the other paging occasions in the plurality PO1, and so on). Any suitable identifier may be used as the paging occasion identifier, including, for example, an identifier comprising one or more of a PO index, PO version number or P-RNTI number, as previously discussed.

In another example, the characteristic of the scheduling signal is a scrambling of the scheduling signal. All periodic paging occasions associated with the terminal device may be associated with the same scrambling of the scheduling signal (thus, for example, each paging occasion in the plurality of paging occasions PO1 may be associated with the same scrambling of the scheduling signal, each paging occasion in the plurality of paging occasions PO2 may be associated with the same scrambling of the scheduling signal, and so on). Alternatively, each periodic paging occasion associated with the terminal device may be associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device (thus, for example, each paging occasion in the plurality of paging occasions PO1 may be associated with a different scrambling of the scheduling signal to the scrambling of the scheduling signal associated with the other paging occasions in the plurality PO1, each paging occasion in the plurality of paging occasions PO2 may be associated with a different scrambling of the scheduling signal to the scrambling of the scheduling signal associated with the other paging occasions in the plurality PO2, and so on).

In another example, the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space. For example, the radio search space may be a CSS and the scheduling signal may be the repeatedly transmitted NB-PDCCH. In this case the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a radio search space

with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

In this first embodiment, the present technique also provides infrastructure equipment 101 for use with a wireless telecommunications network. The infrastructure equipment comprises a transceiver 411, 412 and a controller 413. The controller is operable to control the transceiver to begin transmitting, during the one of the plurality of periodic paging occasions associated with the terminal device 104, the scheduling signal scheduling the paging message for paging the terminal device in the way as described.

It will also be appreciated that, in a second embodiment, the present technique provides a terminal device 101for use with a wireless telecommunications network. The terminal device comprises a transceiver 401, 402 and a controller 403. The controller is operable to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device (for example, the plurality of periodic paging occasions PO1 or PO2), a scheduling signal (carried by the NB-PDCCH, for example) scheduling a paging message for paging the terminal device. The scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods (in other words, the periodic repeats of the scheduling signal are segmented, as shown in Figures 9 to 11, for example), each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal. The controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

In one example, the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated. Scheduling signals with a duration of that of CSS1 or CSS 5 (shown in Figures 9 to 11) are examples of such scheduling signals.

In one example, the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network. This is shown, for example, in Figures 9 to 11, in which paging occasions belonging to the plurality PO1 are interleaved with paging occasions belonging to the plurality PO2.

In one example, the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods. In this case, for example, information indicative of the predetermined plurality of separate time periods (in other words, the segmentation pattern of the repeatedly transmitted scheduling signal) is stored in the storage medium 422 of the infrastructure equipment 101 and is signalled to the terminal device 104 using the transceiver 411, 412. The transceiver 401, 402 of the terminal device then receives the signal and the information indicative of the predetermined plurality of separate time periods is stored in the storage medium 420.

In one example, the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device. In this case, for example, there are at least two terminal devices in the wireless telecommunications network, wherein one terminal device is associated with the plurality of periodic paging occasions PO1 and the other terminal device is associated with the plurality of periodic paging occasions PO2, as shown in Figures 9 to 11. In another example, there may be no other terminal devices associated with a plurality of different periodic paging occasions (in which case, the only paging occasions present are those associated with the terminal device 104). It is noted that the present technique will still work in this case, in that if the terminal device knows the predetermined plurality of separate time periods over which the scheduling signal is repeatedly transmitted, the terminal device will know which paging occasion a particular set of repeats of the scheduling signal belongs to (thus avoiding the confusion arising from the situation shown in Figure 8, for example).

In this second embodiment, the present technique also provides infrastructure equipment 101 for use with a wireless telecommunications network. The infrastructure equipment comprises a transceiver 411, 412 and a controller 413. The controller is operable to control the transceiver to begin transmitting, during the one of the plurality of periodic paging occasions associated with a terminal device 104, the scheduling signal scheduling the paging message for paging the terminal device in the way as described.

Figure 12 illustrates a flow chart schematically showing a method according to the first embodiment of the present technique. The method starts at step 1201. At step 1202, the terminal device 104 begins receiving a scheduling signal during one of a plurality of periodic paging occasions associated with the terminal device. At step 1204, it is determined whether a value of a predetermined characteristic associated with each of the received scheduling signal and the one of the plurality of paging occasions matches. In the case that there is no match, the method ends at step 1208. On the other hand, in the case

that there is a match, the method moves on to step 1206, in which the terminal device receives a paging message scheduled by the scheduling signal. The method then ends at step 1208.

Figure 13 illustrates a flow chart schematically showing a method according to the second embodiment of the present technique. The method starts at step 1301. At step 1302, the terminal device 104 begins receiving a scheduling signal during one of a plurality of periodic paging occasions associated with the terminal device. At step 1303, the terminal device receives a predetermined number of repeats of the scheduling signal over a predetermined plurality of separate time periods. At step 1304, the terminal device receives a paging message scheduled by the scheduling signal. The method then ends at step 1305.

Features of various embodiments of the present technique are described by the following numbered clauses:

1. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

2. A terminal device according to clause 1, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

3. A terminal device according to clause 2, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

4. A terminal device according to clause 2, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

5. A terminal device according to clause 1, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

6. A terminal device according to clause 5, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

7. A terminal device according to clause 5, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

8. A terminal device according to any preceding clause, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

9. A terminal device according to clause 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space, wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a

radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

10. A terminal device according to any preceding clause, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

11. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

12. Infrastructure equipment according to clause 11, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

13. Infrastructure equipment according to clause 12, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

14. Infrastructure equipment according to clause 12, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

15. Infrastructure equipment according to clause 11, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

16. Infrastructure equipment according to clause 15, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

17. Infrastructure equipment according to clause 15, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

18. Infrastructure equipment according to any one of clauses 11 to 17, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate.

19. Infrastructure equipment according to clause 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, , wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, the starting time of the radio search space matching the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

20. Infrastructure equipment according to any one of clauses 11 to 19, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

21. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, controlling the transceiver to receive the paging message scheduled by the received scheduling message.

22. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

23. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver element to receive the paging message scheduled by the received scheduling message.

24. Integrated circuitry for infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

25. A wireless telecommunications network comprising a terminal device according to clause 1 and infrastructure equipment according to clause 11.

26. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

27. A terminal device according to clause 26, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

28. A terminal device according to clause 26 or 27, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

29. A terminal device according to any one of clauses 26 to 28, wherein the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods.

30. A terminal device according to any one of clauses 26 to 29, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

31. A terminal device according to any one of clauses 26 to 30, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

32. A terminal device according to any one of clauses 26 to 31, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

33. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

34. Infrastructure equipment according to clause 33, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the transceiver is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

35. Infrastructure equipment according to clause 33 or 34, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

36. Infrastructure equipment according to any one of claims 33 to 35, wherein the controller is operable to control the transceiver to transmit a signal to the terminal device indicative of the predetermined plurality of separate time periods.

37. Infrastructure equipment according to any one of clauses 33 to 36, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

38. Infrastructure equipment according to any one of clauses 33 to 37, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate..

39. Infrastructure equipment according to any one of clauses 33 to 38, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

40. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

transceiver is controlled to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

41. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the transceiver is controlled to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

42. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin receiving the scheduling signal; and

the controller element is operable to control the transceiver element to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

43. Integrated circuitry for operating infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller element is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin transmitting the scheduling signal.

44. A wireless telecommunications network comprising a terminal device according to clause 26 and infrastructure equipment according to clause 33.

Numerous modifications and variations of the present disclosure are possible in light of the above teachings. It is therefore to be understood that within the scope of the appended claims, the disclosure may be practiced otherwise than as specifically described herein.

In so far as embodiments of the disclosure have been described as being implemented, at least in part, by software-controlled data processing apparatus, it will be appreciated that a non-transitory machine-readable medium carrying such software, such as an optical disk, a magnetic disk, semiconductor memory or the like, is also considered to represent an embodiment of the present disclosure.

It will be appreciated that the above description for clarity has described embodiments with reference to different functional units, circuitry and/or processors. However, it will be apparent that any suitable distribution of functionality between different functional units, circuitry and/or processors may be used without detracting from the embodiments.

Described embodiments may be implemented in any suitable form including hardware, software, firmware or any combination of these. Described embodiments may optionally be implemented at least partly as computer software running on one or more data processors and/or digital signal processors. The elements and components of any embodiment may be physically, functionally and logically implemented in any suitable way. Indeed the functionality may be implemented in a single unit, in a plurality of units or as part of other functional units. As such, the disclosed embodiments may be implemented in a single unit or may be physically and functionally distributed between different units, circuitry and/or processors.

Although the present disclosure has been described in connection with some embodiments, it is not intended to be limited to the specific form set forth herein. Additionally, although a feature may appear to be described in connection with particular embodiments, one skilled in the art would recognize that various features of the described embodiments may be combined in any manner suitable to implement the technique.

Annex 1:

The simplified structure of the downlink of an LTE wireless access interface presented in Figure 2, also includes an illustration of each subframe 201, which comprises a control region 205 for the transmission of control data, a data region 206 for the transmission of user data , reference signals 207 and synchronisation signals which are interspersed in the control and data regions in accordance with a predetermined pattern. The control region 204 may contain a number of physical channels for the transmission of control data, such as a physical downlink control channel PDCCH, a physical control format indicator channel PCFICH and a physical HARQ indicator channel PHICH. The data region may contain a number of physical channel for the transmission of data, such as a physical downlink shared channel PDSCH and a physical broadcast channels PBCH. Although these physical channels provide a wide range of functionality to LTE systems, in terms of resource allocation and the present disclosure PDCCH and PDSCH are most relevant. Further information on the structure and functioning of the physical channels of LTE systems can be found in [1].

Resources within the PDSCH may be allocated by an eNodeB to UEs being served by the eNodeB. For example, a number of resource blocks of the PDSCH may be allocated to a UE in order that it may receive data that it has previously requested or data which is being pushed to it by the eNodeB, such as radio resource control RRC signalling. In Figure 2, UE1 has been allocated resources 208 of the data region 206, UE2 resources 209 and UE resources 210. UEs in a an LTE system may be allocated a fraction of the available resources of the PDSCH and therefore UEs are required to be informed of the location of their allocated resources within the PDCSH so that only relevant data within the PDSCH is detected and estimated. In order to inform the UEs of the location of their allocated communications resources, resource control information specifying downlink resource allocations is conveyed across the PDCCH in a form termed downlink control information DCI, where resource allocations for a PDSCH are communicated in a preceding PDCCH instance in the same subframe. During a resource allocation procedure, UEs thus monitor the PDCCH for DCI addressed to them and once such a DCI is detected, receive the DCI and detect and estimate the data from the relevant part of the PDSCH.

Each uplink subframe may include a plurality of different channels, for example a physical uplink shared channel PUSCH 305, a physical uplink control channel PUCCH 306, and a physical random access channel PRACH. The physical Uplink Control Channel PUCCH may carry control information such as ACK/NACK to the eNodeB for downlink transmissions, scheduling request indicators SRI for UEs wishing to be scheduled uplink resources, and feedback of downlink channel state information CSI for example. The PUSCH may carry UE uplink data or some uplink control data. Resources of the PUSCH are granted via PDCCH, such a grant being typically triggered by communicating to the network the amount of data ready to be transmitted in a buffer at the UE. The PRACH may be scheduled in any of the

resources of an uplink frame in accordance with a one of a plurality of PRACH patterns that may be signalled to UE in downlink signalling such as system information blocks. As well as physical uplink channels, uplink subframes may also include reference signals. For example, demodulation reference signals DMRS 307 and sounding reference signals SRS 308 may be present in an uplink subframe where the DMRS occupy the fourth symbol of a slot in which PUSCH is transmitted and are used for decoding of PUCCH and PUSCH data, and where SRS are used for uplink channel estimation at the eNodeB. Further information on the structure and functioning of the physical channels of LTE systems can be found in [1].

In an analogous manner to the resources of the PDSCH, resources of the PUSCH are required to be scheduled or granted by the serving eNodeB and thus if data is to be transmitted by a UE, resources of the PUSCH are required to be granted to the UE by the eNodeB. At a UE, PUSCH resource allocation is achieved by the transmission of a scheduling request or a buffer status report to its serving eNodeB. The scheduling request may be made, when there is insufficient uplink resource for the UE to send a buffer status report, via the transmission of Uplink Control Information UCI on the PUCCH when there is no existing PUSCH allocation for the UE, or by transmission directly on the PUSCH when there is an existing PUSCH allocation for the UE. In response to a scheduling request, the eNodeB is configured to allocate a portion of the PUSCH resource to the requesting UE sufficient for transferring a buffer status report and then inform the UE of the buffer status report resource allocation via a DCI in the PDCCH. Once or if the UE has PUSCH resource adequate to send a buffer status report, the buffer status report is sent to the eNodeB and gives the eNodeB information regarding the amount of data in an uplink buffer or buffers at the UE. After receiving the buffer status report, the eNodeB can allocate a portion of the PUSCH resources to the sending UE in order to transmit some of its buffered uplink data and then inform the UE of the resource allocation via a DCI in the PDCCH. For example, presuming a UE has a connection with the eNodeB, the UE will first transmit a PUSCH resource request in the PUCCH in the form of a UCI. The UE will then monitor the PDCCH for an appropriate DCI, extract the details of the PUSCH resource allocation, and transmit uplink data , at first comprising a buffer status report, and/or later comprising a portion of the buffered data, in the allocated resources.

Although similar in structure to downlink subframes, uplink subframes have a different control structure to downlink subframes, in particular the upper 309 and lower 310 subcarriers/frequencies/resource blocks of an uplink subframe are reserved for control signalling rather than the initial symbols of a downlink subframe. Furthermore, although the resource allocation procedure for the downlink and uplink are relatively similar, the actual structure of the resources that may be allocated may vary due to the different characteristics of the OFDM and SC-FDM interfaces that are used in the downlink and uplink respectively. In OFDM each subcarrier is individually modulated and therefore it is not necessary that frequency/subcarrier allocation are contiguous however, in SC-FDM subcarriers are modulation in

combination and therefore if efficient use of the available resources are to be made contiguous frequency allocations for each UE are preferable.

As a result of the above described wireless interface structure and operation, one or more UEs may communicate data to one another via a coordinating eNodeB, thus forming a conventional cellular telecommunications system. Although cellular communications system such as those based on the previously released LTE standards have been commercially successful, a number of disadvantages are associated with such centralised systems. For example, if two UEs which are in close proximity wish to communicate with each other, uplink and downlink resources sufficient to convey the data are required. Consequently, two portions of the system's resources are being used to convey a single portion of data. A second disadvantage is that an eNodeB is required if UEs, even when in close proximity, wish to communicate with one another. These limitations may be problematic when the system is experiencing high load or eNodeB coverage is not available, for instance in remote areas or when eNodeBs are not functioning correctly. Overcoming these limitations may increase both the capacity and efficiency of LTE networks but also lead to the creations of new revenue possibilities for LTE network operators.

CLAIMS

1. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver to receive the paging message scheduled by the received scheduling message.

2. A terminal device according to claim 1, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

3. A terminal device according to claim 2, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

4. A terminal device according to claim 2, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

5. A terminal device according to claim 1, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

6. A terminal device according to claim 5, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

7. A terminal device according to claim 5, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

8. A terminal device according to claim 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

9. A terminal device according to claim 1, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space, wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, and the controller is operable to determine, on the basis of the starting time of the radio search space and a starting time of the scheduling signal, whether the scheduling signal belongs to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device, wherein the controller determines a match when the scheduling signal is determined to belong to a radio search space with a starting time which matches the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

10. A terminal device according to claim 1, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

11. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

12. Infrastructure equipment according to claim 11, wherein the characteristic of the scheduling signal is a paging occasion identifier identified by the scheduling signal.

13. Infrastructure equipment according to claim 12, wherein all periodic paging occasions associated with the terminal device are associated with the same identifier of the scheduling signal.

14. Infrastructure equipment according to claim 12, wherein each periodic paging occasion associated with the terminal device is associated with an identifier of the scheduling signal which is different from the identifier of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

15. Infrastructure equipment according to claim 11, wherein the characteristic of the scheduling signal is a scrambling of the scheduling signal.

16. Infrastructure equipment according to claim 15, wherein all periodic paging occasions associated with the terminal device are associated with the same scrambling of the scheduling signal.

17. Infrastructure equipment according to claim 15, wherein each periodic paging occasion associated with the terminal device is associated with a scrambling of the scheduling signal which is different from the scrambling of the scheduling signal associated with each of the other periodic paging occasions associated with the terminal device.

18. Infrastructure equipment according to claim 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate.

19. Infrastructure equipment according to claim 11, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, , wherein the characteristic of the scheduling signal is a starting time of the radio search space indicated by the scheduling signal, the starting time of the radio search space matching the starting time of the one of the plurality of periodic paging occasions associated with the terminal device.

20. Infrastructure equipment according to claim 11, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

21. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

determining whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, controlling the transceiver to receive the paging message scheduled by the received scheduling message.

22. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the

plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

23. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging one or more terminal devices of the wireless telecommunications network, each periodic paging occasion associated with the terminal device being associated with a value of a characteristic of the scheduling signal which is different from a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network;

to determine whether the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device; and

if the value of the characteristic of the received scheduling signal matches the value of the characteristic of the scheduling signal associated with the one of the plurality of periodic paging occasions associated with the terminal device, to control the transceiver element to receive the paging message scheduled by the received scheduling message.

24. Integrated circuitry for infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device, wherein a value of a characteristic of the scheduling signal is associated with the one of the plurality of periodic paging occasions associated with the terminal device, each periodic paging occasion associated with the terminal device being associated with a value of the characteristic of the scheduling signal which is different from

a value of the characteristic of the scheduling signal associated with one or more of each of the other periodic paging occasions associated with the terminal device and each of periodic paging occasions associated with one or more other terminal devices of the wireless telecommunications network.

25. A wireless telecommunications network comprising a terminal device according to claim 1 and infrastructure equipment according to claim 11.

26. A terminal device for use with a wireless telecommunications network, the terminal device comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

the controller is operable to control the transceiver to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

27. A terminal device according to claim 26, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the network is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

28. A terminal device according to claim 26, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

29. A terminal device according to claim 26, wherein the controller is operable to control the transceiver to receive a signal from the wireless telecommunications network indicative of the predetermined plurality of separate time periods.

30. A terminal device according to claim 26, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

31. A terminal device according to claim 26, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate, and wherein the controller is operable to control the transceiver to attempt to receive the scheduling signal from each candidate of the radio search space.

32. A terminal device according to claim 26, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

33. Infrastructure equipment for use with a wireless telecommunications network, the infrastructure equipment comprising:

a transceiver; and

a controller operable:

to control the transceiver to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

34. Infrastructure equipment according to claim 33, wherein the total time taken for the scheduling signal to be repeatedly transmitted by the transceiver is greater than the time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated.

35. Infrastructure equipment according to claim 33, wherein the plurality of periodic paging occasions associated with the terminal device are interleaved with the plurality of periodic paging occasions associated with any other terminal device of the wireless telecommunications network.

36. Infrastructure equipment according to claim 33, wherein the controller is operable to control the transceiver to transmit a signal to the terminal device indicative of the predetermined plurality of separate time periods.

37. Infrastructure equipment according to claim 33, wherein the number of other terminal devices of the wireless telecommunications network with which a plurality of periodic paging occasions is associated is one or more, and the plurality of periodic paging occasions associated with the one or more other terminal devices is different to the plurality of periodic paging occasions associated with the terminal device.

38. Infrastructure equipment according to claim 33, wherein the scheduling signal is transmitted using a candidate of a radio search space, the radio search space being defined by a plurality of candidates and each candidate of the radio search space being defined by a set of time and/or frequency radio resources for use in repeatedly transmitting the scheduling signal a number of times associated with that candidate..

39. Infrastructure equipment according to claim 33, wherein the terminal device is a Narrow Band Internet of Things (NB-IoT) terminal device and the scheduling signal is carried by a Narrow Band Physical Downlink Control Channel (NB-PDCCH).

40. A method of operating a terminal device for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the terminal device to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the

plurality of periodic paging occasions during which the transceiver is controlled to begin receiving the scheduling signal; and

transceiver is controlled to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

41. A method of operating infrastructure equipment for use with a wireless telecommunications network, the method comprising:

controlling a transceiver of the infrastructure equipment to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the transceiver is controlled to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver is controlled to begin transmitting the scheduling signal.

42. Integrated circuitry for a terminal device for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin receiving, during one of a plurality of periodic paging occasions associated with the terminal device, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the scheduling signal is repeatedly transmitted by the network a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin receiving the scheduling signal; and

the controller element is operable to control the transceiver element to receive the repetitions of the scheduling signal over the predetermined plurality of separate time periods.

43. Integrated circuitry for operating infrastructure equipment for use with a wireless telecommunications network, the integrated circuitry comprising:

a transceiver element; and

a controller element operable:

to control the transceiver element to begin transmitting, during one of a plurality of periodic paging occasions associated with a terminal device of the wireless telecommunications network, a scheduling signal scheduling a paging message for paging the terminal device; wherein

the controller element is operable to control the transceiver to repeatedly transmit the scheduling signal a predetermined number of times over a predetermined plurality of separate time periods, each of the separate time periods having a duration less than or equal to a time period between consecutive periodic paging occasions associated with the terminal device and with any other terminal device of the wireless telecommunications network with which a plurality of periodic paging occasions is associated, and one of the separate time periods being during a periodic paging occasion or between periodic paging occasions other than the one of the plurality of periodic paging occasions during which the transceiver element is controlled to begin transmitting the scheduling signal.

44. A wireless telecommunications network comprising a terminal device according to claim 26 and infrastructure equipment according to claim 33.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/EP2017/057758

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

☒ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-25

   Identification of paging/scheduling signal for a given mobile terminal

   ---

2. claims: 26-44

   Avoiding interference for paging where paging signals are transmitted multiple times (Coverage Enhancement)

(54) Title: METHOD AND USER EQUIPMENT FOR RECEIVING DOWNLINK CONTROL INFORMATION, AND METHOD AND BASE STATION FOR TRANSMITTING DOWNLINK CONTROL INFORMATION

(57) **Abstract:** A search space (hereinafter, CSS) for a control channel for scheduling a random access response may be configured by a system information block. A user equipment (UE) may attempt to receive a control channel for a random access response on the assumption that CSS is configured in accordance with a configuration based on the system information block. The UE may attempt to receive the control channel within a UE-specific search space (USS) by assuming that the USS is configured in accordance with the configuration of the CSS until a configuration for the USS is received.

WO 2017/052199 A1

Description

Title of Invention: METHOD AND USER EQUIPMENT FOR RECEIVING DOWNLINK CONTROL INFORMATION, AND METHOD AND BASE STATION FOR TRANSMITTING DOWNLINK CONTROL INFORMATION

Technical Field

[1] The present invention relates to a wireless communication system, and more particularly, to a method for transmitting or receiving downlink control information and a device therefor.

Background Art

[2] With appearance and spread of machine-to-machine (M2M) communication and a variety of devices such as smartphones and tablet PCs and technology demanding a large amount of data transmission, data throughput needed in a cellular network has rapidly increased. To satisfy such rapidly increasing data throughput, carrier aggregation technology, cognitive radio technology, etc. for efficiently employing more frequency bands and multiple input multiple output (MIMO) technology, multi-base station (BS) cooperation technology, etc. for raising data capacity transmitted on limited frequency resources have been developed.

[3] A general wireless communication system performs data transmission/reception through one downlink (DL) band and through one uplink (UL) band corresponding to the DL band (in case of a frequency division duplex (FDD) mode), or divides a prescribed radio frame into a UL time unit and a DL time unit in the time domain and then performs data transmission/reception through the UL/DL time unit (in case of a time division duplex (TDD) mode). A base station (BS) and a user equipment (UE) transmit and receive data and/or control information scheduled on a prescribed time unit basis, e.g. on a subframe basis. The data is transmitted and received through a data region configured in a UL/DL subframe and the control information is transmitted and received through a control region configured in the UL/DL subframe. To this end, various physical channels carrying radio signals are formed in the UL/DL subframe. In contrast, carrier aggregation technology serves to use a wider UL/DL bandwidth by aggregating a plurality of UL/DL frequency blocks in order to use a broader frequency band so that more signals relative to signals when a single carrier is used can be simultaneously processed.

[4] In addition, a communication environment has evolved into increasing density of nodes accessible by a user at the periphery of the nodes. A node refers to a fixed point

capable of transmitting/receiving a radio signal to/from the UE through one or more antennas. A communication system including high-density nodes may provide a better communication service to the UE through cooperation between the nodes.

Disclosure of Invention

Technical Problem

[5] Due to introduction of new radio communication technology, the number of user equipments (UEs) to which a BS should provide a service in a prescribed resource region increases and the amount of data and control information that the BS should transmit to the UEs increases. Since the amount of resources available to the BS for communication with the UE(s) is limited, a new method in which the BS efficiently receives/transmits uplink/downlink data and/or uplink/downlink control information using the limited radio resources is needed.

[6] The technical objects that can be achieved through the present invention are not limited to what has been particularly described hereinabove and other technical objects not described herein will be more clearly understood by persons skilled in the art from the following detailed description.

Solution to Problem

[7] A search space (hereinafter, CSS_RAR) for a control channel for scheduling a random access response may be configured by a system information block. A user equipment (UE) may attempt to receive a control channel for a random access response by assuming that CSS_RAR is configured in accordance with a configuration based on the system information block. If the UE receives the control channel for a random access response, the UE may receive the random access response to a random access preamble transmitted therefrom in accordance with control information carried by the control channel. The UE may attempt to receive a control channel within a UE-specific search space (hereinafter, USS) by assuming that the USS is configured in accordance with the configuration of the CSS until a configuration for the USS is received.

[8] In an aspect of the present invention, provided herein is a method for receiving, by a user equipment (UE), downlink control information (DCI) for the UE. The method comprises: receiving, by the UE, a common search space configuration for a common search space; receiving, by the UE, a first physical downlink control channel (PDCCH) scheduling a random access response; and receiving, by the UE, a second PDCCH carrying the DCI for the UE. The UE can monitor first PDCCH candidates of the common search space according to the common search space configuration in order to receive the first PDCCH. The UE can monitor second PDCCH candidates of a UE-specific search space in order to receive the second PDCCH. The UE can assume that configuration of the UE-specific search space is the same as that of the common search

space until the UE receives a UE-specific search space configuration.

[9] In another aspect of the present invention, provided herein is a method for transmitting, by a base station (BS), downlink control information (DCI) for a user equipment (UE). The method comprises: transmitting, by the BS, common search space configuration for a common search space; transmitting, by the BS to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response; and transmitting, by the BS to the UE, a second PDCCH carrying the DCI for the UE. The BS can transmit the first PDCCH by using one of first PDCCH candidates of the common search space according to the common search space configuration. The BS can transmit the second PDCCH by using one of second PDCCH candidates of a UE-specific search space. The BS can configure the UE-specific search space according to the same configuration as the common search space configuration until the BS transmits a UE-specific search space configuration to the UE.

[10] In still another aspect of the present invention, provided herein a user equipment (UE) for receiving downlink control information (DCI) for the UE. The UE comprises a radio frequency (RF) unit and a processor connected to the RF unit. The processor can be configured to control the RF unit to receive common search space configuration for a common search space; control the RF unit to receive a first physical downlink control channel (PDCCH) scheduling a random access response; and control the RF unit to receive a second PDCCH carrying the DCI for the UE. The processor can be configured to monitor first PDCCH candidates of the common search space according to the common search space configuration in order to detect the firs PDCCH. The processor can be configured to monitor second PDCCH candidates of a UE-specific search space in order to detect the second PDCCH. The processor can be configured to assume that configuration of the UE-specific search space is the same as that of the common search space until the UE receives a UE-specific search space configuration.

[11] In a further aspect of the present invention, provided herein a base station (BS) for transmitting downlink control information (DCI) for a user equipment (UE). The BS comprises a radio frequency (RF) unit and a processor connected to the RF unit. The processor can be configured to control the RF unit to transmit common search space configuration for a common search space; control the RF unit to transmit a first physical downlink control channel (PDCCH) scheduling a random access response; and control the RF unit to transmit a second PDCCH carrying the DCI for the UE. The processor can be configured to control the RF unit to transmit the first PDCCH using one of first PDCCH candidates of the common search space according to the common search space configuration. The processor can be configured to control the RF unit to transmit the second PDCCH using one of second PDCCH candidates of a UE-specific search space. The processor can configure the UE-specific search space according to

the same as that of the common search space until the BS transmits a UE-specific search space configuration.

[12] In each aspect of the present invention, the common search space configuration can include information on a narrowband for the common search space. The second PDCCH candidates of the UE-specific search space can be configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[13] In each aspect of the present invention, the common search space configuration can include information on a maximum number of repetitions for the first common search space. The second PDCCH candidates of the UE-specific search space can be configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.

[14] In each aspect of the present invention, the common search space configuration can include information on a first physical resource block (PRB) set for transmitting the first PDCCH. The same physical resource block set as the first PRB set can be used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE

[15] In each aspect of the present invention, the first PDCCH candidates of the common search space can be configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, whereas the second PDCCH candidates of the UE-specific search space can be configured according to the plurality of aggregation levels.

[16] In each aspect of the present invention, the UE can transmit a random access preamble using a physical random access channel (PRACH) resource. The UE can monitor the first PDCCH candidates in response to transmission of the random access preamble. The UE can receive the random access response according to control information carried by the first PDCCH. The BS can receive a random access preamble using a physical random access channel (PRACH) resource. The BS can transmit the first PDCCH in response to reception of the random access preamble. The BS can transmit the random access response according to control information carried by the first PDCCH.

[17] The above technical solutions are merely some parts of the embodiments of the present invention and various embodiments into which the technical features of the present invention are incorporated can be derived and understood by persons skilled in the art from the following detailed description of the present invention.

Advantageous Effects of Invention

[18] According to the present invention, uplink/downlink signals can be efficiently transmitted/received. Therefore, overall throughput of a radio communication system can be improved.

[19] According to one embodiment of the present invention, a low cost/complexity UE can perform communication with a BS at low cost while maintaining compatibility with a legacy system.

[20] According to one embodiment of the present invention, the UE can be implemented at low cost/complexity.

[21] According to one embodiment of the present invention, coverage can be enhanced.

[22] According to one embodiment of the present invention, the UE and the BS can perform communication with each other at a narrowband.

[23] It will be appreciated by persons skilled in the art that that the effects that can be achieved through the present invention are not limited to what has been particularly described hereinabove and other advantages of the present invention will be more clearly understood from the following detailed description.

Brief Description of Drawings

[24] The accompanying drawings, which are included to provide a further understanding of the invention, illustrate embodiments of the invention and together with the description serve to explain the principle of the invention.

[25] FIG. 1 illustrates the structure of a radio frame used in a wireless communication system.

[26] FIG. 2 illustrates the structure of a downlink (DL)/uplink (UL) slot in a wireless communication system.

[27] FIG. 3 illustrates a radio frame structure for transmission of a synchronization signal (SS).

[28] FIG. 4 illustrates the structure of a DL subframe used in a wireless communication system.

[29] FIG. 5 illustrates the structure of a UL subframe used in a wireless communication system.

[30] FIG. 6 illustrates an example of a signal band for MTC.

[31] FIG. 7 illustrates repeated transmission of a channel for coverage enhancement.

[32] FIG. 8 illustrates a configuration of a common search space (CSS) for paging according to the present invention.

[33] FIG. 9 illustrates a configuration of a common search space (CSS) for random access response (RAR) according to the present invention.

[34] FIG. 10 illustrates the example of the monitoring time region of USS and CSS.

[35] FIG. 11 illustrates a procedure of configuring a search space according to the present

invention.

[36] FIG. 12 illustrates a configuration of M-PDCCH repeated transmission according to the present invention.

[37] FIG. 13 is a block diagram illustrating elements of a transmitting device 10 and a receiving device 20 for implementing the present invention.

Mode for the Invention

[38] Reference will now be made in detail to the exemplary embodiments of the present invention, examples of which are illustrated in the accompanying drawings. The detailed description, which will be given below with reference to the accompanying drawings, is intended to explain exemplary embodiments of the present invention, rather than to show the only embodiments that can be implemented according to the invention. The following detailed description includes specific details in order to provide a thorough understanding of the present invention. However, it will be apparent to those skilled in the art that the present invention may be practiced without such specific details.

[39] In some instances, known structures and devices are omitted or are shown in block diagram form, focusing on important features of the structures and devices, so as not to obscure the concept of the present invention. The same reference numbers will be used throughout this specification to refer to the same or like parts.

[40] The following techniques, apparatuses, and systems may be applied to a variety of wireless multiple access systems. Examples of the multiple access systems include a code division multiple access (CDMA) system, a frequency division multiple access (FDMA) system, a time division multiple access (TDMA) system, an orthogonal frequency division multiple access (OFDMA) system, a single carrier frequency division multiple access (SC-FDMA) system, and a multicarrier frequency division multiple access (MC-FDMA) system. CDMA may be embodied through radio technology such as universal terrestrial radio access (UTRA) or CDMA2000. TDMA may be embodied through radio technology such as global system for mobile communications (GSM), general packet radio service (GPRS), or enhanced data rates for GSM evolution (EDGE). OFDMA may be embodied through radio technology such as institute of electrical and electronics engineers (IEEE) 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802.20, or evolved UTRA (E-UTRA). UTRA is a part of a universal mobile telecommunications system (UMTS). 3rd generation partnership project (3GPP) long term evolution (LTE) is a part of evolved UMTS (E-UMTS) using E-UTRA. 3GPP LTE employs OFDMA in DL and SC-FDMA in UL. LTE-advanced (LTE-A) is an evolved version of 3GPP LTE. For convenience of description, it is assumed that the present invention is applied to 3GPP LTE/LTE-A. However, the

technical features of the present invention are not limited thereto. For example, although the following detailed description is given based on a mobile communication system corresponding to a 3GPP LTE/LTE-A system, aspects of the present invention that are not specific to 3GPP LTE/LTE-A are applicable to other mobile communication systems.

[41] For example, the present invention is applicable to contention based communication such as Wi-Fi as well as non-contention based communication as in the 3GPP LTE/LTE-A system in which an eNB allocates a DL/UL time/frequency resource to a UE and the UE receives a DL signal and transmits a UL signal according to resource allocation of the eNB. In a non-contention based communication scheme, an access point (AP) or a control node for controlling the AP allocates a resource for communication between the UE and the AP, whereas, in a contention based communication scheme, a communication resource is occupied through contention between UEs which desire to access the AP. The contention based communication scheme will now be described in brief. One type of the contention based communication scheme is carrier sense multiple access (CSMA). CSMA refers to a probabilistic media access control (MAC) protocol for confirming, before a node or a communication device transmits traffic on a shared transmission medium (also called a shared channel) such as a frequency band, that there is no other traffic on the same shared transmission medium. In CSMA, a transmitting device determines whether another transmission is being performed before attempting to transmit traffic to a receiving device. In other words, the transmitting device attempts to detect presence of a carrier from another transmitting device before attempting to perform transmission. Upon sensing the carrier, the transmitting device waits for another transmission device which is performing transmission to finish transmission, before performing transmission thereof. Consequently, CSMA can be a communication scheme based on the principle of "sense before transmit" or "listen before talk". A scheme for avoiding collision between transmitting devices in the contention based communication system using CSMA includes carrier sense multiple access with collision detection (CSMA/CD) and/or carrier sense multiple access with collision avoidance (CSMA/CA). CSMA/CD is a collision detection scheme in a wired local area network (LAN) environment. In CSMA/CD, a personal computer (PC) or a server which desires to perform communication in an Ethernet environment first confirms whether communication occurs on a network and, if another device carries data on the network, the PC or the server waits and then transmits data. That is, when two or more users (e.g. PCs, UEs, etc.) simultaneously transmit data, collision occurs between simultaneous transmission and CSMA/CD is a scheme for flexibly transmitting data by monitoring collision. A transmitting device using CSMA/CD adjusts data transmission thereof by sensing data transmission performed by another

device using a specific rule. CSMA/CA is a MAC protocol specified in IEEE 802.11 standards. A wireless LAN (WLAN) system conforming to IEEE 802.11 standards does not use CSMA/CD which has been used in IEEE 802.3 standards and uses CA, i.e. a collision avoidance scheme. Transmission devices always sense carrier of a network and, if the network is empty, the transmission devices wait for determined time according to locations thereof registered in a list and then transmit data. Various methods are used to determine priority of the transmission devices in the list and to re-configure priority. In a system according to some versions of IEEE 802.11 standards, collision may occur and, in this case, a collision sensing procedure is performed. A transmission device using CSMA/CA avoids collision between data transmission thereof and data transmission of another transmission device using a specific rule.

[42] In the present invention, a user equipment (UE) may be a fixed or mobile device. Examples of the UE include various devices that transmit and receive user data and/or various kinds of control information to and from a base station (BS). The UE may be referred to as a terminal equipment (TE), a mobile station (MS), a mobile terminal (MT), a user terminal (UT), a subscriber station (SS), a wireless device, a personal digital assistant (PDA), a wireless modem, a handheld device, etc. In addition, in the present invention, a BS generally refers to a fixed station that performs communication with a UE and/or another BS, and exchanges various kinds of data and control information with the UE and another BS. The BS may be referred to as an advanced base station (ABS), a node-B (NB), an evolved node-B (eNB), a base transceiver system (BTS), an access point (AP), a processing server (PS), etc. In describing the present invention, a BS will be referred to as an eNB.

[43] In the present invention, a node refers to a fixed point capable of transmitting/receiving a radio signal through communication with a UE. Various types of eNBs may be used as nodes irrespective of the terms thereof. For example, a BS, a node B (NB), an e-node B (eNB), a pico-cell eNB (PeNB), a home eNB (HeNB), a relay, a repeater, etc. may be a node. In addition, the node may not be an eNB. For example, the node may be a radio remote head (RRH) or a radio remote unit (RRU). The RRH or RRU generally has a lower power level than a power level of an eNB. Since the RRH or RRU (hereinafter, RRH/RRU) is generally connected to the eNB through a dedicated line such as an optical cable, cooperative communication between RRH/RRU and the eNB can be smoothly performed in comparison with cooperative communication between eNBs connected by a radio line. At least one antenna is installed per node. The antenna may mean a physical antenna or mean an antenna port, a virtual antennIn the present invention, a cell refers to a prescribed geographical area to which one or more nodes provide a communication service. Accordingly, in the present invention, communicating with a specific cell may mean communicating with an eNB

or a node which provides a communication service to the specific cell. In addition, a DL/UL signal of a specific cell refers to a DL/UL signal from/to an eNB or a node which provides a communication service to the specific cell. A node providing UL/DL communication services to a UE is called a serving node and a cell to which UL/DL communication services are provided by the serving node is especially called a serving cell. Furthermore, channel status/quality of a specific cell refers to channel status/ quality of a channel or communication link formed between an eNB or node which provides a communication service to the specific cell and a UE. The UE may measure DL channel state received from a specific node using cell-specific reference signal(s) (CRS(s)) transmitted on a CRS resource and/or channel state information reference signal(s) (CSI-RS(s)) transmitted on a CSI-RS resource, allocated by antenna port(s) of the specific node to the specific node. Detailed CSI-RS configuration may be understood with reference to 3GPP TS 36.211 and 3GPP TS 36.331 documents.

[44] Meanwhile, a 3GPP LTE/LTE-A system uses the concept of a cell in order to manage radio resources and a cell associated with the radio resources is distinguished from a cell of a geographic region.

[45] A "cell" of a geographic region may be understood as coverage within which a node can provide service using a carrier and a "cell" of a radio resource is associated with bandwidth (BW) which is a frequency range configured by the carrier. Since DL coverage, which is a range within which the node is capable of transmitting a valid signal, and UL coverage, which is a range within which the node is capable of receiving the valid signal from the UE, depends upon a carrier carrying the signal, the coverage of the node may be associated with coverage of the "cell" of a radio resource used by the node. Accordingly, the term "cell" may be used to indicate service coverage of the node sometimes, a radio resource at other times, or a range that a signal using a radio resource can reach with valid strength at other times. The "cell" of the radio resource will be described later in more detail.

[46] 3GPP LTE/LTE-A standards define DL physical channels corresponding to resource elements carrying information derived from a higher layer and DL physical signals corresponding to resource elements which are used by a physical layer but which do not carry information derived from a higher layer. For example, a physical downlink shared channel (PDSCH), a physical broadcast channel (PBCH), a physical multicast channel (PMCH), a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), and a physical hybrid ARQ indicator channel (PHICH) are defined as the DL physical channels, and a reference signal and a synchronization signal are defined as the DL physical signals. A reference signal (RS), also called a pilot, refers to a special waveform of a predefined signal known to both a BS and a UE. For example, a cell-specific RS (CRS), a UE-specific RS (UE-RS), a po-

sitioning RS (PRS), and channel state information RS (CSI-RS) may be defined as DL RSs. Meanwhile, the 3GPP LTE/LTE-A standards define UL physical channels corresponding to resource elements carrying information derived from a higher layer and UL physical signals corresponding to resource elements which are used by a physical layer but which do not carry information derived from a higher layer. For example, a physical uplink shared channel (PUSCH), a physical uplink control channel (PUCCH), and a physical random access channel (PRACH) are defined as the UL physical channels, and a demodulation reference signal (DM RS) for a UL control/data signal and a sounding reference signal (SRS) used for UL channel measurement are defined as the UL physical signals.

[47] In the present invention, a physical downlink control channel (PDCCH), a physical control format indicator channel (PCFICH), a physical hybrid automatic retransmit request indicator channel (PHICH), and a physical downlink shared channel (PDSCH) refer to a set of time-frequency resources or resource elements (REs) carrying downlink control information (DCI), a set of time-frequency resources or REs carrying a control format indicator (CFI), a set of time-frequency resources or REs carrying downlink acknowledgement (ACK)/negative ACK (NACK), and a set of time-frequency resources or REs carrying downlink data, respectively. In addition, a physical uplink control channel (PUCCH), a physical uplink shared channel (PUSCH) and a physical random access channel (PRACH) refer to a set of time-frequency resources or REs carrying uplink control information (UCI), a set of time-frequency resources or REs carrying uplink data and a set of time-frequency resources or REs carrying random access signals, respectively. In the present invention, in particular, a time-frequency resource or RE that is assigned to or belongs to PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH is referred to as PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH RE or PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH time-frequency resource, respectively. Therefore, in the present invention, PUCCH/PUSCH/PRACH transmission of a UE is conceptually identical to UCI/uplink data/random access signal transmission on PUSCH/PUCCH/PRACH, respectively. In addition, PDCCH/PCFICH/PHICH/PDSCH transmission of an eNB is conceptually identical to downlink data/DCI transmission on PDCCH/PCFICH/PHICH/PDSCH, respectively.

[48] Hereinafter, OFDM symbol/subcarrier/RE to or for which CRS/DMRS/CSI-RS/SRS/UE-RS/TRS is assigned or configured will be referred to as CRS/DMRS/CSI-RS/SRS/UE-RS/TRS symbol/carrier/subcarrier/RE. For example, an OFDM symbol to or for which a tracking RS (TRS) is assigned or configured is referred to as a TRS symbol, a subcarrier to or for which the TRS is assigned or configured is referred to as a TRS subcarrier, and an RE to or for which the TRS is

assigned or configured is referred to as a TRS RE. In addition, a subframe configured for transmission of the TRS is referred to as a TRS subframe. Moreover, a subframe in which a broadcast signal is transmitted is referred to as a broadcast subframe or a PBCH subframe and a subframe in which a synchronization signal (e.g. PSS and/or SSS) is transmitted is referred to a synchronization signal subframe or a PSS/SSS subframe. OFDM symbol/subcarrier/RE to or for which PSS/SSS is assigned or configured is referred to as PSS/SSS symbol/subcarrier/RE, respectively.

[49] In the present invention, a CRS port, a UE-RS port, a CSI-RS port, and a TRS port refer to an antenna port configured to transmit a CRS, an antenna port configured to transmit a UE-RS, an antenna port configured to transmit a CSI-RS, and an antenna port configured to transmit a TRS, respectively. Antenna ports configured to transmit CRSs may be distinguished from each other by the locations of REs occupied by the CRSs according to CRS ports, antenna ports configured to transmit UE-RSs may be distinguished from each other by the locations of REs occupied by the UE-RSs according to UE-RS ports, and antenna ports configured to transmit CSI-RSs may be distinguished from each other by the locations of REs occupied by the CSI-RSs according to CSI-RS ports. Therefore, the term CRS/UE-RS/CSI-RS/TRS ports may also be used to indicate a pattern of REs occupied by CRSs/UE-RSs/CSI-RSs/TRSs in a predetermined resource region. In the present invention, both a DMRS and a UE-RS refer to RSs for demodulation and, therefore, the terms DMRS and UE-RS are used to refer to RSs for demodulation.

[50] FIG. 1 illustrates the structure of a radio frame used in a wireless communication system.

[51] Specifically, FIG. 1(a) illustrates an exemplary structure of a radio frame which can be used in frequency division multiplexing (FDD) in 3GPP LTE/LTE-A and FIG. 1(b) illustrates an exemplary structure of a radio frame which can be used in time division multiplexing (TDD) in 3GPP LTE/LTE-A.

[52] Referring to FIG. 1, a 3GPP LTE/LTE-A radio frame is 10ms ($307,200T_s$) in duration. The radio frame is divided into 10 subframes of equal size. Subframe numbers may be assigned to the 10 subframes within one radio frame, respectively. Here, T_s denotes sampling time where T_s=1/(2048*15kHz). Each subframe is 1ms long and is further divided into two slots. 20 slots are sequentially numbered from 0 to 19 in one radio frame. Duration of each slot is 0.5ms. A time interval in which one subframe is transmitted is defined as a transmission time interval (TTI). Time resources may be distinguished by a radio frame number (or radio frame index), a subframe number (or subframe index), a slot number (or slot index), and the like.

[53] A radio frame may have different configurations according to duplex modes. In FDD mode for example, since DL transmission and UL transmission are discriminated

according to frequency, a radio frame for a specific frequency band operating on a carrier frequency includes either DL subframes or UL subframes. In TDD mode, since DL transmission and UL transmission are discriminated according to time, a radio frame for a specific frequency band operating on a carrier frequency includes both DL subframes and UL subframes.

[54] Table 1 shows an exemplary UL-DL configuration within a radio frame in TDD mode.

[55] [Table 1]

DL-UL configuration	Downlink-to-Uplink Switch-point periodicity	Subframe number									
		0	1	2	3	4	5	6	7	8	9
0	5ms	D	S	U	U	U	D	S	U	U	U
1	5ms	D	S	U	U	D	D	S	U	U	D
2	5ms	D	S	U	D	D	D	S	U	D	D
3	10ms	D	S	U	U	U	D	D	D	D	D
4	10ms	D	S	U	U	D	D	D	D	D	D
5	10ms	D	S	U	D	D	D	D	D	D	D
6	5ms	D	S	U	U	U	D	S	U	U	D

[56] In Table 1, D denotes a DL subframe, U denotes a UL subframe, and S denotes a special subframe. The special subframe includes three fields, i.e. downlink pilot time slot (DwPTS), guard period (GP), and uplink pilot time slot (UpPTS). DwPTS is a time slot reserved for DL transmission and UpPTS is a time slot reserved for UL transmission. Table 2 shows an example of the special subframe configuration.

[57] [Table 2]

Special subframe configuration	Normal cyclic prefix in downlink			Extended cyclic prefix in downlink		
	DwPTS	UpPTS		DwPTS	UpPTS	
		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink
0	$6592 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$	$7680 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$
1	$19760 \cdot T_s$			$20480 \cdot T_s$		
2	$21952 \cdot T_s$			$23040 \cdot T_s$		
3	$24144 \cdot T_s$			$25600 \cdot T_s$		
4	$26336 \cdot T_s$			$7680 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$
5	$6592 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$	$20480 \cdot T_s$		
6	$19760 \cdot T_s$			$23040 \cdot T_s$		
7	$21952 \cdot T_s$			$12800 \cdot T_s$		
8	$24144 \cdot T_s$			-	-	-
9	$13168 \cdot T_s$			-	-	-

[58] FIG. 2 illustrates the structure of a DL/UL slot structure in a wireless communication system.

[59] Referring to FIG. 2, a slot includes a plurality of orthogonal frequency division multiplexing (OFDM) symbols in the time domain and includes a plurality of resource blocks (RBs) in the frequency domain. The OFDM symbol may refer to one symbol duration. Referring to FIG. 2, a signal transmitted in each slot may be expressed by a resource grid including $N^{DL/UL}_{RB} * N^{RB}_{sc}$ subcarriers and $N^{DL/UL}_{symb}$ OFDM symbols. N^{DL}_{RB} denotes the number of RBs in a DL slot and N^{UL}_{RB} denotes the number of RBs in a UL slot. N^{DL}_{RB} and N^{UL}_{RB} depend on a DL transmission bandwidth and a UL transmission bandwidth, respectively. N^{DL}_{symb} denotes the number of OFDM symbols in a DL slot, N^{UL}_{symb} denotes the number of OFDM symbols in a UL slot, and N^{RB}_{sc} denotes the number of subcarriers configuring one RB.

[60] An OFDM symbol may be referred to as an OFDM symbol, a single carrier frequency division multiplexing (SC-FDM) symbol, etc. according to multiple access schemes. The number of OFDM symbols included in one slot may be varied according to channel bandwidths and CP lengths. For example, in a normal cyclic prefix (CP) case, one slot includes 7 OFDM symbols. In an extended CP case, one slot includes 6

OFDM symbols. Although one slot of a subframe including 7 OFDM symbols is shown in FIG. 2 for convenience of description, embodiments of the present invention are similarly applicable to subframes having a different number of OFDM symbols. Referring to FIG. 2, each OFDM symbol includes $N^{DL/UL}_{RB} * N^{RB}_{sc}$ subcarriers in the frequency domain. The type of the subcarrier may be divided into a data subcarrier for data transmission, a reference signal (RS) subcarrier for RS transmission, and a null subcarrier for a guard band and a DC component. The null subcarrier for the DC component is unused and is mapped to a carrier frequency f_0 in a process of generating an OFDM signal or in a frequency up-conversion process. The carrier frequency is also called a center frequency f_c.

[61] One RB is defined as $N^{DL/UL}_{symb}$ (e.g. 7) consecutive OFDM symbols in the time domain and as N^{RB}_{sc} (e.g. 12) consecutive subcarriers in the frequency domain. For reference, a resource composed of one OFDM symbol and one subcarrier is referred to a resource element (RE) or tone. Accordingly, one RB includes $N^{DL/UL}_{symb} * N^{RB}_{sc}$ REs. Each RE within a resource grid may be uniquely defined by an index pair (k, l) within one slot. k is an index ranging from 0 to $N^{DL/UL}_{RB} * N^{RB}_{sc} - 1$ in the frequency domain, and l is an index ranging from 0 to $N^{DL/UL}_{symb} - 1$ in the time domain.

[62] Meanwhile, one RB is mapped to one physical resource block (PRB) and one virtual resource block (VRB). A PRB is defined as N^{DL}_{symb} (e.g. 7) consecutive OFDM or SC-FDM symbols in the time domain and N^{RB}_{sc} (e.g. 12) consecutive subcarriers in the frequency domain. Accordingly, one PRB is configured with $N^{DL/UL}_{symb} * N^{RB}_{sc}$ REs. In one subframe, two RBs each located in two slots of the subframe while occupying the same N^{RB}_{sc} consecutive subcarriers are referred to as a physical resource block (PRB) pair. Two RBs configuring a PRB pair have the same PRB number (or the same PRB index).

[63] FIG. 3 illustrates a radio frame structure for transmission of a synchronization signal (SS). Specifically, FIG. 3 illustrates a radio frame structure for transmission of an SS and a PBCH in frequency division duplex (FDD), wherein FIG. 3(a) illustrates transmission locations of an SS and a PBCH in a radio frame configured as a normal cyclic prefix (CP) and FIG. 3(b) illustrates transmission locations of an SS and a PBCH in a radio frame configured as an extended CP.

[64] If a UE is powered on or newly enters a cell, the UE performs an initial cell search procedure of acquiring time and frequency synchronization with the cell and detecting a physical cell identity N^{cell}_{ID} of the cell. To this end, the UE may establish synchronization with the eNB by receiving synchronization signals, e.g. a primary synchronization signal (PSS) and a secondary synchronization signal (SSS), from the eNB and obtain information such as a cell identity (ID).

[65] An SS will be described in more detail with reference to FIG. 3. An SS is categorized

into a PSS and an SSS. The PSS is used to acquire time-domain synchronization of OFDM symbol synchronization, slot synchronization, etc. and/or frequency-domain synchronization and the SSS is used to acquire frame synchronization, a cell group ID, and/or CP configuration of a cell (i.e. information as to whether a normal CP is used or an extended CP is used). Referring to FIG. 3, each of a PSS and an SSS is transmitted on two OFDM symbols of every radio frame. More specifically, SSs are transmitted in the first slot of subframe 0 and the first slot of subframe 5, in consideration of a global system for mobile communication (GSM) frame length of 4.6 ms for facilitation of inter-radio access technology (inter-RAT) measurement. Especially, a PSS is transmitted on the last OFDM symbol of the first slot of subframe 0 and on the last OFDM symbol of the first slot of subframe 5 and an SSS is transmitted on the second to last OFDM symbol of the first slot of subframe 0 and on the second to last OFDM symbol of the first slot of subframe 5. A boundary of a corresponding radio frame may be detected through the SSS. The PSS is transmitted on the last OFDM symbol of a corresponding slot and the SSS is transmitted on an OFDM symbol immediately before an OFDM symbol on which the PSS is transmitted. A transmit diversity scheme of an SS uses only a single antenna port and standards therefor are not separately defined. That is, a single antenna port transmission scheme or a transmission scheme transparent to a UE (e.g. precoding vector switching (PVS), time switched transmit diversity (TSTD), or cyclic delay diversity (CDD)) may be used for transmit diversity of an SS.

[66] Upon detecting a PSS, a UE may discern that a corresponding subframe is one of subframe 0 and subframe 5 because the PSS is transmitted every 5ms but the UE cannot discern whether the subframe is subframe 0 or subframe 5. Accordingly, the UE cannot recognize the boundary of a radio frame only by the PSS. That is, frame synchronization cannot be acquired only by the PSS. The UE detects the boundary of a radio frame by detecting an SSS which is transmitted twice in one radio frame with different sequences.

[67] The UE, which has determined time and frequency parameters necessary for demodulating a DL signal and transmitting a UL signal at an accurate time by performing a cell search procedure using PSS/SSS, can communicate with the eNB only after acquiring system information necessary for system configuration of the UE from the eNB.

[68] The system information is configured by a master information block (MIB) and system information blocks (SIBs). Each SIB includes a set of functionally associated parameters and is categorized into an MIB, SIB Type 1 (SIB 1), SIB Type 2 (SIB2), and SIB3 to SIB17 in accordance with the parameters.

[69] The MIB includes most frequently transmitted parameters which are essential for

initial access of the UE to a network of the eNB. The UE may receive the MIB through a broadcast channel (e.g. PBCH). The MIB includes a DL bandwidth (BW), PHICH configuration, and a system frame number (SFN). Accordingly, the UE may be explicitly aware of information about the DL BW, SFN, and PHICH configuration by receiving the MIB. Meanwhile, information which may be implicitly recognized by the UE through reception of the PBCH includes the number of transmit antenna ports of the eNB. Information about the number of transmit antennas of the eNB is implicitly signaled by masking (e.g. XOR operation) a sequence corresponding to the number of transmit antennas to a 16-bit cyclic redundancy check (CRC) used for error detection of the PBCH.

[70] The SIB1 includes parameters needed to determine if a specific cell is suitable for cell selection, as well as information about time-domain scheduling of the other SIBs. The SIB1 is received by the UE through broadcast signaling or dedicated signaling.

[71] DL carrier frequency and corresponding system bandwidth may be acquired by the MIB carried by the PBCH. UL carrier frequency and corresponding system bandwidth may be acquired by system information which is a DL signal. The UE which has received the MIB applies a DL BW value within the MIB to a UL-bandwidth (UL BW) until system information block type 2 (SystemInformationBlockType2, SIB2) is received if there is no valid system information stored in a corresponding cell. For example, the UE may identify a full UL system band, which may be used by itself for UL transmission, through UL-carrier frequency and UL-bandwidth information within the SIB2 by acquiring system information block type 2 (SystemInformationBlockType2, SIB2).

[72] In the frequency domain, a PSS/SSS and a PBCH are transmitted only in a total of 6 RBs, i.e. a total of 72 subcarriers, irrespective of actual system BW, wherein 3 RBs are in the left and the other 3 RBs are in the right centering on a DC subcarrier on corresponding OFDM symbols. Therefore, the UE is configured to detect or decode the SS and the PBCH irrespective of DL BW configured for the UE.

[73] After initial cell search, the UE may perform a random access procedure to complete access to the eNB. To this end, the UE may transmit a preamble through a physical random access channel (PRACH) and receive a response message to the preamble through a PDCCH and a PDSCH. In contention based random access, the UE may perform additional PRACH transmission and a contention resolution procedure of a PDCCH and a PDSCH corresponding to the PDCCH.

[74] After performing the aforementioned procedure, the UE may perform PDDCH/PDSCH reception and PUSCH/PUCCH transmission as general uplink/downlink transmission procedures.

[75] The random access procedure is also called RACH (random access channel)

procedure. The random access procedure is used for initial access, uplink synchronization adjustment, resource assignment, handover, etc. The random access procedure is classified into a contention-based process and a dedicated (i.e. non-contention-based) process. The contention-based random access procedure includes initial access and is normally used, whereas the dedicated random access procedure is limitedly used for handover. In the contention-based random access procedure, a UE randomly select a RACH preamble sequence. Accordingly, a plurality of UEs can simultaneously transmit the same RACH preamble sequence and thus a contention resolution procedure is not needed. In the dedicated random access procedure, a UE uses a RACH preamble sequence uniquely allocated thereto by an eNB. Accordingly, the UE can perform the random access procedure without colliding with other UEs.

[76] The contention-based random access procedure has the following four steps. Hereinafter, messages transmitted in steps 1 to 4 may be respectively referred to as Msg 1 to Msg 4.

[77] - Step 1: RACH preamble (via PRACH) (UE to eNB)

[78] - Step 2: Random access response (RAR) (via PDCCH and PDSCH) (eNB to UE)

[79] - Step 3: Layer 2/Layer 3 message (via PUSCH) (UE to eNB)

[80] - Step 4: Contention resolution message (eNB to UE)

[81] The dedicated random access procedure includes the following three steps. Hereinafter, uplink transmission (i.e. step 3) corresponding to a RAR may be performed as a part of the random access procedure. The dedicated random access procedure can be triggered using a PDCCH (hereinafter, referred to as PDCCH order) used for an eNB to command RACH preamble transmission.

[82] - Step 0: PACH preamble allocation through dedicated signaling (eNB to UE)

[83] - Step 1: RACH preamble (via PRACH) (UE to eNB)

[84] - Step 2: RAR (via PDCCH and PDSCH) (eNB to UE)

[85] After transmission of RACH preamble, the UE attempts to receive a random access response (RAR) within a predetermined time window. Specifically, the UE attempts to detect a PDCCH (hereinafter, referred to as RA-RNTI PDCCH) having an RA-RNTI (Random Access RNTI) (e.g., CRC is masked with RA-RNTI in the PDCCH) within the time window. The UE checks whether a RAR therefor is present in a PDSCH corresponding to the RA-RNTI PDCCH during RA-RNTI PDCCH detection. The RAR includes timing advance (TA) information indicating timing offset information for UL synchronization, UL resource allocation information (UL grant information), a temporary UE identifier (e.g., temporary cell-RNTI, TC-RNTI), etc. The UE can perform UL transmission (e.g., Msg3) in accordance with resource allocation information and TA value in the RAR. HARQ is applied to UL transmission corresponding to the RAR. Accordingly, the UE can receive acknowledgement information

(e.g., PHICH) corresponding to Msg 3 after transmission of Msg 3.

[86] The random access preamble, i.e., RACH preamble consists of a cyclic prefix of length T_{CP} and a sequence part of length T_{SEQ} in the physical layer. T_{CP} and T_{SEQ} depend on the frame structure and the random access configuration. The preamble format is controlled by higher layers. The following table shows examples of T_{CP} and T_{SEQ}.

[87] [Table 3]

Preamble format	T_{CP}	T_{SEQ}
0	$3168 \cdot T_s$	$24576 \cdot T_s$
1	$21024 \cdot T_s$	$24576 \cdot T_s$
2	$6240 \cdot T_s$	$2 \cdot 24576 \cdot T_s$
3	$21024 \cdot T_s$	$2 \cdot 24576 \cdot T_s$
4(see NOTE)	$448 \cdot T_s$	$4096 \cdot T_s$
NOTE: Frame structure type 2 and special subframe configuration with UpPTS lengths $4384 \cdot T_s$ and $5120 \cdot T_s$ only.		

[88] The random access preamble is transmitted in UL subframe(s). The transmission of a random access preamble is restricted to certain time and frequency resources. These resources are called PRACH resources. The PRACH resources, are enumerated in increasing order of the subframe number within the radio frame and the PRBs in the frequency domain such that index 0 correspond to the lowest numbered PRB and subframe within the radio frame. PRACH resources within the radio frame are indicated by a PRACH configuration index.

[89] For frame structure type 1 with preamble format 0-3, for each of the PRACH configurations there is at most one random access resource per subframe. The following table shows examples of the preamble formats and the subframes in which random access preamble transmission is allowed for a given configuration in frame structure type 1. The PRACH configuration index is given by a higher layer signal (transmitted by an eNB).

[90] [Table 4]

PRACH Configuration Index	Preamble Format	SFN	Subframe number	PRACH Configuration Index	Preamble Format	SFN	Subframe number
0	0	Even	1	32	2	Even	1
1	0	Even	4	33	2	Even	4
2	0	Even	7	34	2	Even	7
3	0	Any	1	35	2	Any	1
4	0	Any	4	36	2	Any	4
5	0	Any	7	37	2	Any	7
6	0	Any	1,6	38	2	Any	1,6
7	0	Any	2,7	39	2	Any	2,7

28	1	Any	0,2,4,6,8	60	N/A	N/A	N/A
29	1	Any	1,3,5,7,9	61	N/A	N/A	N/A
30	N/A	N/A	N/A	62	N/A	N/A	N/A
31	1	Even	9	63	3	Even	9

[91] In Table 4, SFN denotes a system frame number.

[92] The first PRB, n^{RA}_{PRB}, allocated to the PRACH opportunity considered for preamble formats 0, 1, 2 and 3 is defined by $n^{RA}_{PRB}=n^{RA}_{PRBoffset}$, where the PRACH frequency offset $n^{RA}_{PRBoffset}$ is a PRB configured by higher layers and satisfies $0\leq n^{RA}_{PRBoffset}\leq N^{UL}_{RB}-6$.

[93] In case of frame structure type 2 with preamble formats 0 to 4, a plurality of random access resources may exist within UL subframe (or UpPTS for preamble format 4) in accordance with UL/DL configuration. The random access resources for the frame structure type 2 are defined in accordance with PRACH configuration index (see 3GPP TS 36.211 standard document).

[94] FIG. 4 illustrates the structure of a DL subframe used in a wireless communication system.

[95] Referring to FIG. 4, A DL subframe is divided into a control region and a data region in the time domain. Referring to FIG. 4, a maximum of 3 (or 4) OFDM symbols located in a front part of a first slot of a subframe corresponds to the control region. Hereinafter, a resource region for PDCCH transmission in a DL subframe is referred to as a PDCCH region. OFDM symbols other than the OFDM symbol(s) used in the control region correspond to the data region to which a physical downlink shared channel (PDSCH) is allocated. Hereinafter, a resource region available for PDSCH transmission in the DL subframe is referred to as a PDSCH region.

[96] Examples of a DL control channel used in 3GPP LTE include a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), a physical hybrid ARQ indicator channel (PHICH), etc.

[97] The PCFICH is transmitted in the first OFDM symbol of a subframe and carries information about the number of OFDM symbols available for transmission of a control channel within a subframe. The PCFICH notifies the UE of the number of OFDM symbols used for the corresponding subframe every subframe. The PCFICH is located at the first OFDM symbol. The PCFICH is configured by four resource element groups (REGs), each of which is distributed within a control region on the basis of cell ID. One REG includes four REs.

[98] A set of OFDM symbols available for the PDCCH at a subframe is given by the following Table.

[99] [Table 5]

Subframe	Number of OFDM symbols for PDCCH when $N^{DL}_{RB}>10$	Number of OFDM symbols for PDCCH when $N^{DL}_{RB}\leq 10$
Subframe 1 and 6 for frame structure type 2	1, 2	2
MBSFN subframes on a carrier supporting PDSCH, configured with 1 or 2 cell-specific antenna ports	1, 2	2
MBSFN subframes on a carrier supporting PDSCH, configured with 4 cell-specific antenna ports	2	2
Subframes on a carrier not supporting PDSCH	0	0
Non-MBSFN subframes (except subframe 6 for frame structure type 2) configured with positioning reference signals	1, 2, 3	2, 3
All other cases	1, 2, 3	2, 3, 4

[100] A subset of downlink subframes within a radio frame on a carrier for supporting PDSCH transmission may be configured as MBSFN subframe(s) by a higher layer. Each MBSFN subframe is divided into a non-MBSFN region and an MBSFN region. The non-MBSFN region spans first one or two OFDM symbols, and its length is given by Table 5. The same CP as cyclic prefix (CP) used for subframe 0 is used for transmission within the non-MBSFN region of the MBSFN subframe. The MBSFN region within the MBSFN subframe is defined as OFDM symbols which are not used in the non-MBSFN region.

[101] The PCFICH carries a control format indicator (CFI), which indicates any one of values of 1 to 3. For a downlink system bandwidth $N^{DL}_{RB}>10$, the number 1, 2 or 3 of OFDM symbols which are spans of DCI carried by the PDCCH is given by the CFI. For a downlink system bandwidth $N^{DL}_{RB}\leq 10$, the number 2, 3 or 4 of OFDM symbols which are spans of DCI carried by the PDCCH is given by CFI+1. The CFI is coded in accordance with the following Table.

[102] [Table 6]

CFI	CFI code word<b_0, b_1, ..., b_{31}>
1	<0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1>
2	<1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0>
3	<1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1>
4(Reserved)	<0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0>

[103] The PHICH carries a HARQ (Hybrid Automatic Repeat Request) ACK/NACK (acknowledgment/negative-acknowledgment) signal as a response to UL transmission. The PHICH includes three REGs, and is scrambled cell-specifically. ACK/NACK is indicated by 1 bit, and the ACK/NACK of 1 bit is repeated three times. Each of the repeated ACK/NACK bits is spread with a spreading factor (SF) 4 or 2 and then mapped into a control region.

[104] The control information transmitted through the PDCCH will be referred to as downlink control information (DCI). The DCI includes resource allocation information for a UE or UE group and other control information. Transmit format and resource allocation information of a downlink shared channel (DL-SCH) are referred to as DL scheduling information or DL grant. Transmit format and resource allocation information of an uplink shared channel (UL-SCH) are referred to as UL scheduling information or UL grant. The size and usage of the DCI carried by one PDCCH are varied depending on DCI formats. The size of the DCI may be varied depending on a coding rate. In the current 3GPP LTE system, various formats are defined, wherein formats 0 and 4 are defined for a UL, and formats 1, 1A, 1B, 1C, 1D, 2, 2A, 2B, 2C, 3 and 3A are defined for a DL. Combination selected from control information such as a hopping flag, RB allocation, modulation coding scheme (MCS), redundancy version (RV), new data indicator (NDI), transmit power control (TPC), cyclic shift, cyclic shift demodulation reference signal (DM RS), UL index, channel quality information (CQI) request, DL assignment index, HARQ process number, transmitted precoding matrix indicator (TPMI), precoding matrix indicator (PMI) information is transmitted to the UE as the DCI. The following table shows examples of DCI formats.

[105] [Table 7]

DCI format	Description
0	Resource grants for the PUSCH transmissions (uplink)
1	Resource assignments for single codeword PDSCH transmissions
1A	Compact signaling of resource assignments for single codeword PDSCH
1B	Compact signaling of resource assignments for single codeword PDSCH
1C	Very compact resource assignments for PDSCH (e.g. paging/broadcast system information)
1D	Compact resource assignments for PDSCH using multi-user MIMO
2	Resource assignments for PDSCH for closed-loop MIMO operation
2A	Resource assignments for PDSCH for open-loop MIMO operation
2B	Resource assignments for PDSCH using up to 2 antenna ports with UE-specific reference signals
2C	Resource assignment for PDSCH using up to 8 antenna ports with UE-specific reference signals
3/3A	Power control commands for PUCCH and PUSCH with 2-bit/1-bit power adjustments
4	Scheduling of PUSCH in one UL Component Carrier with multi-antenna port transmission mode

[106] Other DCI formats in addition to the DCI formats defined in Table 7 may be defined.

[107] A plurality of PDCCHs may be transmitted within a control region. A UE may monitor the plurality of PDCCHs. An eNB determines a DCI format depending on the DCI to be transmitted to the UE, and attaches cyclic redundancy check (CRC) to the DCI. The CRC is masked (or scrambled) with an identifier (for example, a radio network temporary identifier (RNTI)) depending on usage of the PDCCH or owner of the PDCCH. For example, if the PDCCH is for a specific UE, the CRC may be masked with an identifier (for example, cell-RNTI (C-RNTI)) of the corresponding UE. If the PDCCH is for a paging message, the CRC may be masked with a paging identifier (for example, paging-RNTI (P-RNTI)). If the PDCCH is for system information (in more detail, system information block (SIB)), the CRC may be masked with system information RNTI (SI-RNTI). If the PDCCH is for a random access response, the CRC may be masked with a random access RNTI (RA-RNTI). For example, CRC masking

(or scrambling) includes XOR operation of CRC and RNTI at the bit level.

[108] Generally, a DCI format, which may be transmitted to the UE, is varied depending on a transmission mode configured for the UE. In other words, certain DCI format(s) corresponding to the specific transmission mode not all DCI formats may only be used for the UE configured to a specific transmission mode.

[109] For example, a transmission mode is semi-statically configured for the UE by a higher layer so that the UE may receive a PDSCH transmitted in accordance with one of a plurality of transmission modes which are previously defined. The UE attempts to decode a PDCCH using DCI formats only corresponding to its transmission mode. In other words, in order to maintain UE operation load according to blind decoding attempt, at a certain level or less, all DCI formats are not searched by the UE at the same time. Table 8 illustrates transmission modes for configuring multi-antenna technology and DCI formats for allowing a UE to perform blind decoding at the corresponding transmission mode. Particularly, Table 8 illustrates a relation between PDCCH and PDSCH configured by C-RNTI (Cell RNTI(Radio Network Temporary Identifier)).

[110] [Table 8]

Transmission mode	DCI format	Search Space	Transmission scheme of PDSCH corresponding to PDCCH
Mode 1	DCI format 1A	Common andUE specific by C-RNTI	Single-antenna port, port 0
	DCI format 1	UE specific by C-RNTI	Single-antenna port, port 0
Mode 2	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1	UE specific by C-RNTI	Transmit diversity
Mode 3	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 2A	UE specific by C-RNTI	Large delay CDD or Transmit diversity
Mode 4	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 2	UE specific by C-RNTI	Closed-loop spatial multiplexing or Transmit diversity
Mode 5	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1D	UE specific by C-RNTI	Multi-user MIMO
Mode 6	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1B	UE specific by C-RNTI	Closed-loop spatial multiplexing using a single transmission layer
Mode 7	DCI format	Common andUE	If the number of PBCH antenna ports

	1A	specific by C-RNTI	is one, Single-antenna port, port 0 is used, otherwise Transmit diversity
	DCI format 1	UE specific by C-RNTI	Single-antenna port, port 5
Mode 8	DCI format 1A	Common andUE specific by C-RNTI	If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity
	DCI format 2B	UE specific by C-RNTI	Dual layer transmission, port 7 and 8 or single-antenna port, port 7 or 8
Mode 9	DCI format 1A	Common andUE specific by C-RNTI	Non-MBSFN subframe: If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity.MBSFN subframe: Single-antenna port, port 7
	DCI format 2C	UE specific by C-RNTI	Up to 8 layer transmission, ports 7-14 or single-antenna port, port 7 or 8
Mode 10	DCI format 1A	Common andUE specific by C-RNTI	Non-MBSFN subframe: If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity.MBSFN subframe: Single-antenna port, port 7
	DCI format 2D	UE specific by C-RNTI	Up to 8 layer transmission, ports 7-14 or single antenna port, port 7 or 8

[111] Although transmission modes 1 to 10 are listed in Table 8, other transmission modes in addition to the transmission modes defined in Table 8 may be defined.

[112] Referring to Table 8, a UE configured to a transmission mode 9, for example, tries to decode PDCCH candidates of a UE-specific search space (USS) to a DCI format 1A, and tries to decode PDCCH candidates of a common search space (CSS) and the USS to a DCI format 2C. The UE may decode a PDSCH in accordance with DCI based on the DCI format successfully decoded. If DCI decoding from one of a plurality of PDCCH candidates to the DCI format 1A is successfully performed, the UE may decode the PDSCH by assuming that up to 8 layers from antenna ports 7 to 14 are transmitted thereto through the PDSCH, or may decode the PDSCH by assuming that a single layer from the antenna port 7 or 8 is transmitted thereto through the PDSCH.

[113] The PDCCH is allocated to first m number of OFDM symbol(s) within a subframe.

In this case, m is an integer equal to or greater than 1, and is indicated by the PCFICH.

[114] The PDCCH is transmitted on an aggregation of one or a plurality of continuous control channel elements (CCEs). The CCE is a logic allocation unit used to provide a coding rate based on the status of a radio channel to the PDCCH. The CCE corresponds to a plurality of resource element groups (REGs). For example, one CCE corresponds to nine resource element groups (REGs), and one REG corresponds to four REs. Four QPSK symbols are mapped to each REG. A resource element (RE) occupied by the reference signal (RS) is not included in the REG. Accordingly, the number of REGs within given OFDM symbols is varied depending on the presence of the RS. The REGs are also used for other downlink control channels (that is, PCFICH and PHICH).

[115] Assuming that the number of REGs not allocated to the PCFICH or the PHICH is N_{REG}, the number of available CCEs in a DL subframe for PDCCH(s) in a system is numbered from 0 to N_{CCE}—1, where $N_{CCE} = \text{floor}(N_{REG}/9)$.

[116] A PDCCH format and the number of DCI bits are determined in accordance with the number of CCEs. The CCEs are numbered and consecutively used. To simplify the decoding process, a PDCCH having a format including n CCEs may be initiated only on CCEs assigned numbers corresponding to multiples of n. The number of CCEs used for transmission of a specific PDCCH is determined by a network or the eNB in accordance with channel status. For example, one CCE may be required for a PDCCH for a UE (for example, adjacent to eNB) having a good downlink channel. However, in case of a PDCCH for a UE (for example, located near the cell edge) having a poor channel, eight CCEs may be required to obtain sufficient robustness. Additionally, a power level of the PDCCH may be adjusted to correspond to a channel status.

[117] In a 3GPP LTE/LTE-A system, a set of CCEs on which a PDCCH can be located for each UE is defined. A CCE set in which the UE can detect a PDCCH thereof is referred to as a PDCCH search space or simply as a search space (SS). An individual resource on which the PDCCH can be transmitted in the SS is called a PDCCH candidate. A set of PDCCH candidates that the UE is to monitor is defined in terms of SSs, where a search space $S^{(L)}_k$ at aggregation level $L \in \{1,2,4,8\}$ is defined by a set of PDCCH candidates. SSs for respective PDCCH formats may have different sizes and a dedicated SS and a common SS are defined. The dedicated SS is a UE-specific SS (USS) and is configured for each individual UE. The common SS (CSS) is configured for a plurality of UEs.

[118] The following table shows an example of aggregation levels for defining SS.

[119] [Table 9]

Search space $S^{(L)}_k$			Number of PDCCH candidates $M^{(L)}$
Type	Aggregation level L	Size [in CCEs]	
UE-specific	1	6	6
	2	12	6
	4	8	2
	8	16	2
Common	4	16	4
	8	16	2

[120] For each serving cell on which PDCCH is monitored, the CCEs corresponding to PDCCH candidates m of the search space $S^{(L)}_k$ are configured by "$L*\{Y_k+m'\}$ mod floor($N_{CCE,k}/L$}+i", where i=0,...,L—1. For the common search space $m'=m$. For the PDCCH UE specific search space, for the serving cell on which PDCCH is monitored, if the monitorng UE is configured with carrier indicator field then $m'=m+M^{(L)}*n_{CI}$ where n_{CI} is the carrier indicator field (CIF) value, else if the monitoring UE is not configured with carrier indicator field then $m'=m$, where m=0,1,...,$M^{(L)}$—1. $M^{(L)}$ is the number of PDCCH candidates to monitor at aggregation level L in the given search space. The carrier indication field value can be the same as a serving cell index (*ServCellIndex*). For the common search space, Y_k is set to 0 for the two aggregation levels L=4 and L=8. For the UE-specific search space $S^{(L)}_k$ at aggregation level D, the variable Y_k is defined by "$Y_k = (A\cdot Y_{k-1})$ mod D", where $Y_{-1}=n_{RNTI}\neq 0$, A=39827, D=65537 and k =floor($n_s/2$). n_s is the slot number within a radio frame.

[121] The eNB transmits an actual PDCCH (DCI) on a PDCCH candidate in a search space and the UE monitors the search space to detect the PDCCH (DCI). Here, monitoring implies attempting to decode each PDCCH in the corresponding SS according to all monitored DCI formats. The UE may detect a PDCCH thereof by monitoring a plurality of PDCCHs. Basically, the UE does not know the location at which a PDCCH thereof is transmitted. Therefore, the UE attempts to decode all PDCCHs of the corresponding DCI format for each subframe until a PDCCH having an ID thereof is detected and this process is referred to as blind detection (or blind decoding (BD)).

[122] For example, it is assumed that a specific PDCCH is CRC-masked with a radio network temporary identity (RNTI) 'A' and information about data transmitted using a radio resource 'B' (e.g. frequency location) and using transport format information 'C' (e.g. transmission block size, modulation scheme, coding information, etc.) is transmitted in a specific DL subframe. Then, the UE monitors the PDCCH using RNTI

information thereof. The UE having the RNTI 'A' receives the PDCCH and receives the PDSCH indicated by 'B' and 'C' through information of the received PDCCH.

[123] FIG. 5 illustrates the structure of a UL subframe used in a wireless communication system.

[124] Referring to FIG. 5, a UL subframe may be divided into a data region and a control region in the frequency domain. One or several PUCCHs may be allocated to the control region to deliver UCI. One or several PUSCHs may be allocated to the data region of the UE subframe to carry user data.

[125] In the UL subframe, subcarriers distant from a direct current (DC) subcarrier are used as the control region. In other words, subcarriers located at both ends of a UL transmission BW are allocated to transmit UCI. A DC subcarrier is a component unused for signal transmission and is mapped to a carrier frequency f_0 in a frequency up-conversion process. A PUCCH for one UE is allocated to an RB pair belonging to resources operating on one carrier frequency and RBs belonging to the RB pair occupy different subcarriers in two slots. The PUCCH allocated in this way is expressed by frequency hopping of the RB pair allocated to the PUCCH over a slot boundary. If frequency hopping is not applied, the RB pair occupies the same subcarriers.

[126] The PUCCH may be used to transmit the following control information.

[127] - Scheduling request (SR): SR is information used to request a UL-SCH resource and is transmitted using an on-off keying (OOK) scheme.

[128] - HARQ-ACK: HARQ-ACK is a response to a PDCCH and/or a response to a DL data packet (e.g. a codeword) on a PDSCH. HARQ-ACK indicates whether the PDCCH or PDSCH has been successfully received. 1-bit HARQ-ACK is transmitted in response to a single DL codeword and 2-bit HARQ-ACK is transmitted in response to two DL codewords. A HARQ-ACK response includes a positive ACK (simply, ACK), negative ACK (NACK), discontinuous transmission (DTX), or NACK/DRX. HARQ-ACK is used interchangeably with HARQ ACK/NACK and ACK/NACK.

[129] - Channel state information (CSI): CSI is feedback information for a DL channel. CSI may include channel quality information (CQI), a precoding matrix indicator (PMI), a precoding type indicator, and/or a rank indicator (RI). In the CSI, MIMO-related feedback information includes the RI and the PMI. The RI indicates the number of streams or the number of layers that the UE can receive through the same time-frequency resource. The PMI is a value reflecting a space characteristic of a channel, indicating an index of a preferred precoding matrix for DL signal transmission based on a metric such as an SINR. The CQI is a value of channel strength, indicating a received SINR that can be obtained by the UE generally when the eNB uses the PMI.

[130] A general wireless communication system performs data transmission/reception through one downlink (DL) band and through one uplink (UL) band corresponding to

the DL band (in case of a frequency division duplex (FDD) mode), or divides a prescribed radio frame into a UL time unit and a DL time unit in the time domain and then performs data transmission/reception through the UL/DL time unit (in case of a time division duplex (TDD) mode). Recently, to use a wider frequency band in recent wireless communication systems, introduction of carrier aggregation (or BW aggregation) technology that uses a wider UL/DL BW by aggregating a plurality of UL/DL frequency blocks has been discussed. A carrier aggregation (CA) is different from an orthogonal frequency division multiplexing (OFDM) system in that DL or UL communication is performed using a plurality of carrier frequencies, whereas the OFDM system carries a base frequency band divided into a plurality of orthogonal subcarriers on a single carrier frequency to perform DL or UL communication. Hereinbelow, each of carriers aggregated by carrier aggregation will be referred to as a component carrier (CC).

[131] For example, three 20MHz CCs may be aggregated on each of a UL and a DL to support a bandwidth of 60MHz. The respective CCs may be contiguous or non-contiguous in the frequency domain. For convenience, although it has been described that the bandwidth of UL CC and the bandwidth of DL CC are the same as each other and symmetric to each other, the bandwidth of each CC may be independently determined. Asymmetrical carrier aggregation in which the number of UL CCs is different from the number of DL CCs may be implemented. DL/UL CC limited to a specific UE may be referred to as a serving UL/DL CC configured for the specific UE.

[132] Meanwhile, the 3GPP LTE-A standard uses the concept of a cell to manage radio resources. The "cell" associated with the radio resources is defined by combination of downlink resources and uplink resources, that is, combination of DL CC and UL CC. The cell may be configured by downlink resources only, or may be configured by downlink resources and uplink resources. If carrier aggregation is supported, linkage between a carrier frequency of the downlink resources (or DL CC) and a carrier frequency of the uplink resources (or UL CC) may be indicated by system information. For example, combination of the DL resources and the UL resources may be indicated by linkage of system information block type 2 (SIB2). In this case, the carrier frequency means a center frequency of each cell or CC. A cell operating on a primary frequency may be referred to as a primary cell (Pcell) or PCC, and a cell operating on a secondary frequency may be referred to as a secondary cell (Scell) or SCC. The carrier corresponding to the Pcell on downlink will be referred to as a downlink primary CC (DL PCC), and the carrier corresponding to the Pcell on uplink will be referred to as an uplink primary CC (UL PCC). A Scell means a cell that may be configured after completion of radio resource control (RRC) connection establishment and used to provide additional radio resources. The Scell may form a set of serving cells for the UE

together with the Pcell in accordance with capabilities of the UE. The carrier corresponding to the Scell on the downlink will be referred to as downlink secondary CC (DL SCC), and the carrier corresponding to the Scell on the uplink will be referred to as uplink secondary CC (UL SCC). Although the UE is in RRC-CONNECTED state, if it is not configured by carrier aggregation or does not support carrier aggregation, a single serving cell configured by the Pcell only exists.

[133] The eNB may activate all or some of the serving cells configured in the UE or deactivate some of the serving cells for communication with the UE. The eNB may change the activated/deactivated cell, and may change the number of cells which is/are activated or deactivated. If the eNB allocates available cells to the UE cell-specifically or UE-specifically, at least one of the allocated cells is not deactivated unless cell allocation to the UE is fully reconfigured or unless the UE performs handover. Such a cell which is not deactivated unless CC allocation to the UE is fully reconfigured will be referred to as Pcell, and a cell which may be activated/deactivated freely by the eNB will be referred to as Scell. The Pcell and the Scell may be discriminated from each other on the basis of the control information. For example, specific control information may be set to be transmitted and received through a specific cell only. This specific cell may be referred to as the Pcell, and the other cell(s) may be referred to as Scell(s).

[134] A configured cell refers to a cell in which carrier aggregation is performed for a UE based on measurement report from another eNB or UE among cells of an eNB and is configured per UE. The cell configured for the UE may be a serving cell in terms of the UE. For the cell configured for the UE, i.e. the serving cell, resources for ACK/NACK transmission for PDSCH transmission are reserved in advance. An activated cell refers to a cell configured to be actually used for PDSCH/PUSCH transmission among cells configured for the UE and CSI reporting and SRS transmission for PDSCH/PUSCH transmission are performed in the activated cell. A deactivated cell refers to a cell configured not to be used for PDSCH/PUSCH transmission by the command of an eNB or the operation of a timer and, if a cell is deactivated, CSI reporting and SRS transmission are also stopped in the cell.

[135] For reference, a carrier indicator (CI) denotes a serving cell index (*ServCellIndex*), CI=0 is applied to Pcell. The serving cell index is a short ID used to identify a serving cell. For example, any one of integers from 0 to 'maximum number of carrier frequencies which can be configured for the UE at a time - 1' may be allocated to one serving cell as the serving cell index. That is, the serving cell index may be a logical index used to identify a specific serving cell among cells allocated to the UE rather than a physical index used to identify a specific carrier frequency among all carrier frequencies.

[136] Meanwhile, the 3GPP LTE-A standard uses the concept of a cell to manage radio

resources.

[137] The cell mentioned in the present invention means a cell of carrier aggregation which is combination of UL CC and DL CC unless specifically noted.

[138] Meanwhile, since one serving cell is only present in case of communication based on a single carrier, a PDCCH carrying UL/DL grant and corresponding PUSCH/PDSCH are transmitted on one cell. In other words, in case of FDD under a single carrier environment, a PDCCH for a DL grant for a PDSCH, which will be transmitted on a specific DL CC, is transmitted on the specific CC, and a PDCCH for a UL grant for a PUSCH, which will be transmitted on a specific UL CC, is transmitted on a DL CC linked to the specific UL CC. In case of TDD under a single carrier environment, a PDCCH for a DL grant for a PDSCH, which will be transmitted on a specific DL CC, is transmitted on the specific CC, and a PDCCH for a UL grant for a PUSCH, which will be transmitted on a specific UL CC, is transmitted on the specific CC.

[139] On the contrary, since a plurality of serving cells may be configured in a multi-carrier system, transmission of UL/DL grant through a serving cell having a good channel status may be allowed. In this way, if a cell carrying UL/DL grant which is scheduling information is different from a cell where UL/DL transmission corresponding to the UL/DL grant is performed, this will be referred to as cross-carrier scheduling.

[140] Hereinafter, the case where the cell is scheduled from itself and the case where the cell is scheduled from another cell will be referred to as self-CC scheduling and cross-CC scheduling, respectively.

[141] For data transmission rate enhancement and stable control signaling, the 3GPP LTE/LTE-A may support aggregation of a plurality of CCs and a cross carrier-scheduling operation based on the aggregation.

[142] If cross-carrier scheduling (or cross-CC scheduling) is applied, a PDCCH for downlink allocation for a DL CC B or DL CC C, that is, carrying a DL grant may be transmitted through a DL CC A, and a corresponding PDSCH may be transmitted through the DL CC B or DL CC C. For cross-CC scheduling, a carrier indicator field (CIF) may be introduced. The presence or absence of the CIF within the PDCCH may be semi-statically and UE-specifically (or UE-group-specifically) configured by higher layer signaling (e.g., RRC signaling).

[143] Meanwhile, if RRH technology, cross-carrier scheduling technology, etc. are introduced, the amount of PDCCH which should be transmitted by the eNB is gradually increased. However, since a size of a control region within which the PDCCH may be transmitted is the same as before, PDCCH transmission acts as a bottleneck of system throughput. Although channel quality may be improved by the introduction of the aforementioned multi-node system, application of various communication schemes, etc., the introduction of a new control channel is required to apply the legacy commu-

nication scheme and the carrier aggregation technology to a multi-node environment. Due to the need, a configuration of a new control channel in a data region (hereinafter, referred to as PDSCH region) not the legacy control region (hereinafter, referred to as PDCCH region) has been discussed. Hereinafter, the new control channel will be referred to as an enhanced PDCCH (hereinafter, referred to as EPDCCH).

[144] The EPDCCH may be configured within rear OFDM symbols starting from a configured OFDM symbol, instead of front OFDM symbols of a subframe. The EPDCCH may be configured using continuous frequency resources, or may be configured using discontinuous frequency resources for frequency diversity. By using the EPDCCH, control information per node may be transmitted to a UE, and a problem that a legacy PDCCH region may not be sufficient may be solved. For reference, the PDCCH may be transmitted through the same antenna port(s) as that(those) configured for transmission of a CRS, and a UE configured to decode the PDCCH may demodulate or decode the PDCCH by using the CRS. Unlike the PDCCH transmitted based on the CRS, the EPDCCH is transmitted based on the demodulation RS (hereinafter, DMRS). Accordingly, the UE decodes/demodulates the PDCCH based on the CRS and decodes/demodulates the EPDCCH based on the DMRS. The DMRS associated with EPDCCH is transmitted on the same antenna port $p \in \{107,108,109,110\}$ as the associated EPDCCH physical resource, is present for EPDCCH demodulation only if the EPDCCH transmission is associated with the corresponding antenna port, and is transmitted only on the PRB(s) upon which the corresponding EPDCCH is mapped. For example, the REs occupied by the UE-RS(s) of the antenna port 7 or 8 may be occupied by the DMRS(s) of the antenna port 107 or 108 on the PRB to which the EPDCCH is mapped, and the REs occupied by the UE-RS(s) of antenna port 9 or 10 may be occupied by the DMRS(s) of the antenna port 109 or 110 on the PRB to which the EPDCCH is mapped. In other words, a certain number of REs are used on each RB pair for transmission of the DMRS for demodulation of the EPDCCH regardless of the UE or cell if the type of EPDCCH and the number of layers are the same as in the case of the UE-RS for demodulation of the PDSCH.

[145] For each serving cell, higher layer signalling can configure a UE with one or two EPDCCH-PRB-sets for EPDCCH monitoring. The PRB-pairs corresponding to an EPDCCH-PRB-set are indicated by higher layers. Each EPDCCH-PRB-set consists of set of ECCEs numbered from 0 to $N_{ECCE,p,k}-1$, where $N_{ECCE,p,k}$ is the number of ECCEs in EPDCCH-PRB-set p of subframe k. Each EPDCCH-PRB-set can be configured for either localized EPDCCH transmission or distributed EPDCCH transmission.

[146] The UE shall monitor a set of EPDCCH candidates on one or more activated serving cells as configured by higher layer signaling for control information.

[147] The set of EPDCCH candidates to monitor are defined in terms of EPDCCH UE-

specific search spaces. For each serving cell, the subframes in which the UE monitors EPDCCH UE-specific search spaces are configured by higher layers.

[148] An EPDCCH UE-specific search space $ES^{(L)}_k$ at aggregation level $L\in\{1,2,4,8,16,32\}$ is defined by a set of EPDCCH candidates.

[149] For an EPDCCH-PRB-set p, the ECCEs corresponding to EPDCCH candidate m of the search space $ES^{(L)}_k$ are given by the following equation.

[150] [Math.1]

$$L\left\{(Y_{p,k}+\left\lfloor\frac{m\cdot N_{ECCE,p,k}}{L\cdot M_p^{(L)}}\right\rfloor+b)\bmod\left\lfloor N_{\mathrm{ECCE},p,k}/L\right\rfloor\right\}+i$$

[151] where $i=0,\ldots,L-1$. $b=n_{CI}$ if the UE is configured with a carrier indicator field for the serving cell on which EPDCCH is monitored, otherwise $b=0$. n_{CI} is the carrier indicator field (CIF) value, which is the same as a serving cell index (*ServCellIndex*). $m=0,1,\ldots,M^{(L)}_p-1$. $M^{(L)}_p$ is the number of EPDCCH candidates to monitor at aggregation level L in EPDDCH-PRB-set p. The variable $Y_{p,k}$ is defined by '$Y_{p,k}=(A_p\cdot Y_{p,k-1})\bmod D$', where $Y_{p,-1}=n_{RNTI}\neq 0$, $A_0=39827$, $A_1=39829$, $D=65537$ and $k=\mathrm{floor}(n_s/2)$. n_s is the slot number within a radio frame.

[152] A UE is not expected to monitor an EPDCCH candidate, if an ECCE corresponding to that EPDCCH candidate is mapped to a PRB pair that overlaps in frequency with a transmission of either PBCH or PSS/SSS in the same subframe.

[153] An EPDCCH is transmitted using an aggregation of one or several consecutive enhanced control channel elements (ECCEs). Each ECCE consists of multiple enhanced resource element groups (EREGs). EEREGs are used for defining the mapping of enhanced control channels to resource elements. There are 16 EREGs, numbered from 0 to 15, per physical resource block (PRB) pair. Number all resource elements (REs), except resource elements carrying DMRS (hereinafter EPDCCH DMRS) for demoduation of the EPDCCH, in a physical resource-block pair cyclically from 0 to 15 in an increasing order of first frequency, then time. Therefore all the REs, except REs carrying the EPDCCH DMRS, in the PRB pair has any one of numbers 0 to 15. All REs with number i in that PRB pair constitutes EREG number i.As described above, it is noted that EREGs are distributed on frequency and time axes within the PRB pair and an EPDCCH transmitted using aggregation of one or more ECCEs, each of which includes a plurality of EREGs, is also distributed on frequency and time axes within the PRB pair.

[154] The number of ECCEs used for one EPDCCH depends on the EPDCCH format as given by Table 10, the number of EREGs per ECCE is given by Table 11. Table 10 shows an example of supported EPDCCH formats, and Table 11 shows an example of

the number of EREGs per ECCE, N^{EREG}_{ECCE}. Both localized and distributed transmission is supported.

[155] [Table 10]

EPDCCH format	Number of ECCEs for one EPDCCH, N^{ECCE}_{EPDCCH}			
	Case A		Case B	
	Localized transmission	Distributed transmission	Localized transmission	Distributed transmission
0	2	2	1	1
1	4	4	2	2
2	8	8	4	4
3	16	16	8	8
4	-	32	-	16

[156] [Table 11]

Normal cyclic prefix			Extended cyclic prefix	
Normal subframe	Special subframe,configuration3, 4, 8	Special subframe,configuration1, 2, 6, 7, 9	Normal subframe	Special subframe,configuration1, 2, 3, 5, 6
4		8		

[157] An EPDCCH can use either localized or distributed transmission, differing in the mapping of ECCEs to EREGs and PRB pairs. One or two sets of PRB pairs which a UE shall monitor for EPDCCH transmissions can be configured. All EPDCCH candidates in EPDCCH set S_p (i.e., EPDCCH-PRB-set) use either only localized or only distributed transmission as configured by higher layers. Within EPDCCH set S_p in subframe k, the ECCEs available for transmission of EPDCCHs are numbered from 0 to $N_{ECCE,p,k}-1$. ECCE number n is corresponding to the following EREG(s):

[158] - EREGs numbered $(n \bmod N^{ECCE}_{RB})+jN^{ECCE}_{RB}$ in PRB index $\text{floor}(n/N^{ECCE}_{RB})$ for localized mapping, and

[159] - EREGs numbered $\text{floor}\ (n/N^{Sp}_{RB})+jN^{ECCE}_{RB}$ in PRB indices $(n+j\max(1,N^{Sp}_{RB}/N^{EREG}_{ECCE}))\bmod N^{Sp}_{RB}$ for distributed mapping.

[160] where $j=0,1,\ldots,N^{EREG}_{ECCE}-1$, N^{EREG}_{ECCE} is the number of EREGs per ECCE, and $N^{ECCE}_{RB}=16/N^{EREG}_{ECCE}$ is the number of ECCEs per RB pair. The PRB pairs constituting EPDCCH set S_p are assumed to be numbered in ascending order from 0 to $N^{Sp}_{RB}-1$.

[161] Case A in Table 10 applies when:

[162] - DCI formats 2, 2A, 2B, 2C or 2D is used and $N^{DL}_{RB}\geq 25$, or

[163] - any DCI format when n_{EPDCCH}<104 and normal cyclic prefix is used in normal subframes or special subframes with configuration 3, 4, 8.

[164] Otherwise case B is used. The quantity n_{EPDCCH} for a particular UE is defined as the number of downlink resource elements (k,l) in a PRB pair configured for possible EPDCCH transmission of EPDCCH set S_0 and and fulfilling all of the following criteria,

[165] - they are part of any one of the 16 EREGs in the physical resource-block pair,

[166] - they are assumed by the UE not to be used for CRSs or CSI-RSs,

[167] - the index l in a subframe fulfils $l \geq l_{EPDCCHStart}$.

[168] where $l_{EPDCCHStart}$ is given based on higher layer signaling '*epdcch*-StartSymbol-r11', higher layer signaling '*pdsch*-Start-r11', or CFI value carried by PCFICH.

[169] The mapping to resource elements (k,l) on antenna port p meeting the criteria above is in increasing order of first the index k and then the index l, starting with the first slot and ending with the second slot in a subframe.

[170] For localized transmission, the single antenna port p to use is given by Table 12 with $n' = n_{ECCE,low} \bmod N^{ECCE}_{RB} + n_{RNTI} \bmod \min(N^{ECCE}_{EPDCCH}, N^{ECCE}_{RB})$, where $n_{ECCE,low}$ is the lowest ECCE index used by this EPDCCH transmission in the EPDCCH set, n_{RNTI} corresponds to the RNTI associated with the EPDCCH transmission, and N^{ECCE}_{EPDCCH} is the number of ECCEs used for this EPDCCH.

[171] [Table 12]

n'	Normal cyclic prefix		Extended cyclic prefix
	Normal subframes,Special subframes,configurations3, 4, 8	Special subframes, configurations1, 2, 6, 7, 9	Any subframe
0	107	107	107
1	108	109	108
2	109	-	-
3	110	-	-

[172] For distributed transmission, each resource element in an EREG is associated with one out of two antenna ports in an alternating manner where $p \in \{107,109\}$ for normal cyclic prefix and $p \in \{107,108\}$ for extended cyclic prefix.

[173] Recently, machine type communication (MTC) has come to the fore as a significant communication standard issue. MTC refers to exchange of information between a machine and an eNB without involving persons or with minimal human intervention. For example, MTC may be used for data communication for measurement/

sensing/reporting such as meter reading, water level measurement, use of a surveillance camera, inventory reporting of a vending machine, etc. and may also be used for automatic application or firmware update processes for a plurality of UEs. In MTC, the amount of transmission data is small and UL/DL data transmission or reception (hereinafter, transmission/reception) occurs occasionally. In consideration of such properties of MTC, it would be better in terms of efficiency to reduce production cost and battery consumption of UEs for MTC (hereinafter, MTC UEs) according to data transmission rate. Since the MTC UE has low mobility, the channel environment thereof remains substantially the same. If an MTC UE is used for metering, reading of a meter, surveillance, and the like, the MTC UE is very likely to be located in a place such as a basement, a warehouse, and mountain regions which the coverage of a typical eNB does not reach. In consideration of the purposes of the MTC UE, it is better for a signal for the MTC UE to have wider coverage than the signal for the conventional UE (hereinafter, a legacy UE).

[174] When considering the usage of the MTC UE, there is a high probability that the MTC UE requires a signal of wide coverage compared with the legacy UE. Therefore, if the eNB transmits a PDCCH, a PDSCH, etc. to the MTC UE using the same scheme as a scheme of transmitting the PDCCH, the PDSCH, etc. to the legacy UE, the MTC UE has difficulty in receiving the PDCCH, the PDSCH, etc. Therefore, the present invention proposes that the eNB apply a coverage enhancement scheme such as subframe repetition (repetition of a subframe with a signal) or subframe bundling upon transmission of a signal to the MTC UE having a coverage issue so that the MTC UE can effectively receive a signal transmitted by the eNB. For example, the PDCCH and PDSCH may be transmitted to the MTC UE having the coverage issue in a plurality of subframes (e.g. about 100 subframes).

[175] FIG. 6 illustrates an example of signals band for MTC.

[176] As one method for reducing the cost of the MTC UE, an operation of the MTC UE may be performed at a reduced UE downlink and uplink bandwidth of 1.4 MHz, for example, regardless of an operating system bandwidth of a cell. At this time, a subband (narrowband) for operating the MTC UE may always be located at the center (e.g., 6 center PRBs) of a cell as shown in FIG. 6(a), or several subbands for MTC may be provided for one subframe to multiplex MTC UEs as shown in FIG. 6(b), whereby the UEs may use their respective subbands different from each other or the UEs use the same subband not the subband of 6 center PRBs.

[177] In this case, the MTC UE cannot receive a legacy PDCCH transmitted through a full system band normally, and transmission of PDCCH for the MTC UE from an OFDM symbol region within which the legacy PDCCH is transmitted may not be preferable due to multiplexing issue with a PDCCH transmitted to another UE. As one method for

solving this, it is required to introduce a control channel transmitted within a subband where MTC is operated for the MTC UE. As a downlink control channel for such a low-complexity MTC UE, the legacy EPDCCH may be used as it is. Or, M-PDCCH for the MTC UE which is a control channel of a modified type of the legacy PDCCH/ EPDCCH may be introduced. Hereinafter, in the present invention, the legacy EPDCCH or M-PDCCH for the low-complexity MTC UE or normal complexity MTC UE will be referred to as M-PDCCH. Also, MTC-EPDCCH is hereinafter used to refer to M-PDCCH.

[178] A data channel (e.g., PDSCH, PUSCH) and/or a control channel (e.g., M-PDCCH, PUCCH, PHICH) may be transmitted for coverage enhancement (CE) of the UE by using a repetition or TTI bundling scheme through multiple subframes. The control/ data channel may be transmitted by additionally using cross-subframe channel estimation and frequency (narrowband) hopping for CE. In this case, cross-subframe channel estimation means a channel estimation method means channel estimation using a reference signal within a subframe of a corresponding channel and a reference signal within neighboring subframe(s).

[179] The MTC UE may need CE of 15dB, for example. However, all MTC UEs do not exist in an environment that CE is needed. Also, the same requirements of QoS are not applied to all MTC UEs. For example, since devices such as sensor and meter have low mobility and are likely to be located in a shaded area even while having a small amount of data transmission and reception, the devices may need high CE. However, wearable devices such as smart watch may have mobility and are likely to be located in a place not a shaded area while having a relatively large amount of data transmission and reception. Therefore, all MTC UEs do not need CE of high level, and their requirement capability may be varied depending on their type.

[180] In the present invention, an operation for monitoring M-PDCCH by means of an MTC UE (which needs coverage enhancement (CE)) will be suggested. Hereinafter, M-PDCCH monitoring, search space monitoring, or M-PDCCH candidates monitoring may mean that reception or detection of M-PDCCH is attempted within a corresponding search space or from one of M-PDCCH candidates configuring the corresponding search space.

[181] In the following embodiments, the expression "assume" may mean that an entity for transmitting a channel transmits the channel to be suitable for the corresponding "assumption". An entity for receiving the channel may receive or decode the channel to be suitable for the corresponding "assumption" provided that the channel has been transmitted to be suitable for the corresponding "assumption".

[182] FIG. 7 illustrates repeated transmission of a channel for coverage enhancement.

[183] A search space for M-PDCCH may be configured over a plurality of downlink

subframes. For example, M-PDCCH search space having an aggregation level L and a repetition level R is defined by a set of M-PDCCH candidates. In this case, each M-PDCCH candidate may be repeated within a set of R number of consecutive downlink subframes. Referring to FIG. 7, in an example of maximum repetitions R_{max}=8 and a possible repetition level of $R \in \{1, 2, 4, 0\}$, a UE may attempt decoding of M-PDCCH by assuming that repetition of M-PDCCH (transmitted at an aggregation level L) exists in each of R number of consecutive downlink subframes. For example, the UE may attempt decoding of M-PDCCH by regarding signals received from each of 8 subframes as those of the same M-PDCCH in case of a repetition level $R = 8$ and attempt decoding of different M-PDCCHs in each of 8 subframes in case of a repetition level $R = 1$.

[184] In FIG. 7, repetition of a channel is performed over consecutive downlink subframes. However, a data channel and/or a control channel (hereinafter, data/control channel) transmitted to/from the MTC UE which needs CE may be transmitted by being repeated through non-consecutive subframes. For example, the control/data channel for a specific MTC UE may not be in all downlink subframes but may be restricted to some downlink subframes. Non-consecutive downlink subframes available at the MTC UE may be configured in such a manner that a downlink subframe group comprised of one or more consecutive downlink subframes is repeated with a periodicity greater than the number of subframes within the downlink subframe group. In other words, the data/control channel may be transmitted not in physically consecutive subframes, but transmitted in transmitted in each of physically non-consecutive subframes (excluding uplink subframes in case of downlink transmission, downlink subframes in case of uplink transmission, and/or subframes except subframe used for other purpose of use and cannot be used for data/control channel transmission). Use of non-consecutive (downlink or uplink) subframes for repeated transmission of the data/control channel of the MTC UE may increase transmission/reception latency. However, as time diversity effect is obtained in the time domain by use of non-consecutive subframes, the number of repetitions or the number of subframes used for channel transmission may be reduced as compared with transmission based on consecutive subframes. Therefore, overall system throughput may be increased. The embodiments of the present invention, which will be described later, suggest UE operation and transmission subframe during transmission/reception of a corresponding channel when a data/control channel transmitted from MTC UE is transmitted with repetition through consecutive subframes or non-consecutive subframes.

[185] In the following embodiments, each search space within an interval where a UE monitors M-PDCCH (CSS and/or USS) may be configured over one or more (consecutive or non-consecutive) downlink subframes. That is, a search space for

reception of the same M-PDCCH may be configured in each of one or more downlink subframes.

[186] For example, referring to FIG. 8, in case of no CE or CE having a repetition level = 1, each of CSSs of FIG. 8 may be CSS on which a respective M-PDCCH can be transmitted. At this time, a CSS starting subframe may mean a first subframe of paging occasions for allowing a UE to monitor M-PDCCH for a paging message. As another example, referring to FIG. 9, in case of no CE or CE having a repetition level = 1, each of CSSs of FIG. 9 may be CSS on which a respective M-PDCCH can be transmitted. At this time, a CSS starting subframe may mean a first subframe of a RAR window for allowing a UE to monitor M-PDCCH for scheduling RAR.

[187] In case of coverage enhancement (CE), M-PDCCH may be transmitted by being repeated once or multiple times. Therefore, a search space where M-PDCCH (hereinafter, paging M-PDCCH) will be monitored may be configured repeatedly over a plurality of downlink subframes, and a UE may attempt repeated reception of M-PDCCH within search spaces within the plurality of downlink subframes. If CE having a repetition level greater than 1 is applied, for example, each CSS shown in FIG. 8 may be a plurality of consecutive subframes that may have repetitions of M-PDCCH. If CE having a repetition level greater than 1 is applied, as another example, a plurality of CSSs within the same paging occasion shown in FIG. 8 may be CSSs for repetitions of the same M-PDCCH. If CE having a repetition level greater than 1 is applied, as still another example, a plurality of CSSs over a plurality of paging occasions shown in FIG. 8 may be CSSs for repetitions of the same M-PDCCH.

[188] ■ Section 1. M-PDCCH CSS for paging message scheduling

[189] In Section 1, details on M-PDCCH CSS for paging message scheduling are discussed.

[190] The paging message is used to notify UE(s) under RRC_IDLE and UE(s) under RRC_CONNECTED of system information modification.

[191] An eNB initiates a paging process by transmitting the paging message at a paging occasion of a UE. The eNB may address a plurality of UEs within the paging message by including a paging record (*PagingRecord*) per UE. The paging record may include information indicating NAS (non-access stratum) identifier of a UE which is paged and information indicating the origin of paging. One paging occasion means a subframe having P-RNTI transmitted on PDCCH/M-PDCCH addressing the paging message. A paging frame (PF) means one radio frame that includes one or a plurality of paging occasion(s).

[192] The UE may use discontinuous reception (DRX) in an idle mode to reduce power consumption. If DRX is used, the UE monitors only one paging occasion per DRX cycle.

[193] The paging message may be transmitted through a PDSCH, and the PDSCH carrying the paging message may be scheduled by PDCCH/M-PDCCH.

[194] For paging message scheduling, multiple narrowbands can be configured by eNB. Then, a narrowband location for a paging occasion monitoring of a UE is determined by at least UE ID at least for paging record(s). However, the narrowband location and paging occasion for common signal transmission (e.g., SI update, earthquake and tsunami warning system (ETWS), and/or commercial mobile alert system (CMAS)) is not determined yet. To reduce UE complexity, it would be beneficial to apply the same paging occasion and narrowband location for paging record(s) reception and other information reception such as SI update, ETWS, and CMAS. For example, the UE may attempt reception of M-PDCCH for scheduling the paging message on the same narrowband at the same paging occasion for SI update and reception of ETWS and CMAS instead of monitoring different paging occasions and/or different narrowbands for SI update and reception of ETWS and CMAS.

[195] FIG. 8 illustrates a configuration of a common search space (CSS) for paging according to the present invention.

[196] Under the assumption that a paging occasion is a time region for M-PDCCH monitoring for paging message scheduling, a UE can monitor a common search space (CSS) within a paging occasion to check paging message transmission. Depending on duration of paging occasion and period of CSS starting subframe, there can be multiple CSS monitoring opportunities within a paging occasion as shown in FIG. 8. The period and offset of CSS starting subframe location can be configured by eNB. In this case, offset k_{offset} of the CSS starting subframe may mean a difference from a reference subframe n (e.g., subframe 0) to a subframe $n+k_{offset}$ in which the CSS starting subframe is first applied.

[197] The composition of decoding candidates (i.e. M-PDCCH candidates) and a subset of $\{L, R\}$ for CSS for paging should be composed to supports all UEs with different CE levels. In this case, L indicates an aggregation level, and M-PDCCH of the aggregation level L is transmitted using aggregation of L number of M-CCEs. ECCE may be used as M-CCE, and CCE for MTC UE may newly be defined as M-CCE for MTC UE.

[198] To transmit paging message adapt to the target CE level, a subset of $\{L, R\}$ of CSS for paging needs to be composed to cover all range of CE levels or all range of repetition numbers. One simple configuration is $\{8, R1\}$, $\{16, R1\}$, $\{24, R1\}$, $\{24, R2\}$, $\{24, R3\}$, $\{24, R4\}$ where $R1 = 1$ and $R4$ is the maximum repetition level.

[199] In the present invention, a paging occasion may be defined as an interval where a UE monitors a paging M-PDCCH. For example, the UE may attempt reception of (same) paging M-PDCCH (or M-PDCCH scrambled by P-RNTI) within CSS(s) existing in the paging occasion or paging M-PDCCH search space(s) as shown in FIG. 8. Since the

paging M-PDCCH may be transmitted in any one of CSS(s) within the paging occasion, the UE continuously monitors the CSS(s) within the paging occasion. If the paging M-PDCCH (or M-PDCCH scrambled by P-RNTI) is received within the corresponding interval, the UE may receive a PDSCH carrying the corresponding paging message even though a paging message scheduled by the corresponding M-PDCCH, that is, a PDSCH carrying paging is transmitted outside a paging occasion interval.

[200] A duration of the paging occasion may be configured to be a multiple of the number of subframes configuring CSSs or search spaces on which the paging M-PDCCH is transmitted. For example, if the paging M-PDCCH search space is configured in each of R number of (consecutive or non-consecutive) downlink subframes, the paging occasion may be configured to have a duration of R*X number of subframes (where X is a positive integer).

[201] ■ Section 2. M-PDCCH CSS for RAR scheduling

[202] FIG. 9 illustrates a configuration of a common search space (CSS) for RAR according to the present invention.

[203] There would be multiple narrowbands for CSS for RAR scheduling, and the narrowband location of a UE for RAR monitoring is determined by PRACH resource set.

[204] After transmitting PRACH, a UE would try to receive RAR. Similar to paging occasion, there can be multiple CSS regions within a RAR window as depicted in Figure 9. So, the UE can monitor M-PDCCH scheduling RAR in CSS region(s) within the RAR window.

[205] A subset of $\{L, R\}$ and composition of decoding candidates of CSS for RAR can depend on CE level of corresponding PRACH resource set. For example, for each CE level, PRACH resource set(s) and available repetition level(s) may be configured. In this case, the UE may monitor a CSS, that is, M-PDCCH in accordance with a set of $\{L, R\}$ configured for a CE level associated with a PRACH resource used for a successful RACH procedure. Regardless of CSS and USS, same composition of decoding candidates and same subset of $\{L, R\}$ can be used for same CE level of the search space. For example, the UE may monitor a CSS and a USS in accordance with $\{L, R\}$ of the same set with respect to the same CE level.

[206] The present invention suggests that a RAR window interval should be defined as an interval where a UE monitor M-PDCCH (hereinafter, RAR M-PDCCH) for scheduling RAR. That is, as shown in FIG. 9, the UE may attempt reception of RAR M-PDCCH (e.g., M-PDCCH scheduled by RA-RNTI) on CSS(s) existing within a RAR window or a search space(s) (hereinafter, RAR M-PDCCH search space) on which RAR M-PDCCH is transmitted. If the UE receives RAR M-PDCCH within the corresponding interval, the UE may receive a PDSCH through which the corresponding RAR is

transmitted, even though RAR (e.g., PDSCH carrying RAR) scheduled by the corresponding M-PDCCH is transmitted outside the RAR window interval.

[207] A duration of the RAR window may be configured to become a multiple of the number of subframes configuring CSSs or RAR M-PDCCH search spaces. For example, if RAR M-PDCCH search space is configured in each of R number of (consecutive or non-consecutive) downlink subframes, the RAR window may be configured to have a duration of R*X number of subframes (in this case, X is a positive integer).

[208] ■ Section 3. M-PDCCH CSS for other purposes

[209] M-PDCCH CSS can be used to transmit DCIs for other purposes except paging message and RAR scheduling. For example, M-PDCCH CSS can be used for transmission of DCI for unicast data, DCI for TPC, DCI for enhanced interference management and traffic adaptation (eIMTA), and DCI for enhanced PHICH (EPHICH). If CSS is used to transmit these DCIs, the narrowband location, monitoring subframe location, and decoding candidates composition need to be specified. Hereinafter, the CSS will be referred to as CSS_regular or CSS_others.

[210] CSS for these purposes (i.e. CSS_regular) can be located in the same narrowband to USS. Then, a UE does not need to re-tune its operating frequency to monitor this CSS.

[211] To reconfigure CE level of a UE, the CSS needs to support the maximum CE level of the cell considering CE level reconfiguration message can be transmitted by this CSS. Therefore, CE level or a subset of $\{L, R\}$ composing the CSS should support all CE level of the cell.

[212] FIG. 10 illustrates the example of the monitoring time region of USS and CSS.

[213] Period of starting subframe for M-PDCCH USS monitoring and CSS monitoring can be configured independently. The period of CSS monitoring can be longer than the period of USS, since CE level of USS and CSS can be different and CSS can be occurred sparsely to reduce UE complexity.

[214] Referring to Math Figure 1 which is a hashing function, it is noted that $Y_{p,k}$ is varied depending on n_{RNTI} which is UE ID. In this way, CCE(s) or ECCE(s) configuring decoding candidates in the USS is(are) determined UE-specifically to be monitored by a specific UE. M-PDCCH CSS can be monitored by a group of MTC UEs. Therefore, for CSS, there should not be a hashing function to randomize the starting ECCE location composing a search space UE-specifically.

[215] ■ Section 4. Coverage enhancement level of CSS

[216] For transmission of a broadcast PDSCH (e.g., paging, RAR), CSSs for other purposes such as unicast data, TPC, eIMTA DCI and EPHICH may exist, and USS where a UE monitors unicast data may exist. Hereinafter, a coverage enhancement level of corresponding search spaces will be described.

[217] The present invention suggests that a plurality of SS types exist as follows in accordance with a coverage enhancement level supported by a search space or repetitions of M-PDCCH.

[218] - Method 1.

[219] In view of the UE, two types of search spaces (SSs) may exist as follows:

[220] * SS type 1: SS supporting all coverage enhancement levels or all repetitions of M-PDCCH, and

[221] * SS type 2: SS where the number of repetitions of M-PDCCH which is supported is varied depending on a coverage enhancement level of the UE.

[222] In this case, the UE may assume that CSS for paging and/or CSS_regular has SS type 1, and CSS and/or USS for RAR has SS type 2.

[223] Alternatively, as SS monitored by the UE, one SS having SS type 1 and one SS having SS type 2 may exist. CSS for paging and/or CSS_regular may be the same as SS having SS type 1, and CSS and/or USS for RAR may be the same as SS having SS type 2.

[224] - Method 2.

[225] When N number of coverage enhancement levels (or the number of repetitions of M-PDCCH) supported by a cell exist, in view of the cell, a plurality of SS types may exist as follows:

[226] * SS type 1: SS supporting coverage enhancement level 1 (or the number of repetitions R_1 of M-PDCCH),

[227] * SS type 2: SS supporting coverage enhancement level 2 (or the number of repetitions R_2 of M-PDCCH),

[228] ...

[229] * SS type N: SS supporting coverage enhancement level N (or the number of repetitions R_N of M-PDCCH),

[230] * SS type N+1: SS supporting all coverage enhancement levels (or all repetitions for M-PDCCH).

[231] In this case, SS supporting the coverage enhancement level n may mean SS supporting the coverage enhancement levels 1 to n or the maximum number of repetitions R_n of M-PDCCH.

[232] In this case, the UE may assume that the CSS for paging and CSS_regular has SS type N+1, and the CSS for RAR and/or USS has SS type k if the coverage enhancement level of the UE is k.

[233] ■ Section 5. Relationship between search spaces

[234] **CSS for paging (i.e., CSS_paging)**

[235] It is a CSS for paging monitoring in RRC_IDLE state. Since UEs in different CE levels monitor the same CSS for paging scheduling, it should be designed to cover all

the CE levels. CSS_paging are configured by SIB. In other words, the configuration of CSS_paging may be transmitted through SIB. The UE may identify the configuration of CSS_paging by reading SIB. The UE may monitor M-PDCCH candidates of CSS within subframe(s) and/or narrowband(s) according to the CSS_paging configuration.

[236] **CSS for** RAR corresponding to initial RACH procedure (i.e., CSS_RAR)

[237] Using CSS for RAR, a UE can monitor RAR, Msg3 (for retransmission), and Msg4. Though it can be considered to allow separate SS configurations for Msg3 re-transmission and Msg4 scheduling M-PDCCH from the SS configuration for RAR, given that those (i.e. RAR, Msg3 and Msg4) will be used only for initial access, the present invention proposes that the same configuration is used for initial RACH procedure. Required configurations for CSS_RAR can be configured by SIB per CE level. Then, in a UE perspective, configurations for CSS_RAR can be determined based on the CE level of PRACH resource set used for the latest PRACH transmission.

[238] **CSS for others (i.e., CSS_others or CSS_regular)**

[239] M-PDCCH CSS can be used to transmit DCIs for other purposes except paging message and initial RAR scheduling. For example, CSS is required to transmit TPC, unicast data for reconfiguration (such as CE level, transmission mode, USS reconfiguration), a DCI transmitting multiple HARQ-ACK corresponding to PUSCH to multiple UEs (if supported), transmit RAR corresponding to PRACH triggered by M-PDCCH order. CSS for these purposes can be located in the same narrowband to USS once a UE is connected to the network. Then, a UE does not need to re-tune its operating frequency to monitor this CSS. A UE can monitor CSS_others (i.e., CSS_regular) and USS simultaneously.

[240] If there is a complexity issue, TDM of CSS and USS monitoring can be considered. In other words, CSS and USS are time-division multiplexed, whereby the CSS and the USS may not be monitored at the same time.

[241] If CSS for other purposes are not defined, legacy PUCCH TPC via DCI format 3/3A cannot be supported. Then, if downlink traffic is occurred sparsely, it could be difficult to adopt PUCCH power since PUCCH TPC is accomplished by accumulated way. So, other way to handle this issue needs to be considered such as absolute PUCCH TPC via DL grant or unicast DCI for PUCCH TPC transmitted by USS. Thus, at least for CE mode A (for TCP and reconfiguration), CSS_others needs to be supported.

[242] **USS**

[243] USS is a search space for unicast data scheduling. Configurations for USS can be configured by SIB and Msg4. If necessary, reconfiguration can be utilized by radio resource control (RRC) layer (i.e. RRC signal). Configurations for USS also can be applied for CSS_others. In this case, individual configurations for CSS_others and USS may not be required.

[244] FIG. 11 illustrates a procedure of configuring a search space according to the present invention.

[245] Referring to FIG. 11, the UE may receive a list of search space (SS) configurations per CE level for RAR through SIB (S1101). The UE may transmit RACH preamble through PRACH by using a PRACH resource. PRACH resource(s) per CE level may be configured by SIB. The UE may monitor M-PDCCH for scheduling a response to the RACH preamble transmitted therefrom, that is, a response to transmission of the PRACH in a search space (S1103). The UE may assume that a search space for M-PDCCH scheduling the RAR depends on SS configuration (e.g., CSS_RAR configuration) received through the SIB. The UE which has received RAR M-PDCCH may receive RAR in accordance with DCI carried by the RAR M-PDCCH (S1105).

[246] Initial configuration for RAR, Msg3 and/or Msg4 may depend on SS configuration per CE level received (S1101) through SIB (S1121). The UE may monitor M-PDCCH for scheduling Msg4, which includes CSS configuration/reconfiguration and/or USS configuration/reconfiguration parameters, in the SS according to initial configuration through SIB (S1121). For example, the UE may monitor Msg4 M-PDCCH by assuming that the maximum number of repetitions, narrowband, PRB-set, etc. which are the same as those of CSS for RAR, are also applied to M-PDCCH (hereinafter, Msg4 M-PDCCH) for scheduling Msg4 (S1121). The UE which has received Msg4 M-PDCCH may receive Msg4 in accordance with DCI of the Msg4 M-PDCCH (S1123). The Msg4 may carry RRC message that includes UE-specific configuration for USS and/or CSS. In this case, the UE may monitor M-PDCCH by applying the UE-specific SS configuration instead of initial SS configuration (S1125).

[247] The UE may monitor M-PDCCH order within the CSS according to the UE-specific CSS configuration (S1141). The UE which has received the M-PDCCH order may receive RAR in accordance with scheduling information carried by the M-PDCCH order (S1143).

[248] The UE may monitor M-PDCCH for scheduling RRC message having UE-specific reconfiguration parameter(s) within the CSS according to the UE-specific CSS configuration (S1161). The UE-specific reconfiguration may include M-PDCCH configuration. The UE which has received the M-PDCCH may receive a PDSCH carrying the RRC message in accordance with scheduling information (that is, DCI) of the M-PDCCH (S1163). The UE may reconfigure M-PDCCH search space in accordance with the UE-specific reconfiguration.

[249] Table 13 illustrates parameters and configuration details required for search spaces. All or some of the parameters illustrated in Table 13 may be configured and/or re-configured in accordance with Table 13.

[250] [Table 13]

Parameters	Configuration details				Description
	CSS_paging	CSS_RAR	CSS_others	USS	
Subset of L	Fixed to {8, 16, 24}			{1, 2, 4, 8, 16, 24}	
R_{max}	Configurable by SIB.	Configured by SIB per CE level (configuration can be shared for CSS_RAR, CSS_others, USS).For CSS_others/USS, it can be reconfigured by RRC.			Subset of repetition numbers is determined based on R_{max}. Details are described in Subsection 5.1.
PRB-sets	Configured by SIB.	Configured by SIB per CE level specific and cell-specific.	Alt 1. Configured by Msg4 per UE.Alt 2. Configured by SIB per CE level (in this case, same configuration for CSS_RAR, CSS_others, USS).It can be reconfigured by RRC.		This configuration includes the number of PRB-sets, PRB size/ location of each PRB-set.
Transmission type	Configured by SIB per PRB-set.	Configured by SIB per PRB-set.	Alt 1. Configured by Msg4 per UE (the network ensures the same type is used beween CSS_others and USS in case both are monitored at the same time).Alt 2. Configured by SIB per CE level (in this case, same configuration for CSS_RAR, CSS_others, USS).It can be reconfigured by RRC.		
Narrowband	Determined	Based on	Default value can be		

	by UE ID among paging narrowbands configured by SIB.	PRACH resource set where RAR narrowband corresponding to each PRACH resource set is configured by SIB.	CSS_RAR's narrowband location. Configurable by Msg 4 per UEIt can be reconfigured by RRC.	
M-PDCCH monitoring starting	Alt 1. Configured by SIB per CE level.Alt 2. Configured by SIB regardless of CE level (one maximum value to reset monitoring starting subframe).			See FIG. 7 and Subsection 5.1.
M-PDCCH starting subframe	Determined by repetition number R per repetition number R.	Alt 1. Determined by R_{max} for CE Mode A, determined by repetition number R per repetition number R for CE Mode B.Alt 2. Determined by repetition number R per repetition number R.		See FIG. 7 and Subsection 5.1.

[251] In Table 13, a merged cell means that the configuration can be shared by corresponding search spaces, so individual configuration is not needed for each search space. For example, referring to Table 13, "Fixed to {8, 16, 24}" which is the description of a subset of an aggregation level *L* exists within a cell merged for CSS_paging, CSS_RAR and CSS_others (i.e., CSS_regular), and thus means that a corresponding parameter is not required to be configured individually for CSS_paging, CSS_RAR and CSS_others(i.e. CSS_reguar) and a common parameter is applied to CSS_paging, CSS_RAR and CSS_others. According to Table 13, the UE may attempt reception of M-PDCCH at an aggregation level $L \in \{8, 16, 24\}$ for CSS_paging, CSS_RAR and CSS_others, and may attempt reception of M-PDCCH at $L \in \{1, 2, 4, 8, 16, 24\}$ for the USS.

[252] Reconfigurable parameters in Table 13 mean that the same value as initial configuration or default configuration is applied until a corresponding parameter is reconfigured, whereby search space(s) is(are) configured.

[253] For example, referring to Table 13, the maximum number of repetitions R_{max} of M-PDCCH may be provided through SIB as a configuration for CSS_RAR. The UE may monitor CSS_RAR, CSS_others and/or USS by assuming that R_{max} included in the SIB is applied to CSS_RAR, CSS_others, and USS. That is, the UE may monitor rep-

etitions of M-PDCCH in SS within maximum R_{max} number of subframes. According to Table 13, since R_{max} for CSS_others and/or USS (hereinafter, CSS_others/USS) may be reconfigured, if R_{max} for CSS_others/USS is reconfigured by RRC signal, the UE may monitor CSS_others/USS in accordance with the reconfigured R_{max}. In other words, the UE may monitor CSS_others/USS in accordance with R_{max} for CSS_RAR until R_{max} for CSS_others/USS is received.

[254] For another example, referring to parameters of PRB-sets in Table 13, PRBs on which PRB-set(s) for CSS_RAR, that is, RAR M-PDCCH may be transmitted may be configured CE level-specifically and cell-specifically by SIB. Referring to Alt 2, these PRB-sets configured per CE level may be applied to CSS_others and USS by SIB. Since PRB-set parameter for CSS_others and USS may be reconfigured by RRC, the UE may monitor CSS_others/USS by applying PRB-set(s) for CSS_RAR until reconfiguration PRB-set parameter for CSS_others/USS is received, and may monitor CSS_others/USS by applying the reconfiguration PRB-set parameter if the reconfiguration PRB-set parameter for CSS_others/USS is received. For example, if PRB-set(s) of CSS_RAR are fixed to 6, the UE may monitor M-PDCCH USS by assuming all PRBs within a narrowband according to CSS_RAR configuration as PRB-set(s) for USS until configuration of separate PRB-set(s) for USS is received.

[255] For still another example, referring to a narrowband parameter of Table 13, a narrowband (hereinafter, RAR narrowband) having CSS_RAR may be determined based on a PRACH resource set. In this case, a corresponding RAR narrowband per PRACH resource set is configured by SIB. A default narrowband location of CSS_others and/or USS may be a narrowband location of CSS_RAR. A narrowband for CSS_others/USS may be configured per UE by Msg4, and may be reconfigured by RRC. Therefore, the UE may monitor CSS_others/USS on the same narrowband as that for CSS_RAR until a narrowband parameter for CSS_others/USS is received, and if Msg4 for CSS_others/USS or reconfiguration RRC message is received, may monitor CSS_others/USS on a narrowband according to the Msg4 or the RRC message.

[256] □ Subsection 5.1. Aggregation levels and repetition numbers

[257] Search space configuration parameters of Table 13 may be applied as follows in view of an aggregation level and the number of repetitions. For example, a subset (and/or starting subframe of M-PDCCH SS and/or starting subframe of M-PDCCH) of the number of repetitions R based on R_{max} may be determined in accordance with the following description.

[258] **CSS for paging (i.e., CSS_paging)**

[259] - Aggregation levels:

[260] Since data transmission scheduled by CSS is targeted to multicast/broadcast, similar

to PDCCH CSS, some high aggregation levels can be supported. Aggregation levels (ALs) {8, 16, 24} can be supported for normal CP and ALs {4, 8, 12} can be supported for extended CP.

[261] - Repetition numbers:

[262] A subset of R for CSS for paging monitoring depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB. To support wide range of repetition numbers, the subset of R monitored for CSS_paging can be {$R_{max}/64$, $R_{max}/16$, $R_{max}/4$, R_{max}}.

[263] **CSS for** RAR corresponding to initial RACH procedure (i.e., CSS_RAR)

[264] - Aggregation levels:

[265] Similar to CSS_paging, ALs $L\in\{8, 16, 24\}$ can be supported for normal CP and ALs $L\in\{4, 8, 12\}$ can be supported for extended CP.

[266] - Repetition numbers:

[267] For CSS scheduling RAR, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level. The subset of R monitored for CSS_RAR can be {$R_{max}/4$, $R_{max}/2$, R_{max}}.

[268] **CSS for others (i.e., CSS_others)**

[269] - Aggregation levels:

[270] Similar to CSS_paging, ALs $L\in\{8, 16, 24\}$ can be supported for normal CP and ALs $L\in\{4, 8, 12\}$ can be supported for extended CP.

[271] - Repetition numbers:

[272] For CSS_others, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level or Msg4. R_{max} can be reconfigured by RRC if necessary. The subset of R monitored for CSS_others can be {$R_{max}/4$, $R_{max}/2$, R_{max}}. Or, to reduce UE complexity, the subset of R monitored for CSS_others can be {$R_{max}/2$, R_{max}}.

[273] **USS**

[274] - Aggregation levels:

[275] For CE Mode A, ALs $L\in\{1, 2, 4, 8, 16, 24\}$ are supported for normal CP. ALs $L\in\{1, 2, 4, 8, 12\}$ are supported for extended CP. For CE Mode B, ALs $L\in\{8, 16, 24\}$ is supported for normal CP. ALs $L\in\{4, 8, 12\}$ are supported for extended CP.

[276] - Repetition numbers:

[277] For USS, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level or Msg4. R_{max} can be reconfigured by RRC if necessary. The subset of R monitored for USS can be {$R_{max}/4$, $R_{max}/2$, R_{max}}. Or, to support higher R to CSS_others for CE level reconfiguration reliably, subset of R monitored for USS can be {$R_{max}/8$, $R_{max}/4$, $R_{max}/2$}.

[278] ■ Section 6. Collision of M-PDCCH(s)

[279] If there are some subframes not available for downlink transmission, M-

PDCCH/PDSCH transmission or repetitions can be postponed till the next available subframe. It can be applied in case unavailable subframes are aligned between eNB and UE.

[280] FIG. 12 illustrates a configuration of M-PDCCH repeated transmission according to the present invention.

[281] If a small interval (e.g., cycle of starting subframe of M-PDCCH search space) of M-PDCCH search space is configured or a large number of invalid subframes, which cannot have M-PDCCH, are provided between M-PDCCH search space starting subframes, M-PDCCH2 transmission may not end until next starting subframe of the search space, in the same manner as M-PDCCH2 transmission of FIG. 12. That is, the subframes configuring two search spaces may be overlapped with each other. In this case, the UE may be in the status that the UE should perform monitoring for M-PDCCH transmitted in a previous search space and monitoring for M-PDCCH transmitted in a next search space. However, this operation may not be preferable due to buffer size and complexity issue of the UE. In this case, the UE may perform reception of M-PDCCH as follows.

[282] - Method 1. If a starting time (hereinafter, subframe #n) of next search space occurs before reception of M-PDCCH is ended, the UE may assume that the M-PDCCH is transmitted up to subframe #n-1 and is not transmitted in subframe #n. In this case, the UE may attempt reception of the M-PDCCH by using repetitions smaller than the number of expected repetitions of M-PDCCH.

[283] - Method 2. If a starting time (hereinafter, subframe #n) of next search space occurs before reception of M-PDCCH is ended, the UE may determine that the M-PDCCH that the UE is receiving is invalid, and may not perform reception of the corresponding M-PDCCH.

[284] - Method 3. If subframe(s) configuring two search spaces are overlapped with each other, the UE may determine that a search space existing at an earlier time is invalid, and may not perform reception of M-PDCCH for one of the two search space, which is first started in a time domain.

[285] FIG. 13 is a block diagram illustrating elements of a transmitting device 10 and a receiving device 20 for implementing the present invention.

[286] The transmitting device 10 and the receiving device 20 respectively include Radio Frequency (RF) units 13 and 23 capable of transmitting and receiving radio signals carrying information, data, signals, and/or messages, memories 12 and 22 for storing information related to communication in a wireless communication system, and processors 11 and 21 operationally connected to elements such as the RF units 13 and 23 and the memories 12 and 22 to control the elements and configured to control the memories 12 and 22 and/or the RF units 13 and 23 so that a corresponding device may

perform at least one of the above-described embodiments of the present invention.

[287] The memories 12 and 22 may store programs for processing and controlling the processors 11 and 21 and may temporarily store input/output information. The memories 12 and 22 may be used as buffers.

[288] The processors 11 and 21 generally control the overall operation of various modules in the transmitting device and the receiving device. Especially, the processors 11 and 21 may perform various control functions to implement the present invention. The processors 11 and 21 may be referred to as controllers, microcontrollers, microprocessors, or microcomputers. The processors 11 and 21 may be implemented by hardware, firmware, software, or a combination thereof. In a hardware configuration, application specific integrated circuits (ASICs), digital signal processors (DSPs), digital signal processing devices (DSPDs), programmable logic devices (PLDs), or field programmable gate arrays (FPGAs) may be included in the processors 11 and 21. Meanwhile, if the present invention is implemented using firmware or software, the firmware or software may be configured to include modules, procedures, functions, etc. performing the functions or operations of the present invention. Firmware or software configured to perform the present invention may be included in the processors 11 and 21 or stored in the memories 12 and 22 so as to be driven by the processors 11 and 21.

[289] The processor 11 of the transmitting device 10 performs predetermined coding and modulation for a signal and/or data scheduled to be transmitted to the outside by the processor 11 or a scheduler connected with the processor 11, and then transfers the coded and modulated data to the RF unit 13. For example, the processor 11 converts a data stream to be transmitted into K layers through demultiplexing, channel coding, scrambling, and modulation. The coded data stream is also referred to as a codeword and is equivalent to a transport block which is a data block provided by a MAC layer. One transport block (TB) is coded into one codeword and each codeword is transmitted to the receiving device in the form of one or more layers. For frequency up-conversion, the RF unit 13 may include N_t (where N_t is a positive integer) transmit antennas.

[290] A signal processing process of the receiving device 20 is the reverse of the signal processing process of the transmitting device 10. Under control of the processor 21, the RF unit 23 of the receiving device 20 receives radio signals transmitted by the transmitting device 10. The RF unit 23 may include N_r (where N_r is a positive integer) receive antennas and frequency down-converts each signal received through receive antennas into a baseband signal. The processor 21 decodes and demodulates the radio signals received through the receive antennas and restores data that the transmitting device 10 intended to transmit.

[291] The RF units 13 and 23 include one or more antennas. An antenna performs a function for transmitting signals processed by the RF units 13 and 23 to the exterior or receiving radio signals from the exterior to transfer the radio signals to the RF units 13 and 23. The antenna may also be called an antenna port. Each antenna may correspond to one physical antenna or may be configured by a combination of more than one physical antenna element. The signal transmitted from each antenna cannot be further deconstructed by the receiving device 20. An RS transmitted through a corresponding antenna defines an antenna from the view point of the receiving device 20 and enables the receiving device 20 to derive channel estimation for the antenna, irrespective of whether the channel represents a single radio channel from one physical antenna or a composite channel from a plurality of physical antenna elements including the antenna. That is, an antenna is defined such that a channel carrying a symbol of the antenna can be obtained from a channel carrying another symbol of the same antenna. An RF unit supporting a MIMO function of transmitting and receiving data using a plurality of antennas may be connected to two or more antennas.

[292] In the embodiments of the present invention, a UE operates as the transmitting device 10 in UL and as the receiving device 20 in DL. In the embodiments of the present invention, an eNB operates as the receiving device 20 in UL and as the transmitting device 10 in DL. Hereinafter, a processor, an RF unit, and a memory included in the UE will be referred to as a UE processor, a UE RF unit, and a UE memory, respectively, and a processor, an RF unit, and a memory included in the eNB will be referred to as an eNB processor, an eNB RF unit, and an eNB memory, respectively.

[293] The eNB processor of the present invention may configure or reconfigure CSS_paging in accordance with section 1, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_paging, to the UE in accordance with section 1, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for scheduling a paging message within CSS_paging according to CSS_paging configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_paging from the eNB in accordance with section 1, section 5 and/or section 6. The UE may attempt reception of paging M-PDCCH from CSS_paging according to the CSS_paging configuration.

[294] The eNB processor of the present invention may configure or reconfigure CSS_RAR in accordance with section 2, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_RAR, to the UE in accordance with section 2, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for

scheduling RAR, Msg3 and/or Msg4 within a CSS according to CSS_RAR configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_RAR from the eNB in accordance with section 2, section 5 and/or section 6. The UE may attempt reception of RAR M-MPDCCH, Msg3 M-PDCCH and/or Msg4 M-PDCCH from the CSS according to the CSS_RAR configuration.

[295] The eNB processor of the present invention may configure or reconfigure CSS_others in accordance with section 3, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_others, to the UE in accordance with section 3, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for other purpose within a CSS according to CSS_others configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_others from the eNB in accordance with section 3, section 5 and/or section 6. The UE may attempt reception of M-PDCCH for other purpose from the CSS according to the CSS_others configuration.

[296] The eNB processor of the present invention may transmit initial configuration for CSS through SIB in accordance with section 6. The eNB processor may configure CSS and/or USS in accordance with the initial configuration until the other configuration (e.g., UE-specific configuration/reconfiguration) for SS is transmitted. The initial configuration may include a configuration (e.g., narrowband, PRB-set(s), starting subframe and/or period, and the number of maximum repetitions of SS) of time-frequency resources of SS. The eNB processor may transmit M-PDCCH in accordance with the initial configuration until the other configuration for SS is transmitted. For example, the eNB processor may control the eNB RF unit to transmit M-PDCCH by applying the number of repetitions R based on maximum R_{max} according to the initial configuration within the PRB-set according to the initial configuration on a narrowband according to the initial configuration. If the other configuration for SS is transmitted, the eNB processor may control the eNB RF unit to transmit M-PDCCH on the SS configured in accordance with the other configuration. The UE processor may receive the initial configuration for CSS through SIB in accordance with section 6. The UE processor may assume that CSS and/or USS is configured in accordance with the initial configuration until the other configuration (e.g., UE-specific configuration/reconfiguration) for SS is received. The UE processor may monitor M-PDCCH in accordance with the initial configuration until the other configuration for SS is transmitted. For example, the UE processor may control the UE RF unit to receive or monitor M-PDCCH by applying the number of repetitions R based on maximum R_{max} according to the initial configuration within the PRB-set according to the initial con-

figuration on a narrowband according to the initial configuration. If the other configuration for SS is received, the UE processor may control the UE RF unit to receive or monitor M-PDCCH on the SS configured in accordance with the other configuration.

[297] As described above, the detailed description of the preferred embodiments of the present invention has been given to enable those skilled in the art to implement and practice the invention. Although the invention has been described with reference to exemplary embodiments, those skilled in the art will appreciate that various modifications and variations can be made in the present invention without departing from the spirit or scope of the invention described in the appended claims. Accordingly, the invention should not be limited to the specific embodiments described herein, but should be accorded the broadest scope consistent with the principles and novel features disclosed herein.

Industrial Applicability

[298] The embodiments of the present invention are applicable to a BS, a UE, or other devices in a wireless communication system.

Claims

[Claim 1] A method for receiving, by a user equipment (UE), downlink control information (DCI) for the UE, the method comprising:
receiving, by the UE, a common search space configuration for a common search space;
receiving, by the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by monitoring first PDCCH candidates of the common search space according to the common search space configuration; and
receiving, by the UE, a second PDCCH carrying the DCI for the UE by monitoring second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are monitored according to the same configuration as the common search space configuration until the UE receives a UE-specific search space configuration.

[Claim 2] The method according to claim 1,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored on the same narrowband as the narrowband for the common search space until the UE receives a UE-specific search space configuration.

[Claim 3] The method according to claim 1 or 2,
wherein the common search space configuration includes information on a maximum number of repetitions for the common common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored based on the same number as the maximum number of repetitions for the common search space until the UE receives a UE-specific search space configuration.

[Claim 4] The method according to any one of claims 1 to 3,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for monitoring the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for monitoring the second PDCCH candidates until the UE receives a UE-specific search space configuration.

[Claim 5] The method according to any one of claims 1 to 4,
wherein the first PDCCH candidates of the common search space are monitored according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are monitored according to the plurality of aggregation levels.

[Claim 6] A method for transmitting, by a base station (BS), downlink control information (DCI) for a user equipment (UE), the method comprising:
transmitting, by the BS, common search space configuration for a common search space;
transmitting, by the BS to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by using one of first PDCCH candidates of the common search space according to the common search space configuration; and
transmitting, by the BS to the UE, a second PDCCH carrying the DCI for the UE by using one of second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are configured according to the same configuration as the common search space configuration until a UE-specific search space configuration is transmitted to the UE.

[Claim 7] The method according to claim 6,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 8] The method according to claim 6 or 7,
wherein the common search space configuration includes information on a maximum number of repetitions for the first common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 9] The method according to any one of claims 6 to 8,
wherein the common search space configuration includes information

on a first physical resource block (PRB) set for transmitting the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE.

[Claim 10] The method according to any one of claims 6 to 9,
wherein the first PDCCH candidates of the common search space are configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are configured according to the plurality of aggregation levels.

[Claim 11] A user equipment (UE) for receiving downlink control information (DCI) for the UE, the UE comprising:
a radio frequency (RF) unit, and
a processor connected to the RF unit, the processor configured to:
control the RF unit to receive common search space configuration for a common search space;
control the RF unit to receive a first physical downlink control channel (PDCCH) scheduling a random access response by monitoring first PDCCH candidates of the common search space according to the common search space configuration; and
control the RF unit to receive a second PDCCH carrying the DCI for the UE by monitoring second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are monitored according to the same configuration as the common search space configuration until the UE receives a UE-specific search space configuration.

[Claim 12] The UE according to claim 11,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored on the same narrowband as the narrowband for the common search space until the UE receives a UE-specific search space configuration.

[Claim 13] The UE according to claim 11 or 12,
wherein the common search space configuration includes information on a maximum number of repetitions for the common common search

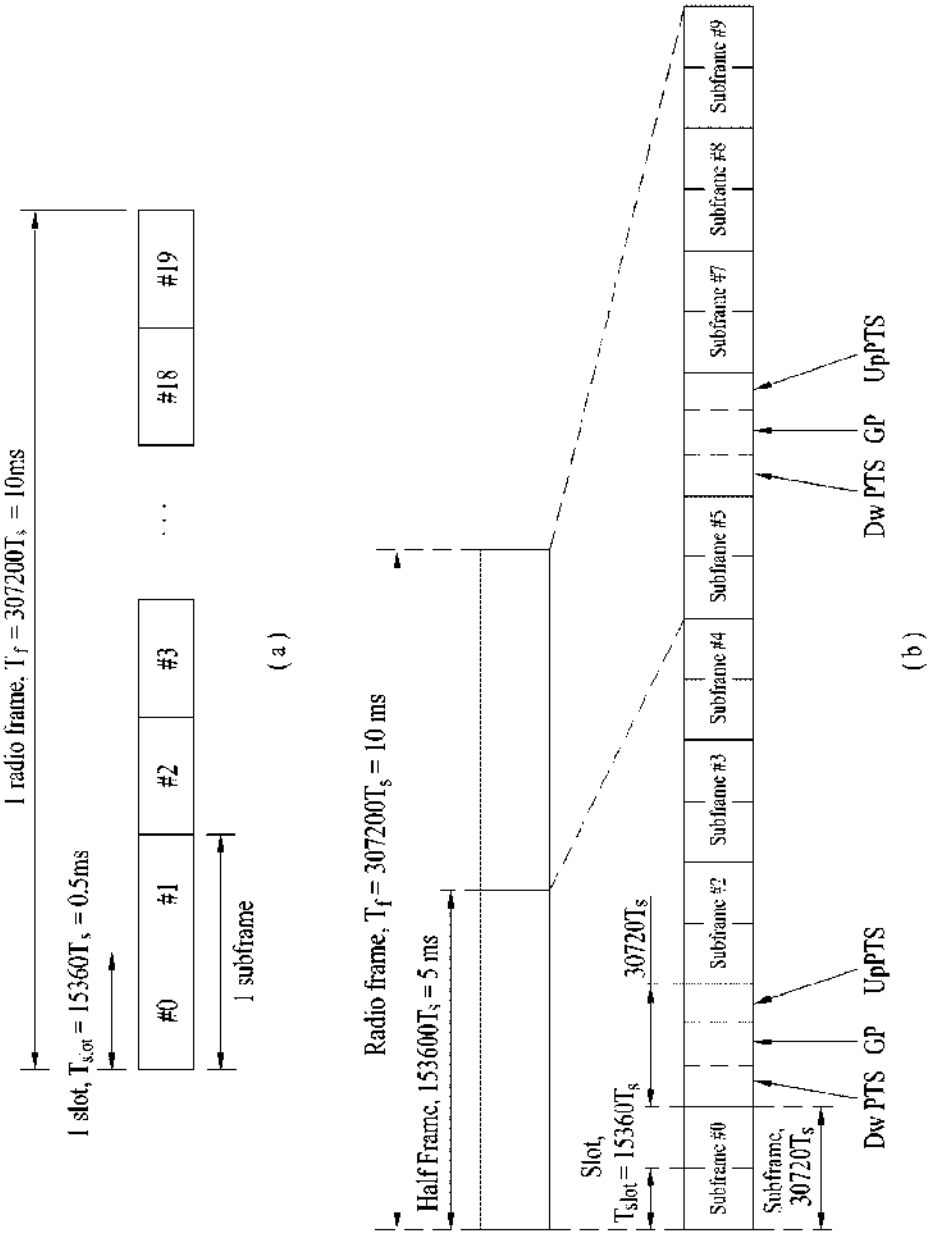
space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored based on the same number as the maximum number of repetitions for the common search space until the UE receives a UE-specific search space configuration.

[Claim 14] The UE according to any one of claims 11 to 13,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for monitoring the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for monitoring the second PDCCH candidates until the UE receives a UE-specific search space configuration.

[Claim 15] The UE according to any one of claims 11 to 14,
wherein the first PDCCH candidates of the common search space are monitored according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are monitored according to the plurality of aggregation levels.

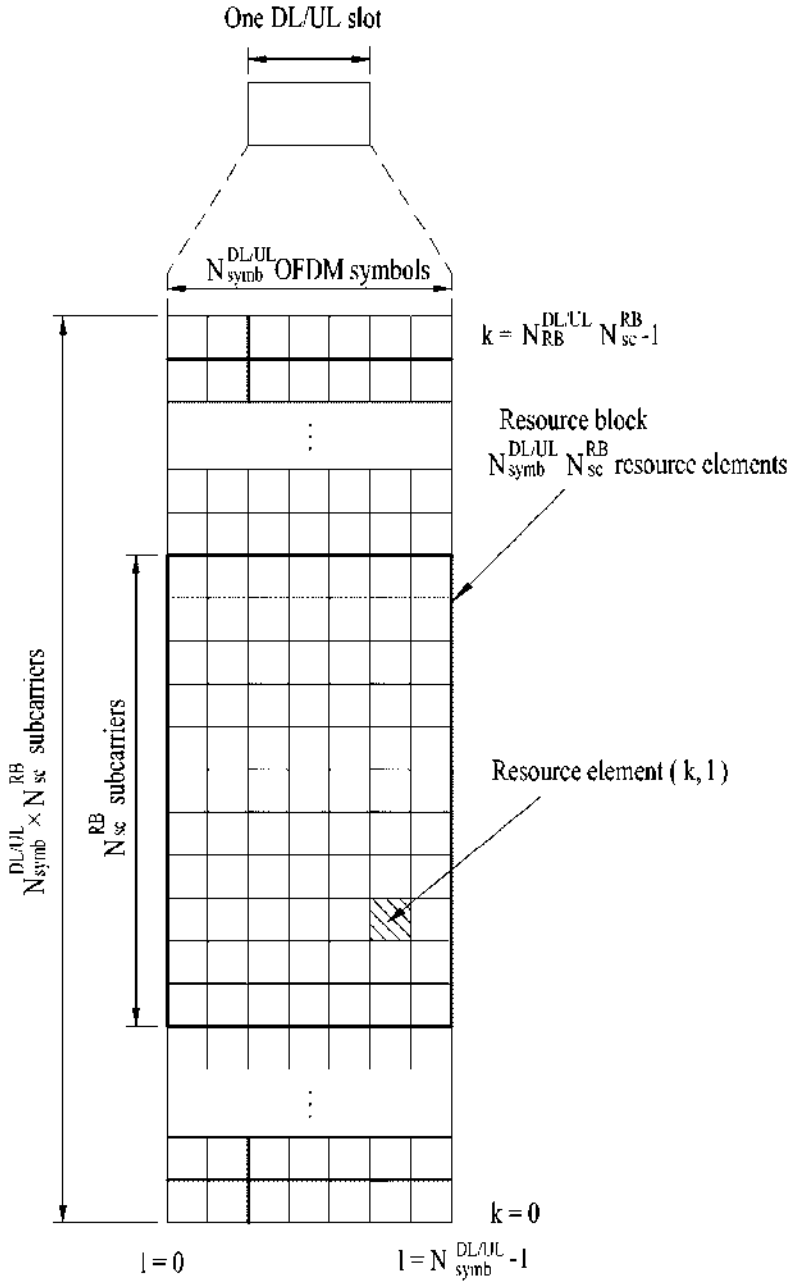
[Claim 16] A base station (BS) for transmitting downlink control information (DCI) to a user equipment (UE), the BS comprising:
a radio frequency (RF) unit, and
a processor connected to the RF unit, the processor configured to:
control the RF unit to transmit common search space configuration for a common search space;
control the RF unit to transmit, to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by using one of first PDCCH candidates of the common search space according to the common search space configuration; and
control the RF unit to transmit, to the UE, a second PDCCH carrying the DCI for the UE by using one of second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are configured according to the same configuration as the common search space configuration until a UE-specific search space configuration is transmitted to the UE.

[Claim 17] The BS according to claim 16,
wherein the common search space configuration includes information on a narrowband for the common search space, and



wherein the second PDCCH candidates of the UE-specific search space are configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 18] The BS according to claim 16 or 17,
wherein the common search space configuration includes information on a maximum number of repetitions for the first common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.



[Claim 19] The BS according to any one of claims 16 to 18,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for transmitting the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE.

[Claim 20] The BS according to any one of claims 16 to 19,
wherein the first PDCCH candidates of the common search space are configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are configured according to the plurality of aggregation levels.

(54) **Title**: DEVICE, SYSTEM AND METHOD EMPLOYING UNIFIED FLEXIBLE 5G AIR INTERFACE

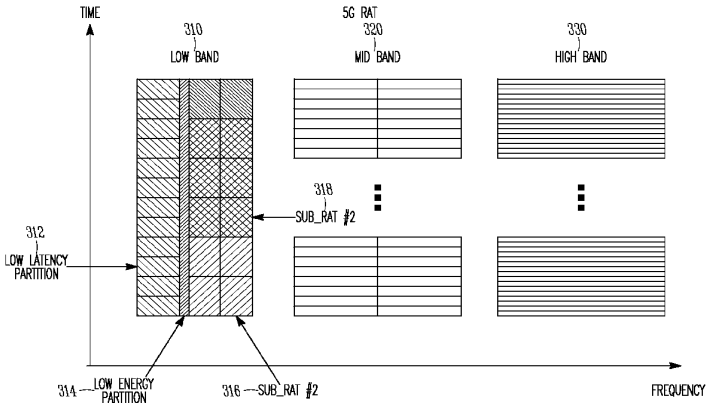

FIG. 3

(57) **Abstract**: An eNodeB (eNB), user equipment (UE) and method of providing a flexible Radio Access Technology (FRAT) are generally described. The information (resource allocation, partition information and numerology) of at least one of a plurality of RATs used by the eNB is provided to a UE. Each RAT has a flexible subcarrier spacing and symbol duration, which are integer multiples of a base subcarrier spacing and symbol duration, and is associated with at least one of different temporal and frequency resources. The symbol and/or frame structure of each RAT are independent. A Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration. The information of the RATs is provided either via a different RAT than the RAT used by the UE for communication or via a dedicated carrier in the RAT used by the UE for communication.

WO 2016/130175 A1

DEVICE, SYSTEM AND METHOD EMPLOYING UNIFIED FLEXIBLE 5G AIR INTERFACE

PRIORITY CLAIM

[0001] This application claims the benefit of priority to United States Provisional Patent Application Serial No. 62/114,733, filed February 11, 2015, and entitled "UNIFIED FLEXIBLE 5G NEW AIR INTERFACE DESIGN," which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

[0002] Embodiments pertain to radio access networks. Some embodiments relate to a unified communication framework using Radio Access Technologies (RAT) in 5th generation (5G) cellular networks.

BACKGROUND

[0003] The use of personal communication devices has increased astronomically over the last several decades. The penetration of mobile devices in modern society has continued to drive demand for a wide variety of networked devices in a number of disparate environments. The variety of available applications, especially video-related applications, has led to a concomitant increase in demand for increased bandwidth beyond that provided by Third Generation Partnership Project Long Term Evolution (3GPP LTE) and LTE advanced (LTE-A) systems.

[0004] The next generation wireless communication system, 5G, may provide access to information and sharing of data using a network that may be required to meet vastly different and sometimes conflicting performance dimensions and services driven by different services and use cases. It is therefore desirable that the next generation communication system be flexible and capable of providing high speed communications services for a wide ambit of devices under a multiplicity of circumstances.

BRIEF DESCRIPTION OF THE FIGURES

[0005] In the figures, which are not necessarily drawn to scale, like numerals may describe similar components in different views. Like numerals having different letter suffixes may represent different instances of similar components. The figures illustrate generally, by way of example, but not by way of limitation, various embodiments discussed in the present document.

[0006] FIG. 1 is a functional diagram of a 3GPP network in accordance with some embodiments.

[0007] FIG. 2 is a block diagram of a 3GPP device in accordance with some embodiments.

[0008] FIG. 3 illustrates one embodiment of a flexible Radio Access Technology (FRAT) of a 5G system in accordance with some embodiments.

[0009] FIG. 4 illustrates a unified frame structure in accordance with some embodiments.

[0010] FIG. 5 illustrates a Transmission Time Interval (TTI) boundary alignment in accordance with some embodiments.

[0011] FIG. 6 illustrates a symbol structure in accordance with some embodiments.

[0012] FIG. 7 illustrates frame structures within a TTI in accordance with some embodiments.

[0013] FIGS. 8A and 8B illustrate flowcharts of a uniform framework utilization method in accordance with some embodiments.

DETAILED DESCRIPTION OF THE INVENTION

[0014] The following description and the drawings sufficiently illustrate specific embodiments to enable those skilled in the art to practice them. Other embodiments may incorporate structural, logical, electrical, process, and other changes. Portions and features of some embodiments may be included in, or substituted for, those of other embodiments. Embodiments set forth in the claims encompass all available equivalents of those claims.

[0015] FIG. 1 is a functional diagram of a 3GPP network in accordance with some embodiments. The network may comprise a radio access network (RAN) (e.g., as depicted, the E-UTRAN or evolved universal terrestrial radio

access network) 100 and the core network 120 (e.g., shown as an evolved packet core (EPC)) coupled together through an S1 interface 115. For convenience and brevity sake, only a portion of the core network 120, as well as the RAN 100, is shown.

[0016] The core network 120 includes mobility management entity (MME) 122, serving gateway (serving GW) 124, and packet data network gateway (PDN GW) 126. The RAN 100 includes eNBs 104 (which may operate as base stations) for communicating with UE 102. The eNBs 104 may include macro eNBs and low power (LP) eNBs.

[0017] The MME is similar in function to the control plane of legacy Serving GPRS Support Nodes (SGSN). The MME manages mobility aspects in access such as gateway selection and tracking area list management. The serving GW 124 terminates the interface toward the RAN 100, and routes traffic packets (such as data packets or voice packets) between the RAN 100 and the core network 120. In addition, it may be a local mobility anchor point for inter-eNB handovers and also may provide an anchor for inter-3GPP mobility. Other responsibilities may include lawful intercept, charging, and some policy enforcement. The serving GW 124 and the MME 122 may be implemented in one physical node or separate physical nodes. The PDN GW 126 terminates a SGi interface toward the packet data network (PDN). The PDN GW 126 routes traffic packets between the EPC 120 and the external PDN, and may be a key node for policy enforcement and charging data collection. It may also provide an anchor point for mobility with non-LTE accesses. The external PDN can be any kind of IP network, as well as an IP Multimedia Subsystem (IMS) domain. The PDN GW 126 and the serving GW 124 may be implemented in one physical node or separated physical nodes.

[0018] The eNBs 104 (macro and micro) terminate the air interface protocol and may be the first point of contact for a UE 102. The eNBs 104 may communicate both with UEs 102 in a normal coverage mode and UEs 104 in one or more enhanced coverage modes. In some embodiments, an eNB 104 may fulfill various logical functions for the RAN 100 including but not limited to RNC (radio network controller functions) such as radio bearer management, uplink and downlink dynamic radio resource management and traffic packet

scheduling, and mobility management. In accordance with some embodiments, UEs 102 may be configured to communicate via orthogonal multiple access (OMA) communications such as Time Division Multiple Access (TDMA), Frequency Division Multiple Access (FDMA) Orthogonal FDMA (OFDMA), SC-FDMA or other communication signals with an eNB 104 over a multicarrier communication channel in accordance with the appropriate communication technique. The OFDM signals may comprise a plurality of orthogonal subcarriers. In accordance with some embodiments, UEs 102 may be configured to communicate via non-orthogonal multiple access (NOMA) signals.

[0019] The S1 interface 115 is the interface that separates the RAN 100 and the EPC 120. It is split into two parts: the S1-U, which carries traffic packets between the eNBs 104 and the serving GW 124, and the S1-MME, which is a signaling interface between the eNBs 104 and the MME 122.

[0020] With cellular networks, LP cells are typically used to extend coverage to indoor areas where outdoor signals do not reach well, or to add network capacity in areas with very dense phone usage, such as train stations. As used herein, the term low power (LP) eNB refers to any suitable relatively low power eNB for implementing a narrower cell (narrower than a macro cell) such as a femtocell, a picocell, or a micro cell. Femtocell eNBs are typically provided by a mobile network operator to its residential or enterprise customers. A femtocell is typically the size of a residential gateway or smaller and generally connects to the user's broadband line. Once plugged in, the femtocell connects to the mobile operator's mobile network and provides extra coverage in a range of typically 30 to 50 meters for residential femtocells. Thus, a LP eNB might be a femtocell eNB since it is coupled through the PDN GW 126. Similarly, a picocell is a wireless communication system typically covering a small area, such as in-building (offices, shopping malls, train stations, etc.), or more recently in-aircraft. A picocell eNB can generally connect through the X2 link to another eNB such as a macro eNB through its base station controller (BSC) functionality. Thus, LP eNB may be implemented with a picocell eNB since it is coupled to a macro eNB via an X2 interface. Picocell eNBs or other LP eNBs may incorporate some or all functionality of a macro eNB. In some cases, this may be referred to as an access point base station or enterprise femtocell.

[0021] As indicated in more detail below, communication over a 4G LTE network may be split up into 10ms frames, each of which may contain ten 1ms subframes. Each subframe of the frame, in turn, may contain two slots of 0.5ms. The eNB may schedule uplink and downlink transmissions over a variety of frequency bands. The allocation of resources in subframes used in one frequency band and may differ from those in another frequency band. Each slot of the subframe may contain 6-7 symbols, depending on the system used. In some embodiments, the subframe may contain 12 or 24 subcarriers. A resource grid may be used for downlink and uplink transmissions between an eNB and a UE. The resource grid may be a time-frequency grid, which is the physical resource in each slot. The smallest time-frequency unit in a resource grid may be denoted as a resource element (RE). Each column and each row of the resource grid may correspond to one OFDM symbol and one OFDM subcarrier, respectively. The resource grid may contain resource blocks (RBs) that describe the mapping of physical channels to resource elements and physical RBs (PRBs). A PRB may be the smallest unit of resources that can be allocated to a UE in the current 3GPP standard. A resource block may be 180 kHz wide in frequency and 1 slot long in time. In frequency, resource blocks may be either 12 x 15 kHz subcarriers or 24 x 7.5 kHz subcarriers wide. For most channels and signals, 12 subcarriers may be used per resource block, dependent on the system bandwidth. The duration of the resource grid in the time domain corresponds to one subframe or two resource blocks. Each resource grid may comprise 12 (subcarriers) *14 (symbols) =168 resource elements for normal cyclic prefix (CP) case. Several different physical channels may be conveyed using such resource blocks. As discussed in more detail below, in a 5G network, the sizes of the resource blocks, resource elements, and symbols, among others, may vary.

[0022] There may be several different physical downlink channels that are conveyed using such resource blocks, including the physical downlink control channel (PDCCH) and the physical downlink shared channel (PDSCH). Each subframe may contain a PDCCH, physical hybrid-ARQ indicator channel (PHICH), physical control format indicator channel (PCFICH) and the PDSCH. The PDCCH may normally occupy the first up to three symbols (four in the case

of narrow bandwidths of 1.4MHz) of each subframe and carry, among other things, information about the transport format and resource allocations related to the PDSCH channel and uplink scheduling grants for a physical uplink shared channel (PUSCH) transmission. The PHICH may be used to signal HARQ information in response to a PUSCH transmission. The PCFICH may inform the UE the control region size (e.g. one, two or three OFDM symbols) in each downlink subframe. The PDSCH may carry user data and higher layer signaling to a particular UE and occupy the remainder of the downlink subframe to avoid the resources in which downlink control channels (PDCCH/PHICH/PCFICH) are transmitted. Typically, downlink scheduling (assigning control and shared channel resource blocks to UEs within a cell) may be performed at the eNB based on channel quality information provided by the UEs, and then the downlink resource assignment information may be sent to a scheduled UE on the PDCCH used for (assigned to) PDSCH reception of the UE.

[0023] The PDCCH may contain downlink control information (DCI) in one of a number of formats that tell the UE where to find and how to decode the data, transmitted on PDSCH in the same subframe, from the resource grid. The DCI may provide details such as the number of resource blocks, resource allocation type, modulation scheme, transport block, redundancy version, coding rate etc. Each DCI format may have a cyclic redundancy code (CRC) and be scrambled with a Radio Network Temporary Identifier (RNTI) that identifies the target UE for which the PDSCH is intended. Use of the RNTI, which may be UE-specific, may limit decoding of the DCI information (and hence the corresponding PDSCH) to only the intended UE. The PDCCH may be located in any of a number of frequency/temporal regions, depending on whether the PDCCH is UE-Specific or common, as well as the aggregation level. The set of possible candidate locations for the PDCCH is defined in terms of search spaces. A search space is defined by a set of Control Channel Element (CCE) candidates with a number of aggregation level $L \in \{1,2,4,8\}$ where the UE may monitor to find its PDCCHs. A common search space may carry DCIs that are common for all UEs; for example, system information (using the SI-RNTI), paging (P-RNTI), PRACH responses (RA-RNTI), or UL TPC commands (TPC-PUCCH/PUSCH-RNTI). A UE-specific search space may carry DCIs for UE-

specific allocations using a Cell Radio-Network Temporary Identifier (C-RNTI) assigned to the UE, a semi-persistent scheduling (SPS C-RNTI), or an initial allocation (temporary C-RNTI). When configuring an SPS (either uplink or downlink), the SPS C-RNTI is provided by the eNB and the UE is configured by higher layers to decode a PDCCH with a CRC scrambled by the SPS C-RNTI. The UE may monitor the PDCCH having a CRC scrambled by the SPS C-RNTI in every subframe as the eNB can activate/re-activate/release the SPS at any time using a DCI format with a CRC scrambled by an SPS C-RNTI. The received DCI format with a CRC scrambled by the SPS C-RNTI can be a grant/assignment for a retransmission or for activation/re-activation/release of the SPS. 3GPP Technical Specification 36.213 has tabulated the validation procedure for activation/re-activation/release of SPS.

[0024] In addition to the PDCCH, an enhanced PDCCH (EPDCCH) may be used by the eNB and UE. The PDSCH may thus contain data in some of the resource blocks (RBs) and then EPDCCH contains the downlink control signals in others of the RBs of the bandwidth supported by the UE. Different UEs may have different EPDCCH configurations. The sets of RBs corresponding to EPDCCH may be configured, for example, by higher layer signaling such as Radio Resource Control (RRC) signaling for EPDCCH monitoring.

[0025] The Physical Uplink Control Channel (PUCCH) may be used by the UE to send Uplink Control Information (UCI) to the eNB. The PUCCH may be mapped to an UL control channel resource defined by an orthogonal cover code and two resource blocks (RBs), consecutive in time, with hopping potentially at the boundary between adjacent slots. The PUCCH may take several different formats, with the UCI containing information dependent on the format. Specifically, the PUCCH may contain a scheduling request (SR), acknowledgement responses/retransmission requests (ACK/NACK) or a Channel Quality Indication (CQI)/Channel State Information (CSI). The CQI/CSI may indicate to the eNB an estimate of the current downlink channel conditions as seen by the UE to aid channel-dependent scheduling and, if one MIMO transmission mode is configured to the UE, may include MIMO-related feedback (e.g. Precoder matrix indication, PMI).

[0026] FIG. 2 is a functional diagram of a 3GPP device in accordance with some embodiments. The device may be a UE or eNB, for example. In some embodiments, the eNB may be a stationary non-mobile device. The 3GPP device 200 may include physical layer circuitry 202 for transmitting and receiving signals using one or more antennas 201. The 3GPP device 200 may also include medium access control layer (MAC) circuitry 204 for controlling access to the wireless medium. The 3GPP device 200 may also include processing circuitry 206 and memory 208 arranged to perform the operations described herein.

[0027] In some embodiments, mobile devices or other devices described herein may be part of a portable wireless communication device, such as a personal digital assistant (PDA), a laptop or portable computer with wireless communication capability, a web tablet, a wireless telephone, a smartphone, a wireless headset, a pager, an instant messaging device, a digital camera, an access point, a television, a medical device (e.g., a heart rate monitor, a blood pressure monitor, etc.), or other device that may receive and/or transmit information wirelessly. In some embodiments, the mobile device or other device can be a UE 102 or eNB 104 configured to operate in accordance with 3GPP standards. In some embodiments, the mobile device or other device may be configured to operate according to other protocols or standards, including IEEE 802.11 or other IEEE standards. In some embodiments, the mobile device or other device may include one or more of a keyboard, a display, a non-volatile memory port, multiple antennas, a graphics processor, an application processor, speakers, and other mobile device elements. The display may be an LCD screen including a touch screen.

[0028] The antennas 201 may comprise one or more directional or omnidirectional antennas, including, for example, dipole antennas, monopole antennas, patch antennas, loop antennas, microstrip antennas or other types of antennas suitable for transmission of RF signals. In some multiple-input multiple-output (MIMO) embodiments, the antennas 201 may be effectively separated to take advantage of spatial diversity and the different channel characteristics that may result.

[0029] Although the 3GPP device 200 is illustrated as having several separate functional elements, one or more of the functional elements may be combined and may be implemented by combinations of software-configured elements, such as processing elements including digital signal processors (DSPs), and/or other hardware elements. For example, some elements may comprise one or more microprocessors, DSPs, field-programmable gate arrays (FPGAs), application specific integrated circuits (ASICs), radio-frequency integrated circuits (RFICs) and combinations of various hardware and logic circuitry for performing at least the functions described herein. In some embodiments, the functional elements may refer to one or more processes operating on one or more processing elements.

[0030] Embodiments may be implemented in one or a combination of hardware, firmware and software. Embodiments may also be implemented as instructions stored on a computer-readable storage device, which may be read and executed by at least one processor to perform the operations described herein. A computer-readable storage device may include any non-transitory mechanism for storing information in a form readable by a machine (e.g., a computer). For example, a computer-readable storage device may include read-only memory (ROM), random-access memory (RAM), magnetic disk storage media, optical storage media, flash-memory devices, and other storage devices and media. Some embodiments may include one or more processors and may be configured with instructions stored on a computer-readable storage device.

[0031] The term "machine readable medium" may include a single medium or multiple media (e.g., a centralized or distributed database, and/or associated caches and servers) configured to store one or more instructions. The term “machine readable medium” may include any medium that is capable of storing, encoding, or carrying instructions for execution by the 3GPP device 200 and that cause it to perform any one or more of the techniques of the present disclosure, or that is capable of storing, encoding or carrying data structures used by or associated with such instructions. The term “transmission medium” shall be taken to include any intangible medium that is capable of storing, encoding or carrying instructions for execution, and includes digital or analog

communications signals or other intangible medium to facilitate communication of such software.

[0032] As above, the upcoming 5G wireless communications technology systems may have a number of unique challenges, including carrying the inherent ability to provide different performances requirements for numerous different types of wireless devices. Higher data rates in particular may continue to drive network development and evolution for 5G system. It may be desirable for a 5G system to support a peak data rate of more than 10Gps and a minimum guaranteed user data rate of at least 100Mbps. In addition, it may be desirable for the 5G system to support the huge increase in variety and number of Internet of Things (IoT) and Machine-Type Communication (MTC)-type devices. MTC devices have been increasingly employed for different applications, using low operational power consumption and infrequent small burst transmissions. Moreover, it may be desirable for the 5G system to provide an extremely high level of reliable connectivity with guaranteed low latency, availability and reliability-of-service for mission critical MTC use cases.

[0033] In general, 5G systems may use a plurality of Radio Access Technologies (RATs), unlike previous 2G, 3G and 4G, systems. For example, an enormous amount of spectrum may be available through the use of higher frequency bands. In one example, the use of millimeter wave (mmWave) frequency bands ranging from 30 to 300GHz may provide the desired scalability, capacity and density for the 5G system. In this case, a new RAT may be defined for the mmWave band to achieve low latency and higher peak data rate. The RAT for mmWave band communications may differ from the RAT for one or more of the other frequency bands used to provide communication services. In some embodiments, the RATs may be used simultaneously by a single eNB for communications with different UEs.

[0034] In some embodiments, a 5G system may be provided that contains multiple RATs in a unified framework to support diverse applications, use cases and services and inter-networking in multiple frequency bands, including both licensed and unlicensed frequency bands. The RATs used in the licensed and unlicensed may be independent of each other. In some embodiments, flexible subcarrier spacing and symbol duration (i.e., configurable

numerology) may be provided across the frequency bands used in the 5G system. In addition, the 5G system may include mechanisms to multiplex multiple RATs, sub-RATs and other partitions in different or the same frequency resource or frequency bands.

[0035] The inter-networking in the unified frame structure may include, in some embodiments, a Transmission Time Interval (TTI) boundary alignment between multiple RATs may be provided to allow seamless scheduling, fallback and support of different RATs. In some embodiments, a TTI is the smallest unit of time in which the eNB is capable of scheduling any UE for uplink or downlink transmission. In some embodiments, the TTI boundary alignment may occur at a subframe or frame boundary. As used herein, a unified RAT with flexible air interface for the 5G system is referred to as a flexible Radio Access Technology (FRAT). A UE that communicates with an eNB operating using the FRAT may remain using a single air interface technology (i.e., RAT) or may switch between different RATs.

[0036] In some embodiments, a unified RAT with configurable numerologies may be used in the 5G system in which a base subcarrier spacing (Δf) and symbol duration (T) can be defined in the FRAT. In one example, to maintain the backward compatibility for existing LTE and LTE-Advanced systems, a base subcarrier spacing and symbol duration can be specified as Δf = 15KHz and T=66.7μs. Moreover, for convenience in some embodiments a single oscillator may be used, with the subcarrier spacing and symbol duration for different RATs specified as an integer number of the base subcarrier spacing and symbol duration, respectively.

[0037] Similarly, when a low latency use case and service is desired, a shortened symbol duration may be employed to reduce the latency by using larger subcarrier spacing. The subcarrier spacing and symbol duration may in this case be defined as $\Delta f_i = K*\Delta f$ and $T_i=(1/K)*T$. In one example, for frequency band between 6GHz and 30GHz, K can be chosen as 10, leading to a subcarrier spacing and symbol duration of 150KHz and 6.67μs, respectively. This may result in a 0.1ms TTI for low latency use case. In another example, for frequency bands below 6GHz, which includes the current LTE frequency range,

K can be selected by the network to be 2 or 4, and the corresponding subcarrier spacing and symbol duration changed proportional to the selected K value. Alternatively, the same subcarrier spacing and symbol duration can be defined for frequency bands below 6GHz (i.e., K =1), but a shorter TTI can be considered, e.g., with a fewer number of symbols, to support low latency use cases.

[0038] To efficiently support a massive number of MTC devices used in the 5G network, in other embodiments, the subcarrier spacing and symbol duration can be defined as $\Delta f_i = (1/K)*\Delta f$ and $T_i=K*T$. In such embodiments, K can be selected to be 10, and the subcarrier spacing and symbol duration 1.5KHz and 667μs, respectively. In this case, the subframe duration for MTC use cases can be defined to be 10ms, in the current generation LTE systems the length of a typical frame, rather than the typical 1ms. This may reduce the power consumption of MTC UEs by reducing the amount of time the MTC UE is active, thereby increasing the battery life of the MTC UEs.

[0039] A UE may be initially assigned the appropriate RAT by the eNB or other network device (such as the MME). In some embodiments, the UE may be configurable to communicate using any of the RATs, as indicated via the eNB, and can configure the subcarrier spacing and symbol duration accordingly. In some embodiments, the UE may be limited to communicating only using a subset of the RATs, and perhaps only a single RAT, e.g., when the UE is an MTC UE having a limited bandwidth and capabilities. The RAT may depend on the type of UE as well as the operating mode of the UE. For example, some UEs may change mode between a normal mode and an enhanced coverage mode in situations in which the link budget to the nearest serving eNB is worse than a typical link budget value in the network and additional link budget is to be obtained without increasing transmission power. Enhanced coverage mode may be employed by a variety of UEs, including a normal UE (e.g., a smartphone or the like), a machine-to-machine (M2M) UE or a stationary wireless UE (i.e., a UE that remains indefinitely in a single location) using MTC. The UE may determine whether additional link budget is desired, as well as how much additional link budget is desired, and enter an appropriate enhanced coverage mode (that provides the appropriate additional link budget). The different

enhanced coverage modes may correspond to different RATs. Some UEs, such as low cost, low complexity MTC UEs, further may be band limited and operate in a narrow bandwidth of e.g., to 1.4 MHz, for both control and data channels, leading to the ability to operate, e.g., in a single RAT unless the RAT is modified by the network.

[0040] FIG. 3 illustrates one embodiment of a FRAT of a 5G system in accordance with some embodiments. The FRAT 300 may contain one or more partitions in different frequency band regions 310, 320, 330. In one example, the low frequency band 310 may include frequencies used in 4G systems (up to 6 GHz), the mid-frequency band 320 may include higher frequencies (e.g., 6-30 GHz) and the high frequency band 330 may include the highest frequencies in the 5G system (e.g., mmWave, above 30 GHz). Although the RATs of only a low frequency band 310, a mid-frequency band 320, and a high frequency band 330 are shown, any number of RATs of different frequency bands may exist. The various RATs in frequency bands may each have a subcarrier spacing and symbol duration that is independent of the subcarrier spacing and symbol duration of another RAT in another frequency band (i.e., the RATs have configurable numerologies). Moreover, within each frequency band, one or more sub-RATs and partitions 312, 314, 316, 318 may be present with each sub-RAT or partition 312, 314, 316, 318 having a subcarrier spacing and symbol duration independent of the subcarrier spacing and symbol duration of another sub-RAT or partition 312, 314, 316, 318 and independent of the RAT in other frequency bands. As shown in FIG. 3, the sub_RATs 316, 318 in the low frequency band 310 may have the same subcarrier spacing and symbol duration and may be separated by frequency and/or time, while partitions 312, 314 may have different subcarrier spacings and symbol durations from each other and the sub_RATs 316, 318 and may be separated by frequency and/or time. Although the low frequency band 310 is shown as having multiple partitions 312, 314 and sub_RATs 316, 318, the mid frequency band 320 is shown as having two sub_RATs and the high frequency band 330 is shown as having no sub_RATs, the eNB may establish the number and type of RATs used within a particular frequency band differently.

[0041] In some embodiments, RATs and sub-RATs with same or different numerologies can be multiplexed. The multiplexing may be via Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), code-division multiplex (CDM), spatial division multiplex (SDM), other possible orthogonal or non-orthogonal multiplexing schemes, or any combination thereof. For example, multiple RATs, sub-RATs or partitions with same or different numerologies can be multiplexed in a TDM manner. Each RAT, sub-RAT and partition may have a numerology, access scheme and modulation scheme that is independent of the numerology, access scheme and modulation scheme of the other RATs, sub-RATs and partitions. The numerologies, resource allocation and partition information in the time domain can be predefined or configured by higher layer signaling, e.g. via a Master Information Block (MIB), System Information Block (SIB) or UE-specific dedicated RRC signaling. If a MIB is used to indicate the partition configuration for multiple RATs, sub-RATs or partitions, the resource for the transmission physical broadcast channel (PBCH) used to carry the MIB may be predefined and known at the UEs. In some embodiments, the PBCH may be transmitted in a predetermined RAT, independent of the UE or number of RATs, sub-RATs or partitions supported. Once the UE receives the configuration information via the PBCH on the predetermined RAT, the UE may use a different RAT for further control and data communications; that is, the predetermined RAT and the RAT used by the UE to communicate may be independent.

[0042] In some embodiments, multiple RATs, sub-RATs or partitions with same or different numerologies can be multiplexed in a FDM manner. To minimize the interference between multiple RATs, sub-RATs or partitions with different numerologies, guard bands may be inserted at the edge of frequency resources allocated for the RATs, sub-RATs or partitions. Similar to the above, the numerologies and/or resource partition for multiple RATs, sub-RATs or partitions may be predefined or configured by high layer signaling via a MIB, SIB or UE-specific dedicated RRC signaling.

[0043] In embodiments in which numerologies and/or resource partition for multiple RATs, sub-RATs or partitions is predefined or dedicated carriers are allocated for different RATs, a dedicated downlink synchronization signal and

PBCHs may be transmitted on each RAT, sub-RAT or partition. In embodiments in which the numerologies and/or resource partition for multiple RATs, sub-RATs or partitions is configured using a MIB or SIB, a single MIB or SIB may be transmitted on one of the RAT, sub-RAT or partition. After successfully decoding the MIB or SIB, the UEs may be able to derive the resource information or numerologies for other RATs, sub-RATs or partitions. Thus, information provided from the eNB to the UE via a single transmission in a particular RAT, sub-RAT or partition may enable communications using different RATs, sub-RATs or partitions.

[0044] Particular RATs/sub-RATs/partitions may be used for different types of communications, with each having independently sized resource blocks. For example, as shown, the resources in a first partition 312 may be used for low-latency communications while the resources in a second partition 314 may be used for low energy communications. The first and second partitions 312, 314 may be multiplexed, as shown, using FDM such that the first and second partitions 312, 314 occupy the same time but different frequency resources. The first partition 312 may be associated with low latency communications in which the UE operates in a low latency mode and may have a short symbol duration and TTI, while the second partition 314 may be associated with low energy communications in which the UE operates in a low energy mode and may have a long symbol duration and TTI.

[0045] Other sub-RATs 316, 318 may similarly be FDM multiplexed with the first and second partitions 312, 314 and TDM multiplexed with each other. The sub-RATs 316, 318 may have a symbol duration and TTI between those associated with the first and second partitions 312, 314.

[0046] The RATs 320, 330 for the mid- and high- frequency band may be supported simultaneously with each other and the RAT 310 for low frequency band, while maintaining TTI boundary alignment between the different RATs 310, 320, 330. The RATs 320, 330 may similarly be FDM multiplexed with the first and second partitions 312, 314 and sub-RATs 316, 318. The RATs 320, 330 may have a symbol duration and TTI smaller than those associated with the first partition 312. As shown in FIG. 3, in some embodiments, the amount of temporal and/or frequency resources associated with the different RATs, sub-

RATs and partitions may differ among the different types, and the same type may be associated either with different amounts of temporal and/or frequency resources (e.g., as partitions 312, 314) or the same amount of temporal and/or frequency resources (e.g., as sub-RATs 316, 318). A given frequency and temporal range may be associated with a particular frame and symbol structure (as well as subcarrier spacing and symbol duration), with the frame and symbol structures of the frequency and temporal range independent of the frame and symbol structures of other frequency and temporal ranges.

[0047] FIG. 4 illustrates a unified frame structure in accordance with some embodiments. The unified frame structure contains frames 400, subframes 410, slots 420 and symbols 430. More specifically, each frame 400 may contain L subframes of equal duration and have an overall duration of X ms. Each subframe 410 may similarly comprise N slots of equal duration and have an overall duration of Y ms. Each slot may, in turn, comprise M symbols of equal duration. The slot and symbol durations may be different between subframes of different RATs depending on specific use cases, frequency bands and deployment scenarios. The frame structure of each of RAT may be independent of the frame structure of the other RATs. Thus, a particular RAT may have one or more of different L, N and/or M values, as well as different X and/or Y values, as the other RATs. This may also apply to the sub-RATs and partitions shown in FIG. 3.

[0048] FIG. 5 illustrates a Transmission Time Interval (TTI) boundary alignment in accordance with some embodiments. In some embodiments of the unified frame structure, it may be beneficial from a simplified design standpoint to periodically align the TTI boundary 530 between different RATs 510, 520, e.g., at a particular subframe or frame boundary after a predetermined number of subframes or frames. Thus, in some embodiments an integral number of TTIs 540 of a RAT 510 having a smaller TTI duration (low latency RAT) may be disposed within a single TTI 550 of a RAT 520 having a larger TTI duration. In the example shown in FIG. 5, the smaller TTI duration RAT 510 may have a TTI 540 of 0.1ms while the larger TTI RAT 520 may have a TTI 550 of 1ms. By implementing a TTI of 1ms, a low latency RAT TTI may align with the existing LTE specification TTI boundary. Having a common TTI boundary may support

cross-carrier/RAT scheduling for high frequency band RATs from low frequency band RATs based an anchor booster architecture. This is to say that, in some embodiments for cross-carrier/RAT scheduling, as shown a common PDCCH may be used to schedule other RATs, with the UE switching to a particular RAT to obtain the scheduling and then switching to another RAT to communicate and perhaps to obtain further scheduling information using that RAT. In some embodiments, the other RAT may contain a PDCCH for additional scheduling, while in other embodiments the other RAT may not contain a PDCCH, in which case the UE may periodically switch to the scheduling RAT to obtain scheduling information for the other RAT. In some embodiments, a UE may obtain initial scheduling information (e.g., when it initially powers on or otherwise accesses the eNB) from the initial RAT (e.g., a conventional 4G system RAT) and from then on, after switching to its assigned RAT, obtains scheduling information using that RAT. In other embodiments, each RAT may contain a PDCCH and scheduling is performed for the UE operating on the RAT. A licensed low frequency band RAT may provide reliable coverage for control signaling as an anchor cell, using the PDCCH shown in FIG. 5, while a high frequency band RAT may provide opportunistic boosting in data rate when channel conditions are favorable as booster cell.

[0049] FIG. 6 illustrates a symbol structure in accordance with some embodiments. FIG. 6 shows an OFDM symbol 610 and a unique word (UW) OFDM symbol 620. Each OFDM symbol 610 may contain a cyclic prefix (CP) 612 that comprises a replication of the initial portion of the OFDM symbol 610. The CP 612 may range in size from 1/4 to 1/32 of the symbol period 614. The CP 612 may be disposed at the end of the symbol or outside the symbol, depending on specific waveform, thereby creating a guard between the symbol and the adjacent symbol. In some embodiments, when OFDM downlink and SC-FDMA uplink waveforms are selected for a 5G RAT, the CP 612 may be inserted outside the symbol 610. In embodiments in which a UW OFDM symbol 620 or UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM) symbol is used, the UW 622 may be inserted within one symbol duration 624. The symbol structure may be independent for each of the RATs, such that whether or not a particular RAT a

CP or UW and whether the CP or UW is outside or within a symbol is independent of the symbol structure of any other RAT.

[0050] As shown in FIG. 6, the UW-OFDM 620 may be used to support different UW lengths based on different channel delay spreads while maintaining the same symbol duration (or FFT size). This enables both shorter UW 622 and longer UW 626 to be used in the same size symbol 624 as the UW 622, 624 is inserted within the FFT instead of being adding after the FFT size. The ability to maintain the same symbol duration may provide a greater flexibility to support a unified RAT design. In one example, using an OFDM symbol for a low frequency band (below 6GHz), a subcarrier spacing of 60KHz (i.e., K = 4, Δf =60KHz) may be used to achieve a 0.1ms TTI. This translates to OFDM symbols of T=16.7μs (66.7μs/K). Thus, 5 OFDM symbols may be able to be accommodated within one subframe (83.5μs) with a CP length of approximately 3.3μs (0.1ms - 83.5μs =16.5μs/5 CPs).

[0051] FIG. 7 illustrates frame structures within a TTI in accordance with some embodiments. In FIG. 7, various TTIs 710, 720, 730, 740 are illustrated in which the TTIs 710, 720, 730, 740 comprise UW-OFDM waveforms. The first TTI 710 shown in FIG. 7 may comprise a UW 712 and symbol 714 of typical length. In this example, the subcarrier spacing may be 15KHz and the symbol duration 716 may be 66.7μs. A total of 3 OFDM symbols 716 may be present in a TTI 710 of 200μs.

[0052] The second TTI 720 shown in FIG. 7 may comprise a low latency TTI 720 with short symbol duration. Such a TTI 720 can be used for use cases such as mission critical MTC applications and Vehicle–to-Vehicle applications, among others. The UW 722 and symbol 724 may each be smaller than the first TTI 710. In this example, the subcarrier spacing may be 30KHz and the symbol duration 726 may be 33.3μs. For a TTI 720 of the same length as the first TTI (e.g., 200μs), a total of 6 short OFDM symbols 726 may be present.

[0053] The third TTI 730 shown in FIG. 7 may comprise another low latency TTI 730 similar to the low latency TTI 720. The UW 732 and symbol 734 may each be smaller than the first TTI 710, the subcarrier spacing may be 30KHz and the symbol duration 736 may be 33.3μs. However, in this example

the TTI 730 may only be half the length as the first TTI (i.e., 100μs), corresponding to a total of 3 short OFDM symbols 736.

[0054] The fourth TTI 740 shown in FIG. 7 may comprise a low energy TTI 740, e.g., for use by MTC UEs. The UW 742 and symbol 744 may each have a longer duration smaller than the first TTI 710. In one example, the subcarrier spacing may be 5KHz and the symbol duration 746 may be 200μs. In this example, the TTI 740 may be 1ms, corresponding to a total of 5 long OFDM symbols 746.

[0055] The above TTIs 710, 720, 730, 740 may be FDM or TDM multiplexed based on the FRAT design. One or more of the UW-OFDM waveforms may be replaced by other waveforms so long as the same symbol duration is maintained. Other examples of OFDM waveforms may include ZT-OFDM and UW-DFTs-OFDM, among others. When different waveforms are used in the same carrier, multi-RATs can be supported where each RAT may have different waveform design. In some embodiments, existing LTE waveforms may be reused, i.e., OFDM waveforms may be used for downlink and SC-FDMA waveforms may be used for uplink communications. In some embodiments, OFDM may be used both downlink and uplink communications. In some embodiments, UW-based waveforms may be used both downlink and uplink communications. For example, UW-OFDM waveforms may be used for downlink communications and UW-DFT-s-OFDM waveforms may be used for uplink communications or either UW-OFDM or UW-DFT-s-OFDM waveforms may be used for both downlink and uplink communications. In some embodiment, filtered OFDM and filter-bank multiple carrier (FBMC) may be used. FBMC waveforms are produced using a nonrectangular sub-channel pulse shape in the time domain during OFDM-offset quadrature amplitude modulation (OQAM) transmission (in which the real part of QAM symbols are mapped to ½ of the multi-carrier symbols and the imaginary parts are mapped to an interlaced 1/2 of the multi-carrier symbols) and may lack a CP.

[0056] Tables 1-3 below illustrate various examples of 5G numerology.

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform

<3GHz (low power or MTC)	1.5KHz	10ms	OFDM	SC-FDMA
<3GHz	15KHz	1ms	OFDM	SC-FDMA
[3-6]GHz	75KHz	0.2ms	UW-OFDM	UW-DFT-s-OFDM
[6-30]GHz	480KHz	0.1ms	UW-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	DFT-s-OFDM	DFT-s-OFDM

Table 1: First 5G numerology example

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform
<3GHz (low power or MTC)	1.5KHz	10ms	UW-OFDM	UW-OFDM
<3GHz	15KHz	1ms	UW-OFDM	UW-OFDM
[3-6]GHz	75KHz	0.2ms	UW-OFDM	UW-OFDM
[6-30]GHz	480KHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	OFDM	OFDM

Table 2: Second 5G numerology example

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform
<3GHz (low power or MTC)	1.5KHz	10ms	OFDM	OFDM
<3GHz	15KHz	1ms	OFDM	OFDM
[3,6]GHz	75KHz	0.2ms	OFDM	OFDM
[6,30]GHz	480KHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM

Table 3: Third 5G numerology example

[0057] FIGS. 8A and 8B illustrate flowcharts of a uniform framework utilization method in accordance with some embodiments. FIG. 8A in particular illustrates a flowchart of a uniform framework utilization method of an eNB such as the eNB shown in FIGS. 1 or 2 in accordance with some embodiments. As shown in FIG. 8A, the eNB may determine the unified framework at operation 802. The unified framework may include access scheme, modulation

scheme, frame structure, symbol structure, and configurable numerology including subcarrier spacing and symbol duration. The different frame and symbol structures may be associated with different temporal and/or frequency resources multiplexed respectively in a TDM or FDM manner.

[0058] At operation 804, the eNB may communicate specific unified framework configuration information of a particular RAT to one or more UEs serviced by the eNB. Different RAT information may be provided to different UEs attached to the eNB, in which different RATs may be associated with different frequency bands and/or time spans. The eNB may determine the configuration information to be provided to a particular UE based on the device type and/or data to be communicated between the UE and the eNB. The frequency bands may include both licensed and unlicensed frequency bands. The RAT information may include access and modulation scheme, frame and symbol structure, as well as numerology. The RAT information may also include resource allocation and partition information. The unified framework configuration information provided to each UE may be independent of the unified framework configuration information provided to any other UE. The RAT indicated by the eNB to the UE may be dependent on the type and/or operating mode of the UE.

[0059] The eNB may communicate with the UE at operation 806 using the RAT provided at operation 804. The information may include data and/or control information. For example, downlink communications from the eNB to the UE may include paging or control signals for channel estimation on the PDCCH and voice or video data from another UE on the PDSCH. The RAT information may be provided using a dedicated RAT that is different from the RAT used for communication with the UE or using a dedicated carrier on the RAT used for communication with the UE.

[0060] The eNB may, subsequent to communicating with the UE, receive an indication from the UE of a change of operating state of the UE at operation 808. The UE may, for example, be configured to operate in one or more of a normal mode, a low latency and low energy mode. The eNB may, at operation 804, assign the RAT to the UE based on the initial mode of the UE and

determine that an update of the operation mode of the UE has occurred at operation 808.

[0061] In response to determining at operation 808 that an update of the operation mode of the UE has occurred, the eNB may determine a new RAT and transmit the updated unified framework configuration information of the new RAT to the UE at operation 810. The new RAT may include a different frame and/or symbol structure and use a different frequency spectrum and/or time range. The eNB may then continue to communicate with the UE at operation 806.

[0062] FIG. 8B illustrates a uniform framework utilization method as performed by a UE in accordance with some embodiments. The UE may be the UE shown in FIGS. 1 or 2 and may attach to the eNB prior to communicating data. During the attachment, the UE may transmit the initial operation conditions to the eNB at operation 812. In particular, the UE may provide a UE type and/or operating mode during attachment. For example, the UE may be a MTC UE. The UE may moreover be configured to operate in a low latency and/or low energy mode. In some embodiments, a MTC UE may operate in an enhanced coverage, low energy mode.

[0063] In response to transmitting the operating conditions, unified framework configuration (RAT) information may be received by a particular UE at operation 814. The RAT information may be dependent on the type and/or operating mode of the UE. The RAT may be associated with a particular frequency band and/or time range. For example, when the UE operates in the low latency mode, a larger subcarrier spacing and shorter symbol duration may be indicated by the unified framework configuration information; while when the UE operates in the low energy mode, a smaller subcarrier spacing and longer symbol duration may be indicated by the unified framework configuration information.

[0064] Once the RAT received by the UE, the UE may then communicate using the RAT at operation 816. The UE may, for example, adjust FFT operating conditions and processing to meet the RAT information provided at operation 814. The UE may communicate with the eNB or may communicate directly with other UEs using device-to-device communication (D2D)

communication. The information may include uplink and downlink data and/or control information. For example, the information may include uplink communications of voice or video data for another UE or measurements of control signals for channel estimation.

[0065] The UE may, subsequent to communicating with the eNB, determine that a change of operating conditions is warranted at operation 818. For example, the UE may transition between the normal and enhanced coverage/low energy mode dependent on UE location, or between the normal and low latency mode dependent on the type of communication to transmit.

[0066] In response to determining that a change of operating conditions is warranted at operation 818, at operation 820 the UE may transmit an indication to the eNB indicating the change of operating state of the UE. The UE may instead determine that a change of operating conditions is desired at operation 820 and wait to change operating state until a new RAT is assigned to the UE.

[0067] In response to transmitting the indication at operation 820, the UE may return to operation 814 and receive a new RAT at operation 810. The new RAT may include a different frame and/or symbol structure and use a different frequency spectrum and/or time range. The eNB may then continue to communicate with the UE at operation 816.

[0068] Various examples of the disclosure are provided below. These examples are not intended to in any way limit the disclosure herein. In Example 1, user equipment (UE) may comprise processing circuitry configured to: configure a transceiver to receive a resource allocation from a network using a first Radio Access Technology (RAT), the first RAT selected from a plurality of RATs of a flexible RAT (FRAT) employed by the network, the plurality of RATs of the FRAT each comprising configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resources, the transceiver configurable to communicate using the plurality of RATs and configure the subcarrier spacing and symbol duration based on the numerology; and configure the transceiver to communicate using the first RAT.

[0069] In Example 2, the subject matter of Example 1 can optionally include that the processing circuitry is further configured to configure the transceiver to receive from an enhanced NodeB (eNB) higher layer signaling associated with the FRAT, the higher layer signaling indicating numerologies, resource allocation and partition information in at least one of a time and frequency domain.

[0070] In Example 3, the subject matter of one or any combination of Examples 1-2 can optionally include that the FRAT comprises a base subcarrier spacing and symbol duration, and at least one of the subcarrier spacing and symbol duration for different RATs of the FRAT is respectively specified as an integer number of the base subcarrier spacing or symbol duration.

[0071] In Example 4, the subject matter of one or any combination of Examples 1-3 can optionally include that the UE is a Machine-Type Communication (MTC) UE configured to operate in at least one of a low latency and low energy mode, and the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode.

[0072] In Example 5, the subject matter of one or any combination of Examples 1-4 can optionally include that at least one of the plurality of RATs of the FRAT comprises at least one of a plurality of sub-RATs and partitions, each of the at least one of the plurality of sub-RATs and partitions comprising an independent configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resource, and the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using at least one of a Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), Code-Division Multiplexing (CDM), and Spatial Division Multiplexing (SDM).

[0073] In Example 6, the subject matter of one or any combination of Examples 1-6 can optionally include that the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using TDM, and numerologies, resource allocation and partition information in a time domain are at least one of predefined or configured by higher-layer signaling via Master

Information Block (MIB), System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling, or the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using FDM, guard bands are inserted at an edge of frequency resources allocated for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions, and at least one of numerologies and resource partition for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are at least one of predefined or configured by the higher-layer signaling.

[0074] In Example 7, the subject matter of one or any combination of Examples 1-6 can optionally include that a Transmission Time Interval (TTI) boundary between different RATs of the plurality of RATs is common, and the plurality of RATs comprise a common reference TTI duration.

[0075] In Example 8, the subject matter of one or any combination of Examples 1-7 can optionally include that a symbol structure of each of the plurality of RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the plurality of RATs is independent of the symbol structure of the other RATs. ‘

[0076] In Example 9, the subject matter of one or any combination of Examples 1-8 can optionally include that the processing circuitry is further configured to configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

[0077] In Example 10, the subject matter of one or any combination of Examples 1-9 can optionally include that a frame structure in each of the plurality of RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and the frame structure of each of the plurality of RATs is independent of the frame structure of the other RATs.

[0078] In Example 11, the subject matter of one or any combination of Examples 1-10 can optionally include that the processing circuitry is further configured to configure the transceiver to receive numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[0079] In Example 12, the subject matter of one or any combination of Examples 1-11 can optionally include that the processing circuitry is configured to configure the transceiver to receive numerologies, resource allocation and partition information via a dedicated carrier in the first RAT, a dedicated carrier allocated for each of the plurality of RATs, and a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the plurality of RATs.

[0080] In Example 13, the subject matter of one or any combination of Examples 1-12 can optionally include an antenna configured to transmit and receive communications between the transceiver and the eNB.

[0081] Example 14 comprises an apparatus of an eNode B (eNB) comprising processing circuitry configured to: configure a transceiver to transmit resource allocations for different Radio Access Technologies (RATs) to a plurality of user equipment (UE), at least two of the UEs associated with a different RAT, each RAT comprising an independent subcarrier spacing, symbol duration, frame structure and symbol structure; and configure the transceiver to communicate with each UE using the RAT associated with the UE.

[0082] In Example 15, the subject matter of Example 14 can optionally include that the processing circuitry is configured to configure the transceiver to transmit higher layer signaling indicating numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a same RAT to each of the plurality of UEs.

[0083] In Example 16, the subject matter of one or any combination of Examples 14-15 can optionally include that the processing circuitry is

configured to configure the transceiver to transmit numerologies, resource allocation and partition information via a dedicated carrier allocated for each of the RATs, and a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the RATs.

[0084] In Example 17, the subject matter of one or any combination of Examples 14-16 can optionally include that at least one of the subcarrier spacing and symbol duration for each of the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration.

[0085] In Example 18, the subject matter of one or any combination of Examples 14-17 can optionally include that the RATs comprise a first RAT comprising a larger subcarrier spacing and shorter symbol duration configured for a UE operating in a low latency mode and a second RAT comprising a smaller subcarrier spacing and longer symbol duration configured for a UE operating in a low energy mode.

[0086] In Example 19, the subject matter of one or any combination of Examples 14-18 can optionally include that a Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration.

[0087] In Example 20, the subject matter of one or any combination of Examples 14-19 can optionally include that a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the RATs is independent of the symbol structure of the other RATs.

[0088] In Example 21, the subject matter of one or any combination of Examples 14-20 can optionally include that the processing circuitry is configured to at least one of: configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

[0089] In Example 22 a non-transitory computer-readable storage medium that stores instructions for execution by one or more processors of a user equipment (UE) to configure the UE to communicate with an enhanced Node B (eNB), the one or more processors to configure the UE to: receive resource allocation, partition information and numerology, including subcarrier spacing and symbol duration, for a first Radio Access Technology (RAT) of a plurality of RATs used by the eNB, the UE configurable to configure the subcarrier spacing and symbol duration based on the numerology and to communicate using the plurality of RATs; and communicate using the first RAT.

[0090] In Example 23, the subject matter of Example 22 can optionally include that at least one of: a) at least one of the subcarrier spacing and symbol duration for the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration, b) the UE is configured to operate in at least one of a low latency and low energy mode, and the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode, and c) a Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration.

[0091] In Example 24, the subject matter of one or any combination of Examples 22-23 can optionally include that at least one of: a) a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the RATs is independent of the symbol structure of the other RATs, and b) a frame structure in each of the RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and the frame structure of each of the RATs is independent of the frame structure of the other RATs.

[0092] In Example 25, the subject matter of one or any combination of Examples 22-24 can optionally include that the numerology, resource allocation and partition information is received via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[0093] Although an embodiment has been described with reference to specific example embodiments, it will be evident that various modifications and changes may be made to these embodiments without departing from the broader spirit and scope of the present disclosure. Accordingly, the specification and drawings are to be regarded in an illustrative rather than a restrictive sense. The accompanying drawings that form a part hereof show, by way of illustration, and not of limitation, specific embodiments in which the subject matter may be practiced. The embodiments illustrated are described in sufficient detail to enable those skilled in the art to practice the teachings disclosed herein. Other embodiments may be utilized and derived therefrom, such that structural and logical substitutions and changes may be made without departing from the scope of this disclosure. This Detailed Description, therefore, is not to be taken in a limiting sense, and the scope of various embodiments is defined only by the appended claims, along with the full range of equivalents to which such claims are entitled.

[0094] Such embodiments of the inventive subject matter may be referred to herein, individually and/or collectively, by the term “invention” merely for convenience and without intending to voluntarily limit the scope of this application to any single invention or inventive concept if more than one is in fact disclosed. Thus, although specific embodiments have been illustrated and described herein, it should be appreciated that any arrangement calculated to achieve the same purpose may be substituted for the specific embodiments shown. This disclosure is intended to cover any and all adaptations or variations of various embodiments. Combinations of the above embodiments, and other embodiments not specifically described herein, will be apparent to those of skill in the art upon reviewing the above description.

[0095] In this document, the terms "a" or "an" are used, as is common in patent documents, to include one or more than one, independent of any other instances or usages of "at least one" or "one or more." In this document, the term "or" is used to refer to a nonexclusive or, such that "A or B" includes "A but not B," "B but not A," and "A and B," unless otherwise indicated. In this document, the terms "including" and "in which" are used as the plain-English equivalents of the respective terms "comprising" and "wherein." Also, in the following claims, the

terms "including" and "comprising" are open-ended, that is, a system, UE, article, composition, formulation, or process that includes elements in addition to those listed after such a term in a claim are still deemed to fall within the scope of that claim. Moreover, in the following claims, the terms "first," "second," and "third," etc. are used merely as labels, and are not intended to impose numerical requirements on their objects.

[0096] The Abstract of the Disclosure is provided to comply with 37 C.F.R. §1.72(b), requiring an abstract that will allow the reader to quickly ascertain the nature of the technical disclosure. It is submitted with the understanding that it will not be used to interpret or limit the scope or meaning of the claims. In addition, in the foregoing Detailed Description, it can be seen that various features are grouped together in a single embodiment for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed embodiments require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter lies in less than all features of a single disclosed embodiment. Thus the following claims are hereby incorporated into the Detailed Description, with each claim standing on its own as a separate embodiment.

CLAIMS

What is claimed is:

1. User equipment (UE) comprising:

processing circuitry configured to:

configure a transceiver to receive a resource allocation from a network using a first Radio Access Technology (RAT), the first RAT selected from a plurality of RATs of a flexible RAT (FRAT) employed by the network, the plurality of RATs of the FRAT each comprising configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resources, the transceiver configurable to communicate using the plurality of RATs and configure the subcarrier spacing and symbol duration based on the numerology; and

configure the transceiver to communicate using the first RAT.

2. The UE of claim 1, wherein the processing circuitry is configured to:

configure the transceiver to receive from an enhanced NodeB (eNB) higher layer signaling associated with the FRAT, the higher layer signaling indicating numerologies, resource allocation and partition information in at least one of a time and frequency domain.

3. The UE of claim 1, wherein:

the FRAT comprises a base subcarrier spacing and symbol duration, and

at least one of the subcarrier spacing and symbol duration for different RATs of the FRAT is respectively specified as an integer number of the base subcarrier spacing or symbol duration.

4. The UE of claim 3, wherein:

the UE is a Machine-Type Communication (MTC) UE configured to operate in at least one of a low latency and low energy mode, and

the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller

subcarrier spacing and longer symbol duration when the UE operates in the low energy mode.

5. The UE of claim 1, wherein:

at least one of the plurality of RATs of the FRAT comprises at least one of a plurality of sub-RATs and partitions, each of the at least one of the plurality of sub-RATs and partitions comprising an independent configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resource, and

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using at least one of a Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), Code-Division Multiplexing (CDM), and Spatial Division Multiplexing (SDM).

6. The UE of claim 5, wherein one of:

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using TDM, and numerologies, resource allocation and partition information in a time domain are at least one of predefined or configured by higher-layer signaling via Master Information Block (MIB), System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling, or

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using FDM, guard bands are inserted at an edge of frequency resources allocated for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions, and at least one of numerologies and resource partition for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are at least one of predefined or configured by the higher -layer signaling.

7. The UE of claim 1, wherein:

a Transmission Time Interval (TTI) boundary between different RATs of the plurality of RATs is common, and

the plurality of RATs comprise a common reference TTI duration.

8. The UE of claim 1, wherein:

a symbol structure of each of the plurality of RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the plurality of RATs is independent of the symbol structure of the other RATs.

9. The UE of claim 1, wherein the processing circuitry is configured to at least one of:

configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and

configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

10. The UE of claim 1, wherein:

a frame structure in each of the plurality of RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and

the frame structure of each of the plurality of RATs is independent of the frame structure of the other RATs.

11. The UE of claim 1, wherein the processing circuitry is configured to:

configure the transceiver to receive numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

12. The UE of claim 1, wherein:

the processing circuitry is configured to configure the transceiver to receive numerologies, resource allocation and partition information via a dedicated carrier in the first RAT, a dedicated carrier allocated for each of the plurality of RATs, and

a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the plurality of RATs.

13. The UE of claim 1, further comprising an antenna configured to transmit and receive communications between the transceiver and the eNB.

14. An apparatus of an eNode B (eNB) comprising:

processing circuitry configured to:

configure a transceiver to transmit resource allocations for different Radio Access Technologies (RATs) to a plurality of user equipment (UE), at least two of the UEs associated with a different RAT, each RAT comprising an independent subcarrier spacing, symbol duration, frame structure and symbol structure; and

configure the transceiver to communicate with each UE using the RAT associated with the UE.

15. The apparatus of claim 14, wherein the processing circuitry is configured to:

configure the transceiver to transmit higher layer signaling indicating numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a same RAT to each of the plurality of UEs.

16. The apparatus of claim 14, wherein the processing circuitry is configured to:

configure the transceiver to transmit numerologies, resource allocation and partition information via a dedicated carrier allocated for each of the RATs, and

a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the RATs.

17. The apparatus of claim 14, wherein:

at least one of the subcarrier spacing and symbol duration for each of the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration.

18. The apparatus of claim 14, wherein:

the RATs comprise a first RAT comprising a larger subcarrier spacing and shorter symbol duration configured for a UE operating in a low latency mode and a second RAT comprising a smaller subcarrier spacing and longer symbol duration configured for a UE operating in a low energy mode.

19. The apparatus of claim 14, wherein:

a Transmission Time Interval (TTI) boundary between the RATs is common, and

the RATs comprise a common reference TTI duration.

20. The apparatus of claim 14, wherein:

a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the RATs is independent of the symbol structure of the other RATs.

21. The apparatus of claim 14, wherein the processing circuitry is configured to at least one of:

configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and

configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

22. A non-transitory computer-readable storage medium that stores instructions for execution by one or more processors of a user equipment (UE) to configure the UE to communicate with an enhanced Node B (eNB), the one or more processors to configure the UE to:

receive resource allocation, partition information and numerology, including subcarrier spacing and symbol duration, for a first Radio Access Technology (RAT) of a plurality of RATs used by the eNB, the UE configurable to configure the subcarrier spacing and symbol duration based on the numerology and to communicate using the plurality of RATs; and

communicate using the first RAT.

23. The medium of claim 22, wherein at least one of:

a) at least one of the subcarrier spacing and symbol duration for the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration,

b) the UE is configured to operate in at least one of a low latency and low energy mode, and

the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode, and

c) a Transmission Time Interval (TTI) boundary between the RATs is common, and

the RATs comprise a common reference TTI duration.

24. The medium of claim 22, wherein at least one of:

a) a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the RATs is independent of the symbol structure of the other RATs, and

b) a frame structure in each of the RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and

the frame structure of each of the RATs is independent of the frame structure of the other RATs.

25. The medium of claim 22, wherein:

the numerology, resource allocation and partition information is received via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[Continued on next page]

(54) Title: IDENTIFICATION OF DOWNLINK MESSAGES USING REPEATED TRANSMISSION

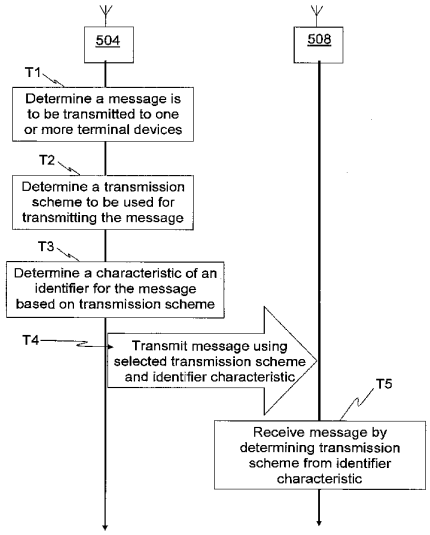

Fig. 9

(57) Abstract: A wireless telecommunication system comprises a base station arranged to communicate messages to one or more terminal devices over a radio interface. The radio interface has a radio frame structure comprising a plurality of subframes, wherein a message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes (e.g. one subframe) or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes (e.g. with repeat transmissions in a plurality of subframes). The message is transmitted in association with an identifier to indicate a terminal device to which the message is addressed. A characteristic for the identifier, for example a value or control region search space for the identifier, is dependent on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme. A terminal device to which the message is addressed determines the transmission scheme from the characteristic of the identifier and receives the message accordingly.

IDENTIFICATION OF DOWNLINK MESSAGES USING REPEATED TRANSMISSION

BACKGROUND

Field

The present disclosure relates to telecommunications apparatus and methods. In particular, certain embodiments relate to schemes for communicating allocations of transmission resources of a shared channel in a wireless telecommunications system.

Description of Related Art

The "background" description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description which may not otherwise qualify as prior art at the time of filing, are neither expressly or impliedly admitted as prior art against the present invention.

Mobile communication systems have evolved over the past ten years or so from the GSM System (Global System for Mobile communications) to the 3G system and now include packet data communications as well as circuit switched communications. The third generation partnership project (3GPP) is developing a fourth generation mobile communication system referred to as Long Term Evolution (LTE) in which a core network part has been evolved to form a more simplified architecture based on a merging of components of earlier mobile radio network architectures and a radio access interface which is based on Orthogonal Frequency Division Multiplexing (OFDM) on the downlink and Single Carrier Frequency Division Multiple Access (SC-FDMA) on the uplink.

Third and fourth generation mobile telecommunication systems, such as those based on the 3GPP defined UMTS and Long Term Evolution (LTE) architecture are becoming able to support more sophisticated services than simple voice and messaging services offered by previous generations of mobile telecommunication systems. For example, with the improved radio interface and enhanced data rates provided by LTE systems, a user is able to enjoy high data rate applications such as mobile video streaming and mobile video conferencing that would previously only have been available via a fixed line data connection. The demand to deploy third and fourth generation networks is therefore strong and there is a corresponding desire to extend the coverage available in such telecommunications systems (i.e. there is a desire to provide more reliable access to wireless telecommunications systems for terminal devices operating in coverage-limited locations).

A typical example of a coverage-limited terminal device might be a so-called machine type communication (MTC) device, such as a smart meter located in a customer's house and periodically transmitting information back to a central MTC server relating to the customer's consumption of a utility, such as gas, water, electricity and so on. Such a terminal device might operate in a coverage-limited location because, for example, it may be located in a basement or other location with relatively high penetration loss. Further information on characteristics of MTC-type devices can be found, for example, in the corresponding standards, such as ETSI TS 122 368 V10.530 (2011-07) / 3GPP TS 22.368 version 10.5.0 Release 10) [1]. Some typical characteristics of MTC type terminal devices / MTC type data might include, for example, characteristics such as low mobility, high delay tolerance, small data transmissions, infrequent transmission and group-based features, policing and addressing.

In some situations a terminal device in a coverage-limited situation in a particular communication cell served by a base station might be unable to receive communications from the base station unless specific provision is made for it to do so. One way to increase coverage in this situation would be for the base station to increase the power of its transmissions. However, a blanket increase in transmission power from a base station could be expected to give rise to increased interference in neighbouring communication cells. An alternative approach would be for the base station to in effect focus / concentrate its available transmission power budget into a subset of transmission resources (e.g. in terms of frequency) which are selected from within the base station's overall transmission resources and allocated for transmissions to coverage-limited terminal devices. However, this approach can again lead to increased interference in neighbouring cells and may in some cases require increased coordination among base stations to optimise performance.

Another approach for providing coverage extension is to rely on repeated transmissions of signalling in multiple subframes. A terminal device may then combine the signalling received for a plurality of repeated transmissions to increase the likelihood of successfully decoding the signalling, e.g. using chase combining / maximal ratio combining techniques. This repeated transmission approach may be applied for control signalling (e.g. sent on a physical downlink control channel such as PDCCH in LTE) and / or other signalling (e.g. sent on a physical downlink shared channel such as PDSCH in LTE).

One draw-back of a repeated transmission approach for providing coverage extension is a corresponding increase in the amount of transmission resources needed to communicate with terminal devices, particularly in the amount of transmission resources needed to provide control messages to the terminal devices, and the inventors have recognised how this issue can be especially significant for certain types of communications, as discussed further below. There is therefore a need for schemes which can allow for communications with terminal devices to be made over a number of subframes with a reduction in the overall amount of transmission resources needed to support this as compared to conventional techniques.

SUMMARY

According to a first aspect of the present disclosure, there is provided a method of operating a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises receiving a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and receiving a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a second aspect of the present disclosure, there is provided a terminal device for communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the

downlink data channel, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a third aspect of the present disclosure, there is provided circuitry for a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the terminal device to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message

According to a forth aspect of the present disclosure, there is provided a method of operating a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises transmitting a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and transmitting a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a fifth aspect of the present disclosure, there is provided a base station for communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the base station comprises a controller unit and a transceiver unit configured to operate together to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a sixth aspect of the present disclosure, there is provided circuitry for a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the

downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the base station to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

According to a seventh aspect of the present disclosure, there is provided a method of operating a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein the method comprises selecting a characteristic for the identifier in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

According to an eighth aspect of the present disclosure, there is provided a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the base station comprises a controller unit and a transceiver unit configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

According to a ninth aspect of the present disclosure, there is provided circuitry for a base station communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the circuitry comprises a controller element and a transceiver element configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

According to a 10th aspect of the present disclosure, there is provided a method of operating a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission

resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the method comprises determining from an identifier associated with the message that the message is addressed to the terminal device, and further determining from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

According to an 11th aspect of the present disclosure, there is provided a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

According to a twelfth aspect of the present disclosure, there is provided circuitry for a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

Further respective aspects and features are defined by the appended claims.

The foregoing paragraphs have been provided by way of general introduction, and are not intended to limit the scope of the following claims. The described embodiments, together with further advantages, will be best understood by reference to the following detailed description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

A more complete appreciation of the disclosure and many of the attendant advantages thereof will be readily obtained as the same becomes better understood by reference to the following detailed description when considered in connection with the accompanying drawings wherein like reference numerals designate identical or corresponding parts throughout the several views, and wherein:

Figure 1 provides a schematic diagram illustrating an example of a mobile telecommunication system;

Figure 2 provides a schematic diagram illustrating a LTE radio frame;

Figure 3 provides a schematic diagram illustrating an example of a LTE downlink radio subframe;

Figure 4 provides a schematic diagram illustrating a LTE "camp-on" procedure;

Figure 5 schematically represents a wireless telecommunications system according to an embodiment of the disclosure;

Figure 6 schematically represents a series of downlink subframes for communicating with a terminal device operating in the wireless telecommunications system of Figure 5;

Figure 7 schematically represents a series of downlink subframes for communicating with a terminal device operating in the wireless telecommunications system of Figure 5 in accordance with an embodiment of the disclosure;

Figure 8 is a signalling ladder diagram representing communications between a base station and a terminal device operating in accordance with an embodiment of the disclosure; and

Figure 9 is a signalling ladder diagram representing communications between a base station and a terminal device operating in accordance with another embodiment of the disclosure.

DETAILED DESCRIPTION OF THE EMBODIMENTS

Figure 1 provides a schematic diagram illustrating some basic functionality of a mobile telecommunications network / system 100 operating in accordance with LTE principles and which may be adapted to implement embodiments of the disclosure as described further below. Various elements of Figure 1 and their respective modes of operation are well-known and defined in the relevant standards administered by the 3GPP (RTM) body and also described in many books on the subject, for example, Holma H. and Toskala A [2]. It will be appreciated that operational aspects of the telecommunications network which are not specifically described below may be implemented in accordance with any known techniques, for example according to the relevant standards.

The network 100 includes a plurality of base stations 101 connected to a core network 102. Each base station provides a coverage area 103 (i.e. a cell) within which data can be communicated to and from terminal devices 104. Data is transmitted from base stations 101 to terminal devices 104 within their respective coverage areas 103 via a radio downlink. Data is transmitted from terminal devices 104 to the base stations 101 via a radio uplink. The core network 102 routes data to and from the terminal devices 104 via the respective base stations 101 and provides functions such as authentication, mobility management, charging and so on. Terminal devices may also be referred to as mobile stations, user equipment (UE), user terminal, mobile radio, and so forth. Base stations may also be referred to as transceiver stations / nodeBs / e-nodeBs, and so forth.

Mobile telecommunications systems such as those arranged in accordance with the 3GPP defined Long Term Evolution (LTE) architecture use an orthogonal frequency division modulation (OFDM) based interface for the radio downlink (so-called OFDMA) and a single carrier frequency division multiple access scheme (SC-FDMA) on the radio uplink. Figure 2 shows a schematic diagram illustrating an OFDM based LTE downlink radio frame 201. The LTE downlink radio frame is transmitted from a LTE base station

(known as an enhanced Node B) and lasts 10 ms. The downlink radio frame comprises ten subframes, each subframe lasting 1 ms. A primary synchronisation signal (PSS) and a secondary synchronisation signal (SSS) are transmitted in the first and sixth subframes of the LTE frame. A physical broadcast channel (PBCH) is transmitted in the first subframe of the LTE frame.

Figure 3 is a schematic diagram of a grid which illustrates the structure of an example conventional downlink LTE subframe. The subframe comprises a predetermined number of symbols which are transmitted over a 1ms period. Each symbol comprises a predetermined number of orthogonal subcarriers distributed across the bandwidth of the downlink radio carrier.

The example subframe shown in Figure 3 comprises 14 symbols and 1200 subcarriers spread across a 20MHz bandwidth and in this example is the first subframe in a frame (hence it contains PBCH). The smallest allocation of physical resource for transmission in LTE is a resource block comprising twelve subcarriers transmitted over one subframe. For clarity, in Figure 3, each individual resource element is not shown, instead each individual box in the subframe grid corresponds to twelve subcarriers transmitted on one symbol.

Figure 3 shows in hatching resource allocations for four LTE terminals 340, 341, 342, 343. For example, the resource allocation 342 for a first LTE terminal (UE 1) extends over five blocks of twelve subcarriers (i.e. 60 subcarriers), the resource allocation 343 for a second LTE terminal (UE2) extends over six blocks of twelve subcarriers (i.e. 72 subcarriers), and so on.

Control channel data can be transmitted in a control region 300 (indicated by dotted-shading in Figure 3) of the subframe comprising the first "n" symbols of the subframe where "n" can vary between one and three symbols for channel bandwidths of 3MHz or greater and where "n" can vary between two and four symbols for a channel bandwidth of 1.4MHz. For the sake of providing a concrete example, the following description relates to host carriers with a channel bandwidth of 3MHz or greater so the maximum value of "n" will be 3 (as in the example of Figure 3). The data transmitted in the control region 300 includes data transmitted on the physical downlink control channel (PDCCH), the physical control format indicator channel (PCFICH) and the physical HARQ indicator channel (PHICH). These channels transmit physical layer control information. Control channel data can also or alternatively be transmitted in a second region of the subframe comprising a number of subcarriers for a time substantially equivalent to the duration of the subframe, or substantially equivalent to the duration of the subframe remaining after the "n" symbols. The data transmitted in this second region is transmitted on the enhanced physical downlink control channel (EPDCCH). This channel transmits physical layer control information which may be in addition to that transmitted on other physical layer control channels.

PDCCH and EPDCCH contain control data indicating which subcarriers of the subframe have been allocated to specific terminals (or all terminals or subset of terminals). This may be referred to as physical-layer control signalling / data. Thus, the PDCCH and/or EPDCCH data transmitted in the control region 300 of the subframe shown in Figure 3 would indicate that UE1 has been allocated the block of resources identified by reference numeral 342, that UE2 has been allocated the block of resources identified by reference numeral 343, and so on.

PCFICH contains control data indicating the size of the control region (i.e. between one and three symbols for channel bandwidths of 3 MHz or greater and between two and four symbols for channel bandwidths of 1.4 MHz).

PHICH contains HARQ (Hybrid Automatic Request) data indicating whether or not previously transmitted uplink data has been successfully received by the network.

Symbols in a central band 310 of the time-frequency resource grid are used for the transmission of information including the primary synchronisation signal (PSS), the secondary synchronisation signal (SSS) and the physical broadcast channel (PBCH). This central band 310 is typically 72 subcarriers wide (corresponding to a transmission bandwidth of 1.08 MHz). The PSS and SSS are synchronisation signals that once detected allow a LTE terminal device to achieve frame synchronisation and determine the physical layer cell identity of the enhanced Node B transmitting the downlink signal. The PBCH carries information about the cell, comprising a master information block (MIB) that includes parameters that LTE terminals use to properly access the cell. Data transmitted to terminals on the physical downlink shared channel (PDSCH), which may also be referred to as a downlink data channel, can be transmitted in other resource elements of the subframe. In general PDSCH conveys a combination of user-plane data and non-physical layer control-plane data (such as Radio Resource Control (RRC) and Non Access Stratum (NAS) signalling). The user-plane data and non-physical layer control-plane data conveyed on PDSCH may be referred to as higher layer data (i.e. data associated with a layer higher than the physical layer).

Figure 3 also shows a region of PDSCH containing system information and extending over a bandwidth of R344. A conventional LTE subframe will also include reference signals which are discussed further below but not shown in Figure 3 in the interests of clarity.

The number of subcarriers in a LTE channel can vary depending on the configuration of the transmission network. Typically this variation is from 72 sub carriers contained within a 1.4MHz channel bandwidth to 1200 subcarriers contained within a 20MHz channel bandwidth (as schematically shown in Figure 3). As is known in the art, data transmitted on the PDCCH, PCFICH and PHICH is typically distributed on the subcarriers across the entire bandwidth of the subframe to provide for frequency diversity. Therefore a conventional LTE terminal must be able to receive the entire channel bandwidth in order to receive and decode the control region.

Figure 4 illustrates a LTE “camp-on” process, that is, the process followed by a terminal so that it can decode downlink transmissions which are sent by a base station via a downlink channel. Using this process, the terminal can identify the parts of the transmissions that include system information for the cell and thus decode configuration information for the cell.

As can be seen in Figure 4, in a conventional LTE camp-on procedure, the terminal first synchronizes with the base station (step 400) using the PSS and SSS in the centre band and then decodes the PBCH (step 401). Once the terminal has performed steps 400 and 401, it is synchronized with the base station.

For each subframe, the terminal then decodes the PCFICH which is distributed across the entire bandwidth of carrier 320 (step 402). As discussed above, a LTE downlink carrier can be up to 20 MHz wide (1200 subcarriers) and a standard LTE-compliant terminal therefore has to have the capability to receive and decode transmissions on a 20 MHz bandwidth in order to decode the PCFICH. Accordingly, at the PCFICH decoding stage, with a 20MHz carrier band, the terminal operates at a larger bandwidth

(bandwidth of R320) than during steps 400 and 401 (bandwidth of R310) relating to synchronization and PBCH decoding.

The terminal then ascertains the PHICH locations (step 403) and decodes the PDCCH (step 404), in particular for identifying system information transmissions and for identifying its dedicated allocation grants. The allocation grants are used by the terminal to locate system information and to locate its data in the PDSCH. Both system information and dedicated allocations are transmitted on PDSCH and scheduled within the carrier band 320. Steps 403 and 404 also require a standard LTE-compliant terminal to operate on the entire bandwidth R320 of the carrier band. Allocation grants may also or alternatively be decoded from EPDCCH.

At steps 402 to 404, the terminal decodes information contained in the control region 300 of a subframe. As explained above, in LTE, the three control channels mentioned above (PCFICH, PHICH and PDCCH) can be found across the control region 300 of the carrier where the control region extends over the range R320 and occupies the first one, two or three OFDM symbols of each subframe as discussed above. In a subframe, typically the control channels do not use all the resource elements within the control region 300, but they are scattered across the entire region, such that a LTE terminal has to be able to simultaneously receive the entire control region 300 for decoding each of the three control channels.

The terminal can then decode the PDSCH (step 405) which contains system information or data transmitted for this terminal.

As explained above, in a LTE subframe the PDSCH generally occupies groups of resource elements which follow the control region. The data in the blocks of resource elements 340, 341, 342, 343 allocated to the different mobile communication terminals (UEs) and the system information data in the block of resources 344 shown in Figure 3 have a smaller bandwidth than the bandwidth of the entire carrier. To decode these blocks a terminal first receives the PDCCH spread across the frequency range R320 and/or the EPDCCH to determine if the (E)PDCCH indicates there are PDSCH resources in the subframe that need to be decoded by the UE. The intended recipient(s) for (E)PDCCH signalling in LTE is established through the use of radio network temporary identifiers (RNTI). (E)PDCCH signalling is addressed to a particular RNTI by using the RNTI to scramble cyclic redundancy check (CRC) bits associated with the (E)PDCCH signalling. Each connected UE in a cell is associated with a Cell RNTI (C-RNTI) that may be used to address PDCCH signalling to that particular UE. In addition there are other RNTIs defined and these may be used to simultaneously address groups of terminal devices. For example, a System Information RNTI (SI-RNTI) is defined and PDSCH transmissions comprising SI are allocated by (E)PDCCH signalling addressed to SI-RNTI. Various other RNTIs are defined for various other types of signalling. Some examples include a random-access RNTI (RA-RNTI), a Paging RNTI (P-RNTI), a Transmit Power Control Physical Uplink Control Channel RNTI (TPC-PUCCH-RNTI) and a Transmit Power Control Physical Uplink Shared Channel-RNTI (TPC-PUSCH-RNTI).

Thus, once a UE has received a downlink subframe, the UE searches for (E)PDCCH signalling associated with any RNTI that apply for the UE in the subframe to identify any corresponding allocations of transmission resources on PDSCH. If there is an allocation message addressed to the UE on (E)PDCCH the UE will proceed to decode the PDSCH in the relevant frequency range (if any) indicated by the PDCCH. So for example, UE 1 discussed above decodes the whole control region 300 to

determine its resource allocation and then extracts the relevant data from the corresponding resource block 342.

Figure 5 schematically shows a telecommunications system 500 according to an embodiment of the disclosure. The telecommunications system 500 in this example is based broadly on a LTE-type architecture. As such many aspects of the operation of the telecommunications system 500 are standard and well understood and not described here in detail in the interest of brevity. Operational aspects of the telecommunications system 500 which are not specifically described herein may be implemented in accordance with any known techniques, for example according to the established LTE-standards and known variations thereof.

The telecommunications system 500 comprises a core network part (evolved packet core) 502 coupled to a radio network part. The radio network part comprises a base station (evolved-nodeB) 504, a first terminal device 506 and a second terminal device 508. It will of course be appreciated that in practice the radio network part may comprise a plurality of base stations serving a larger number of terminal devices across various communication cells. However, only a single base station and two terminal devices are shown in Figure 5 in the interests of simplicity.

As with a conventional mobile radio network, the terminal devices 506, 508 are arranged to communicate data to and from the base station (transceiver station) 504. The base station is in turn communicatively connected to a serving gateway, S-GW, (not shown) in the core network part which is arranged to perform routing and management of mobile communications services to the terminal devices in the telecommunications system 500 via the base station 504. In order to maintain mobility management and connectivity, the core network part 502 also includes a mobility management entity (not shown) which manages the enhanced packet service, EPS, connections with the terminal devices 506, 508 operating in the communications system based on subscriber information stored in a home subscriber server, HSS. Other network components in the core network (also not shown for simplicity) include a policy charging and resource function, PCRF, and a packet data network gateway, PDN-GW, which provides a connection from the core network part 502 to an external packet data network, for example the Internet. As noted above, the operation of the various elements of the communications system 500 shown in Figure 5 may be broadly conventional apart from where modified to provide functionality in accordance with embodiments of the disclosure as discussed herein.

In this example, it is assumed the first terminal device 506 is a conventional smart-phone type terminal device communicating with the base station 504. Thus, and as is conventional, this first terminal device 506 comprises a transceiver unit 506a for transmission and reception of wireless signals and a controller unit 506b configured to control the smart phone 506. The controller unit 506b may comprise a processor unit which is suitably configured / programmed to provide the desired functionality using conventional programming / configuration techniques for equipment in wireless telecommunications systems. The transceiver unit 506a and the controller unit 506b are schematically shown in Figure 5 as separate elements. However, it will be appreciated that the functionality of these units can be provided in various different ways, for example using a single suitably programmed general purpose computer, or suitably configured application-specific integrated circuit(s) / circuitry. As will be appreciated the conventional terminal device 506 will in general comprise various other elements associated with its operating functionality.

In this example, it is assumed the second terminal device 508 is a machine-type communication (MTC) terminal device according to an embodiment of the disclosure and located in an area of restricted coverage. As discussed above, MTC devices may be typically characterised as semi-autonomous or autonomous wireless communication devices communicating small amounts of data. Examples include so-called smart meters which, for example, may be located in a customer's house and periodically transmit information back to a central MTC server data relating to the customer's consumption of a utility such as gas, water, electricity and so on. MTC devices may in some respects be seen as devices which can be supported by relatively low bandwidth communication channels having relatively low quality of service (QoS), for example in terms of latency. It is assumed here the MTC terminal device 508 in Figure 5 is such a device. It will, however, the appreciated that embodiments of the disclosure may also be implemented for other types of terminal device.

As with the smart phone 506, the MTC device 508 comprises a transceiver unit 508a for transmission and reception of wireless signals and a controller unit 508b configured to control the MTC device 508. The controller unit 508b may comprise a processor unit which is suitably configured / programmed to provide the desired functionality described herein using conventional programming / configuration techniques for equipment in wireless telecommunications systems. The transceiver unit 508a and the controller unit 508b are schematically shown in Figure 5 as separate elements for ease of representation. However, it will be appreciated that the functionality of these units can be provided in various different ways, for example using a single suitably programmed general purpose computer, or suitably configured application-specific integrated circuit(s) / circuitry, or using a plurality of discrete circuitry / processing elements for providing different elements of the desired functionality. It will be appreciated the MTC device 508 will in general comprise various other elements associated with its operating functionality in accordance with established wireless telecommunications techniques (e.g. a power source, possibly a user interface, and so forth).

The base station 504 comprises a transceiver unit 504a for transmission and reception of wireless signals and a controller unit 504b configured to control the base station 504. The controller unit 504b may comprise a processor unit which is suitably configured / programmed to provide the desired functionality described herein using conventional programming / configuration techniques for equipment in wireless telecommunications systems. The transceiver unit 504a and the controller unit 504b are schematically shown in Figure 5 as separate elements for ease of representation. However, it will be appreciated that the functionality of these units can be provided in various different ways, for example using a single suitably programmed general purpose computer, or suitably configured application-specific integrated circuit(s) / circuitry or using a plurality of discrete circuitry / processing elements for providing different elements of the desired functionality. It will be appreciated the base station 504 will in general comprise various other elements associated with its operating functionality. For example, the base station 504 will in general comprise a scheduling entity responsible for scheduling communications. The functionality of the scheduling entity may, for example, be subsumed by the controller unit 504b.

Thus, the base station 504 is configured to communicate data with the smart phone 506 over a first radio communication link 510 and communicate data with the MTC device 508 over a second radio communication link 512. Both radio links may be supported within a single radio frame structure associated with the base station 504. It is assumed here the base station 504 is configured to communicate with the smart phone 506 over the first radio communication link 510 in accordance with the

established principles of LTE-based communications and to communicate with the MTC-device 506 over the second radio communication link 512 in accordance with embodiments of the disclosure as described herein. It will be appreciated the base station may readily obtain information indicating the different classes of terminal device which are attached to the base station in accordance with conventional techniques. That is to say, the base station will be aware that the smart phone is of a device class that includes conventional smartphones and the MTC device is of a device class that includes MTC devices. Furthermore, the base station may establish using conventional techniques that the MTC device 508 is a device operating in a coverage limited situation such that steps are needed to increase the likelihood of the MTC device being able to decode downlink transmissions.

As noted above, in a LTE-based wireless telecommunications system some of the fundamental information required for a terminal device to operate in a cell is transmitted on PBCH in the Master Information Block (MIB). Other information regarding the system configuration is divided among System Information Blocks (SIBs) referred to as SIB1, SIB2, SIB3,...etc. (there are 16 SIBs defined as of Release 11 LTE). The SIBs are transmitted in system information (SI) messages, which, apart from SIB1, may contain multiple SIBs (termed first SI, second SI, etc.). There may be one or several SI messages transmitted at different periodicities. Each SI message may convey multiple SIBs suitable for scheduling with the same periodicity. The timings for SIB1 message transmissions are fixed on an 80 ms period and they occur in the fifth subframe of radio frames when System Frame Number (SFN) is a multiple of 8 (i.e. SFN mod 8 = 0). There are retransmissions of SIB1 messages provided in every other radio frame within the 80 ms period. The timings for other SIB transmission messages are configured in SIB1. The transmission resource allocations for the SI messages on PDSCH within a subframe are provided to terminal devices using PDCCH allocation messages addressed to SI-RNTI (System Information Radio Network Temporary Identifier - currently 0xFFFF in LTE). At higher layers, SI is carried on the logical broadcast control channel (BCCH).

In LTE the SI messages are transmitted within periodically occurring time domain windows (referred to as SI-windows) using dynamic scheduling. Each SI message is associated with a SI-window and the SI-windows of different SI messages do not overlap. That is, within one SI-window only the corresponding SI message is transmitted. The length of the SI-window is common for all SI messages, and is configurable. Within the SI-window, the corresponding SI message can be transmitted a number of times in any subframe other than MBSFN (multicast-broadcast single frequency network) subframes, uplink subframes in TDD (time division duplex), and subframe #5 of radio frames for which SFN (system frame number) mod 2 = 0. Terminal devices acquire the detailed time-domain scheduling (and other information, e.g. frequency-domain scheduling, transport format) from decoding SI-RNTI on PDCCH. A single SI-RNTI is used to address SystemInformationBlockType1 as well as all SI messages. SystemInformationBlockType1 configures the SI-window length and the transmission periodicity for the SI messages.

The system information in a cell may be changed, although typically this happens rarely with system information perhaps remaining unchanged for hours, days, or even weeks.

For changes of system information other than those related to EAB (Extended Access Barring), ETWS (Earthquake Tsunami Warning System) and CMAS (Commercial Mobile Alert System), there is a BCCH modification period defined (which may be referred to as a “SI modification period”). SI modification period boundaries are defined on radio frames for which SFN mod q = 0, for a cell-specific value of q.

When there is a change in system information, the new system information is transmitted from the start of a new SI modification period.

The general process for implementing a change in system information in a LTE-based network is described, for example, in Section 5.2.1.3 of ETSI TS 136 331 V11.4.0 (2013-07) / 3GPP TS 36.331 version 11.4.0 Release 11 [3]. In summary, a base station indicates a change of system information as follows.

1. When the network changes system information it notifies terminal devices about the change by transmitting a PDCCH resource allocation message addressed to the paging RNTI (P-RNTI). This directs the terminal devices to decode PDSCH resources containing a Paging message with a SystemInfoModification flag set to true. This may be done, for example, throughout one SI modification period. Both RRC_IDLE and RRC_CONNECTED terminal devices check for paging messages periodically. It may be noted that EAB alterations, ETWS and CMAS notifications may be separately modified with separate flags in a paging message (but can also be modified along with other SIBs).

2. In a following SI modification period, the network transmits the modified system information, and may increment a SystemInfoValueTag in SIB1. This value tag can indicate changes in any SIB, but it might not be used for EAB, ETWS, CMAS and some regularly changing SI parameters such as CDMA2000 system time. Terminal devices can use SystemInfoValueTag to verify if currently stored system information is still valid, for example on return from being out of coverage when the UE may have missed a system information change notification in paging.

More details on system information and changes in system information in a LTE-based system can be found in ETSI TS 136 331 V11.4.0 (2013-07) / 3GPP TS 36.331 version 11.4.0 Release 11 [3].

As discussed above, it has been proposed to improve coverage for terminal devices in a wireless telecommunications system by introducing repetitions of a transmission which a terminal device may combine to provide an increased likelihood of successful decoding.

Figure 6 schematically represents an approach for providing coverage extension through repeated transmissions for an SI message in accordance with existing techniques. Figure 6 schematically shows a sequence of LTE downlink subframes (labelled as subframes "A", "B", "C", …, "L" to aid explanation) with shading to schematically indicate which regions in which subframes are used to convey system information. The subframes represented in Figure 6 comprise four groups of three contiguous subframes with spaces between the groups as schematically indicated by dotted lines and discussed further below. Although not shown in Figure 6, the gaps between the groups comprise a continuing sequence of subframes used for other communications that are not relevant to the system information messaging considered here. As discussed above, each subframe comprises a control region 600 and a PDSCH region 602. The control regions 600 for the respective subframes are labelled in Figure 6 with the identification letter for the relevant subframe, i.e. as 600A, 600B, 600C, etc. The PDSCH regions for the respective subframes are similarly labelled in Figure 6 as 602A, 602B, 602C, etc. Each subframe represented in Figure 6 is in essence a simplified version of what is represented in Figure 3. Thus, the control regions 600 support the PCFICH, PHICH and PDCCH channels as discussed above while the PDSCH regions 602 support user-plane data and system information (among other things) and the EPDCCD if implemented. The most significant aspect of the control region 600 in the context of

embodiments of the present disclosure relate to the PDCCH and so for simplicity the control regions 600 may sometimes be referred to herein as PDCCH regions 600.

Before explaining the repeated transmissions approach to providing coverage extension represented in Figure 6 it is considered helpful to clarify some aspects of the terminology to be used herein. The term "repeat transmission" (and related terms) will be used to refer to a transmission in an individual subframe which is part of a sequence of transmissions that are being repeated for the purposes of providing coverage extension for a message being conveyed between a base station and a terminal device (such as a PDCCH message or a PDSCH message). Thus in a coverage extension context, the transmission of a (E)PDCCH message comprises a plurality of "repeat transmissions" on (E)PDCCH and the transmission of a PDSCH message comprises a plurality of "repeat transmissions" on PDSCH. The term "re-transmission" (and related terms) will be used to refer to the transmission of a message that has already been sent at least once before. These terms should be interpreted accordingly unless the context demands otherwise.

For the example repeat transmission approach to coverage extension represented in Figure 6 it is assumed for ease of representation the approach relies on providing only three repeat transmissions for each PDCCH message and each PDSCH message. It will, however, be appreciated that in practice larger numbers of repeat transmissions will typically be involved, for example there may be tens or hundreds of repeats comprising each message to provide a correspondingly higher degree of coverage extension. Furthermore, it will be appreciated that PDCCH messages and PDSCH messages may comprise different numbers of repeat transmissions (for example because different coding schemes are adopted meaning that different numbers of repeat transmissions are needed for a given probability of successful reception).

Thus, referring to Figure 6, subframes A, B and C are used to signal a PDCCH message addressed to SI-RNTI by sending three repeat PDCCH transmissions in the respective PDCCH regions 600A, 600B, 600C. Each PDCCH repeat transmission addressed to SI-RNTI in the PDCCH regions 600A, 600B, 600C in effect comprises a duplication of the same downlink control information which a terminal device can combine to seek to establish the content of the PDCCH message. For this example repeat-transmission based coverage extension scheme it is assumed a particular type of message subject to repeat transmissions is addressed to the same RNTI (e.g. SI-RNTI for a system information related type of messages) as if the same type of message were subject to conventional single-subframe transmission. However, as discussed further below, in accordance with certain embodiments of the disclosure identifiers having different characteristics (e.g. values) may be used for a given type of message depending on whether the messages to be sent in accordance with a first transmission scheme (e.g. using a conventional single subframe based transmission approach) or a second transmission scheme (e.g. using a repeat-transmission scheme for coverage extension). Furthermore, it will be appreciated the approach of using identifiers associated with a particular type of message having different characteristics according to what transmission scheme is to be used to transmit the message can be used in accordance with embodiments of the disclosure with or without the use of validity periods as disclosed herein.

The PDCCH message comprising the three repeat transmissions in the PDCCH regions of subframes A, B and C indicates resource blocks to be used for a subsequent PDSCH message comprising the transmission of system information. This PDSCH message itself comprises a plurality of repeat transmissions, and, in this example, are represented by shading in the PDSCH regions 602D, 602E and 602F of subframes D, E and F. The transmission resources, for example in terms of specific resource

elements, used to convey the repeat transmissions of the system information message in the PDSCH regions 602D, 602E and 602F are indicated in the corresponding PDCCH message addressed to SI-RNTI and comprising the repeat transmissions in PDCCH regions 600A, 600B, 600C in accordance with conventional resource allocation techniques in the context of coverage extension using repeat transmissions. Whilst the shading in Figure 6 schematically represents the same frequency resources being used for each repeat transmission in the respective PDSCH regions 602D, 602E and 602F of the subframes D, E, F, in principle the repeat-transmission approach may be configured to include frequency hopping for the different repeat transmissions comprising the PDSCH message sent in subframes D, E, F. The nature of any such frequency hopping may be pre-defined, for example it may be pre-specified according to an operating standard for the wireless telecommunications system, or it may be established in previous RRC (radio resource control) signalling, or it may be indicated in the PDCCH message.

As schematically represented in Figure 6 there is a gap between subframes C and D. This follows the currently-proposed approaches for repeat-transmission coverage extension whereby the transmission of a PDSCH message comprising a plurality of repeat transmissions does not start until after all repeat transmissions of the corresponding PDCCH message have been sent. This is to help reduce the buffering requirements at the terminal device. Furthermore, current proposals indicate there should be no overlap between the end of the repeat transmissions comprising the PDCCH message and the start of the repeat transmissions comprising the PDSCH message. It will, however, be appreciated the specific implementation of such aspects of a repeat transmission approach for providing coverage extension are not significant to the principles underlying the present disclosure. That is to say, the principles described herein may equally be implemented in association with other repeat transmission approaches (e.g. with repeat transmissions of PDCCH and its corresponding PDSCH occurring in the same subframe).

In subframes following the transmission of the system information message as schematically indicated in subframes D, E and F in Figure 6, the wireless telecommunications system continues to operate in accordance with its normal operating techniques until subframe G represented. Subframe G represents the beginning of another system information message. As noted above, system information messages can be regularly retransmitted in accordance with LTE techniques, and in this regard the system information message beginning at subframe G is considered in this example to be a re-transmission of the system information message transmitted using subframes A to F as discussed above. The specific timing of the re-transmission of system information (i.e. the timing of subframe G relative to subframe A) may follow any conventional system information re-transmission schedule. The principles underlying the re-transmission of the system information message starting from subframe G follow those described above. Thus, a PDCCH message addressed to SI-RNTI is sent using the PDCCH regions 600G, 600H and 600I of subframes G, H and I to allocate resources for a PDSCH message comprising three repeat transmissions in the PDSCH regions 602J, 602K and 602L in subframes J, K and L as indicated by shading in Figure 6. It may be noted in this example the frequencies of the resource elements for the re-transmission of the system information message on PDSCH in subframes J, K, L is different from that used in subframes D, E, F for the previous transmission, but this is not of any particular significance. Furthermore, the transmissions of the PDSCH message in subframes D, E, F, J, K, L may comprise different so-called redundancy versions of the PDSCH message comprising different combinations of information bits and redundancy bits arising from a forward error correction coding process.

It will be appreciated the transmission resources represented in Figure 6 which are not involved in the SI message signalling discussed above can be used for other communications in the network in the usual manner. In particular, it will be appreciated that although the entirety of the PDCCH regions associated with repeat transmissions of the PDCCH for the system information messages are shown shaded in Figure 6, this is merely to highlight those subframes in which a PDCCH for the system information messages is transmitted compared to those where it is not, and in practice these regions will comprise multiple PDCCH messages addressing different terminal devices for allocating resources for various different types of communication on PDSCH.

System information signalling in LTE is sent on what is approaching a more or less continuous basis. This means there is a considerable amount of PDSCH traffic for broadcasting system information messages comprising the SIBs. There is a corresponding requirement for PDCCH signalling to schedule the PDSCH resources for system information messages. The inventors have recognised that this can become a significant issue in a coverage extension scenario where a number of repetitions are expected, as illustrated in Figure 6. This is because for each PDSCH message comprising a plurality of PDSCH repeat transmissions (i.e. the PDSCH message sent using resources in subframes D, E and F and the PDSCH message sent using resources in subframes J, K and L) there is a corresponding SI-RNTI PDCCH message comprising a plurality of PDCCH repeat transmissions (i.e. the PDCCH message sent using resources in subframes A, B and C and the PDCCH message sent using resources in subframes G, H and I). With the potential for perhaps a hundred or more repeat transmissions to provide coverage extension to the edge of a base station's corresponding cell for system information messages a large fraction of the available control region resources will be needed to support this function following the approach of Figure 6. There is of course a corresponding increase in the use of PDSCH resources with the approach represented in Figure 6, but it is to be expected that in many situations it will be PDCCH resources that are more at a premium owing to the limited resources available in the control channel region for PDCCH and the priority typically given to PDSCH over EPDCCH in the PDSCH region. This is especially likely in networks supporting large numbers of MTC devices since these are likely to have a higher ratio of control signalling to data signalling as compared to the traffic profiles typically associated with conventional terminal devices. The increased PDCCH and/or EPDCCH resources needed to support repeat transmissions of system information messages could ultimately make it difficult to schedule unicast PDSCH transmissions to terminal devices operating within the system because of a lack an availability of control region resources to indicate the allocation of PDSCH resources and/or a lack of PDSCH region resource to indicate the allocation of PDSCH resources.

To address this type of issue there have been proposals to stop using PDCCH and EPDCCH messages resource allocations for PDSCH messages comprising system information (i.e. for system information messages). One proposal (described in the 3GPP document R1-135422, "On the need of PDCCH for SIB and other Common Channel", Mediatek, RAN1#75, San Francisco, November 2013 [4]) is to avoid providing any scheduling information in respect of system information-carrying PDSCH transmissions. Instead, a terminal device will be expected to perform blind searching of the PDSCH region to identify if there are any relevant system information transmissions. A drawback with this approach is a significant increase in the processing load required for terminal devices. To reduce the processing load required at the terminal device to a more manageable level the system information messages could be confined to a restricted subset of transmission resources comprising the PDSCH region. However, this approach still requires additional processing tasks to be performed by the terminal device and introduces reduced

scheduling flexibility. Another proposal (described in the 3GPP document R1-134207, "Coverage enhancement techniques for PBCH", Alcatel-Lucent, Alcatel-Lucent Shanghai Bell, RAN1#74bis, Guangzhou, October 2013 [5]) is to avoid using PDCCH messages to provide scheduling information in respect of system information-carrying PDSCH messages. Instead it is proposed that some of the spare bits currently available in the Master Information Block (MIB) in LTE are used for providing scheduling indications for system information messages. However, there are a limited number of spare bits available for this and so the approach does not allow for any significant degree of flexibility in scheduling system information messages, and furthermore the approach further reduces the number of spare bits available for other uses.

In view of these issues, the inventors have developed an alternative approach for reducing the amount of control signalling required to support resource allocations for higher-layer transmissions in a wireless telecommunications system. In particular, but not exclusively, the inventors have developed an approach which may be applied for reducing the amount of control-channel signalling required to support resource allocations for downlink messages, such as system information messages, and in particular for messages which may be subject to re-transmissions on a defined schedule and which may, in some cases, be sent using a repeat transmission approach to provide a degree of coverage extension.

Figure 7 is similar to, and represents various aspects that will be understood from, Figure 6, but shows an approach in accordance with certain embodiments of the present disclosure. Figure 8 is a signalling ladder diagram schematically representing modes of operation for the terminal device 508 and the base station 504 schematically represented in Figure 5 in accordance with some embodiments of the present disclosure for implementing an approach of the kind represented in Figure 7. In broad summary, some embodiments of the disclosure introduce the concept of a validity period for a PDCCH message to thereby indicate transmission resources that may be used for a plurality of PDSCH messages within the validity period. That is to say the control message transmitted on the PDCCH is considered valid for a period that is longer than the period needed to transmit a single PDSCH message (whether in one subframe or with repeat transmissions in a plurality of subframes to provide coverage extension). This means multiple PDSCH messages can in effect be scheduled using the control-region resources of only a single PDCCH message. There are various different ways in which the validity period may be established/determined, as discussed further below.

For the example represented in Figure 7, and as with Figure 6, it is assumed system information is being transmitted from a base station to a terminal device with a repeat transmission approach to providing coverage extension. Again the example approach to coverage extension represented in Figure 7 is assumed for ease of representation to rely on providing only three repeat transmissions for each PDCCH and PDSCH message. However, as noted above, it will be appreciated that in practice larger numbers of repeat transmissions will typically be involved, for example there may be tens or hundreds of repeats comprising each message to provide a correspondingly higher degree of coverage extension. Furthermore, it will be appreciated that PDCCH messages and PDSCH messages need not necessarily comprise the same number of repeat transmissions (for example different coding schemes may be adopted meaning that different numbers of repeat transmissions are appropriate to provide a desired probability of successful reception for each message).

Thus Figure 7 schematically represents an approach for providing coverage extension through repeated transmissions for a plurality of SI messages with reduced control signalling overhead in accordance with

an embodiment of the disclosure. Figure 7 schematically shows a sequence of LTE downlink subframes (labelled as subframes "O", "P", "Q", …, "Z" to aid explanation) with shading to schematically indicate which regions in which subframes are used to convey messages associated with the system information. The subframes represented in Figure 7 comprise four groups of three contiguous subframes with spaces between the groups as schematically indicated by dotted lines. Although not shown in Figure 7, the gaps between the groups comprise a continuing sequence of subframes used for other communications that are not relevant to the system information messaging considered here. As discussed above, each subframe comprises a control region 700 and a PDSCH region 702. The control regions 700 for the respective subframes are labelled in Figure 7 with the identification letter for the relevant subframe, i.e. as 700O, 700P, 700Q, etc. The PDSCH regions for the respective subframes are similarly labelled in Figure 6 as 702O, 702P, 702Q, etc.

As already noted above, aspects of the operation of a wireless telecommunications system in accordance with embodiments of the disclosure, for example as shown in Figure 7 and 8, which are not specifically described herein may be implemented in accordance with any conventional techniques. In this regard, insofar as the operation of embodiments of the disclosure follow conventional techniques the respective subframes represented in Figure 7 may be similar to that is represented in Figure 3. Thus, the control regions 700 support PCFICH, PHICH and PDCCH channels as discussed above while the PDSCH regions 702 support user-plane data and system information (among other things) and EPDCCH if implemented. The most significant aspect of the control region 700 in the context of embodiments of the present disclosure relate to the PDCCH and so for simplicity the control regions 700 may sometimes be referred to herein as PDCCH regions 700.

Thus referring to Figure 7 subframes O, P and Q are used to signal a PDCCH message addressed to SI-RNTI by sending three repeat PDCCH transmissions in the respective PDCCH regions 700O, 700P, 700Q. Each PDCCH repeat transmission addressed to SI-RNTI in the PDCCH regions 700O, 700P, 700Q in effect comprises a duplication of the same downlink control information which a terminal device can combine to seek to establish the content of the PDCCH message addressed to SI-RNTI in accordance with conventional techniques for coverage extension through repeat transmissions. For this example implementation of a repeat-transmission based coverage extension scheme it is again assumed a particular type of message subject to repeat transmissions is addressed to the same RNTI (e.g. SI-RNTI for a system information related type of messages) as if the same type of message were subject to conventional single-subframe transmission. However, as discussed further below, in accordance with certain embodiments of the disclosure identifiers having different characteristics (e.g. in terms of their value or control region search space) may be used for a given type of message depending on whether the messages to be sent in accordance with a first transmission scheme (e.g. using a conventional single subframe based transmission approach) or a second transmission scheme (e.g. using a repeat-transmission scheme for coverage extension). Furthermore, it will be appreciated the approach of using identifiers associated with a particular type of message having different characteristics according to the transmission scheme is to be used in accordance with embodiments of the disclosure may or may not also implement an approach using validity periods as disclosed herein.

The PDCCH message sent in subframes O, P and Q in Figure 7 differs from a conventional PDCCH message, for example of the kind transmitted in subframes A, B and C of Figure 6, in that it is associated with a validity period that is sufficient to span the transmission of a plurality of PDSCH messages. This is

different from the conventional approach in which a PDCCH message is simply associated with a single PDSCH message. The validity period for the PDCCH message is known to both the base station and the terminal device. For example, the validity period may be based on a defined standard for operations in accordance with an embodiment of the disclosure, whereby the base station and the terminal device can each determine the validity period from the defined standard. In other embodiments the base station may have flexibility to select the validity period, for example according to current scheduling requirements, and to communicate an indication of the validity period to the terminal device(s) to which the PDCCH message is addressed. Some example implementation of this approach are discussed further below.

The PDCCH message comprising the three repeat transmissions in the PDCCH regions of subframes O, P and Q indicate transmission resource blocks to be used for a subsequent PDSCH message comprising the transmission of system information. This PDSCH message itself comprises a plurality of repeat transmissions, and, in this example, are represented by shading in the PDSCH regions 702R, 702S and 702T of subframes D, E and F. The manner in which the PDCCH message indicates the corresponding PDSCH resources in subframes R, S and T may be in accordance with conventional techniques/signalling protocols. That is to say, the transmission resources, for example in terms of specific resource elements, used to convey the repeat transmissions of the system information message in the PDSCH regions 702R, 702S and 702T may be indicated in the corresponding PDCCH message addressed to SI-RNTI and comprising the repeat transmissions in PDCCH regions 700O, 700P, 700Q in accordance with conventional resource allocation techniques in the context of coverage extension using repeat transmissions. Whilst the shading in Figure 7 schematically represents the same frequency resources being used for each repeat transmission in the respective PDSCH regions 702R, 702S and 702T of the subframes R, S and T, in principle the repeat-transmission approach may be configured to include frequency hopping for the different repeat transmissions comprising the PDSCH message sent in subframes R, S and T. The nature of any such frequency hopping may be pre-defined, for example it may be pre-specified according to an operating standard for the wireless telecommunications system, or it may be established in previous RRC (radio resource control) signalling, or it may be indicated in the PDCCH message.

As schematically represented in Figure 7 there is a gap between subframes C and D. This again follows the currently-proposed approaches for repeat-transmission coverage extension whereby the transmission of a PDSCH message comprising a plurality of repeat transmissions does not start until after all repeat transmissions of the corresponding PDCCH message have been sent. Furthermore, some proposals indicate there should be no overlap between the end of the repeat transmissions comprising the PDCCH message and the start of the repeat transmissions comprising the PDSCH message. It will, however, be appreciated the specific implementation of such aspects of a repeat transmission approach for providing coverage extension are not significant to the principles underlying the present disclosure. That is to say, the principles described herein may equally be implemented in association with other repeat transmission approaches (e.g. with repeat transmissions of PDCCH and an associated PDSCH occurring in the same subframe).

Thus, the communication of the PDCCH message in subframes O, P and Q and the corresponding communication of the PDSCH message conveying system information in subframes R, S and T as represented in Figure 7 may follow the same general principles as the approach represented in Figure 6. Similarly, in subframes following the repeat-transmission approach for transmitting the system information

message as schematically indicated in subframes R, S and T in Figure 7, the wireless telecommunications system may continue to operate in accordance with its normal operating techniques for conveying other messages.

As noted above, system information messages are regularly retransmitted in accordance with LTE techniques, and the approach of Figure 7 differs from the approach of Figure 6 in respect of how a subsequent transmission of system information is scheduled on PDSCH in subframes X, Y and Z. In particular, the approach of Figure 7 differs from the approach of Figure 6 if the subsequent retransmission of system information occurs within the validity period associated with the previously-received PDCCH message in subframes O, P and Q initially sent in association with the previously-received system information message on PDSCH in subframes R, S and T. In LTE the transmission of system information follows a defined timing schedule, for example based on the system information window defined for the relevant system information. Thus, a base station and a terminal device are able to independently determine in which subframe a system information message will be transmitted on PDSCH (or which plurality of subframes in the case of coverage extension through repeat-transmissions as in this example). Thus, in the example of Figure 7, a terminal device to which the system information is addressed can determine that a system information message is to be transmitted in subframes X, Y and Z.

Referring back to Figure 6, the terminal device receiving the system information on PDSCH in subframes J, K and L can similarly determine in accordance with conventional techniques that the transmission will occur in these subframes. However, to determine the specific resources (e.g. in terms of specific OFDM carriers / resource blocks) on which the transmissions will occur within the relevant subframe(s) the terminal device must first receive the corresponding PDCCH allocation message sent in subframes G, H and I.

However, in the approach of Figure 7 in accordance with an embodiment of the present disclosure the resource allocation used for the PDSCH transmissions of the system information message on subframes X, Y and Z is determined from the previous resource allocation message sent on PDCCH in subframes O, P and Q. For example, in accordance with one approach the specific PDSCH resources (e.g. in terms of frequency) to be used for transmitting the subsequent system information message in subframes X,Y and Z are assumed to be the same as the specific PDSCH resources (e.g. in terms of frequency) used for transmitting the system information message in subframes R, S and T and indicated in the PDCCH message sent in subframes O, P and Q. However, it will be appreciated that other mappings can be adopted. For example, the frequencies to be used can be configured to shift in accordance with a predefined pattern for each retransmission within the validity period for the PDCCH message.

Thus, in accordance with an embodiment of the disclosure, and in contrast to the approach in the corresponding subframes in Figure 6, there is no PDCCH message sent in subframes U, V and W to support the system information message sent on PDSCH in subframes X, Y and Z. Instead it is determined that a previous PDCCH message remains valid (because its associated validity period has yet to expire), and the resources used for conveying the system information message on PDSCH in subframes X, Y and Z are derived from the previous PDCCH.

This approach has an advantage of freeing up the control-channel resources, in particular in subframes U, V and W for the example subframes represented in Figure 7. The approach can also help reduce the

amount of processing required by the terminal device (since the terminal device does not need to decode a separate PDCCH message for each and every PDSCH message). Furthermore the approach can reduce latency in situations that require high repetition numbers because there is no need to wait to receive a series of PDCCH repetitions before receiving each series of PDSCH repetitions.

It will be appreciated the transmission resources represented in Figure 7 that are not involved in the SI message signalling discussed above can be used for other communications in the network in the usual manner. In particular, it will be appreciated that although the entirety of the PDCCH regions associated with repeat transmissions of the PDCCH for the system information messages are shown shaded in Figure 7, this is merely to highlight those subframes in which a PDCCH for the system information messages is transmitted compared to those where it is not, and in practice these regions will comprise multiple PDCCH messages addressing different terminal devices for allocating resources for various different types of communication on PDSCH.

Thus, to summarise an approach in accordance with an embodiment of the disclosure as represented in Figure 7, and with reference to Figure 8, a base station 504 is transmitting system information messages to terminal devices, including terminal device 508, according to a pre-defined timing schedule. The predefined timing schedule may follow conventional LTE techniques for transmitting system information. It is assumed the processing represented in Figure 8 starts just prior to subframe O at the beginning of the series of subframes represented in Figure 7 and while there is no currently valid PDCCH message for the relevant system information. Thus, in a first step S1 in Figure 8 the base station determines a validity period that is to apply for an upcoming control-plane message that is to be transmitted to allocate resources for system information messages on PDSCH. The duration of a validity period for a given PDCCH message may be fixed / predetermined according to a specific implementation, for example by a network operator, or may be selectable by a base station according to current conditions. The validity period might be relatively short, for example it might only comprise the time required to transmit two PDSCH messages to provide a potential saving of one PDCCH message transmission. On the other hand, the validity period might be significant number, for example hundreds, thousands, tens of thousands, or even more subframes. In general a longer validity period may be preferred to reduce the number of PDCCH message transmissions, while an overly-long validity period may be considered to overly restrict scheduling flexibility. An appropriate validity period in a given situation may depend on current traffic conditions within a cell supported by a base station. For example, if a base station is currently supporting a large number of terminal devices it may be more appropriate to select a relatively long validity period to provide a correspondingly large saving in PDCCH message transmissions. However, if a base station is currently supporting only a small number of terminal devices with low traffic requirements (i.e. such that PDCCH congestion is not an overly significant concern), it may be more appropriate to select a relatively short validity period to provide a corresponding increase in scheduling flexibility (example to take better account of fluctuations in radio propagation conditions or traffic changes). In one example a current proportion of non-MTC traffic may be used to help determine an appropriate validity period for a repeated PDCCH. Generally speaking, the higher this proportion, the higher the proportion of non-delay-tolerant non-small-message terminal devices in the cell whose performance may be disrupted by a heavy use of control channel resources due to repeated PDCCH transmission. Therefore, as the proportion of relatively higher priority terminal devices (e.g. non-MTC terminal devices) increases, the base station may opt for longer PDCCH validity times, especially for use in association with SI-messages.

In step S2 the base station transmits a control-plane message, which can also be referred to as a control message (using repeat transmissions for coverage extension in this example) to allocate the resources for subsequent system information messages on PDSCH. This control message is received and decoded by the terminal device 508. This aspect of the operation may be based generally on conventional techniques, for example using a PDCCH message addressed to an SI-RNTI in LTE. Furthermore, the specific resources selected by the base station for allocation to the system information messages may be selected in accordance with established scheduling techniques in wireless communication systems. Thus, step S2 correspond with the transmissions made in subframes O, P and Q of Figure 7.

In step S3 the terminal device determines the validity period for the control-plane message received in step S2. There are various ways in which the terminal device may determine the validity period for the control-plane resource allocation message in accordance with various embodiments of the disclosure, and some examples are discussed further below.

In step S4 the base station proceeds to transmit a system information message (using repeat transmissions for coverage extension in this example) in accordance with the resource allocation identified by the control-plane (PDCCH) message of step S2. This aspect of the operation may be made broadly in accordance with conventional techniques. The terminal device seeks to receive and decode this system information message (SI message #1) in accordance with conventional techniques.

In step S5 the base station determines it is time to transmit another system information message (SI message #2) according to the predefined timing for periodic system information transmissions in the wireless telecommunications system. The base station further determines the validity period for the control-plane message sent in step S2 has not yet expired. Accordingly, the base station does not send any new control-plane message to support the new system information message that is about to be transmitted (SI message#2). Instead the base station proceeds to transmit the system information message (using repeat transmissions for coverage extension in this example) in accordance with resource allocations derived from the previously-sent control-plane (PDCCH) message of step S2. For example, the base station may be configured to simply use the same frequency resources for transmitting SI message #2 in step S5 as were used for transmitting SI message #1 in step S2. The terminal device likewise determines the expected transmission timing for the new system information message (SI message #2) from the predefined timing for system information transmissions and also determines the validity period for the previous control-plane message received in step S2 has not expired. Accordingly, the terminal device need not seek to receive a new control-plane message to indicate the PDSCH resources for the new system information message that is to be next transmitted (SI message#2). Instead the terminal device simply assumes the transmission is to be made in the relevant subframes (determined according to the predefined timing) on frequency resources derived from the previously-sent control-plane (PDCCH) message of step S2. Once the terminal device has determined the specific resources on which to expect the system information message in step S5 (SI message #2) it may proceed to receive and decode the system information message in accordance with conventional PDSCH transmission techniques.

As noted above the timing s for specific SI messages in LTE are based on SI windows. Conventionally it is the transmission of an associated PDCCH message addressed to the relevant system information RNTI which determines the precise subframe(s) in which the system information message PDSCH is transmitted. However, in accordance with certain embodiments of the disclosure there can be PDSCH

messages conveying system information in an SI windows without there being a corresponding PDCCH message in that SI window. There are a number of different ways in which a terminal device can determine the relevant subframe for a further PDSDH message transmitted within the validity period of a previously-received PDCCH message in accordance with embodiments of the disclosure. In one case, the base station may be configured to send the PDSCH message in a predefined subframe of the SI window. In principle this could be permanently fixed for all PDSCH system information messages at the cost of reduced scheduling flexibility. In another case the subframe(s) could be based on the subframe(s) used in association with the initial PDCCH message. For example, if the initial PDCCH indicates a system information message is to be sent in subframe number n (or starting in subframe n for repeat transitions for coverage extension) within a particular SI window, subsequent PDSCH messages within the validity period of the PDCCH might also be sent in (or start in) subframe n of the relevant SI window. In another example, the base station may retain the flexibility to send (or start sending when using repeat transmissions) the subsequent system information message in any subframe within the SI window. In this case a terminal device may check for a newly addressed PDCCH message in the subframes in the SI window in the normal way, and if a new PDCCH message is not found, the terminal device may decode the PDSCH resources indicated in accordance with a previously-received still valid PDCCH message in the same subframe(s) relative to the SI window as for the previous transmission. In principle, with sufficient processing power, the terminal device could simply seek to decode the relevant resources in all subframes of an SI window to see if an SI message can be decoded.

The process of the base station sending further system information messages, and the terminal device receiving the further information messages, based on transmission resource allocation information indicated in the control-plane message of step S2 may continue (as schematically indicated in step S6 for transmitting SI message #n) until the validity period for the control-plane message received in step S2 has expired, as schematically indicated in step S7.

Following step S7 the processing in effect cycles back to where it started prior to step S1. The base station may thus determine a new validity period for a new control message to be sent in a further step corresponding with step S2 (the base station determines that a new PDCCH message is required because the previous one has expired). Processing may then continue from this point in the manner discussed above.

Thus, the various example schemes represented in Figures 7 and 8, and described above, provide an approach in which control-plane messages, and in particular SI-messages, are associated with a validity period that extends for more than one message transmission of the associated PDSCH. For example, for SIBs in SI-messages, one SI-RNTI addressed PDCCH message can provide the control information for multiple transmissions of SIBs, and in general over multiple SI-windows. Similar operation for other types of message, for example messages addressed to other common search-space RNTIs, may be adopted in accordance with other examples. This kind of approach can help reduce control resource requirements, which can be especially important in the context of coverage extension where according to conventional techniques PDCCH (comprising multiple repeat transmissions) messages would have to be transmitted every time an SI-message (comprising multiple repeat transmissions) needed to be sent.

As noted above, SIBs in system information messages can in some cases remain unchanged for extended period, for example a few hours. A terminal device may thus combine system information message transmissions from across multiple SI-windows if it does not successfully decode an SI-

message at first attempt and with a sufficiently long validity period this can be achieved in accordance with the approaches described herein with reduced control signalling requirements than current schemes.

As noted above, there are various different ways in which the validity period for a PDCCH message may be established. In one simple example the period may be defined according to an operating standard of the wireless telecommunications system. Both the base station and the terminal device can in effect be hardwired with the validity period (or multiple validity periods associated with different types of messages). In another example the base station may have flexibility for determining a suitable validity period according to the implementation and traffic conditions at hand. In this case there are various different ways in which the validity period could be conveyed to a terminal device.

In one example the base station may be configured to convey a selected validity period to terminal devices by selecting a particular transmission characteristic, for example timing, for the PDCCH message with which the validity period is associated. According to current proposals for repeat transmission coverage extension in LTE, the starting subframe of a PDCCH message being transmitted in multiple subframes should be confined to a subset of subframes. This is because in some circumstances the terminal device may be required to blindly search over the possible numbers of repetitions the PDCCH might comprise. If it were allowed for a PDCCH messages comprising an arbitrary number of repeat transmissions to start in an arbitrary subframe this could be expected to give rise to significant complexity in the processing required of the terminal device. To address this there has been proposed an approach in which, for example, a PDCCH message comprising N repeats can only begin in subframes having a subframe number that is a multiple of N (i.e. 0, N, 2N, 3N,...). This reduces the set of possible repetition numbers the UE needs to consider per subframe. Thus, a similar approach could be used to convey information on PDCCH validity. This can be done by linking the validity period to the starting subframe number of the associated PDCCH message. For example, a PDCCH message commencing in subframe M might be taken to indicate a validity period corresponding to M SI-windows for the relevant system information. Thus, a terminal device can readily establish the relevant validity period from the timing of the relevant control-claim message. It may be noted that in some circumstances it may be preferable to assign longer PDCCH validity periods to PDSCH messages that comprise high numbers of repetitions.

In another example the base station may be configured to convey a selected validity period to terminal devices through explicit signalling, for example in the downlink control information (DCI) of the relevant PDCCH message. Thus, the DCI may comprise an indication of a number of subframes / radio frames corresponding to the validity period or may comprise an indication of a specific subframe / radio frame in which the validity period is to expire. In the application to the transmission of system information messages it may be preferable to indicate timings in respect of a number of SI-windows of validity.

In yet another example the terminal devices may be configured to simply assume the validity period for a given PDCCH message addressed to a given RNTI (e.g. SI-RNTI) extends until a subsequent PDCCH message addressed to the relevant RNTI is received. That is to say, the PDCCH message may be considered to remain valid until it is replaced by another PDCCH message. In this respect, in terms of the processing schematically represented in Figure 8, this corresponds with the terminal device determining the validity period for the control message (corresponding to step S3) at the same time at which the validity period expires (responding to step S7), with this being triggered by a new PDCCH message being received by the terminal device. In this approach a terminal device may thus monitor for a new PDCCH message addressed to the relevant RNTI in each subframe of each SI-window in the normal way until a

new PDCCH message is received to in effect define the end the validity period for the previous PDCCH message addressed to that RNTI.

Thus, one principle of the approaches described above in accordance with some embodiments of the disclosure is to associate a PDCCH message with a time defining its validity, that time being extensible beyond the time taken to convey a corresponding PDSCH message. A terminal device may thus assume the PDSCH resource allocation, MCS (modulation and coding scheme), TBS (transport block size), etc. in the DCI of the PDCCH message is valid for receiving multiple PDSCH messages during the PDCCH validity time. No further PDCCHs for multiple PDSCH messages need be sent during the validity time. Thus, in the case of SIB transmissions, the transmission of all SI-messages (including all transmissions within a SI-window of a particular SI-message), may be scheduled with a single transmission of SI-RNTI PDCCH with an appropriately configured validity period.

One particular situation in which approaches in accordance with the embodiments described above might be expected to be useful is where the transmissions are used to provide coverage extension on both PDCCH and PDSCH. However, similar principles can be applied where coverage extension is not being used, for example in respect of messages sent within single subframes.

Whilst the above-described embodiments have focused on system information messages, it will be appreciated that similar principles can be applied for other types of messages in wireless telecommunications systems, and especially for messages which rely on resource allocations occurring with some degree of predictable timing. For example, similar principles can be used for control signalling addressed to other common search space RNTIs, such as RA-RNTI and P-RNTI.

Thus a random access RNTI addressed PDCCH message received by a terminal device during an initial cell access may be associated with a validity period such that the transmission resources identified in association with the random access RNTI PDCCH message are taken to apply for later random access procedures in accordance with the principles set out above. The specific subframe of a RAR (random access response) window in which a subsequent RAR arrives can be established in a manner similar to that described above for system information within a predefined series of subframes comprising an SI-window

Similarly, a paging RNTI addressed PDCCH message may be associated with an extended validity in accordance with the principles described above. Thus a PDSCH resource allocation associated with a PDCCH message addressed to a paging RNTI transmitted in one subframe may be taken to indicate a PDSCH resource allocation in a subsequent subframe within a validity period associated with the PDCCH message. This may be especially appropriate for paging when a terminal device is in idle mode since there is a higher degree of predictability as to when paging messages may be sent according to a currently configured DRX, discontinuous reception, cycle. That is to say, the concept of PDDCH validity timers as discussed herein may be applied to the most recent P-RNTI PDCCH used to decode a paging message by an RRC_IDLE UE. An RRC_IDLE UE is only expected to monitor specific subframes for P-RNTI and is in DRX for other subframes. If the relevant PDCCH validity timer expires before a subsequent paging message is to be sent, the base station may provide a new P-RNTI PDCCH message to schedule the next paging message as normal. Otherwise the IDLE UE may assume the most recent such PDCCH is still valid. For an RRC_CONNECTED UE, there is less predictability as regards whether a particular subframe should contain P-RNTI PDCCH or not. For a connected mode terminal device the

principles described herein for paging messages might, for example, be used for subframes in which the UE would check for P-RNTI if it were in fact in IDLE mode. In other subframes the base station may send conventional paging signalling using PDCCH to page the UE in connected mode.

In a wireless telecommunications using repeat-transmissions for coverage extension there may be terminal devices which are not in coverage-limited locations and able to successfully decode individual ones of the PDCCH (or EPDCCH) repeat transmissions in each subframe. For example, and referring to Figure 7, a non-coverage-limited terminal device may be able to successfully decode the individual PDCCH repeat transmission in the control region 700O of subframe O. If this terminal device is not aware of the use of repeat-transmissions for coverage extension (for example because it is a legacy / conventional terminal device) it might be expected to assume the PDCCH information derived from the control region 700O subframe O applies to a system information transmission on PDSCH in the same subframe (i.e. in PDSCH region 702O). However, the terminal device would fail to receive the system information transmission (because it is not sent in accordance with this particular repeat-transmission protocol). Potentially this terminal device could seek to do this for each and every repeat transmission and so waste a considerable amount of processing effort needlessly decoding individual PDCCH repeat transmissions and associated PDSCH resources in the expectation of receiving system information messages which are not in fact being sent in those subframes. This is an issue which applies generally for repeat transmission approaches for coverage extension and is not specific to approaches based on validity periods as discussed herein.

Thus in accordance with certain embodiments of the disclosure an identifier (RNTI) having different characteristics (e.g. in terms of value or associated control region search space) may be associated with SI messages sent using a repeat transmission approach as compared to SI messages sent without using a repeat transmission approach. More generally, in a wireless telecommunications system supporting different transmission schemes for a given type (classification / category) of message (e.g. a message comprising a given radio resource control, RRC, information element, such as a system information related message or a paging request related message), a characteristic of an identifier associated with the message (i.e. an identifier to indicate which terminal device(s) the message is for) may be selected according to the transmission scheme used for the message. This approach may be implemented in accordance with certain embodiments of the disclosure regardless of whether the wireless telecommunications system also implements an approach using validity periods as described herein (i.e. the approach may be implemented in association with the principles of the repeat transmission scheme represented in Figure 6 as well as that represented in Figure 7). That is to say, the concept of associating a validity period with a control message and the concept of using different identifier characteristics according to a transmission scheme being used may be used together in combination or separately from one another in accordance with different embodiments of the disclosure.

A terminal device having the ability to receive transmissions using the repeat transmission approach can identify the transmissions as such directly from the associated identifier characteristic and receive the message accordingly. The characteristic for the identifier can be selected so that a terminal device not having the ability to receive transmissions using a repeat transmission approach, for example a legacy terminal device, does not recognise the message as being addressed to the terminal device, and so in effect ignores it. Such a terminal device may in effect ignore the message because, for example, the identifier has a value which is not recognised as a value relevant to the terminal device or because a search space for a control message conveying the identifier is not searched by the terminal device.

Thus, if in a particular implementation it is assumed that a repeat transmission approach to coverage extension is intended primarily for MTC-type devices, an MTC-specific system information radio network temporary identifier (MTC-SI-RNTI) may be established. PDCCH messages associated with repeat transmissions for conveying system information messages may thus be addressed to MTC-SI-RNTI instead of an SI-RNTI used for conveying system information that is not sent using repeat transmissions. More generally some embodiments of the disclosure propose introducing other repetition specific RNTIs to address messages that rely on repetitions for coverage extension to complement corresponding RNTIs in existing systems. Thus, system information messages to be sent in accordance with a non-repeat transmission technique may be associated with a conventional system information identifier (e.g. SI-RNTI) while system information messages to be sent in accordance with a repeat-transmission technique may be associated with a modified system information identifier (e.g. REPEAT-SI-RNTI).

Similar issues can arises for other common RNTIs associated with other types of message that may be sent using a repeat transmission approach. Thus corresponding RNTIs having different characteristics may also be established for these. For example, for each of SI-RNTI, P-RNTI, RA-RNTI, TPC-PUCCH-RNTI, TPC-PUSCH-RNTI and M-RNTI to be used for addressing non-repeat transmission messages, there may be established a corresponding RNTI having a different value to be used for addressing repeat-transmission messages (e.g. what might be generally referred to as REPEAT-RNTIs, such as REPEAT-SI-RNTI, REPEAT-P-RNTI, REPEAT-RA-RNTI, REPEAT-TPC-PUCCH-RNTI, REPEAT-TPC-PUSCH-RNTI and REPEAT-M-RNTI). Thus an approach in accordance with an embodiment of the disclosure may be used in association with messages selected from the group comprising: (i) a message associated with transmitting system information; (ii) a message associated with transmitting a paging message; (iii) a message associated with transmitting a random access response message; (iv) a message associated with transmitting power control information for an uplink control channel; (v) a message associated with transmitting power control information for an uplink data channel; and (vi) a message associated with a broadcast and / or multicast service. A similar approach can be taken for types of message associated with other common RNTIs which may be introduced in future.

In some implementations in which a message to be transmitted using a repeat-transmission approach in association with an identifier having a characteristic selected to indicate this, a component part of the message (e.g. a repeat transmission) may also be transmitted in one, or more, subframes in association with an identifier having a characteristic that would be used if the message were being transmitted using a conventional single-transmission approach. This will allow legacy terminal devices who are able to receive the message from only a single repeat transmission to in effect receive the message based on one of the repeat transmissions.

One advantage of associating identifiers for a given type of message with different characteristics based on the transmission scheme is the potential for more complete use of the available transmission resources. For example, referring to Figure 7, the initial SI-RNTI addressed PDCCH repeat transmission in the control region 700O of subframe O is part of a repeat transmission comprising three repeat transmissions in the respective control regions of subframes O, P and Q. This PDCCH message identifies resources (and other parameters) associated with a PDSCH message to be subsequently transmitted starting from subframe R as discussed above. As previously noted, it is expected for repeat-transmission based coverage extension there will be no PDSCH signalling associated with the PDCCH message until after the repeat transmissions comprising the PDCCH message had been made. In principle the PDSCH

transmission resources in the PDSCH regions 702O, 702P and 702Q of subframes O, P and Q corresponding to the resources allocated by the PDCCH message for use in subframe starting from subframe R could be used to support other transmissions. For example, the respective control regions 700O, 700P, 700R could include conventional single-subframe PDCCH messages allocating the relevant PDSCH transmission resources for another purpose, for example unicast data. However, it would be confusing for a legacy terminal device to decode a unicast PDCCH message and a SI PDCCH message resource allocation identifying the same resources in the same subframe. Thus by preventing the legacy terminal device from decoding the SI PDCCH signalling (through use of an appropriate distinguishing characteristic for the identifier as discussed herein), the legacy terminal device is free to receive unicast data on the relevant PDSCH resources (in association with an appropriately addressed PDCCH transmission indicating these resources).

In implementations in which the distinguishing characteristic for the identifier is its value (i.e. with one value, such as SI-RNTI, indicating conventional single-subframe transmission, and another value, such as REPEAT-SI-RNTI, indicating repeat-transmission coverage extension), the "new" REPEAT-RNTIs may be defined in accordance with an operating standard for the wireless telecommunications network in parallel with the corresponding RNTIs. For example, as noted above, in LTE the SI-RNTI has a fixed value 0xFFFF. In accordance with an embodiment of the disclosure a fixed value for a REPEAT-SI-RNTI may be selected from one of the currently reserved RNTIs in LTE (from 0xFFF4 to 0xFFC). Thus, if, for example, a value 0xFFF5 is allocated as REPEAT-SI-RNTI (i.e. an identifier for a system information related message sent using repeat transmissions), a PDCCH addressed to 0xFFFF can be identified as corresponding to a system information message sent without repetition whereas a PDCCH addressed to 0xFFF5 can be identified as corresponding to a system information message sent using repetition. A terminal device that is unaware of repetition will in effect ignore the PDCCH addressed to 0xFFF5 as this will not be recognised as a valid RNTI for the terminal device. Corresponding principles apply where EPDCCH is used.

In the above-described example the value of the RNTI is the characteristic used to distinguish between the different transmission schemes. However, in accordance with other embodiments of the disclosure, other characteristics can be used to distinguish identifiers to indicate different transmission schemes. For example, in LTE there are currently eight "spare" values that could be used as new REPEAT-RNTIs. This is a sufficient number of values to provide a corresponding RNTI to be used in association with a transmission scheme comprising repeat transmissions for all currently-existing common RNTIs. However, it may be considered preferable in some cases to avoid using these "spare" values so they remain free for other uses, or there may be a need for more REPEAT-RNTIs (for example, to provide multiple extra RNTI for a given type of message, e.g. a system information message, to indicate another aspect of the transmission scheme, for example the number of repeats). Thus, in accordance with some embodiments a REPEAT-RNTI may in fact have a value that is the same as its corresponding "conventional" RNTI (e.g. 0xFFFF for SI-RNTI and REPEAT-SI-RNTI) but be associated with a different search space. As is well known a terminal device will typically search a defined subset of control region resources to seek to identify any control messages associated with an identifier (RNTI) common to a plurality of terminal devices. The subset of control region resources is known as a search space and comprises a plurality of candidate PDCCH for the terminal device to check. This search space approach is taken to reduce the amount of processing required by the terminal device to seek to identify any relevant control messages. Thus, PDCCH signalling associated with the existing common RNTIs are constrained to a particular set of

candidate PDCCH comprising the common search space. In accordance with some embodiments of the disclosure the characteristic of the identifier which is used to distinguish the different potential transmission schemes may be based on the specific PDCCH resources used.

For example, a PDCCH message to be transmitted in accordance with a conventional single-subframe approach may be associated with an identifier, such as SI-RNTI, in the common search space in the usual way. However, a PDCCH message to be transmitted in accordance with a repeat-transmission approach may instead be associated with the same value of identifier, such as SI-RNTI, but transmitted on PDCCH resources outside the common search space. Thus in accordance with some implementations the distinguishing characteristic for the identifier based on the transmission scheme may be a search space with which the identifier is associated. Thus a PDCCH message addressed to SI-RNTI within a particular search space (e.g. the common search space in LTE) can be identified as corresponding to a system information message sent without repetition whereas a PDCCH transmission addressed to SI-RNTI outside the particular search space (e.g. outside the common search space in LTE) can be identified as corresponding to a system information message sent using repetition. A terminal device that is unaware of repetition will in effect ignore the PDCCH addressed to SI-RNTI outside the common search space as the terminal device will not search for the SI-RNTI outside the common search. Corresponding principles apply where EPDCCH is used. Thus in effect, identifiers associated with repeat transmissions may be associated with a newly-defined search space which is outside the search space used for the corresponding identifiers for conventional single-subframe transmissions. In some examples the new search space may support only a single aggregation level, for example an aggregation level 8 (the high aggregation level being appropriate in view of the coverage extension context). The new search space may be smaller (i.e. comprise fewer candidate PDCCH) than the search space for existing common RNTIs. This can help reduce the blind search load associated with the repeat transmissions comprising a message transmitted using a repeat transmission for coverage extension.

It will appreciated the advantages of establishing a new search space comprising a reduced number of candidate PDCCHs with a single relatively high aggregation level to be used in association with identifiers for repeat transmission messages can be applied even in circumstances where different identifier values are associated with the different transmission schemes. In such cases the repeat-specific identifier values may be selected from among the values that are available for use as identifiers in the wireless telecommunications system. In one example, as referred to above, a repeat-specific identifier values may simply match its corresponding non-repeat specific identify value (e.g. SI-RNTI) with the different search space in which a control message associated with the identifier is transmitted providing the distinguishing characteristic for the identifier for the selected transmission scheme. However, in another implementation the repeat-specific identifier values may be selected from, for example, identifiers available for other uses, for example in LTE from identifiers available for cell-specific RNTIs (which may range from 0x001 to 0xFFF3). This approach can in principle provide a relatively large number of repeat-specific identifiers. For example, one or more of the values normally used for C-RNTI can be in effect reserved as one or more repeat-specific RNTIs, such as REPEAT-SI-RNTI in the terminology used above, and likewise for types / classes / classifications of messages other than system information related messages, such as paging messages and random access a response messages etc. Thus a base station could in effect reserve (re-allocate) in its cell a number of RNTI values for one purpose as actually being for use as repeat-specific RNTIs. If any of the re-allocated subset of RNTIs comprising the repeat-specific RNTI is detected by a terminal device as addressing a PDCCH in the newly-defined search space, the terminal

device may be configured to interpret this as a repeat-specific RNTI. This may be based on the base station conveying in previous signalling to terminal devices that support repeat-transmission communications an indication of the relevant RNTI(s). Alternatively, or in addition, the relevant RNTI(s) may be defined in accordance with an operating standard of the network for reallocation within the new search space. If the PDCCH candidates comprising the new search space do not overlap with those of the pre-existing common search space and UE-specific search space used by legacy devices, then the RNTIs allocated as repeat-specific RNTIs within the new search space could continue to be used in the other search space without giving rise to the potential for confusion for legacy terminal devices. If, on the other hand, the PDCCH candidates comprising the new search space do overlap with those of the pre-existing common search space or UE-specific search space, then the base station may be configured to avoid allocating any of a currently re-allocated RNTI to terminal devices in accordance with the usual function for the RNTI (i.e. a C-RNTI reallocated for use as a repeat-specific identifier should not be allotted to a terminal device for use as a C-RNTI). This can be remedied as a straightforward matter of RNTI scheduling (for example, the base station can in effect simply treat the re-allocated RNTIs as being already allotted for use).

If multiple RNTI are made available for use for a given type of message, the particular RNTI selected for use in association with a particular message may be used to indicate a further characteristic of the message, for example a number of repeats or a specific PDCCH validity period where implemented. This can provide the base station with a simple mechanism for modifying the specific repeat and all validity period parameters associated with a particular message, thereby improving overall flexibility.

Determining which identifiers a terminal device should search for to seek to identify messages to be sent to the terminal device using a repeat transmission scheme can be done in accordance with the usual principles by linking it to transmission mode (TM) configuration. In one implementation the repeat-specific RNTIs provided in accordance with embodiments of the disclosure might apply in all transmission modes as the principles governing their use will in many respects be similar to conventional, search space RNTIs. There could also be a link with the category/type of the terminal device. For example, a new terminal device category identifier could be introduced (e.g. category 0) to indicate the terminal device is a particular type of terminal device, for example an MTC-based terminal device. The repeat-specific identifiers may then be considered to apply to all transmission modes for terminal devices of category 0 (if the repeat-transmission based scheme is limited to category 0 terminal devices), as well as for additional terminal device categories if the use of the repeat-transmission based scheme is more widely supported.

Figure 9 is a signalling ladder diagram schematically representing modes of operation for the terminal device 508 and the base station 504 schematically represented in Figure 5 in accordance with some embodiments of the present disclosure.

Processing begins in step T1 when the base station determines that a message is to be transmitted to one or more terminal devices. The message may, for example, be a broadcast message or a multicast message. The determination that a message is to be transmitted may be made in accordance with conventional operating procedures for the wireless communications system. For example, if the message is a system information message, step T1 may arise in accordance with a conventional timing schedule for transmitting system information messages. If the message is a paging message, step T1 may arise because an event has arisen which requires a terminal device to be paged. In this example it is assumed the message which is to be transmitted is a system information message which is relevant for (i.e.

address to an identifier associated with) terminal device 508. Furthermore, it is assumed the message may be transmitted in accordance with either one of a first transmission scheme using transmission resources in a first number of radio subframes (e.g. using conventional single-subframe transmission) or a second transmission scheme using transmission resources in a plurality radio subframes (e.g. using repeat-transmission for coverage extension).

In step T2 the base station determines which of the first and second transmission schemes are to be used for transmitting the message. That is to say, in this example, the base station determines whether or not a conventional single subframe approach or a repeat-transmission approach for coverage extension will be used for the message. There are a number of factors that may govern this determination, either individually or in combination. For example, the terminal devices in the wireless telecommunication system may comprise a first set of terminal devices and a second set of terminal devices step and T2 may be based on whether the one or more terminal devices to which the message is to be sent comprises terminal devices in the first or second sets. For example, the first set of terminal devices may comprise terminal devices that do not require coverage extension techniques to receive messages (or simply do not support coverage extension), whereas the second set of terminal devices may comprise terminal devices that do require coverage extension techniques to receive messages (and support repeat-transmission based coverage extension). Whether or not a specific terminal device requires coverage extension may, for example, be based on a measured radio propagation metric associated with the terminal device, for example a path loss, block error rate, a bit error rate, a packet error rate, a frame error rate, a symbol error rate, or negative or positive acknowledgement signalling rate (ACK/NACK) associated with communications with the terminal device. In another implementation the decision may take account of a specific identity or category for the one or more terminal devices to which the messages to be sent.

In step T3 the base station determines a characteristic of an identifier for the message based on the transmission scheme determined in step T2. This characteristic may be selected in accordance with any of the principles discussed above (e.g. use of different values for the identifier or different search spaces to be used with the identifier).

In step T4 the message is transmitted in accordance with the transmission scheme determined in step T2 and in association with an identifier, e.g. RNTI, having the characteristic determined in step T3. For example, the message may be transmitted in accordance with a repeat-transmission scheme as described herein with an identifier selected to have a characteristic to identify this, for example in accordance with any of the principles discussed above. In this regard the message may comprise one or other or both of a control message transmitted on a downlink control channel, e.g. a PDCCH message and another message transmitted on a downlink data channel, e.g. PDSCH (i.e. such that the identifier is transmitted separately from the message).

In step T5 the terminal device receives the transmitted signalling from the base station and determines the transmission scheme being used from the characteristic of the identifier. The terminal device may then proceed to receive and decode the message in accordance with the transmission scheme being used.

Thus, the process represented in Figure 9 demonstrates a mechanism by which a base station can readily indicates to terminal devices the transmission scheme being used for a given message. Once the terminal device has determined the transmission scheme, subsequent operation, for example in terms of

receiving the message, they be performed in accordance with conventional principles for receiving such messages. Furthermore, these techniques may be modified to incorporate a validity period approach such as discussed above.

Thus there has been described a wireless telecommunication system that comprises a base station and a terminal device communicating over a radio interface. The radio interface supports a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel (e.g. a physical downlink shared channel) for conveying other messages from the base station to the terminal device. The control messages convey information on resource allocations for the other messages on the downlink data channel. The other messages may comprise user-plane messages or control-plane messages. The terminal device is configured to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel and determine a validity period for the control message. During the validity period for the control message the terminal device is configured to receive a plurality of the other messages from the base station on the downlink data channel using the allocated transmission resources.

There has also been described a wireless telecommunication system that comprises a base station arranged to communicate messages to one or more terminal devices over a radio interface. The radio interface has a radio frame structure comprising a plurality of subframes, wherein a message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes (e.g. one subframe) or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes (e.g. with repeat transmissions in a plurality of subframes). The message is transmitted in association with an identifier to indicate a terminal device to which the message is addressed. A characteristic for the identifier, for example a value or control region search space for the identifier, is dependent on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme. A terminal device to which the message is addressed determines the transmission scheme from the characteristic of the identifier and receives the message accordingly.

Further particular and preferred aspects of the present invention are set out in the accompanying independent and dependent claims. It will be appreciated that features of the dependent claims may be combined with features of the independent claims in combinations other than those explicitly set out in the claims.

Thus, the foregoing discussion discloses and describes merely exemplary embodiments of the present invention. As will be understood by those skilled in the art, the present invention may be embodied in other specific forms without departing from the spirit or essential characteristics thereof. Accordingly, the disclosure of the present invention is intended to be illustrative, but not limiting of the scope of the invention, as well as other claims. The disclosure, including any readily discernible variants of the teachings herein, define, in part, the scope of the foregoing claim terminology such that no inventive subject matter is dedicated to the public.

Respective features of the present disclosure are defined by the following two groups of numbered paragraphs:

Group 1 of numbered paragraphs:

Paragraph 1. A method of operating a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises receiving a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and receiving a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 2. The method of paragraph 1, wherein the other messages comprise system information messages.

Paragraph 3. The method of any preceding paragraph, wherein the system information messages comprise one or more system information blocks.

Paragraph 4. The method of any preceding paragraph, wherein the radio interface is based on a radio frame structure comprising a plurality of subframes, wherein each subframe comprises a control channel region for supporting the downlink control channel and a shared channel region for supporting the downlink data channel, and wherein respective ones of the control and / or the other messages comprise transmissions over a plurality of subframes.

Paragraph 5. The method of any preceding paragraph, wherein the validity period for the control message is determined in dependence on an identifier used in association with the control message.

Paragraph 6. The method of paragraph 5, wherein the identifier comprises an indication of one or more terminal devices to which the control message is addressed.

Paragraph 7. The method of any preceding paragraph, wherein the validity period for the control message is determined in dependence on a transmission characteristic of the control message.

Paragraph 8. The method of paragraph 7, wherein the transmission characteristic of the control message comprises a transmission time associated with the control message.

Paragraph 9. The method of any preceding paragraph, wherein the radio interface is based on a radio frame structure comprising a plurality of subframes, and wherein the timing of a subframe used to convey a first one of the plurality of other messages is used to determine the timing of a subframe used to convey a second one of the plurality of other messages within the validity period for the control message.

Paragraph 10. The method of any preceding paragraph, wherein the timing of a subframe used to convey the first one of the plurality of other messages relative to a first predefined range of subframes is used to determine the timing of a subframe used to convey the second one of the plurality of other messages relative to a second predefined range of subframes.

Paragraph 11. The method of any preceding paragraph, wherein the validity period is determined in dependence on a validity period indicator received in association with the control message.

Paragraph 12. The method of any preceding paragraph, wherein the validity period is determined in dependence on the time at which a subsequent control message is received.

Paragraph 13. The method of any preceding paragraph, wherein the other messages comprise random access response messages and / or paging messages..

Paragraph 14. A terminal device for communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 15. Circuitry for a terminal device communicating with a base station in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the terminal device to receive a control message from the base station conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to receive a plurality of other messages from the base station on the downlink data channel using the allocated transmission resources within the validity period for the control message

Paragraph 16. A method of operating a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the method comprises transmitting a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, determining a validity period for the control message, and transmitting a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 17. A base station for communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the base station comprises a controller unit and a transceiver unit configured to operate together to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data

channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Paragraph 18. Circuitry for a base station communicating with a terminal device in a telecommunications system over a radio interface supporting a downlink control channel for conveying control messages from the base station to the terminal device and a downlink data channel for conveying other messages from the base station to the terminal device, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to cause the base station to transmit a control message to the terminal device conveying an indication of allocated transmission resources on the downlink data channel, to determine a validity period for the control message, and to transmit a plurality of other messages to the terminal device on the downlink data channel using the allocated transmission resources within the validity period for the control message.

Group 2 of numbered paragraphs:

Paragraph 1. A method of operating a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein the method comprises selecting a characteristic for the identifier in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 2. The method of any preceding paragraph, wherein the first number of radio subframes comprises a single radio subframe and the second number of radio subframes comprises a plurality of radio subframes.

Paragraph 3. The method of any preceding paragraph, wherein terminal devices in the wireless telecommunications system comprise a first set of terminal devices and a second set of terminal devices, and wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on whether a terminal device to which the message is to be transmitted is a member of the first set of terminal devices or the second set of terminal devices.

Paragraph 4. The method of any preceding paragraph, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on a radio propagation parameter associated with radio communications between the base station and a terminal device to which the message is to be transmitted.

Paragraph 5. The method of paragraph 4, wherein the radio propagation parameter is selected from the group comprising: a path loss; an error rate; a positive acknowledgment, ACK, signalling rate; and a negative acknowledgment signalling, NACK, rate.

Paragraph 6. The method of any preceding paragraph, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on an identity and / or type of a terminal device to which the message is to be transmitted.

Paragraph 7. The method of any preceding paragraph, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises a control message transmitted on the downlink control channel.

Paragraph 8. The method of any preceding paragraph, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises one of the other messages transmitted on the downlink data channel.

Paragraph 9. The method of any preceding paragraph, wherein the identifier to indicate a terminal device to which the message is addressed is transmitted separately from the message.

1 Paragraph 0. The method of any preceding paragraph, wherein the identifier comprises a radio network temporary identifier, RNTI.

Paragraph 11. The method of any preceding paragraph, wherein the identifier is a common to a plurality of terminal devices.

Paragraph 12. The method of any preceding paragraph, wherein the message comprises a broadcast message.

Paragraph 13. The method of any preceding paragraph, wherein the message comprises a multicast message.

Paragraph 14. The method of any preceding paragraph, wherein for a given type of message the characteristic for the identifier is selected from a first predefined characteristic for the identifier associated with the given type of message and a second predefined characteristic for the identifier associated with the given type of message according to whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 15. The method of any preceding paragraph, wherein the message is selected from the group comprising: (i) a message associated with transmitting system information; (ii) a message associated with transmitting a paging message; (iii) a message associated with transmitting a random access response message; (iv) a message associated with transmitting power control information for an uplink control

channel; (v) a message associated with transmitting power control information for an uplink data channel; and (vi) a message associated with a broadcast and / or multicast service.

Paragraph 16. The method of any preceding paragraph, wherein for a message to be transmitted in accordance with the second transmission scheme, a component of the message transmitted in one of the second number of subframes is associated with a characteristic for the identifier corresponding to that which would be used if the message were to be transmitted in accordance with the first transmission scheme.

Paragraph 17. The method of any preceding paragraph, wherein the characteristic for the identifier comprises a value for the identifier.

Paragraph 18. The method of any preceding paragraph, wherein the characteristic for the identifier comprises a search space in which a terminal device searches using the identifier to determine if a message has been addressed to the terminal device.

Paragraph 19. The method of any preceding paragraph, wherein the method comprises selecting the characteristic for the identifier from a plurality of different characteristics associated with different types of message.

Paragraph 20. The method of any preceding paragraph, wherein the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme is defined in accordance with an operating standard for the wireless telecommunications system.

Paragraph 21. The method of any preceding paragraph, further comprising the base station pre-defining the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme.

Paragraph 22. The method of paragraph 21, wherein the pre-defining the characteristic for the identifier is a value for the identifier selected from among a plurality of values.

Paragraph 23. A base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the base station comprises a controller unit and a transceiver unit configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 24. Circuitry for a base station communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the circuitry comprises a controller element and a transceiver element configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of

radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 25. A method of operating a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the method comprises determining from an identifier associated with the message that the message is addressed to the terminal device, and further determining from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 26. A terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

Paragraph 27. Circuitry for a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

CLAIMS

What is claimed is:

1. A method of operating a base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein the method comprises selecting a characteristic for the identifier in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

2. The method of claim 1, wherein the first number of radio subframes comprises a single radio subframe and the second number of radio subframes comprises a plurality of radio subframes.

3. The method of claim 1, wherein terminal devices in the wireless telecommunications system comprise a first set of terminal devices and a second set of terminal devices, and wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on whether a terminal device to which the message is to be transmitted is a member of the first set of terminal devices or the second set of terminal devices.

4. The method of claim 1, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on a radio propagation parameter associated with radio communications between the base station and a terminal device to which the message is to be transmitted.

5. The method of claim 4, wherein the radio propagation parameter is selected from the group comprising: a path loss; an error rate; a positive acknowledgment, ACK, signalling rate; and a negative acknowledgment signalling, NACK, rate.

6. The method of claim 1, wherein the method comprises determining whether to transmit the message in accordance with the first transmission scheme or the second transmission scheme in dependence on an identity and / or type of a terminal device to which the message is to be transmitted.

7. The method of claim 1, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises a control message transmitted on the downlink control channel.

8. The method of claim 1, wherein the radio interface supports a downlink control channel for conveying control messages from the base station to terminal devices and a downlink data channel for conveying other messages from the base station to terminal devices, wherein the control messages convey information on resource allocations for the other messages on the downlink data channel, and wherein the message comprises one of the other messages transmitted on the downlink data channel.

9. The method of claim 1, wherein the identifier to indicate a terminal device to which the message is addressed is transmitted separately from the message.

10. The method of claim 1, wherein the identifier comprises a radio network temporary identifier, RNTI.

11. The method of claim 1, wherein the identifier is a common to a plurality of terminal devices.

12. The method of claim 1, wherein the message comprises a broadcast message.

13. The method of claim 1, wherein the message comprises a multicast message.

14. The method of claim 1, wherein for a given type of message the characteristic for the identifier is selected from a first predefined characteristic for the identifier associated with the given type of message and a second predefined characteristic for the identifier associated with the given type of message according to whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

15. The method of claim 1, wherein the message is selected from the group comprising: (i) a message associated with transmitting system information; (ii) a message associated with transmitting a paging message; (iii) a message associated with transmitting a random access response message; (iv) a message associated with transmitting power control information for an uplink control channel; (v) a message associated with transmitting power control information for an uplink data channel; and (vi) a message associated with a broadcast and / or multicast service.

16. The method of claim 1, wherein for a message to be transmitted in accordance with the second transmission scheme, a component of the message transmitted in one of the second number of subframes is associated with a characteristic for the identifier corresponding to that which would be used if the message were to be transmitted in accordance with the first transmission scheme.

17. The method of claim 1, wherein the characteristic for the identifier comprises a value for the identifier.

18. The method of claim 1, wherein the characteristic for the identifier comprises a search space in which a terminal device searches using the identifier to determine if a message has been addressed to the terminal device.

19. The method of claim 1, wherein the method comprises selecting the characteristic for the identifier from a plurality of different characteristics associated with different types of message.

20. The method of claim 1, wherein the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme is defined in accordance with an operating standard for the wireless telecommunications system.

21. The method of claim 1, further comprising the base station pre-defining the characteristic for the identifier to be selected for a message to be transmitted in accordance with the second transmission scheme.

22. The method of claim 21, wherein the pre-defining the characteristic for the identifier is a value for the identifier selected from among a plurality of values.

23. A base station for communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the base station comprises a controller unit and a transceiver unit configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

24. Circuitry for a base station communicating a message to one or more terminal devices in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the circuitry comprises a controller element and a transceiver element configured to operate together such that the message may be transmitted in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, wherein the message is associated with an identifier to indicate a terminal device to which the message is addressed, and wherein a characteristic for the identifier is selected in dependence on whether the message is to be transmitted in accordance with the first transmission scheme or the second transmission scheme.

25. A method of operating a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the method comprises determining from an identifier associated with the message that the message is addressed to the terminal device, and further determining from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

26. A terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the terminal device comprises a controller unit and a transceiver unit configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

27. Circuitry for a terminal device for receiving a message from a base station in a wireless telecommunications system over a radio interface having a radio frame structure comprising a plurality of subframes, wherein the message may be transmitted by the base station in accordance with a first transmission scheme using transmission resources in a first number of radio subframes or transmitted by the base station in accordance with a second transmission scheme using transmission resources in a second number of radio subframes, wherein the second number is greater than the first number, and wherein the circuitry comprises a controller element and a transceiver element configured to operate together to determine from an identifier associated with the message that the message is addressed to the terminal device, and to further determine from a characteristic of the identifier whether the message transmission is in accordance with the first transmission scheme or the second transmission scheme.

(54) **Title**: ENHANCED PHYSICAL SIGNAL STRUCTURE FOR LTE V2V COMMUNICATIONS

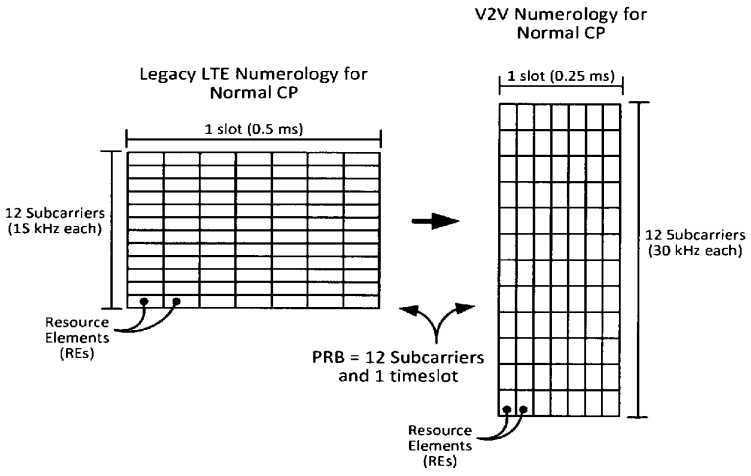

Fig. 4

(57) **Abstract**: A vehicle may wirelessly communicate with another vehicle via a physical channel (a vehicle-to-vehicle (V2V) channel) that is robust and reliable under high mobility propagation conditions. The physical channel may be created by modifying an existing long-term evolution (LTE) physical channel, such as an LTE sidelink (SL) channel. For instance, the V2V physical channel may be created by increasing, by a particular factor, the subcarrier spacing of legacy LTE channels (e.g., from 15 kilohertz (kHz) to 30 kHz). Additionally, a symbol duration and a fast Fourier transform (FFT) size for the V2V physical channel may each be reduced by the same factor. Doing so may enable the V2V physical channel to be implemented without significant modifications to other aspects of the LTE standard.

WO 2017/026983 A1

ENHANCED PHYSICAL SIGNAL STRUCTURE FOR LTE V2V COMMUNICATIONS

RELATED APPLICATIONS

The present application claims the benefit of U.S. Provisional Patent Application No. 62/203,301, which was filed on August 10, 2015, the contents of which are hereby incorporated by reference as though fully set forth herein.

BACKGROUND

The so-called "connected car concept" includes the idea that vehicles may be enabled to communicate wirelessly with one another. The 3GPP (3rd Generation Partnership Project) Long Term Evolution (LTE) communications standard has been proposed as the communication standard for implementing the connected car concept (also referred to as vehicle-to-vehicle (V2V) communications). V2V communications include one vehicle establishing a direct connection with one or multiple other vehicles.

Examples of such connections may include an LTE sidelink connection (also referred as direct connection, a proximity services (ProSe) connection, a device-to-device (D2D) connection, etc.). Once connected, vehicles may communicate a variety of information to each other, such as location information, velocity information, acceleration information, directional information, performance information, and more. Such information may be used to provide a variety of functionalities, such as preventing car accidents, determining driving conditions (e.g., traffic jams, icy roads, car accidents, etc.), determining optimal routes for driving from one location to another, etc.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments described herein will be readily understood by the following detailed description in conjunction with the accompanying drawings. To facilitate this description, like reference numerals may designate like structural elements. Embodiments are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings.

Fig. 1 is a diagram of an example environment in which systems and/or methods described herein may be implemented;

Fig. 2 is a diagram illustrating an example process for sending information to another vehicle;

Fig. 3 is a diagram illustrating an example process for receiving information from another vehicle;

Fig. 4 is a diagram of an example physical resource block (PRB) of a legacy long term evolution (LTE) numerology and an example PRB of a vehicle-to-vehicle (V2V) numerology, under normal cyclic prefix (CP) conditions;

Fig. 5 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under extended CP conditions;

Fig. 6 is a diagram of example PRB pairs of a legacy LTE numerology and example PRB pairs of a V2V numerology, under normal CP conditions;

Fig. 7 is a diagram of example PRB pairs of a legacy LTE numerology and PRB pairs of a V2V numerology, under extended CP conditions;

Figs. 8A-8D are diagrams of example PRBs according to one or more embodiments described herein;

Figs. 9A-9D are diagrams of example PRBs according to one or more embodiments described herein;

Fig. 10 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 30 kilohertz (kHz) subcarrier spacing;

Fig. 11 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 60 kHz subcarrier spacing;

Fig. 12 is a table representing an example of legacy LTE and V2V transmission multiplexing; and

Fig. 13 illustrates, for one embodiment, example components of an electronic device.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The following detailed description refers to the accompanying drawings. The same reference numbers in different drawings may identify the same or similar elements. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope of the present disclosure. Therefore, the following detailed description is not to be taken in a limiting sense, and the scope of embodiments defined by the appended claims and their equivalents.

As mentioned above, the 3GPP (3rd Generation Partnership Project) Long Term Evolution (LTE) communications standard has been proposed as the communication standard for vehicle-to-vehicle (V2V) communications. One reason behind the proposal is the reliability and high data rate capabilities of LTE technology. However, the current LTE standard includes

certain limitations when it comes to enabling vehicles to communicate with one another directly. For example, legacy LTE sidelink (SL) physical channels (also referred to as PC5 channels or device-to-device (D2D) channels) are considered to be used or enable V2V communications. At the same time, the legacy SL physical channels were designed with an assumption of substantially lower mobility conditions than the ones considered to be used for V2V communication (e.g., a scenario in which two vehicles are driving toward one another at 140 kilometers per hour (km/h) each). As a result, when subjected to wireless propagation in high mobility conditions (that may cause high Doppler fading and/or frequency shifts), legacy LTE physical channels may experience an unacceptably high block error rate (BLER) performance and/or use an unacceptably high signal-to-interference-noise ratio (SINR) to achieve reliable performance for V2V wireless communication.

Techniques described herein may be used to provide a physical channel (referred to herein as "V2V physical channel") of greater robustness and reliability when subjected to the high mobility conditions of V2V communications. For example, a V2V physical channel may have increased subcarrier spacing (e.g., 30 kilohertz (kHz) subcarriers) instead of the 15 kHz subcarrier spacing used in legacy LTE SL physical channels. The increased subcarrier spacing may improve physical channel robustness (particularly under high mobility wireless propagation effects) via a reduction of the impacts of frequency offset errors on the subcarriers orthogonality, reduced channel variations on the packet transmission duration, etc.

In some embodiments, the V2V physical channel may include additional alterations from current LTE SL physical channels. For example, the V2V physical channel may include a reduced symbol duration (e.g., a single-carrier frequency-division multiple access (SC-FDMA) symbol duration, etc.). The decrease in symbol duration may be proportional to the increased subcarrier spacing. For instance, if the subcarrier spacing of the V2V physical channel is twice as large as subcarrier spacing of a legacy LTE SL physical channel (e.g., 30 kHz instead of 15 kHz), the symbol duration for the V2V physical channel may be halved. Additionally, the decrease in symbol duration may be accompanied by a similar decrease (e.g., half) to a fast Fourier transform (FTT) size.

Additionally, since LTE air interfaces currently implement physical resource blocks (PRBs) as a fundamental unit of allocation for air interface resources, the techniques described herein may include one or more PRB formats for implementing the enhancements described above regarding modified subcarrier spacing and symbol duration of the V2V physical channels. For instance, a PRB of the V2V physical channel may

include time-domain changes, such as a change in the duration of each PRB and/or the number of slots per PRB. Similarly, a PRB of the V2V channel may include frequency-domain changes, such as the number of subcarriers per PRB, the PRB size in terms of frequency, etc. PRB formats may be discussed herein in terms of numerologies (e.g., legacy LTE numerologies and V2V numerologies), which may include a representation of subcarriers, slot durations, and resource elements (REs) of a PRB or PRB pair.

In some embodiments, the techniques described herein may be implemented within the context of cyclic prefixing (CP). For example, in the 3GPP LTE communication standard, CP may include copying a portion of one symbol (e.g., an end portion of the symbol) and adding the copied portion to a beginning portion of the symbol, such that the symbol begins and ends with the same portion. Doing so may, for example, reduce inter-symbol interference.

Fig. 1 is a diagram of an example environment 100 in which systems and/or methods described herein may be implemented. Environment 100 may include one or more vehicles with vehicle-to-X (V2X) devices 110, user equipment devices (UEs) 120, and network 130.

V2X device 110 may include a computing and communication device installed in a vehicle, such as a car, a truck, a sports utility vehicle (SUV), etc. V2X device 110 may be capable of gathering, processing, and communicating information regarding the vehicle in which V2X device 110 is installed. Examples of such information may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, etc. In some embodiments, V2X device 110 may be capable over gathering, processing, and communicating other types of information, such as information relating to a driver or passenger of the vehicle. V2X device 110 may be an example of user equipment device (UE) or another type of end terminal.

As shown, V2X device 110 may be capable of communicating with one or more networks or devices, such as UE 120, the V2X device of another vehicle, network 130, etc. In some embodiments, V2X device 110 may do so by establishing a connection that is based on a particular communications standard, such as the 3GPP LTE communication standard. For instance, V2X device 110 may establish a vehicle-to-pedestrian (V2P) connection with UE 120, which may include a D2D connection, an LTE SL connection, or other type of direct connection. V2X device 110 may also, or alternatively, establish a vehicle-to-infrastructure/network (V2I) connection with network 130. The V2I connection may include a standard connection with a base station (e.g., an evolved Node B (eNB)), a wireless access point (AP), or another device capable of enabling V2X device 110 to communicate with network 130.

As such, the "X" in "V2X device," may represent an ability of V2X device 110 to communicate with one or more types of devices (e.g., other V2X devices, UEs 120, a base station, a network access point (AP), etc.).

Additionally, or alternatively, V2X device 110 may establish a V2V connection with the V2X device of another vehicle. The V2V connection may include a D2D connection, an LTE SL connection, or other type of direct connection between UEs (e.g., a connection that does not, for example, include network 130). In some embodiments, V2X device 110 may be capable of communicating with other V2X devices using one or more of the techniques described herein. For example, V2X device 110 may be capable of using a V2V physical channel that ensure improved robustness and reliability when subjected to the high mobility conditions of V2V communications. The V2V physical channel may, for example, include greater subcarrier spacing and reduced symbol durations to, for example, improve demodulation performance including BLER reduction but still operating within the framework of an established communications standard (such as the 3GPP LTE communications standard).

UE 120 may include a portable computing and communication device, such as a personal digital assistant (PDA), a smart phone, a cellular phone, a laptop computer with connectivity to a cellular wireless network, a tablet computer, etc. UE 120 may also include non-portable computing devices, such as a desktop computer, a consumer or business appliance, or other devices that have the ability to connect to network 130. UE 120 may also include a computing and communication device that may be worn by a user (also referred to as wearable devices) as a watch, a fitness band, a necklace, glasses, an eyeglass, a ring, a belt, a headset, or another type of wearable device. As shown, UE 120 may establish a direct connection (e.g., a D2D connection) with V2X device 110. Additionally, UE 120 may communicate with V2X device 110 regarding the vehicle of V2X device 110, a driver or passenger of the vehicle, a user of UE 120, a location of the vehicle with respect to the user of UE 120, etc.

Network 130 may include one or more wired and/or wireless networks. For example, network 130 may include an LTE network. In some embodiments, network 130 may include one or more additional networks, such as a cellular network (e.g., a second generation (2G) network, a third generation (3G) network, a fourth generation (4G) network, a fifth generation (5G) network, a global system for mobile (GSM) network, a code division multiple access (CDMA) network, an evolution-data optimized (EVDO) network, or the like), a public land mobile network (PLMN), and/or another network. Additionally, or alternatively, network 150 may include a local area network (LAN), a wireless LAN (WLAN), a wide area network (WAN), a metropolitan network (MAN), the Public Switched Telephone Network (PSTN), an

ad hoc network, a managed IP network, a virtual private network (VPN), an intranet, the Internet, a fiber optic-based network, and/or a combination of these or other types of networks.

The quantity of devices and/or networks, illustrated in Fig. 1, is provided for explanatory purposes only. In practice, there may be additional devices and/or networks; fewer devices and/or networks; different devices and/or networks; or differently arranged devices and/or networks than illustrated in Fig. 1. Alternatively, or additionally, one or more of the devices of environment 100 may perform one or more functions described as being performed by another one or more of the devices of system 100. Furthermore, while "direct" connections are shown in Fig. 1, these connections should be interpreted as logical communication pathways, and in practice, one or more intervening devices (e.g., routers, gateways, modems, switches, hubs, etc.) may be present.

Additionally, while some of the techniques described herein may involve V2V communications as an example, the techniques described herein may be applied to various scenarios and/or other types of communications. For example, techniques described herein may be applicable to time division duplexing (TDD) or frequency division duplexing (FDD) communications. In some embodiments, techniques described herein may be applied to all of downlink (DL), uplink (UL), and sidelink (SL) communications, while other embodiments may only apply the techniques described herein to DL or UL or SL communications. Additionally, while the techniques described herein may be described within the context of the 3GPP LTE communications standard, the techniques may also be applied to other communication standards. Additionally, while examples provided herein may include enabling vehicles to communicate with one another more reliably, the techniques described herein may be applied to other scenarios as well (such as another system or device that may experience significant Doppler fading conditions when attempting to communicate wirelessly).

Fig. 2 is a diagram illustrating an example process 200 for sending information to another vehicle. Process 200 may be particularly appropriate for devices capable of wireless communications that may be subjected to high mobility propagation conditions (e.g., wireless propagation in high mobility conditions characterized by high Doppler fading and/or frequency shifts that may jeopardize the integrity or reliability of the wireless communications). Process 200 may be implemented by, for example, V2X device 110. Additionally, process 200 provides an example of how a V2V physical channel may be used; however, it should be noted that the V2V physical channel, as described herein, may

be used in additional and alternative ways, which may include fewer, additional, and/or alternative operations than the operations described below with reference to Fig. 2.

As shown, process 200 may include identifying a physical channel that is appropriate for communicating with another vehicle (block 210). For example, in some embodiments, V2X device 110 may be capable of using multiple physical channels for communicating with another vehicle. As described above, examples of such channels may include an LTE SL physical channel, a V2V physical channel (as described herein), etc. In some embodiments, V2X device 110 may identify the appropriate physical channel based on one or more factors.

Examples of such factors may include whether the physical channel will likely be subjected to high mobility propagation conditions. For instance, if the vehicle of the V2X device 110 and/or the other vehicle are traveling at a high speed, V2X device 110 may determine that communications between the vehicles are likely to be subjected to such conditions. As such, a V2V physical channel (as opposed to, for example, a legacy LTE SL channel) may be appropriate for communicating with the other vehicle.

Another example of a factor that may be considered by V2X device 110 may include the communication capabilities of the other vehicle. For example, V2X device 110 may determine the types of physical channels that the other vehicle is capable of using and select the most appropriate physical channel from on the physical channels that the other vehicle is capable of using. In some embodiments, determining the communication capabilities of the other vehicle may include determining what type of communications device is being implemented by the other vehicle (e.g., a V2X device or another type of communications device).

Additional examples of factors that may be used to identify an appropriate physical channel may include physical channel availability (e.g., whether V2X device is already using one or more physical channels), a measure of importance regarding the information (or type of information) that is to be sent to the other vehicle (e.g., less important information may be allocated with less reliable physical channels), a measure of importance of other information that is to communicated to a different vehicle, etc. In yet another example, V2X device may implement one or more rules for prioritizing which type of physical channel (e.g., an LTE SL channel, a V2V physical channel, etc.) should be implemented in light of one or more of the factors described above.

Process 200 may include generating information to communicate to the vehicle (block 220). For example, V2X device 110 may generate the information that is to be

transmitted to the other vehicle. Examples of such information may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, information relating to a driver or passenger of the vehicle, etc.

Process 200 may include processing the information based on the physical channel identified for communicating with the other vehicle (block 230). For example, V2X device 110 may arrange the information in accordance with a particular PRB format, which may be particular to the type of physical channel identified as the suitable for communicating with the other vehicle. For instance, if the identified physical channel corresponds to a currently available physical channel (such as an LTE LS physical channel), the information may be allocated to accommodate a format where a PRB includes 12 subcarriers (also referred to herein as frequency REs) with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. However, if the identified physical channel corresponds to a V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time. Additional examples of PRB formats are discussed below with reference to Figs. 4-9.

Process 200 may include using the physical channel to communicate information to vehicle (block 240). For example, V2X device 110 may use the physical channel identified as being appropriate for communicating with the vehicle to transmit the information to the vehicle. As described above, the physical channel may include a legacy channel (such as an LTE SL channel) or a V2V physical channel, and the information may be formatted in accordance with a format (e.g., a PRB format) that is particular to the physical channel used to transmit the information.

Fig. 3 is a diagram illustrating an example process 300 for receiving information from another vehicle. Process 300 may be particularly appropriate for devices capable of wireless communications that may be subjected to high mobility conditions (e.g., that may cause high Doppler fading and/or frequency shifts) during V2V communications. Process 300 may be implemented by, for example, V2X device 110.

As shown, process 300 may include receiving information from another vehicle via a physical channel (block 310). For example, V2X device 110 may be capable of using physical channels for communicating with another vehicle. As described above, examples

of such channels may include an LTE SL channel, a V2V physical channel, etc. The information sent and received between vehicles may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, information relating to a driver or passenger of the vehicle, etc.

Process 300 may include determining a physical channel type corresponding to the physical channel (block 320). For example, V2X device 110 may identify the type of physical channel (e.g., an LTE SL channel, a V2V channel, etc.) used to receive the information. In some embodiments, V2X device 110 may determine the manner in which the information is arranged in the physical channel based on the physical channel type may include. For example, if the physical channel corresponds to an LTE SL physical channel, the information may be formatted into PRBs that include 12 subcarriers with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. In another example, if the physical channel corresponds to a V2V physical channel, the information may be formatted into PRBs that include 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for a V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time. Additional examples of PRB formats are discussed below with reference to Figs. 4-9.

Process 300 may include interpreting the information based on the physical channel type of the physical channel (block 330). For example, V2X device 110 may interpret the information, received from another vehicle, based on a type of physical channel used to communicate the information. For instance, if the physical channel corresponds to an LTE LS physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. By contrast, if the physical channel corresponds to a V2V physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for V2V physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time.

Fig. 4 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under normal CP conditions. The legacy LTE numerology may correspond to a legacy LTE physical channel (e.g., an LTE SL channel), while the V2V

numerology may correspond to a V2V physical channel. A numerology, as discussed herein, may include parameters and characteristics of a physical channel (e.g., a legacy LTE SL channel or a V2V physical channel).

Such parameters and characteristics may include a bandwidth supported by the physical channel, a number of subcarriers per channel, a subcarrier spacing, a fast Fourier transform (FFT) size, a symbol duration, a slot duration, a subframe duration. Additional examples of numerological parameters and characteristics may include a direct, or indirect, description of a PRB and/or PRB pair of the physical channel, such as a number of subcarriers per PRB, a PRB duration (e.g., a number of slots per PRB), a number of resource elements (REs) per PRB, a number of symbols per PRB, etc.

Additionally, in the 3GPP LTE communication standard, CP may include copying a small portion of one symbol (e.g., an end portion of the symbol) and adding the copied portion to a beginning portion of the symbol, such that the symbol begins and ends with the same portion. Normal CP (as depicted in Figs. 4 and 6) may be implemented for wireless communications over shorter distances, while extended CP (as depicted in Figs. 5 and 7) may be implemented for wireless communications over longer distances. As such, normal CP may include a PRB of more symbols (or REs) per slot in time domain (e.g., 7), while extended CP may include a PRB of fewer symbols (or REs) per slot in time domain (e.g., 6).

As shown in Fig. 4, a PRB of the legacy LTE numerology for normal CP may include 12 subcarriers with 15 kHz subcarrier spacing, a slot of 0.5 ms in time domain comprising 7 consecutive symbols, and 84 REs in total. By contrast, the PRB of the V2V numerology for normal CP may include 12 subcarriers with 30 kHz subcarrier spacing, 1 slot of 0.25 ms in the time domain, comprising 7 consecutive symbols, and 84 REs in total. As such, each subcarrier of a V2V physical channel PRB may have twice as much subcarrier spacing as the subcarriers of the legacy LTE channel PRB; however, the duration of the slot of the V2V physical channel may be half the duration of the slot of the legacy LTE physical channel. As mentioned above, the decrease in slot duration may be accompanied by a similar decrease (e.g., a factor of 2, 4, etc.) to the FTT size associated with the V2V physical channel. Doing so may help ensure that the sampling time and/or sampling frequency of the V2V physical channel remains the same as the sampling time and sampling frequency of the legacy LTE channel.

For example, sampling time, as described herein, may include the basic time unit for the corresponding physical channel. For instance, in the 3GPP LTE communication standard, sampling time may be represented by "Ts" and may be equal to 1/(subcarrier spacing x FFT

size) (e.g., 1/(1500Hz x 2048)). By contrast, sampling frequency, as described herein, may include the basic frequency unit for a particular physical channel. For example, in the 3GPP LTE communication standard, sampling frequency may be represented by "Fs" and may be equal to subcarrier spacing (e.g., 15 kHz) multiplied by the number of FFT time samples (e.g., 2048).

As described above, a V2V channel may have increased subcarrier spacing (e.g., 30 kHz or 60 kHz instead of 15 kHz) but still be implemented within the LTE framework since decreasing symbol duration and FFT size proportionally may help ensure that sampling frequency and sampling time for the V2V channel are the same as the sampling frequency and sampling time of legacy LTE channels (e.g., an LTE SL channel). For example, since sampling time is equal to the inverse of subcarrier spacing multiplied by the corresponding FFT size, increasing the subcarrier spacing by a factor of two (e.g., from 15 kHz to 30 kHz) or four (e.g., from 15 kHz to 60 kHz) does not change the sampling time so long as the FFT size is reduced by the same factor (e.g., from 2048 to 1024 for factor of two or from 2048 to 512 for factor of four). The same can be said for sampling frequency since sampling frequency may be equal to subcarrier spacing multiplied by the corresponding FFT size. As such, the arrow depicted in Fig. 4 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels (which may be more robust and reliable in high mobility conditions (e.g., that may cause high Doppler fading and/or frequency shifts)) without affecting other aspects of the LTE communications standard.

For example, in some embodiments, the duration for a single subframe of a V2V channel may be set to 0.5 ms, such that the subframe may include 2 slots at 0.25 ms each. In such an implementation, relatively few (if any) modifications to the 3GPP LTE communication standard may implement the V2V channel since, for example, legacy LTE channels also include 2 slots per subframe. In other embodiments, the duration for a single subframe of the V2V channel may be set to 1.0 ms (for example), which may result in a subframe including 4 slots at 0.25 ms each. In such embodiments, certain modifications to the 3GPP LTE communications standard may be beneficial, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

Fig. 5 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under extended CP conditions. The legacy LTE numerology may correspond to a legacy LTE channel (e.g., an LTE SL channel), while the V2V numerology may correspond to a V2V channel. As shown, a PRB of the legacy LTE numerology for extended CP may include 12 subcarriers of 15 kHz each, a slot of 0.5 ms, and 72 REs (6 symbols or (REs)

per slot). By contrast, the PRB of the V2V numerology for normal CP may include 12 subcarriers of 30 kHz each, 1 slot of 0.25 ms, and 84 REs. As such, each subcarrier of a V2V channel PRB may include twice as much bandwidth as the subcarriers of the legacy LTE channel PRB; however, the slot of the V2V channel PRB may be half the duration of the slot of the legacy LTE channel PRB. As mentioned above, the decrease in slot duration may be accompanied by a similar decrease (e.g., a factor of 2, 4, etc.) to the FTT size associated with the V2V channel. The sampling frequency of the V2V channel may remain the same as the sampling frequency of the legacy LTE channel. As such, the arrow depicted in Fig. 5 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels (which may be more robust and reliable in high mobility conditions) without affecting other aspects of the LTE communications standard.

Fig. 6 is a diagram of example PRB pairs of a legacy LTE numerology and example PRB pairs of a V2V numerology, under normal CP conditions. As shown, the legacy LTE numerology and the V2V numerology may each include 4 PRBs, PRB 6.1 through PRB 6.4 and PRB 6.5 through 6.8, respectively. Each PRB of the legacy LTE numerology, and each PRB of the V2V numerology, may be similar to the corresponding PRBs discussed above with reference to Fig. 4. Additionally, the PRBs of Fig. 6 may corresponds to normal CP conditions since the PRB format includes 7 symbols (or REs) for each slot.

In the legacy LTE numerology, the PRB pairs may be differentiated from one another in the frequency domain, such that PRB 6.1 and PRB 6.2 include one pair (e.g., a 1st PRB pair) and PRB 6.3 and PRB 6.4 are another pair (e.g., a 2nd PRB pair). By contrast, in V2V numerology, the PRB pairs may be differentiated from one another in the time domain, such that PRB 6.5 and PRB 6.6 include one pair (e.g., a 1st PRB pair) and PRB 6.7 and PRB 6.8 are another pair (e.g., a 2nd PRB pair). Similar to the arrows in Fig. 4 and Fig. 5, the arrow depicted in Fig. 6 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels affecting other aspects of the LTE communications standard.

Fig. 7 is a diagram of example PRB pairs of a legacy LTE numerology and PRB pairs of a V2V numerology, under extended CP conditions. As shown, the legacy LTE numerology and the V2V numerology may each include 4 PRBs, PRB 7.1 through PRB 7.4 and PRB 7.5 through 7.8, respectively. Each PRB of the legacy LTE numerology, and each PRB of the V2V numerology, may be similar to the corresponding PRBs discussed above with reference to Fig. 5. Additionally, the PRBs of Fig. 7 may correspond to extended CP conditions since the PRB format includes 6 symbols (or REs) for each slot.

In the legacy LTE numerology, the PRB pairs may be differentiated from one another in the frequency domain, such that PRB 7.1 and PRB 7.2 include one pair (e.g., a 1st PRB pair) and PRB 6.3 and PRB 6.4 are another pair (e.g., a 2nd PRB pair). By contrast, in V2V numerology, the PRB pairs may be differentiated from one another in the time domain, such that PRB 7.5 and PRB 7.6 include one pair (e.g., a 1st PRB pair) and PRB 7.7 and PRB 7.8 are another pair (e.g., a 2nd PRB pair). Similar to the arrow in Fig. 6, the arrow depicted in Fig. 7 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels affecting other aspects of the LTE communications standard.

Figs. 8A-8D are diagrams of example PRBs according to one or more embodiments described herein. Additionally, the PRBs of Figs. 8A-8D may corresponds to normal CP conditions since each PRB includes 7 symbols per slot in time domain. The example PRB of Fig. 8A may correspond to the V2V channel PRB described above with reference to Fig. 4. The example PRBs of Fig. 8B may include a PRB pair (PRB 8.1 and PRB 8.2), similar to the V2V channel PRB pairs described above with reference to Fig. 5. Fig. 8C may include an example PRB that is similar to the PRB of Fig. 8A, except that the example PRB of Fig. 8C includes only 6 subcarriers (also, "REs in frequency" or "Frequency REs") of 30 kHz each. Similarly, Fig. 8D may include an example PRB pair (PRB 8.3 and PRB 8.4) that is similar to the PRB pair of Fig. 9B, except that the example PRBs of Fig. 8D include only 6 subcarriers with 30 kHz subcarrier spacing. In some embodiments, reducing the number of subcarriers per V2V channel may increase the number of transmission channels that may be used for V2V communications, which may in turn increase V2V system capacity (e.g., in a location with a high number of vehicles, such as a traffic jam on a freeway or major intersection).

Figs. 9A-9D are diagrams of example PRBs according to one or more embodiments described herein. Additionally, the PRBs of Figs. 9A-9D may correspond to extended CP conditions since each PRB includes 6 symbols per slot. The example PRB of Fig. 9A may correspond to the V2V channel PRB described above with reference to Fig. 5. The example PRBs of Fig. 9B may include a PRB pair (PRB 9.1 and PRB 9.2), similar to the V2V channel PRB pairs described above with reference to Fig. 5. Fig. 9C may include an example PRB that is similar to the PRB of Fig. 9A, except that the example PRB of Fig. 9C includes only 6 subcarriers (also, "REs in frequency" or "Frequency REs") of 30 kHz each. Similarly, Fig. 9D may include an example PRB pair (PRB 9.3 and PRB 9.4) that is similar to the PRB pair of Fig. 9B, except that the example PRBs of Fig. 9D include only 6 (instead of 12) subcarriers of 30 kHz each. As described above with reference to Figs. 8A-8D, in some embodiments, reducing

the number of subcarriers per V2V channel may increase the number of transmission channels that may be used for V2V communications, which may in turn increase the level of V2V system capacity (e.g., in a location with a high number of vehicles, such as a traffic jam on a freeway or major intersection).

Fig. 10 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 30 kHz subcarrier spacing. As shown, the table of Fig. 10 includes a Channel Characteristics column, a Legacy LTE Channel Numerology column, and a V2V Channel numerology column. Fig. 10 provides a non-limiting example of differences and similarities that may exists between a legacy LTE channel and a V2V channel.

For example, a legacy LTE channel may include a subcarrier spacing of 15 kHz, while a V2V channel may include a subcarrier spacing of 30 kHz. Both channels may support the same bandwidths; however, the channels may only support some of the same FTT sizes. For instance, only the legacy LTE channel may use FTT sizes of 1536 and 2048, and the V2V channel may use FTT sizes of 64 and 768. As such, the FFT size for the legacy LTE channel may include a lower limit of 128 for the 1.4 MHz bandwidth and an upper limit of 2048 for 20 MHz bandwidth, while the FFT size for the V2V channel (with 30 kHz subcarrier spacing), may include a lower limit of 64 for 1.4 MHz bandwidth and an upper limit of 1024 for the 20 MHz bandwidth. As described above, this is due to reducing the FTT sizes for the V2V channel by the same factor (e.g., "2") that was used to increase the subcarrier spacing of the V2V channel. The following table may represent a logical relationship between different BWs, legacy LTE FFT sizes, and V2V channel FFT sizes (when the subcarrier spacing for the V2V channel is 30 kHz).

Bandwidth (BW)	Nominal FFT Size	
	Legacy LTE Channel	V2V Channel with 30 kHz
1.4 MHz	128	64
3 MHz	256	128
5 MHz	512	256
10 MHz	1024	512
15 MHz	1536	768
20 MHz	2048	1024

Since the same factor was used to increase and decrease the subcarrier spacing and FFT size (respectively), both channels may have the same sampling time (Ts) of 32.55 nanoseconds

(ns) because sampling time may be calculated by taking the inverse of the product of the subcarrier spacing and the FFT size (e.g., Ts = 1/(subcarrier spacing x FFT size). In some embodiments, for similar reasons, both channels may also have the same sampling frequency (Fs) (e.g., Fs = subcarrier spacing x FFT size). As mentioned above, maintaining the same sampling time and sampling frequency as the legacy LTE channel may help ensure that the V2V channel can be implemented in an LTE environment without having to make significant adjustments to other aspects of the 3GPP LTE communication standard.

Similar to the change in FFT size, the symbol durations for the V2V channel may also be reduced by the same factor (e.g., "2") that was used to increase the subcarrier spacing of the V2V channel. As shown in Figs. 6-7, this may enable PRBs and PRB pairs to be formatted in a manner that enables the V2V channel to reduce the slot duration by half (e.g., from 0.5 ms to 0.25 ms) and output PRBs at the same rate as the legacy LTE channel, even though the subcarrier spacing for the V2V channel was doubled. Similar to maintaining the same sampling time and sampling frequency, maintaining a similar output rate as the legacy LTE channel, may help reduce the impact of the V2V channel on other aspects of the 3GPP LTE communication standard.

Additionally, the single subframe duration for the legacy LTE channel may be 1.0 ms, whereas the single subframe duration for the V2V channel may be 0.5 or 1.0 ms. A single subframe duration of 0.5 ms may enable the V2V channel to have two slots per subframe since the slot duration for the V2V channel was reduced to 0.25 ms. Additionally, since a PRB duration may be 0.25 ms (which corresponds to 1 slot), a 0.5 ms subframe may consist of one PRB pair (i.e., two 0.25 ms PRBs). In other words, the V2V channel may have a subframe-to-PRB-pair ratio of 1:1 when the subframe duration of the V2V channel is 0.5 ms, which may reduce the impact of the V2V channel on the 3GPP LTE communication standard since, for example, the legacy LTE channel also has a subframe-to-PRB-pair ratio of 1:1.

By contrast, a single subframe duration of 1.0 ms may enable the V2V channel to have four slots per subframe since the slot duration for the V2V channel was reduced to 0.25 ms. As such, the subframe may include four slots. In other words, a subframe duration of 1.0 ms, as opposed to the 0.5 ms subframe scenario above, may give rise to a relative increase in the amount of information that may be communicated in one subframe. As a result, implementing a 1.0 ms subframe may additional modifications to the 3GPP LTE communication standard, including changes to the design of physical channels, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

As shown in Fig. 10, whether the legacy LTE channel and the V2V channel have the same number of subcarriers per PRB may depend on the scenario or embodiment. For example, both channels may have 12 subcarriers for each PRB. Additionally, or alternatively, the V2V channel may have 6 subcarriers per PRB. In some embodiments, while allocating 6 subcarriers (instead of 12) to each PRB may decrease the rate at which a channel may transmit data, doing so may also increase the number of V2V channels that are available for V2X devices 110 to communicate with other V2X devices, UEs, etc. As such, allocating 6 subcarriers to each V2V channel may be beneficial in scenarios where V2V channels might not benefit from a high data rate connections and/or a vehicle with a V2X device is in a traffic jam, rush hour traffic, or in another situation involving a lot of V2X devices 110, UEs 110, etc., that within range of one another.

Fig. 11 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 60 kHz subcarrier spacing. As shown, the table of Fig. 11 includes a Channel Characteristics column, a Legacy LTE Channel Numerology column, and a V2V Channel numerology column. Fig. 11 provides a non-limiting example of differences and similarities that may exists between a legacy LTE channel and a V2V channel.

For example, a legacy LTE channel may include a subcarrier spacing of 15 kHz, while a V2V channel may include a subcarrier spacing of 60 kHz. Both channels may support the same bandwidths; however, the channels may only support some of the same FTT sizes. For instance, only the legacy LTE channel may support FTT sizes of 1024, 1536, and 2048, and only the V2V channel may support an FTT size of 32, 64, and 384. As such, the FFT size for the legacy LTE channel may include a lower limit of 128 and an upper limit of 2048, while the FFT size for the V2V channel (with 60 kHz subcarrier spacing), may include a lower limit of 32 kHz and an upper limit of 512 kHz. This may be due to reducing the FTT sizes for the V2V channel by the same factor (e.g., "4") that was used to increase the subcarrier spacing of the V2V channel. The following table may represent a logical relationship between different BWs, legacy LTE FFT sizes, and V2V channel FFT sizes (when the subcarrier spacing for the V2V channel is 30 kHz).

Bandwidth (BW)	Nominal FFT Size	
	Legacy LTE Channel	V2V Channel with 60 kHz
1.5 MHz	128	32
3 MHz	256	64
5 MHz	512	128
10 MHz	1024	256

15 MHz	1536	384
20 MHz	2048	512

Since the same factor was used to increase and decrease the subcarrier spacing and FFT size (respectively), both channels may have the same sampling time (Ts) of 32.55 nanoseconds (ns) because sampling time may be calculated by taking the inverse of the product of the subcarrier spacing and the FFT size (e.g., Ts = 1/(subcarrier spacing x FFT size). In some embodiments, for similar reasons, both channels may also have the same sampling frequency (Fs) (e.g., Fs = subcarrier spacing x FFT size). As mentioned above, maintaining the same sampling time and sampling frequency as the legacy LTE channel may help ensure that the V2V channel can be implemented in an LTE environment without having to make significant adjustments to other aspects of the 3GPP LTE communication standard.

Similar to the change in FFT size, the symbol durations for the V2V channel may also be reduced by the same factor (e.g., "4") that was used to increase the subcarrier spacing of the V2V channel. This may enable PRBs and PRB pairs to be formatted in a manner that enables the V2V channel to reduce the slot duration by one-fourth (e.g., from 1.0 ms to 0.125 ms) and output PRBs at the same rate as the legacy LTE channel, even though the subcarrier spacing for the V2V channel was quadrupled. Similar to maintaining the same sampling time and sampling frequency, maintaining a similar output rate as the legacy LTE channel, may help reduce the impact of the V2V channel on other aspects of the 3GPP LTE communication standard.

Additionally, the single subframe duration for the legacy LTE channel may be 1.0 ms, whereas the single subframe duration for the V2V channel may be 0.25 or 1.0 ms. A single subframe duration of 0.25 ms may enable the V2V channel to have two slots per subframe since the slot duration for the V2V channel was reduced to 0.125 ms. Additionally, since a PRB duration may be 0.125 ms (which corresponds to 1 slot), a 0.25 ms subframe may consist of one PRB pair (i.e., two 0.125 ms PRBs). In other words, the V2V channel may have a subframe-to-PRB-pair ratio of 1:1 when the subframe duration of the V2V channel is 0.25 ms, which may reduce the impact of the V2V channel on the 3GPP LTE communication standard since, for example, the legacy LTE channel also has a subframe-to-PRB-pair ratio of 1:1.

By contrast, a single subframe duration of 1.0 ms may enable the V2V channel to have eight slots per subframe since the slot duration for the V2V channel was reduced to 0.125 ms. As such, the subframe may include eight slots. In other words, a subframe duration of 1.0 ms, as opposed to the 0.25 ms subframe scenario above, may give rise to a relative increase in the amount of information that may be communicated in one subframe. As a result, implementing a

1.0 ms subframe may additional modifications to the 3GPP LTE communication standard, including changes to the design of physical channels, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

As shown in Fig. 11, whether the legacy LTE channel and the V2V channel have the same number of subcarriers per PRB may depend on the scenario or embodiment. For example, both channels may have 12 subcarriers for each PRB. Additionally, or alternatively, the V2V channel may have 3 or 6 subcarriers per PRB. In some embodiments, while allocating 3 or 6 subcarriers (instead of 12) to each PRB may decrease the rate at which a channel may transmit data, doing so may also increase the number of V2V channels that are available for V2X devices 110 to communicate with other V2X devices, UEs, etc. As such, allocating 3 or 6 subcarriers to each V2V channel may be beneficial in scenarios where V2V channels might not benefit from high data rate connections and/or a vehicle with a V2X device is in a traffic jam, rush hour traffic, or in another situation involving a lot of V2X devices 110, UEs 110, etc., that within range of one another.

Fig. 12 is a table representing an example of legacy LTE and V2V transmission multiplexing. As shown, Fig. 12 may include a vertical axis representing frequency and a horizontal axis representing time. V2V devices 110, UEs 110, etc., may support both legacy and V2V PHY numerologies (e.g. for cellular and V2V operation). Time domain multiplexing of legacy and V2V transmissions at one UE 110 may be used for these purposes. To facilitate efficient use of resources the minimum granularity for time domain multiplexing may be a multiple of legacy subframe granularity (e.g., 1.0 ms).

In one example, subframes for legacy LTE and V2V operation may be semi-statically, higher-layer configured, by an eNB (e.g., via radio resource control (RRC) protocol), on a per V2V device basis (or V2V device group basis). Semi-statically may include, for example, physical channels that are predefined by the eNB and assigned to a particular V2V device 210 or UE in a given scenario. In another example, subframes for legacy LTE and V2V operation may be dynamically assigned. In yet another example, subframes for legacy LTE and V2V operation may be specified by a communications standard (such as the 3GPP LTE communication standard).

A V2V transmissions (e.g., transmissions with a V2V numerology) may take place in either TDD or FDD modes. In the latter case, the transmissions may be configured in either a DL or a UL spectrum and can be configured independently (e.g., V2V transmissions on a UL spectrum may not impose use of V2V numerology in a DL spectrum in the same time resources).

In some embodiments, V2V device 110, UE 110, etc., may implement an autonomous selection capability for the numerology for the V2V transmissions (e.g., either a legacy LTE numerology or a V2V numerology) based on one or more instructions, conditions, or other criteria. As such, a V2V receiver (or another type of communication component) may either be informed on the type of the transmission in advance or may dynamically detect the transmission type. In embodiments where the transmission type is dynamically detected, a receiver (or another component of V2V device 110) may attempt to receive information under different hypothesis simultaneously (e.g., attempt to receive a signal under both a 15 kHz subcarrier spacing assumption and a 30 kHz subcarrier spacing assumptions)

As used herein, the term "circuitry" or "processing circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

Embodiments described herein may be implemented into a system using any suitably configured hardware and/or software. Fig. 13 illustrates, for one embodiment, example components of an electronic device 1300. In embodiments, the electronic device 1300 may be a UE, an eNB, a WLAN AP, or some other appropriate electronic device. In some embodiments, the electronic device 1300 may include application circuitry 1302, baseband circuitry 1304, Radio Frequency (RF) circuitry 1306, front-end module (FEM) circuitry 1308 and one or more antennas 1360, coupled together at least as shown.

The application circuitry 1302 may include one or more application processors. For example, the application circuitry 1302 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The processor(s) may include any combination of general-purpose processors and dedicated processors (e.g., graphics processors, application processors, etc.). The processors may be coupled with and/or may include memory/storage, such as storage medium 1303, and may be configured to execute instructions stored in the memory/storage to enable various applications and/or operating systems to run on the system. In some implementations, storage medium 1303 may include a non-transitory computer-readable medium. Application circuitry 1302 may, in some embodiments, connect to or include one or more sensors, such as environmental sensors, cameras, etc.

Baseband circuitry 1304 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry 1304 may include one or more baseband processors and/or control logic to process baseband signals received from a receive signal path of the RF circuitry 1306 and to generate baseband signals for a transmit signal path of the RF circuitry 1306. Baseband processing circuitry 1304 may interface with the application circuitry 1302 for generation and processing of the baseband signals and for controlling operations of the RF circuitry 1306. For example, in some embodiments, the baseband circuitry 1304 may include a second generation (2G) baseband processor 1304a, third generation (3G) baseband processor 1304b, fourth generation (4G) baseband processor 1304c, and/or other baseband processor(s) 1304d for other existing generations, generations in development or to be developed in the future (e.g., fifth generation (5G), 6G, etc.). The baseband circuitry 1304 (e.g., one or more of baseband processors 1304a-d) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry 1306. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some implementations, baseband circuitry 1304 may be associated with storage medium 1303 or with another storage medium.

In some embodiments, modulation/demodulation circuitry of the baseband circuitry 1304 may include FFT, precoding, and/or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry 1304 may include convolution, tail-biting convolution, turbo, Viterbi, and/or Low Density Parity Check (LDPC) encoder/decoder functionality. Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments. In some embodiments, the baseband circuitry 1304 may include elements of a protocol stack such as, for example, elements of an evolved universal terrestrial radio access network (E-UTRAN) protocol including, for example, physical (PHY), MAC, radio link control (RLC), packet data convergence protocol (PDCP), and/or radio resource control (RRC) elements. A central processing unit (CPU) 1304e of the baseband circuitry 1304 may be configured to run elements of the protocol stack for signaling of the PHY, MAC, RLC, PDCP and/or RRC layers. In some embodiments, the baseband circuitry may include one or more audio digital signal processor(s) (DSP) 1304f. The audio DSP(s) 1304f may be include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments.

The baseband circuitry 1304 may further include memory/storage 1304g. The memory/storage 1304g may be used to load and store data and/or instructions for operations

performed by the processors of the baseband circuitry 1304. Memory/storage for one embodiment may include any combination of suitable volatile memory and/or non-volatile memory. The memory/storage 1304g may include any combination of various levels of memory/storage including, but not limited to, read-only memory (ROM) having embedded software instructions (e.g., firmware), random access memory (e.g., dynamic random access memory (DRAM)), cache, buffers, etc. The memory/storage 1304g may be shared among the various processors or dedicated to particular processors.

Components of the baseband circuitry may be suitably combined in a single chip, a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry 1304 and the application circuitry 1302 may be implemented together such as, for example, on a system on a chip (SOC).

In some embodiments, the baseband circuitry 1304 may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry 1304 may support communication with an E-UTRAN and/or other wireless metropolitan area networks (WMAN), a WLAN, a wireless personal area network (WPAN). Embodiments in which the baseband circuitry 1304 is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

RF circuitry 1306 may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry 1306 may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry 1306 may include a receive signal path which may include circuitry to down-convert RF signals received from the FEM circuitry 1308 and provide baseband signals to the baseband circuitry 1304. RF circuitry 1306 may also include a transmit signal path which may include circuitry to up-convert baseband signals provided by the baseband circuitry 1304 and provide RF output signals to the FEM circuitry 1308 for transmission.

In some embodiments, the RF circuitry 1306 may include a receive signal path and a transmit signal path. The receive signal path of the RF circuitry 1306 may include mixer circuitry 1306a, amplifier circuitry 1306b and filter circuitry 1306c. The transmit signal path of the RF circuitry 1306 may include filter circuitry 1306c and mixer circuitry 1306a. RF circuitry 1306 may also include synthesizer circuitry 1306d for synthesizing a frequency for use by the mixer circuitry 1306a of the receive signal path and the transmit signal path. In some

embodiments, the mixer circuitry 1306a of the receive signal path may be configured to down-convert RF signals received from the FEM circuitry 1308 based on the synthesized frequency provided by synthesizer circuitry 1306d. The amplifier circuitry 1306b may be configured to amplify the down-converted signals and the filter circuitry 1306c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals.

Output baseband signals may be provided to the baseband circuitry 1304 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals. In some embodiments, mixer circuitry 1306a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 1306a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 1306d to generate RF output signals for the FEM circuitry 1308. The baseband signals may be provided by the baseband circuitry 1304 and may be filtered by filter circuitry 1306c. The filter circuitry 1306c may include a low-pass filter (LPF), although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may include two or more mixers and may be arranged for quadrature downconversion and/or upconversion respectively. In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a may be arranged for direct downconversion and/or direct upconversion, respectively. In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may be configured for super-heterodyne operation.

In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 1306 may include analog-to-digital converter (ADC) and digital-to-analog converter (DAC) circuitry and the baseband circuitry 1304 may include a digital baseband interface to communicate with the RF circuitry 1306.

In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

In some embodiments, the synthesizer circuitry 1306d may be a fractional-N synthesizer or a fractional N/N+6 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 1306d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

The synthesizer circuitry 1306d may be configured to synthesize an output frequency for use by the mixer circuitry 1306a of the RF circuitry 1306 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 1306d may be a fractional N/N+6 synthesizer.

In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO. Divider control input may be provided by either the baseband circuitry 1304 or the applications processor 1302 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the applications processor 1302.

Synthesizer circuitry 1306d of the RF circuitry 1306 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or N+6 (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into Nd equal packets of phase, where Nd is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

In some embodiments, synthesizer circuitry 1306d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 1306 may include an IQ/polar converter.

FEM circuitry 1308 may include a receive signal path which may include circuitry configured to operate on RF signals received from one or more antennas 1360, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 1306 for further processing. FEM circuitry 1308 may also include a transmit signal path which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 1306 for transmission by one or more of the one or more antennas 1360.

In some embodiments, the FEM circuitry 1308 may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry may include a low-noise amplifier (LNA) to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry 1306). The transmit signal path of the FEM circuitry 1308 may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry 1306), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas 1360.

In some embodiments, the electronic device 1300 may include additional elements such as, for example, memory/storage, display, camera, sensors, and/or input/output (I/O) interface. In some embodiments, the electronic device of Fig. 13 may be configured to perform one or more methods, processes, and/or techniques such as those described herein.

A number of examples, relating to embodiments of the techniques described above, will next be given.

In a first example, a communication device may comprise: a radio frequency (RF) circuitry to communicate with other communication devices via a physical channel; and baseband circuitry to cause the RF circuitry to communicate with another communication device via the physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 2, the subject matter of example 1, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 3, the subject matter of example 1, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6

subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 4, the subject matter of example 1, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In example 5, the subject matter of example 1, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: a vehicle-to-vehicle (V2V) communication, a vehicular-to-infrastructure (V2I) communication, or a vehicular-to-pedestrian (V2P) communication.

In example 6, the subject matter of example 1, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an long-term evolution (LTE) sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In a seventh example, an apparatus for a wireless communication device may comprise: a radio (RF) circuitry to communicate with other communication devices via a physical channel; and a baseband circuitry to: use a physical channel, from a plurality of physical channel types, that is appropriate for communicating with the other wireless communication devices, the plurality of physical channel types including: a long-term evolution (LTE) physical channel, and a V2V physical channel that includes: a bandwidth that is at least as large as a bandwidth of the LTE physical channel; a subcarrier spacing that is greater, by a preselected factor, than a subcarrier spacing corresponding to the LTE physical channel, a fast Fourier transform (FFT) size that is less, by the preselected factor, than an FFT size corresponding to the LTE physical channel, a symbol duration that is less, by the preselected factor, than a symbol duration corresponding to the LTE physical channel, and a sampling frequency that is equal to a sampling frequency of the LTE physical channel, and a sampling time that is equal to a sampling time of the LTE physical channel; and communicate with the other wireless communication devices via the V2V physical channel.

In example 8, the subject matter of example 7, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an LTE sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In example 9, the subject matter of example 7, or any of the examples herein, may further include wherein the V2V physical channel includes physical resource blocks (PRBs) that

each include a number of subcarriers that is less than, or equal to, a number of subcarriers of the PRBs of the LTE physical channel.

In example 10, the subject matter of example 7, or any of the examples herein, may further include wherein: the subcarrier spacing for the V2V physical channel is 30 or 60 kilohertz (kHz); and the subcarrier spacing for the LTE physical channel is 15 kHz.

In example 11, the subject matter of example 7, or any of the examples herein, may further include wherein, for normal cyclic prefix (CP) conditions and extended CP conditions, a number of resource elements (REs) and a number of single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols per a physical resource block (PRB) of the V2V physical channel is equal to the number of REs and a number of SC-FDMA or OFDM symbols per PRB of the LTE physical channel.

In example 12, the subject matter of example 7, or any of the examples herein, may further include wherein application circuitry is to: communicate with a user equipment device (UE) of a vehicle via a vehicle-to-vehicle (V2V) connection, communicate with a UE of a user via a vehicle-to-pedestrian (V2P) connection, or communicate with a wireless telecommunications network via a vehicle-to-infrastructure (V2I) connection.

In example 13, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry uses the type of physical channel that is appropriate for communicating with the other wireless communication device based on at least one of: a likelihood of communications, between the wireless communication device and the other wireless communication device being subjected to high mobility conditions, whether the other wireless communication device is capable of communicating via the LTE physical channel or the V2V physical channel, an availability, of the LTE physical channel or the V2V physical channel, for communicating with the other wireless communication device, a measure of importance regarding information that will be communicated to the other wireless communication device, or a preselected priority for communicating via the LTE physical channel or the V2V physical channel.

In example 14, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry is configured, by via an eNB, to use the V2V physical channel or the LTE physical channel.

In example 15, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry uses time-division multiplexing of the V2V physical channel and the LTE physical channel to communicate in different subframes.

In example 16, the subject matter of example 7, or any of the examples herein, may further include wherein subframes for the V2V physical channel and the LTE physical channel are semi-statically configured by an eNB.

In a seventeenth example, a wireless communication device as in the first or seventh examples, wherein a physical resource block (PRB), corresponding to the vehicle-to-vehicle (V2V) physical channel, includes: 7 consecutive single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols in time domain under normal cyclic prefix (CP) conditions, and 6 consecutive SC-FDMA or OFDM symbols in time domain under extended CP conditions.

In example 18, the subject matter of example 17, or any of the examples herein, may further include a subframe, corresponding to the V2V physical channel, includes two slots, a physical resource block (PRB), corresponding to the V2V physical channel, contains one slot; and a subframe duration, corresponding to the V2V physical channel, is equal to at least one of: 0.5 milliseconds (ms) and a slot duration is 0.25 ms when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz); or 0.25 milliseconds (ms) and a slot duration is 0.125 ms when subcarrier spacing for the V2V physical channel is 60 kilohertz (kHz).

In example 19, the subject matter of example 17, or any of the examples herein, may further include a subframe duration, corresponding to the vehicle-to-vehicle (V2V) physical channel, is equal to 1.0 ms, and the subframe, corresponding to the V2V physical channel, includes four slots with 0.25 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains two slots when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz), or the subframe, corresponding to the V2V physical channel, includes eight slots with 0.125 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains four slots when subcarrier spacing for the V2V physical channel is 60 kHz.

In a twentieth example, a computer readable medium may contain program instructions for causing one or more processors to: communicate with other communication devices via a physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 21, the subject matter of example 20, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 22, the subject matter of example 20, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 23, the subject matter of example 20, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: a vehicle-to-vehicle (V2V) communication, a vehicular-to-infrastructure (V2I) communication, or a vehicular-to-pedestrian (V2P) communication.

In example 24, the subject matter of example 20, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an LTE sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In example 25, the subject matter of example 20, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In a twenty-sixth example, a communication device may comprise: a means for communicating with other communication devices via a physical channel; and a means for causing the means for communicating to communicate with another communication device via the physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 27, the subject matter of example 26, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 28, the subject matter of example 26, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6

subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 29, the subject matter of example 26, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In the preceding specification, various embodiments have been described with reference to the accompanying drawings. It will, however, be evident that various modifications and changes may be made thereto, and additional embodiments may be implemented, without departing from the broader scope as set forth in the claims that follow. The specification and drawings are accordingly to be regarded in an illustrative rather than restrictive sense.

For example, while series of signals and/or operations have been described with regard to Figs. 3-4, the order of the signals and/or operations may be modified in other embodiments. Further, non-dependent signals may be performed in parallel.

It will be apparent that example aspects, as described above, may be implemented in many different forms of software, firmware, and hardware in the embodiments illustrated in the figures. The actual software code or specialized control hardware used to implement these aspects should not be construed as limiting. Thus, the operation and behavior of the aspects were described without reference to the specific software code--it being understood that software and control hardware could be designed to implement the aspects based on the description herein.

Further, certain portions may be implemented as "logic" that performs one or more functions. This logic may include hardware, such as an application-specific integrated circuit ("ASIC") or a field programmable gate array ("FPGA"), or a combination of hardware and software.

Even though particular combinations of features are recited in the claims and/or disclosed in the specification, these combinations are not intended to be limiting. In fact, many of these features may be combined in ways not specifically recited in the claims and/or disclosed in the specification.

No element, act, or instruction used in the present application should be construed as critical or essential unless explicitly described as such. An instance of the use of the term "and," as used herein, does not necessarily preclude the interpretation that the phrase "and/or" was intended in that instance. Similarly, an instance of the use of the term "or," as used herein, does not necessarily preclude the interpretation that the phrase "and/or" was intended in that instance. Also, as used herein, the article "a" is intended to include one or more items, and may be used

interchangeably with the phrase "one or more." Where only one item is intended, the terms "one," "single," "only," or similar language is used.

Samsung Exhibit 1026, Page 31 of 53

WHAT IS CLAIMED IS:

1. A communication device, comprising:

a radio frequency (RF) circuitry to communicate with other communication devices via a physical channel; and

baseband circuitry to cause the RF circuitry to communicate with another communication device via the physical channel, the physical channel including:

a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform,

a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and

a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

2. The communication device of claim 1, wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

3. The communication device of claim 1, wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

4. The communication device of claim 1, wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

5. The communication device of claim 1, wherein the physical channel corresponds to at least one of:

a vehicle-to-vehicle (V2V) communication,

a vehicular-to-infrastructure (V2I) communication, or

a vehicular-to-pedestrian (V2P) communication.

6. The communication device of claim 1, wherein the physical channel corresponds to at least one of:

an long-term evolution (LTE) sidelink (SL) physical channel,

an LTE downlink (DL) physical channel, or

an LTE uplink (UL) physical channel.

7. An apparatus for a wireless communication device, comprising:

a radio (RF) circuitry to communicate with other communication devices via a physical channel; and

a baseband circuitry to:

use a physical channel, from a plurality of physical channel types, that is appropriate for communicating with the other wireless communication devices, the plurality of physical channel types including:

a long-term evolution (LTE) physical channel, and

a V2V physical channel that includes:

a bandwidth that is at least as large as a bandwidth of the LTE physical channel;

a subcarrier spacing that is greater, by a preselected factor, than a subcarrier spacing corresponding to the LTE physical channel,

a fast Fourier transform (FFT) size that is less, by the preselected factor, than an FFT size corresponding to the LTE physical channel,

a symbol duration that is less, by the preselected factor, than a symbol duration corresponding to the LTE physical channel, and

a sampling frequency that is equal to a sampling frequency of the LTE physical channel, and

a sampling time that is equal to a sampling time of the LTE physical channel; and

communicate with the other wireless communication devices via the V2V physical channel.

8. The apparatus of claim 7, wherein the LTE physical channel and the V2V physical channel correspond to at least one of:

long-term evolution (LTE) sidelink (SL) physical channels,

LTE downlink (DL) physical channels, or

LTE uplink (UL) physical channels.

9. The apparatus of claim 7, wherein the V2V physical channel includes physical resource blocks (PRBs) that each include a number of subcarriers that is less than, or equal to, a number of subcarriers of the PRBs of the LTE physical channel.

10. The apparatus of claim 7, wherein:
the subcarrier spacing for the V2V physical channel is 30 or 60 kilohertz (kHz); and
the subcarrier spacing for the LTE physical channel is 15 kHz.

11. The apparatus of claim 7, wherein, for normal cyclic prefix (CP) conditions and extended CP conditions, a number of resource elements (REs) and a number of single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols per a physical resource block (PRB) of the V2V physical channel is equal to the number of REs and a number of SC-FDMA or OFDM symbols per PRB of the LTE physical channel.

12. The apparatus of claim 7, wherein application circuitry is to:
communicate with a user equipment device (UE) of a vehicle via a vehicle-to-vehicle (V2V) connection,
communicate with a UE of a user via a vehicle-to-pedestrian (V2P) connection, or
communicate with a wireless telecommunications network via a vehicle-to-infrastructure (V2I) connection.

13. The apparatus of claim 7, wherein the baseband circuitry uses the type of physical channel that is appropriate for communicating with the other wireless communication device based on at least one of:
a likelihood of communications, between the wireless communication device and the other wireless communication device being subjected to high mobility conditions,
whether the other wireless communication device is capable of communicating via the LTE physical channel or the V2V physical channel,
an availability, of the LTE physical channel or the V2V physical channel, for communicating with the other wireless communication device,
a measure of importance regarding information that will be communicated to the other wireless communication device, or

a preselected priority for communicating via the LTE physical channel or the V2V physical channel.

14. The apparatus of claim 7, wherein the baseband circuitry is configured, by via an eNB, to use the V2V physical channel or the LTE physical channel.

15. The apparatus of claim 7, wherein the baseband circuitry uses time-division multiplexing of the V2V physical channel and the LTE physical channel to communicate in different subframes.

16. The apparatus of either of claims 15, wherein subframes for the V2V physical channel and the LTE physical channel are semi-statically configured by an eNB.

17. A wireless communication device as in claims 1 or 7, wherein a physical resource block (PRB), corresponding to the vehicle-to-vehicle (V2V) physical channel, includes:

7 consecutive single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols in time domain under normal cyclic prefix (CP) conditions, and

6 consecutive SC-FDMA or OFDM symbols in time domain under extended CP conditions.

18. The wireless communication device of claim 17, wherein:

a subframe, corresponding to the V2V physical channel, includes two slots,

a physical resource block (PRB), corresponding to the V2V physical channel, contains one slot; and

a subframe duration, corresponding to the V2V physical channel, is equal to at least one of:

0.5 milliseconds (ms) and a slot duration is 0.25 ms when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz); or

0.25 milliseconds (ms) and a slot duration is 0.125 ms when subcarrier spacing for the V2V physical channel is 60 kilohertz (kHz).

19. The wireless communication device of claim 17, wherein:

a subframe duration, corresponding to the vehicle-to-vehicle (V2V) physical

channel, is equal to 1.0 ms, and

the subframe, corresponding to the V2V physical channel, includes four slots with 0.25 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains two slots when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz), or

the subframe, corresponding to the V2V physical channel, includes eight slots with 0.125 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains four slots when subcarrier spacing for the V2V physical channel is 60 kHz.

20. A computer readable medium containing program instructions for causing one or more processors to:

communicate with other communication devices via a physical channel, the physical channel including:

a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform,

a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and

a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

21. The computer readable medium of claim 20, wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

22. The computer readable medium of claim 20, wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

23. The computer readable medium of claim 20, wherein the physical channel corresponds to at least one of:

a vehicle-to-vehicle (V2V) communication,

a vehicular-to-infrastructure (V2I) communication, or

a vehicular-to-pedestrian (V2P) communication.

24. The computer readable medium of claim 20, wherein the physical channel corresponds to at least one of:

an long-term evolution (LTE) sidelink (SL) physical channel,

an LTE downlink (DL) physical channel, or

an LTE uplink (UL) physical channel.

25. The computer readable medium of claim 20, wherein a PRB pair, of the physical channel, corresponds to two consecutive PRBs in a time-domain.

INTERNATIONAL SEARCH REPORT

International application No
PCT/US2015/000466

A. CLASSIFICATION OF SUBJECT MATTER
INV. H04L5/00 H04L27/26 H04W88/06 H04W84/00
ADD.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
H04L H04W

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
EPO-Internal, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 2014/065563 A1 (LG ELECTRONICS INC) 1 May 2014 (2014-05-01) the whole document -& US 2015/282178 A1 (KIM KITAE [KR] ET AL) 1 October 2015 (2015-10-01) paragraph [0010] paragraph [0023] paragraph [0045] - paragraph [0046] paragraph [0061] - paragraph [0065] paragraph [0082] paragraph [0094] paragraph [0110] - paragraph [0111] paragraph [0131] paragraph [0156] paragraph [0166] - paragraph [0177] figures 6,13,18 tables 1,4,6,8 ----- -/--	1-12,14, 17-25

[X] Further documents are listed in the continuation of Box C. [X] See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage

submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

PRELIMINARY AMENDMENT

Sir/Madam:

Prior to examination of the above-referenced application, applicant respectfully submits the following:

Amendments to the Claims begin on page 2 of this paper.

Remarks begin on page 8 of this paper.

Applicant previously submitted a first preliminary amendment on July 20, 2023 prior to issuance of the first Office action. This is a second preliminary amendment prior to the issuance of the first Office action to facilitate the prosecution of this application. Because applicant believes that the first preliminary was submitted in compliance and should be entered, Amendments in this preliminary amendment are therefore made based on the amendments submitted in the July 20, 2023 preliminary amendment.

AMENDMENTS TO THE CLAIMS

Please amend the claims as reflected in the following marked-up version:

Listing of Claims:

1. (Currently amended) A method in a User Equipment (UE) for paging, comprising:

monitoring a first signaling in X time intervals; and

receiving a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises ~~at least one of {~~occupied time-frequency resource, adopted Modulation Coding Scheme (MCS), and subcarrier spacing of subcarriers in occupied frequency domain resource[[}]]; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and location of the first subband in frequency domain is used for determining the X time intervals.

2. (Original) The method according to claim 1, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

3. (Original) The method according to claim 2, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

4. (Original) The method according to claim 3, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

5. (Original) The method according to claim 1, further comprising:

receiving a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

6. (Currently amended) A method in a base station for paging, comprising:

transmitting a first signaling in a positive integer number of time intervals of X time intervals; and

transmitting a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises ~~at least one of {~~occupied time-frequency resource, adopted MCS, and subcarrier spacing of subcarriers in occupied frequency domain resource[[}]]; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and location of the first subband in frequency domain is used for determining the X time intervals.

7. (Original) The method according to claim 6, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

8. (Original) The method according to claim 7, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames

included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

9. (Original) The method according to claim 8, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

10. (Original) The method according to claim 6, further comprising:

transmitting a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

11. (Currently amended) A UE for paging, comprising:

a first receiver, to monitor a first signaling in X time intervals; and

a second receiver, to receive a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises ~~at least one of {~~occupied time-frequency resource, adopted MCS, and subcarrier spacing of subcarriers in occupied frequency domain resource[[}]]; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and location of the first subband in frequency domain is used for determining the X time intervals.

12. (Original) The UE according to claim 11, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

13. (Original) The UE according to claim 12, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

14. (Original) The method according to claim 13, wherein the second receiver further receives a third signaling, the third signaling is used for configuring Z.

15. (Original) The UE according to claim 11, wherein the first receiver further receives a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

16. (Currently amended) A base station for paging, comprising:

a first transmitter, to transmit a first signaling in a positive integer number of time intervals of X time intervals; and

a second transmitter, to transmit a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises ~~at least one of {~~occupied time-frequency resource, adopted MCS, and subcarrier spacing of subcarriers in occupied frequency domain resource[[}]]; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband location of the first subband in frequency domain is used for determining the X time intervals.

17. (Original) The base station according to claim 16, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included

in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

18. (Original) The base station according to claim 17, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

19. (Original) The method according to claim 18, wherein the second transmitter further transmits a third signaling, the third signaling is used for configuring Z.

20. (Original) The base station according to claim 16, wherein the first transmitter further transmits a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

21. (Previously presented) The method according to claim 1, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

22. (Previously presented) The method according to claim 6, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

23. (Previously presented) The UE according to claim 11, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

24. (Previously presented) The base station according to claim 16, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

REMARKS

Prior to the present preliminary amendment, Applicant submitted a first preliminary amendment on July 20, 2023. Applicant respectfully submits the present preliminary amendment based on the assumption that the first preliminary amendment will be entered.

Claims 1, 6, 11, and 16 are amended. No claims are added. No claims are canceled. Therefore, claims 1 - 24 are presently pending.

Applicant respectfully submits that the amendments to the claims do not add new matters and respectfully requests the entry of the amendments to claims.

An early and favorable action is respectfully requested. If the Examiner believes that issues may be resolved by a telephone interview, the Examiner is invited to telephone the undersigned at (908) 591-2738. The undersigned also may be contacted via e-mail at zhong@zhong-law.com. All correspondence should be directed to our address listed below.

The Commissioner is hereby authorized to charge any fees that may be required, or credit any overpayment, to Deposit Account No. 60-2313.

Respectfully submitted,

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

PRELIMINARY AMENDMENT

Sir/Madam:

Prior to examination of the above-referenced application, applicant respectfully submits the following:

Amendments to the Specification begin on page 2 of this paper.

Amendments to the Claims begin on page 3 of this paper.

Remarks begin on page 8 of this paper.

AMENDMENTS TO THE SPECIFICATION

Please amend the first paragraph as reflected in the following marked-up version:

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This disclosure is a continuation of the application 17/180,885 (issued as U.S. Patent 11,457,426), filed on February 22,2021, which is the continuation of the application 16/577,854 (issued as U.S. Patent 10,966,178), filed on September 20,2019, which is the continuation of the application 15/956,742 (issued as U.S. Patent 10,462,767), filed on April 18,2018, and claims the priority benefit of Chinese Patent Application 201710255811.X, filed on April 19, 2017, all of which [[is]] are incorporated herein by reference.

AMENDMENTS TO THE CLAIMS

Please amend the claims as reflected in the following marked-up version:

Listing of Claims:

1. (Currently amended) A method in a User Equipment (UE) for paging, comprising:

monitoring a first signaling in X time intervals; and

receiving a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted Modulation Coding Scheme (MCS), subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and location of the first subband in frequency domain ~~subcarrier spacing of subcarriers included in the first subband~~ is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH); the PDCCH is transmitted in a Common Search Space (CSS)~~.

2. (Original) The method according to claim 1, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

3. (Original) The method according to claim 2, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time

domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

4. (Original) The method according to claim 3, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

5. (Original) The method according to claim 1, further comprising:

receiving a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

6. (Currently amended) A method in a base station for paging, comprising:

transmitting a first signaling in a positive integer number of time intervals of X time intervals; and

transmitting a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and ~~subcarrier spacing of subcarriers included in the first subband~~ location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

7. (Original) The method according to claim 6, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time

window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

8. (Original) The method according to claim 7, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

9. (Original) The method according to claim 8, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

10. (Original) The method according to claim 6, further comprising:

transmitting a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

11. (Currently amended) A UE for paging, comprising:

a first receiver, to monitor a first signaling in X time intervals; and

a second receiver, to receive a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and ~~subcarrier spacing of subcarriers~~

~~included in the first subband~~ location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

12. (Original) The UE according to claim 11, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

13. (Original) The UE according to claim 12, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

14. (Original) The method according to claim 13, wherein the second receiver further receives a third signaling, the third signaling is used for configuring Z.

15. (Original) The UE according to claim 11, wherein the first receiver further receives a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

16. (Currently amended) A base station for paging, comprising:

a first transmitter, to transmit a first signaling in a positive integer number of time intervals of X time intervals; and

a second transmitter, to transmit a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

17. (Original) The base station according to claim 16, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

18. (Original) The base station according to claim 17, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

19. (Original) The method according to claim 18, wherein the second transmitter further transmits a third signaling, the third signaling is used for configuring Z.

20. (Original) The base station according to claim 16, wherein the first transmitter further transmits a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

21. (New) The method according to claim 1, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

22. (New) The method according to claim 6, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

23. (New) The UE according to claim 11, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

24. (New) The base station according to claim 16, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

REMARKS

The Specification is amended to add priority information. Claims 1, 6, 11, and 16 are amended. Claim 21-24 have been added without adding new matter. No claims are canceled. Therefore, claims 1 - 24 are presently pending.

Applicant respectfully submits that the amendments to the claims do not add new matters and respectfully requests the entry of the amendments to claims.

An early and favorable action is respectfully requested. If the Examiner believes that issues may be resolved by a telephone interview, the Examiner is invited to telephone the undersigned at (908) 591-2738. The undersigned also may be contacted via e-mail at zhong@zhong-law.com. All correspondence should be directed to our address listed below.

The Commissioner is hereby authorized to charge any fees that may be required, or credit any overpayment, to Deposit Account No. 60-2313.

Respectfully submitted,

AMENDMENTS TO THE CLAIMS

Please amend the claims as reflected in the following marked-up version:

Listing of Claims:

1. (Currently amended) A method in a User Equipment (UE) for paging, comprising:

monitoring a first signaling in X time intervals; and

receiving a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted Modulation Coding Scheme (MCS), subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and location of the first subband in frequency domain ~~subcarrier spacing of subcarriers included in the first subband~~ is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH); the PDCCH is transmitted in a Common Search Space (CSS)~~.

2. (Original) The method according to claim 1, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

3. (Original) The method according to claim 2, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time

domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

4. (Original) The method according to claim 3, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

5. (Original) The method according to claim 1, further comprising:

receiving a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

6. (Currently amended) A method in a base station for paging, comprising:

transmitting a first signaling in a positive integer number of time intervals of X time intervals; and

transmitting a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and ~~subcarrier spacing of subcarriers included in the first subband~~ location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

7. (Original) The method according to claim 6, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time

window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

8. (Original) The method according to claim 7, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

9. (Original) The method according to claim 8, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

10. (Original) The method according to claim 6, further comprising:

transmitting a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

11. (Currently amended) A UE for paging, comprising:

a first receiver, to monitor a first signaling in X time intervals; and

a second receiver, to receive a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and ~~subcarrier spacing of subcarriers~~

~~included in the first subband~~ location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

12. (Original) The UE according to claim 11, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

13. (Original) The UE according to claim 12, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

14. (Original) The method according to claim 13, wherein the second receiver further receives a third signaling, the third signaling is used for configuring Z.

15. (Original) The UE according to claim 11, wherein the first receiver further receives a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

16. (Currently amended) A base station for paging, comprising:

a first transmitter, to transmit a first signaling in a positive integer number of time intervals of X time intervals; and

a second transmitter, to transmit a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

17. (Original) The base station according to claim 16, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

18. (Original) The base station according to claim 17, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

19. (Original) The method according to claim 18, wherein the second transmitter further transmits a third signaling, the third signaling is used for configuring Z.

20. (Original) The base station according to claim 16, wherein the first transmitter further transmits a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

21. (New) The method according to claim 1, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

22. (New) The method according to claim 6, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

23. (New) The UE according to claim 11, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

24. (New) The base station according to claim 16, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

REMARKS

The Specification is amended to add priority information. Claims 1, 6, 11, and 16 are amended. Claim 21-24 have been added without adding new matter. No claims are canceled. Therefore, claims 1 - 24 are presently pending.

Applicant respectfully submits that the amendments to the claims do not add new matters and respectfully requests the entry of the amendments to claims.

An early and favorable action is respectfully requested. If the Examiner believes that issues may be resolved by a telephone interview, the Examiner is invited to telephone the undersigned at (908) 591-2738. The undersigned also may be contacted via e-mail at zhong@zhong-law.com. All correspondence should be directed to our address listed below.

The Commissioner is hereby authorized to charge any fees that may be required, or credit any overpayment, to Deposit Account No. 60-2313.

Respectfully submitted,

AMENDMENTS TO THE CLAIMS

Please amend the claims as reflected in the following marked-up version:

Listing of Claims:

1. (Currently amended) A method in a User Equipment (UE) for paging, comprising:

monitoring a first signaling in X time intervals; and

receiving a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted Modulation Coding Scheme (MCS), subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and location of the first subband in frequency domain ~~subcarrier spacing of subcarriers included in the first subband~~ is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH); the PDCCH is transmitted in a Common Search Space (CSS)~~.

2. (Original) The method according to claim 1, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

3. (Original) The method according to claim 2, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time

domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

4. (Original) The method according to claim 3, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

5. (Original) The method according to claim 1, further comprising:

receiving a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

6. (Currently amended) A method in a base station for paging, comprising:

transmitting a first signaling in a positive integer number of time intervals of X time intervals; and

transmitting a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and ~~subcarrier spacing of subcarriers included in the first subband~~ location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

7. (Original) The method according to claim 6, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time

window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

8. (Original) The method according to claim 7, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

9. (Original) The method according to claim 8, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

10. (Original) The method according to claim 6, further comprising:

transmitting a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

11. (Currently amended) A UE for paging, comprising:

a first receiver, to monitor a first signaling in X time intervals; and

a second receiver, to receive a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and ~~subcarrier spacing of subcarriers~~

~~included in the first subband~~ location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

12. (Original) The UE according to claim 11, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

13. (Original) The UE according to claim 12, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

14. (Original) The method according to claim 13, wherein the second receiver further receives a third signaling, the third signaling is used for configuring Z.

15. (Original) The UE according to claim 11, wherein the first receiver further receives a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

16. (Currently amended) A base station for paging, comprising:

a first transmitter, to transmit a first signaling in a positive integer number of time intervals of X time intervals; and

a second transmitter, to transmit a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises at least one of {occupied time-frequency resource, ~~and~~ adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband location of the first subband in frequency domain is used for determining the X time intervals~~; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS)~~.

17. (Original) The base station according to claim 16, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

18. (Original) The base station according to claim 17, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

19. (Original) The method according to claim 18, wherein the second transmitter further transmits a third signaling, the third signaling is used for configuring Z.

20. (Original) The base station according to claim 16, wherein the first transmitter further transmits a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

21. (New) The method according to claim 1, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

22. (New) The method according to claim 6, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

23. (New) The UE according to claim 11, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

24. (New) The base station according to claim 16, wherein the location of the first subband in frequency domain and the subcarrier spacing of subcarriers included in the first subband are used for determining the X time intervals.

REMARKS

The Specification is amended to add priority information. Claims 1, 6, 11, and 16 are amended. Claim 21-24 have been added without adding new matter. No claims are canceled. Therefore, claims 1 - 24 are presently pending.

Applicant respectfully submits that the amendments to the claims do not add new matters and respectfully requests the entry of the amendments to claims.

An early and favorable action is respectfully requested. If the Examiner believes that issues may be resolved by a telephone interview, the Examiner is invited to telephone the undersigned at (908) 591-2738. The undersigned also may be contacted via e-mail at zhong@zhong-law.com. All correspondence should be directed to our address listed below.

The Commissioner is hereby authorized to charge any fees that may be required, or credit any overpayment, to Deposit Account No. 60-2313.

Title:METHOD AND DEVICE IN UE AND BASE STATION USED FOR PAGING

Publication No.US-2023-0224857-A1
Publication Date:07/13/2023

NOTICE OF PUBLICATION OF APPLICATION

The above-identified application will be electronically published as a patent application publication pursuant to 37 CFR 1.211, et seq. The patent application publication number and publication date are set forth above.

The publication may be accessed through the USPTO's publically available Searchable Databases via the Internet at www.uspto.gov. The direct link to access the publication is currently http://www.uspto.gov/patft/.

The publication process established by the Office does not provide for mailing a copy of the publication to applicant. A copy of the publication may be obtained from the Office upon payment of the appropriate fee set forth in 37 CFR 1.19(a)(1). Orders for copies of patent application publications are handled by the USPTO's Public Records Division. The Public Records Division can be reached by telephone at (571) 272-3150 or (800) 972-6382, by facsimile at (571) 273-3250, by mail addressed to the United States Patent and Trademark Office, Public Records Division, Alexandria, VA 22313-1450 or via the Internet.

In addition, information on the status of the application, including the mailing date of Office actions and the dates of receipt of correspondence filed in the Office, may also be accessed via the Internet through the Patent Electronic Business Center at www.uspto.gov using the public side of the Patent Application Information and Retrieval (PAIR) system. The direct link to access this status information is currently https://portal.uspto.gov/pair/PublicPair. Prior to publication, such status information is confidential and may only be obtained by applicant using the private side of PAIR.

Further assistance in electronically accessing the publication, or about PAIR, is available by calling the Patent Electronic Business Center at 1-866-217-9197.

Receipt is acknowledged of this non-provisional utility patent application. The application will be taken up for examination in due course. Applicant will be notified as to the results of the examination. Any correspondence concerning the application must include the following identification information: the U.S. APPLICATION NUMBER, FILING DATE, NAME OF FIRST INVENTOR, and TITLE OF INVENTION. Fees transmitted by check or draft are subject to collection.

Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please submit a written request for a corrected Filing Receipt, including a properly marked-up ADS showing the changes with strike-through for deletions and underlining for additions. If you received a "Notice to File Missing Parts" or other Notice requiring a response for this application, please submit any request for correction to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections provided that the request is grantable.

Statement under 37 CFR 1.55 or 1.78 for AIA (First Inventor to File) Transition Applications: No

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at http://www.uspto.gov/web/offices/pac/doc/general/index.html.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, http://www.stopfakes.gov. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific

countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign AssetsControl, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

SelectUSA

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The U.S. offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to promote and facilitate business investment. SelectUSA provides information assistance to the international investor community; serves as an ombudsman for existing and potential investors; advocates on behalf of U.S. cities, states, and regions competing for global investment; and counsels U.S. economic development organizations on investment attraction best practices. Alexandria, Virginia 22313-1450.

RESPONSE TO NOTICE TO FILE MISSING PARTS

Sir:

In response to the Notice to file Missing Parts dated October 6, 2022, submitted herewith are the following fees:

□ Basic filing fee ($64)

□ Application search fee ($280)

□ Application examination fee ($320)

□ Surcharge ($64)

□ 1 independent claims over 3 ($192)

Also submitted herewith is a 4 month extension of time.

The Commissioner is hereby authorized to charge any additional fees or credit any overpayment to Deposit Account 60-2313.

Respectfully submitted,

Receipt is acknowledged of this non-provisional utility patent application. The application will be taken up for examination in due course. Applicant will be notified as to the results of the examination. Any correspondence concerning the application must include the following identification information: the U.S. APPLICATION NUMBER, FILING DATE, NAME OF FIRST INVENTOR, and TITLE OF INVENTION. Fees transmitted by check or draft are subject to collection.

Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please submit a written request for a corrected Filing Receipt, including a properly marked-up ADS showing the changes with strike-through for deletions and underlining for additions. If you received a "Notice to File Missing Parts" or other Notice requiring a response for this application, please submit any request for correction to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections provided that the request is grantable.

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at http://www.uspto.gov/web/offices/pac/doc/general/index.html.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, http://www.stopfakes.gov. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific

countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign AssetsControl, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

Statement under 37 CFR 1.55 or 1.78 for AIA (First Inventor to File) Transition Applications: No

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at http://www.uspto.gov/web/offices/pac/doc/general/index.html.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, http://www.stopfakes.gov. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign AssetsControl, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

SelectUSA

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The U.S. offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to promote and facilitate business investment. SelectUSA provides information assistance to the international investor community; serves as an ombudsman for existing and potential investors; advocates on behalf of U.S. cities, states, and regions competing for global investment; and counsels U.S. economic development organizations on investment attraction best practices. To learn more about why the United States is the best country in the world to develop technology, manufacture products, deliver services, and grow your business, visit http://www.SelectUSA.gov or call +1-202-482-6800.

FORMALITIES LETTER

OC000000049447600

Date Mailed: 10/06/2022

NOTICE TO FILE MISSING PARTS OF NONPROVISIONAL APPLICATION

FILED UNDER 37 CFR 1.53(b)

Filing Date Granted

An application number and filing date have been accorded to the above-identified nonprovisional application. The item(s) indicated below, however, are missing. Applicant is given **TWO MONTHS** from the date of this Notice within which to file all required items below to avoid abandonment. Extensions of time may be obtained by filing a petition accompanied by the extension fee under the provisions of 37 CFR 1.136(a).

- The statutory basic filing fee has not been received.
- The application search fee must be submitted.
- The application examination fee must be submitted.
- Additional claim fees of $**240** as a small entity, including any required multiple dependent claim fee, are required. Applicant must submit the additional claim fees or cancel the additional claims for which fees are due.
- Surcharge as set forth in 37 CFR 1.16(f) has not been received.

  The surcharge is due for any one of:
  - late submission of the basic filing fee, search fee, or examination fee,
  - late submission of inventor's oath or declaration,
  - filing an application that does not contain at least one claim on filing, or
  - submission of an application filed by reference to a previously filed application.

SUMMARY OF FEES DUE:

The fee(s) required (including the fees noted above) are as follows. Small entity discount is in effect. If applicant is qualified for micro entity status, an acceptable Certification of Micro Entity Status must be submitted to establish micro entity status. (See 37 CFR 1.29 and forms PTO/SB/15A and 15B.)

- $**80** basic filing fee.
- $**80** surcharge.
- $**350** search fee.
- $**400** examination fee.
- $**240** for 1 independent claims over 3.
- $(**0**) previous unapplied payment amount.

- $**1150** TOTAL FEE BALANCE DUE.

Replies must be received in the USPTO within the set time period or must include a proper Certificate of Mailing or Transmission under 37 CFR 1.8 with a mailing or transmission date within the set time period. For more information and a suggested format, see Form PTO/SB/92 and MPEP 512.

Replies should be addressed to:

Mail Stop Missing Parts
Commissioner for Patents
P.O. Box 1450
Alexandria VA 22313-1450

REPLY VIA ELECTRONIC FILING

A reply may be submitted via electronic filing only by registered users of the appropriate USPTO patent electronic filing system and must include:

- A separate document having the document description, "**Applicant response to Pre-Exam Formalities Notice**"; and
- the item(s) for which a reply period is set forth above.

For more information about electronic filing, contact the Patent Electronic Business Center (EBC) 1-866-217-9197 or visit https://www.uspto.gov/ebc

NOTE: If the reply is not being submitted electronically, a copy of this notice must be included.

Questions about the contents of this notice and the requirements it sets forth should be directed to the Office of Data Management, Application Assistance Unit, at **(571) 272-4000** or **(571) 272-4200** or **1-888-786-0101**.

/symohammed/

Doc Code: PA..
Document Description: Power of Attorney

PTO/AIA/82B (07-13)
Approved for use through 01/31/2018. OMB 0651-0035
U.S. Patent and Trademark Office; U.S. DEPARTMENT OF COMMERCE
Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number

POWER OF ATTORNEY BY APPLICANT

I hereby revoke all previous powers of attorney given in the application identified in either the attached transmittal letter or the boxes below.

Application Number	Filing Date

(Note: The boxes above may be left blank if information is provided on form PTO/AIA/82A.)

☑ I hereby appoint the Patent Practitioner(s) associated with the following Customer Number as my/our attorney(s) or agent(s), and to transact all business in the United States Patent and Trademark Office connected therewith for the application referenced in the attached transmittal letter (form PTO/AIA/82A) or identified above: 155075

OR

☐ I hereby appoint Practitioner(s) named in the attached list (form PTO/AIA/82C) as my/our attorney(s) or agent(s), and to transact all business in the United States Patent and Trademark Office connected therewith for the patent application referenced in the attached transmittal letter (form PTO/AIA/82A) or identified above. (Note: Complete form PTO/AIA/82C.)

Please recognize or change the correspondence address for the application identified in the attached transmittal letter or the boxes above to:

☑ The address associated with the above-mentioned Customer Number

OR

☐ The address associated with Customer Number:

OR

☐ Firm or Individual Name					
Address					
City		State		Zip	
Country					
Telephone		Email			

I am the Applicant (if the Applicant is a juristic entity, list the Applicant name in the box):

APEX BEAM TECHNOLOGIES LLC

☐ Inventor or Joint Inventor (title not required below)

☐ Legal Representative of a Deceased or Legally Incapacitated Inventor (title not required below)

☑ Assignee or Person to Whom the Inventor is Under an Obligation to Assign (provide signer's title if applicant is a juristic entity)

☐ Person Who Otherwise Shows Sufficient Proprietary Interest (e.g., a petition under 37 CFR 1.46(b)(2) was granted in the application or is concurrently being filed with this document) (provide signer's title if applicant is a juristic entity)

SIGNATURE of Applicant for Patent

The undersigned (whose title is supplied below) is authorized to act on behalf of the applicant (e.g., where the applicant is a juristic entity).

Signature	Deepak Kumar Sharma	Date (Optional)	11/10/2021
Name	Deepak Sharma		
Title	Managing Director		

NOTE: Signature - This form must be signed by the applicant in accordance with 37 CFR 1.33. See 37 CFR 1.4 for signature requirements and certifications. If more than one applicant, use multiple forms.

☑ Total of 1 forms are submitted.

This collection of information is required by 37 CFR 1.131, 1.32, and 1.33. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.11 and 1.14. This collection is estimated to take 3 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

Privacy Act Statement

The **Privacy Act of 1974 (P.L. 93-579)** requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these records.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

Filing By Reference:

Only complete this section when filing an application by reference under 35 U.S.C. 111(c) and 37 CFR 1.57(a). Do not complete this section if application papers including a specification and any drawings are being filed. Any domestic benefit or foreign priority information must be provided in the appropriate section(s) below (i.e., "Domestic Benefit/National Stage Information" and "Foreign Priority Information").

For the purposes of a filing date under 37 CFR 1.53(b), the description and any drawings of the present application are replaced by this reference to the previously filed application, subject to conditions and requirements of 37 CFR 1.57(a).

Application number of the previously filed application	Filing date (YYYY-MM-DD)	Intellectual Property Authority or Country

Publication Information:

☐ Request Early Publication (Fee required at time of Request 37 CFR 1.219)

☐ **Request Not to Publish.** I hereby request that the attached application not be published under 35 U.S.C. 122(b) and certify that the invention disclosed in the attached application **has not and will not** be the subject of an application filed in another country, or under a multilateral international agreement, that requires publication at eighteen months after filing.

Representative Information:

Representative information should be provided for all practitioners having a power of attorney in the application. Providing this information in the Application Data Sheet does not constitute a power of attorney in the application (see 37 CFR 1.32).
Either enter Customer Number or complete the Representative Name section below. If both sections are completed the customer Number will be used for the Representative Information during processing.

Please Select One:	● Customer Number	US Patent Practitioner	○ Limited Recognition (37 CFR 11.9)
Customer Number	155075		

Domestic Benefit/National Stage Information:

This section allows for the applicant to either claim benefit under 35 U.S.C. 119(e), 120, 121, 365(c), or 386(c) or indicate National Stage entry from a PCT application. Providing benefit claim information in the Application Data Sheet constitutes the specific reference required by 35 U.S.C. 119(e) or 120, and 37 CFR 1.78.
When referring to the current application, please leave the "Application Number" field blank.

Foreign Priority Information:

This section allows for the applicant to claim priority to a foreign application. Providing this information in the application data sheet constitutes the claim for priority as required by 35 U.S.C. 119(b) and 37 CFR 1.55. When priority is claimed to a foreign application that is eligible for retrieval under the priority document exchange program (PDX)[i] the information will be used by the Office to automatically attempt retrieval pursuant to 37 CFR 1.55(i)(1) and (2). Under the PDX program, applicant bears the ultimate responsibility for ensuring that a copy of the foreign application is received by the Office from the participating foreign intellectual property office, or a certified copy of the foreign priority application is filed, within the time period specified in 37 CFR 1.55(g)(1).

Statement under 37 CFR 1.55 or 1.78 for AIA (First Inventor to File) Transition Applications

☐ This application (1) claims priority to or the benefit of an application filed before March 16, 2013 and (2) also contains, or contained at any time, a claim to a claimed invention that has an effective filing date on or after March 16, 2013.
NOTE: By providing this statement under 37 CFR 1.55 or 1.78, this application, with a filing date on or after March 16, 2013, will be examined under the first inventor to file provisions of the AIA.

Authorization or Opt-Out of Authorization to Permit Access:

When this Application Data Sheet is properly signed and filed with the application, applicant has provided written authority to permit a participating foreign intellectual property (IP) office access to the instant application-as-filed (see paragraph A in subsection 1 below) and the European Patent Office (EPO) access to any search results from the instant application (see paragraph B in subsection 1 below).

Should applicant choose not to provide an authorization identified in subsection 1 below, applicant **must opt-out** of the authorization by checking the corresponding box A or B or both in subsection 2 below.

NOTE: This section of the Application Data Sheet is **ONLY** reviewed and processed with the **INITIAL** filing of an application. After the initial filing of an application, an Application Data Sheet cannot be used to provide or rescind authorization for access by a foreign IP office(s). Instead, Form PTO/SB/39 or PTO/SB/69 must be used as appropriate.

1. Authorization to Permit Access by a Foreign Intellectual Property Office(s)

A. Priority Document Exchange (PDX) - Unless box A in subsection 2 (opt-out of authorization) is checked, the undersigned hereby **grants the USPTO authority** to provide the European Patent Office (EPO), the Japan Patent Office (JPO), the Korean Intellectual Property Office (KIPO), the State Intellectual Property Office of the People's Republic of China (SIPO), the World Intellectual Property Organization (WIPO), and any other foreign intellectual property office participating with the USPTO in a bilateral or multilateral priority document exchange agreement in which a foreign application claiming priority to the instant patent application is filed, access to: (1) the instant patent application-as-filed and its related bibliographic data, (2) any foreign or domestic application to which priority or benefit is claimed by the instant application and its related bibliographic data, and (3) the date of filing of this Authorization. See 37 CFR 1.14(h)(1).

B. Search Results from U.S. Application to EPO - Unless box B in subsection 2 (opt-out of authorization) is checked, the undersigned hereby **grants the USPTO authority** to provide the EPO access to the bibliographic data and search results from the instant patent application when a European patent application claiming priority to the instant patent application is filed. See 37 CFR 1.14(h)(2).

The applicant is reminded that the EPO's Rule 141(1) EPC (European Patent Convention) requires applicants to submit a copy of search results from the instant application without delay in a European patent application that claims priority to the instant application.

2. Opt-Out of Authorizations to Permit Access by a Foreign Intellectual Property Office(s)

☐ A. Applicant **DOES NOT** authorize the USPTO to permit a participating foreign IP office access to the instant application-as-filed. If this box is checked, the USPTO will not be providing a participating foreign IP office with any documents and information identified in subsection 1A above.

☐ B. Applicant **DOES NOT** authorize the USPTO to transmit to the EPO any search results from the instant patent application. If this box is checked, the USPTO will not be providing the EPO with search results from the instant application.

NOTE: Once the application has published or is otherwise publicly available, the USPTO may provide access to the application in accordance with 37 CFR 1.14.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1 The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these records.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3 A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent CooperationTreaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

METHOD AND DEVICE IN UE AND BASE STATION USED FOR PAGING

BACKGROUND

Cross Reference to Related Application

This disclosure is a continuation of the application 16/577,854, filed on September 20,2019 which is the continuation of the application 15/956,742, filed on April 18,2018, and claims the priority benefit of Chinese Patent Application 201710255811.X, filed on April 19, 2017, all of which is incorporated herein by reference.

TECHNICAL FIELD

[0001] The present disclosure relates to transmission schemes in wireless communication systems, and in particular to a method and a device for paging transmission in a communication system supporting multiple numerologies.

RELATED ART

[0002] Application scenarios of future wireless communication systems are becoming increasingly diversified, and different application scenarios have different performance demands on systems. In order to meet different performance requirements of various application scenarios, the 3rd Generation Partner Project (3GPP) Radio Access Network (RAN) #72 plenary session decided to conduct the study of New Radio (NR). The working item of 5G NR was agreed as an approved project to standardize the 5G NR at the 3GPP RAN #75 session.

[0003] In order to be applied to various different application scenarios flexibly, future wireless communication systems, especially 5G NR, will support various numerologies. The various numerologies refer to various subcarrier spacings, various symbol time lengths, various Cyclic Prefix (CP) lengths, etc. In order to simplify the design of systems and to reduce the complexity of User Equipment (UE) implementation, the overall design of the system physical layer would best adopt a unified structure for different numerologies.

SUMMARY

[0004] In existing LTE systems, transmission opportunities of paging are defined through a Paging Frame (PF) and a Paging Occasion (PO) uniformly. The PF is a radio frame which is likely to transmit a paging message, and the PO is used for determining a subframe which is likely to transmit a paging message in the PF. The radio frame in LTE has a fixed time length of

10 milliseconds, and the subframe has a fixed time length of 1 millisecond. Since an LTE network generally employs a single numerology or the numerology basically does not change in a long time in the network, the definition of the possible time of paging using the PF and PO having a fixed time length can simplify the design of system, under the premise of guaranteeing the paging capacity and not increasing the power consumption of UE. Under the 5G NR, a network supports different numerologies, thus, a given time length, for example, 1 millisecond, probably includes multiple basic scheduling units (for example, slot). If the legacy design of the current paging opportunity is employed, the UE would detect the paging message different times for different numerologies within the 1 millisecond. Therefore, power consumption in some numerology would be greatly increased. Meanwhile, the paging capacity varies greatly due to the adoption of different numerologies.

[0005] In order to solve the above design problem of paging when multiple numerologies are employed in the 5G NR, the present disclosure provides a solution, which determines the transmission opportunities of paging according to the numerology employed by the paging, thereby guaranteeing that the UE has a small difference in the complexity and power consumption of monitoring the paging message under different numerologies and that the paging capacity basically remains the same. It should be noted the embodiments of the UE of the present disclosure and the characteristics in the embodiments may be applied to the base station if no conflict is caused, and vice versa. Further, the embodiments of the present disclosure and the characteristics in the embodiments may be mutually combined if no conflict is caused.

[0006] The present disclosure discloses a method in a UE used for paging. The method includes the following:

[0007] monitoring a first signaling in X time intervals; and

[0008] receiving a first radio signal.

[0009] Herein, X is a positive integer. The first signaling is used for determining scheduling information for the first radio signal. The scheduling information includes at least one of {occupied time-frequency resource, adopted Modulation Coding Scheme (MCS), subcarrier spacing of subcarriers in occupied frequency domain resource}. The first radio signal carries a paging message. The frequency domain resource used for transmitting the first signaling belongs to a first subband. The first subband includes a positive integer number of consecutive subcarriers in frequency domain. At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[0010] In one embodiment, with the above method, the UE can determine the time interval of monitoring a transmitted paging message according to a subcarrier spacing adopted to transmit the paging message, thereby saving power consumption.

[0011] In one embodiment, the above method designs a uniform calculation approach of paging opportunity based on different subcarrier spacings. Meanwhile, the paging capacity remains the same when different subcarrier spacings are adopted to transmit the paging message.

[0012] In one embodiment, the paging message includes a feature ID of a paged UE.

[0013] In one embodiment, the first signaling is detected P times at most in each one of the X time intervals, P is a positive integer.

[0014] In one embodiment, any two of the X time intervals have an equal time length.

[0015] In one embodiment, two of the X time times have different time lengths.

[0016] In one embodiment, any one of the X time intervals is a slot.

[0017] In one embodiment, any two of the X time intervals have an equal time length, and the time length of each one of the X time intervals is correlated to the subcarrier spacing of subcarriers included in the first subband.

[0018] In one embodiment, any one of the X time intervals comprises M Orthogonal Frequency Division Multiplexing (OFDM) symbols, M is a positive integer smaller than 14.

[0019] In one embodiment, any one of the X time intervals comprises M OFDM symbols, M is a positive integer smaller than 7.

[0020] In one embodiment, any two of the X time intervals are orthogonal in time domain, the orthogonality refers that there is no time unit that belongs to any two of the X time intervals simultaneously.

[0021] In one embodiment, two of the X time intervals are discrete in time domain.

[0022] In one embodiment, the first signaling is a physical layer signaling.

[0023] In one embodiment, the first signaling is Downlink Control Information (DCI).

[0024] In one embodiment, the first signaling is transmitted through a Physical Downlink Control Channel (PDCCH).

[0025] In one embodiment, the first signaling is transmitted through a New Radio Physical Downlink Control Channel (NR-PDCCH).

[0026] In one embodiment, the first signaling is transmitted through a PDCCH. The PDCCH is transmitted in a Common Search Space (CSS).

[0027] In one embodiment, the first signaling is transmitted through a PDCCH, the PDCCH is transmitted in a UE-Specific Search Space (USS).

[0028] In one embodiment, the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI).

[0029] In one embodiment, the MCS includes one of {QPSK, 16QAM, 64QAM, 256QAM, 1024QAM}.

[0030] In one embodiment, the subcarrier spacing is equal to 15kHz multiplied by 2 to the Kth power, where K is an integer.

[0031] In one embodiment, the first subband includes a positive integer multiple of 12 subcarriers.

[0032] In one embodiment, all subcarriers included in the first subband have an equal subcarrier spacing.

[0033] In one embodiment, the location of the first subband in frequency domain refers to the location of the first subband in a carrier where the first subband is located.

[0034] In one embodiment, the location of the first subband in frequency domain refers to the location of a carrier where the first subband is located in frequency domain.

[0035] In one embodiment, the location of the first subband in frequency domain refers to a subband index of the first subband in a carrier where the first subband is located.

[0036] In one embodiment, the location of the first subband in frequency domain refers to the location of the first subband in a frequency resource corresponding to a band where the first subband is located.

[0037] In one embodiment, at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for the UE to determine the X time intervals.

[0038] In one embodiment, at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for the UE to determine the X time intervals based on a given mapping rule.

[0039] In one embodiment, the first radio signal is transmitted through a Downlink Shared

Channel (DL-SCH).

[0040] In one embodiment, the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH).

[0041] In one embodiment, a first bit block is subjected to a modulation mapper, a layer mapper, precoding, a resource element mapper and OFDM single generation in sequence to obtain the first radio signal; the first bit block includes the output obtained after a code block is subjected to channel coding. In one subembodiment, the code block is a Transport Block (TB). In one subembodiment, the code block is one part of a TB.

[0042] According to one aspect of the present disclosure, the above method is characterized in that any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[0043] In one embodiment, the time length of the first time window is fixed.

[0044] In one embodiment, the first time window includes a positive integer number of consecutive multi-carrier symbols.

[0045] In one embodiment, the multi-carrier symbol includes a data symbol and a CP.

[0046] In one embodiment, the first time window has a time length of 1 millisecond.

[0047] In one embodiment, the first time window has a time length of 10 milliseconds.

[0048] In one embodiment, the first time window is a subframe.

[0049] In one embodiment, the first time window is a radio frame.

[0050] In one embodiment, any two of the Y time intervals have an equal time length.

[0051] In one embodiment, two of the Y time intervals have different time lengths.

[0052] In one embodiment, Y is greater than X.

[0053] In one embodiment, Y is proportional to the subcarrier spacing of subcarriers included in the first subband.

[0054] In one embodiment, the subcarrier spacing of subcarriers included in the first subband is used for the UE to determine Y.

[0055] In one embodiment, the subcarrier spacing of subcarriers included in the first subband is used for the UE to determine Y based on a given mapping relationship.

[0056] In one embodiment, the feature ID of the monitor of the first signaling is used for the UE to determine the X time intervals in the Y time intervals.

[0057] In one embodiment, the feature ID of the monitor of the first signaling is used for the UE to determine the X time intervals in the Y time intervals based on a given mapping relationship.

[0058] In one embodiment, the feature ID refers to an International Mobile Subscriber Identification Number (IMSI).

[0059] In one embodiment, the feature ID refers to a remainder when the IMSI is divided by 1024.

[0060] In one embodiment, the feature ID refers to a remainder when the IMSI is divided by 4096.

[0061] In one embodiment, the feature ID refers to a remainder when the IMSI is divided by 16384.

[0062] In one embodiment, the feature ID refers to a Cell Radio Network Temporary Identity (C-RNTI).

[0063] In one embodiment, a physical cell ID of a cell transmitting the first signaling is used for determining the X time intervals in the Y time intervals.

[0064] According to one aspect of the present disclosure, the above method is characterized in that the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[0065] In one embodiment, Z is equal to 10.

[0066] In one embodiment, any two of the Z time windows are orthogonal in time domain.

[0067] In one embodiment, any one of the Z time windows is a subframe, Z is equal to 10,

[0068] In one embodiment, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle.

[0069] In one embodiment, the above method further includes the following:

[0070] receiving a third signaling.

[0071] Herein, the third signaling is used for configuring Z.

[0072] In one embodiment, the feature ID of the monitor of the first signaling is used for the UE to determine the first time window in the Z time windows.

[0073] In one embodiment, the feature ID of the monitor of the first signaling is used for the UE to determine the first time window in the Z time windows based on a given mapping relationship.

[0074] In one embodiment, any one of the Z time windows is a radio frame; The first time window is obtained by the following formula.

[0075] SFN mod Z= (Z div N)*(UE_ID mod N)

[0076] Herein, SFN is a frame number of a radio frame corresponding to the first time window, N= min(Z,nB), nB is equal to one of {4Z, 2Z, Z, Z/2, Z/4, Z/8, Z/16, Z/32, Z/64, Z/128, Z/256, Z/512, Z/1024}.

[0077] According to one aspect of the present disclosure, the above method further includes the following:

[0078] receiving a second radio signal;

[0079] Herein, the second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[0080] In one embodiment, the second radio signal includes a Primary Synchronization Signal (PSS).

[0081] In one embodiment, the second radio signal includes a Second Synchronization Signal (SSS).

[0082] In one embodiment, the second radio signal is transmitted through a Broadcast Channel (BCH).

[0083] In one embodiment, the second radio signal is transmitted through a Physical Broadcast Channel (PBCH).

[0084] In one embodiment, the second radio signal is transmitted through a PDSCH.

[0085] In one embodiment, the second radio signal carries Master Information Block (MIB) information.

[0086] In one embodiment, the second radio signal carries System Information Block (SIB) information.

[0087] In one embodiment, the information carried by the second radio signal is transmitted cyclically.

[0088] In one embodiment, the information carried by the second radio signal is transmitted on-demand.

[0089] In one embodiment, the second radio signal carries first information; The first information is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[0090] In one embodiment, the second radio signal carries first information; The first information indicates at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[0091] In one embodiment, the second radio signal is used for the UE to determine at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[0092] In one embodiment, the second radio signal indicates at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[0093] According to one aspect of the present disclosure, the above method further includes the following:

[0094] receiving a second signaling;

[0095] Herein, the second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

[0096] In one embodiment, in any one of the Q subbands, all the included subcarriers have an equal subcarrier spacing.

[0097] In one embodiment, in any two of the Q subbands, the subcarriers have different subcarrier spacings.

[0098] In one embodiment, in two of the Q subbands, the subcarriers have an equal subcarrier spacing .

[0099] In one embodiment, any two of the Q subbands have an equal frequency domain width.

[00100] In one embodiment, two of the Q subbands have different frequency domain widths.

[00101] In one embodiment, the Q subbands all belong to one same carrier.

[00102] In one embodiment, two of the Q subbands belong to different carriers.

[00103] In one embodiment, the second signaling is a high layer signaling.

[00104] In one embodiment, the second signaling is a physical layer signaling.

[00105] In one embodiment, the second signaling is transmitted through a BCH.

[00106] In one embodiment, the second signaling is transmitted through a PBCH.

[00107] In one embodiment, the second signaling is transmitted through a PDSCH.

[00108] In one embodiment, the second signaling is a Radio Resource Control (RRC) signaling.

[00109] In one embodiment, the second signaling is an SIB.

[00110] In one embodiment, the second signaling is transmitted through a DCI.

[00111] In one embodiment, the feature ID of the monitor of the first signaling is used for the UE to determine the first subband in the Q subbands.

[00112] In one embodiment, the feature ID of the monitor of the first signaling is used for the UE to determine the first subband in the Q subbands based on a specific mapping relationship.

[00113] The present disclosure discloses a method in a base station used for paging. The method includes the following:

[00114] transmitting a first signaling in a positive integer number of time intervals of X time intervals; and

[00115] transmitting a first radio signal.

[00116] Herein, X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00117] According to one aspect of the present disclosure, the above method is characterized in

that any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00118] According to one aspect of the present disclosure, the above method is characterized in that the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00119] According to one aspect of the present disclosure, the above method further includes the following:

[00120] transmitting a second radio signal;

[00121] Herein, the second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00122] According to one aspect of the present disclosure, the above method further includes the following:

[00123] transmitting a second signaling;

[00124] Herein, the second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

[00125] The present disclosure discloses a UE used for paging. The UE includes:

[00126] a first receiver module, to monitor a first signaling in X time intervals; and

[00127] a second receiver module, to receive a first radio signal.

[00128] Herein, X is a positive integer. The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first

subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00129] According to one aspect of the present disclosure, the above UE is characterized in that any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00130] According to one aspect of the present disclosure, the above UE is characterized in that the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00131] According to one aspect of the present disclosure, the above UE is characterized in that the first receiver module further receives a second radio signal; The second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00132] According to one aspect of the present disclosure, the above UE is characterized in that the first receiver module further receives a second signaling; The second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

[00133] The present disclosure discloses a base station device used for paging. The base station device includes:

[00134] a first transmitter module, to transmit a first signaling in a positive integer number of time intervals of X time intervals respectively; and

[00135] a second transmitter module, to transmit a first radio signal;

[00136] Herein, X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied

frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00137] According to one aspect of the present disclosure, the above base station device is characterized in that any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00138] According to one aspect of the present disclosure, the above base station device is characterized in that the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00139] According to one aspect of the present disclosure, the above base station device is characterized in that the first transmitter module further transmits a second radio signal; The second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00140] According to one aspect of the present disclosure, the above base station device is characterized in that the first transmitter module further transmits a second signaling; The second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

BRIEF DESCRIPTION OF THE DRAWINGS

[00141] Other features, purposes and advantages of the present disclosure will become more apparent from the detailed description of non-restrictive embodiments taken in conjunction with the following drawings.

[00142] FIG. 1 is a flowchart illustrating the transmission of a first signaling and a first radio signal according to one embodiment of the present disclosure.

[00143] FIG. 2 is a diagram illustrating a network architecture according to one embodiment of the present disclosure.

[00144] FIG. 3 is a diagram illustrating a radio protocol architecture of a user plane and a control plane according to one embodiment of the present disclosure.

[00145] FIG. 4 is a diagram illustrating a base station device and a UE according to one embodiment of the present disclosure.

[00146] FIG. 5 is a flowchart illustrating the transmission of a radio signal according to one embodiment of the present disclosure.

[00147] FIG. 6 is a diagram illustrating a relationship between Z time windows and Q subbands according to one embodiment of the present disclosure.

[00148] FIG. 7 is a diagram illustrating a relationship between a first time window and X time intervals according to one embodiment of the present disclosure.

[00149] FIG. 8 is a diagram illustrating a relationship among a first signaling, a first radio signal and a second radio signal according to one embodiment of the present disclosure.

[00150] FIG. 9 is a structure block diagram illustrating a processing device in a UE according to one embodiment of the present disclosure.

[00151] FIG. 10 is a structure block diagram illustrating a processing device in a base station according to one embodiment of the present disclosure.

DESCRIPTION OF THE EMBODIMENTS

[00152] The technical scheme of the present disclosure is described below in further detail in conjunction with the drawings. It should be noted that the embodiments in the disclosure and the characteristics of the embodiments may be arbitrarily combined if there is no conflict.

[00153] Embodiment 1

[00154] Embodiment 1 illustrates an example of a flowchart for the transmission of a first signaling and a first radio signal according to one embodiment of the present disclosure, as shown in FIG. 1. In FIG. 1, each box represents a step. In Embodiment 1, the UE of the present disclosure first monitors a first signaling in X time intervals, and then receives a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of

{occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00155] In one embodiment, any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00156] In one embodiment, any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals; The first time window belongs to one of Z time windows, Z being an integer greater than 1. Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00157] In one embodiment, the method further includes the following:

[00158] receiving a second radio signal;

[00159] Herein, the second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00160] In one embodiment, the method further includes the following:

[00161] receiving a second signaling;

[00162] The second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

[00163] Embodiment 2

[00164] Embodiment 2 illustrates an example of a diagram for a network architecture, as shown in FIG. 2. FIG. 2 is a diagram illustrating a system network architecture 200 of NR 5G, LTE and Long-Term Evolution Advanced (LTE-A). The NR 5G or LTE network architecture 200 may be called an Evolved Packet System (EPS) 200. The EPS 200 may include one or more UEs 201, a Next Generation-Radio Access Network (NG-RAN) 202, an Evolved Packet Core /5G-Core Network (EPC/5G-CN) 210, a Home Subscriber Server (HSS) 220 and an Internet Service 230. The EPS may be interconnected with other access networks. For simple description, the entities/interfaces are not shown. As shown in FIG. 2, the EPS provides packet switching services. Those skilled in the art are easy to understand that various concepts presented throughout the present disclosure can be extended to networks providing circuit switching services or other cellular networks. The NG-RAN includes an NR node B (gNB) 203 and other gNBs 204. The gNB 203 provides user plane and control plane protocol terminations towards the UE 201. The gNB 203 may be connected to other gNBs 204 via an Xn interface (for example, backhaul). The gNB 203 may be called a base station, a base transceiver station, a radio base station, a radio transceiver, a transceiver function, a Basic Service Set (BSS), an Extended Service Set (ESS), a TRP or other appropriate terms. The gNB 203 provides an access point of the 5G-CN/EPC 210 for the UE 201. Examples of UE 201 include cellular phones, smart phones, Session Initiation Protocol (SIP) phones, laptop computers, Personal Digital Assistants (PDAs), Satellite Radios, Global Positioning Systems (GPSs), multimedia devices, video devices, digital audio player (for example, MP3 players), cameras, games consoles, unmanned aerial vehicles, air vehicles, narrow-band physical network equipment, machine-type communication equipment, land vehicles, automobiles, wearable equipment, or any other devices having similar functions. Those skilled in the art also can call the UE 201 a mobile station, a subscriber station, a mobile unit, a subscriber unit, a wireless unit, a remote unit, a mobile device, a wireless device, a radio communication device, a remote device, a mobile subscriber station, an access terminal, a mobile terminal, a wireless terminal, a remote terminal, a handset, a user agent, a mobile client, a client or other appropriate terms. The gNB 203 is connected to the EPC/5G-CN 210 via an S1/NG interface. The EPC/5G-CN 210 includes a Mobility Management Entity/Authentication Management Field/User Plane Function (MME/AMF/UPF) 211, other MMEs/AMFs/UPFs 214, a Service Gateway (S-GW) 212 and a Packet Data Network Gateway (P-GW) 213. The MME/AMF/UPF 211 is a control node for processing a signaling between the UE 201 and the 5G-CN/EPC 210. Generally, the MME/AMF/UPF 211 provides bearer and connection management. All user Internet Protocol (IP) packets are transmitted through the S-GW 212. The S-GW 212 is connected to the P-GW

213. The P-GW 213 provides UE IP address allocation and other functions. The P-GW 213 is connected to the internet service 230. The internet service 230 includes IP services corresponding to operators, specifically including internet, intranet, IP Multimedia Subsystems (IP IMSs) and PS Streaming Services (PSSs).

[00165] In one embodiment, the UE 201 corresponds to the UE in the present disclosure.

[00166] In one embodiment, the UE 201 supports the transmission based on multiple numerologies.

[00167] In one embodiment, the gNB 203 corresponds to the base station device in the present disclosure.

[00168] In one embodiment, the gNB 203 supports the transmission based on multiple numerologies.

[00169] Embodiment 3

[00170] Embodiment 3 is a diagram illustrating an embodiment of a radio protocol architecture of a user plane and a control plane according to the present disclosure, as shown in FIG. 3. FIG. 3 is a diagram illustrating an embodiment of a radio protocol architecture of a user plane and a control plane. In FIG. 3, the radio protocol architecture of a UE and a base station device (gNB or eNB) is presented by three layers, which are a layer 1, a layer 2 and a layer 3 respectively. The layer 1 (L1) is the lowest layer and performs signal processing functions of a PHY layer. The layer 1 is called PHY 301 in this paper. The layer 2 (L2) 305 is above the PHY 301, and is in charge of the link between the UE and the gNB via the PHY 301. In the user plane, the L2 305 includes a Medium Access Control (MAC) sublayer 302, a Radio Link Control (RLC) sublayer 303, and a Packet Data Convergence Protocol (PDCP) sublayer 304. All the three sublayers end at the gNB of the network side. Although not described in FIG.3, the UE may include several higher layers above the L2 305, such as network layer (i.e. IP layer) ending at a P-GW of the network side and an application layer ending at the other side of the connection (i.e. a peer UE, a server, etc.). The PDCP sublayer 304 provides multiplexing among variable radio bearers and logical channels. The PDCP sublayer 304 also provides a header compression for a higher layer packet so as to reduce a radio transmission overhead. The PDCP sublayer 304 provides security by encrypting a packet and provides support for UE handover between gNBs. The RLC sublayer 303 provides segmentation and reassembling of a higher layer packet, retransmission of a lost packet, and reordering of a lost packet to as to compensate the disordered receiving caused by Hybrid Automatic Repeat Request (HARQ). The MAC sublayer 302 provides multiplexing between logical channels and transport channels. The MAC sublayer

302 is also responsible for allocating between UEs various radio resources (i.e., resource block) in a cell. The MAC sublayer 302 is also in charge of HARQ operation. In the control plane, the radio protocol architecture of the UE and the gNB is almost the same as the radio protocol architecture in the user plane on the PHY 301 and the L2 305, but there is no header compression for the control plane. The control plane also includes a Radio Resource Control (RRC) sublayer 306 in the layer 3 (L3). The RRC sublayer 306 is responsible for acquiring radio resources (i.e. radio bearer) and configuring the lower layers using an RRC signaling between the gNB and the UE.

[00171] In one embodiment, the radio protocol architecture shown in FIG. 3 is applicable to the UE in the present disclosure.

[00172] In one embodiment, the radio protocol architecture shown in FIG. 3 is applicable to the base station device in the present disclosure.

[00173] In one embodiment, the first signaling in the present disclosure is generated by the PHY 301.

[00174] In one embodiment, the first signaling in the present disclosure is generated by the MAC 302.

[00175] In one embodiment, the first signaling in the present disclosure is generated by the RRC 306.

[00176] In one embodiment, the second signaling in the present disclosure is generated by the PHY 301.

[00177] In one embodiment, the second signaling in the present disclosure is generated by the MAC 302.

[00178] In one embodiment, the second signaling in the present disclosure is generated by the RRC 306.

[00179] In one embodiment, the first radio signal in the present disclosure is generated by the RRC 306.

[00180] In one embodiment, the first radio signal in the present disclosure is generated by the MAC 302.

[00181] In one embodiment, the first radio signal in the present disclosure is generated by the PHY 301.

[00182] In one embodiment, the second radio signal in the present disclosure is generated by

the RRC 306.

[00183] In one embodiment, the second radio signal in the present disclosure is generated by the MAC 302.

[00184] In one embodiment, the second radio signal in the present disclosure is generated by the PHY 301.

[00185] Embodiment 4

[00186] Embodiment 4 illustrates a diagram of a base station device and a given UE according to the present disclosure, as shown in FIG. 4. FIG. 4 is a block diagram of a gNB 410 in communication with a UE 450 in an access network.

[00187] The base station device 410 includes a controller/processor 440, a memory 430, a receiving processor 412, a transmitter/receiver 416 and a transmitting processor 415. The transmitter/receiver 416 includes an antenna 420. A packet from a higher layer is provided to the controller/processor 440. The controller/processor 440 provides header compression/decompression, encryption/decryption, packet segmentation and reordering, multiplexing/de-multiplexing between a logical channel and a transport channel, to implement the L2 protocol used for the user plane and the control plane. The packet from a higher layer may include data or control information, for example, DL-SCH or UL-SCH. The transmitting processor 455 performs signal transmitting processing functions of an L1 layer (that is, PHY), including encoding, interleaving, scrambling, modulation, power control/allocation, precoding, generation of physical layer control signaling (including PBCH, PDCCH, PHICH, PCFICH, reference signal), etc. The receiving processor 412 performs signal receiving processing functions of the L1 layer (that is, PHY), including decoding, de-interleaving, descrambling, demodulation, decoding, extraction of physical layer control signaling, etc. The transmitter 416 is configured to convert a baseband signal provided by the transmitting processor 415 into a radio-frequency signal and transmit the radio-frequency signal via the antenna 420. The receiver 416 is configured to convert a radio-frequency signal received via the antenna 420 into a baseband signal and provide the baseband signal to the receiving processor 412.

[00188] The UE 450 includes a controller/processor 490, a memory 480, a receiving processor 452, a transmitter/receiver 456, a transmitting processor 455, and a data source 467. The transmitter/receiver 456 includes an antenna 460. The data source 467 provides a packet from a higher layer packet to the controller/processor 490. The controller/processor 490 provides header compression/decompression, encryption/decryption, packet segmentation and reordering, multiplexing/de-multiplexing between a logical channel and a transport channel, to implement

the L2 protocol used for the user plane and the control plane. The packet from a higher layer may include data or control information, for example, DL-SCH or UL-SCH. The transmitting processor 490 performs signal transmitting processing functions of an L1 layer (that is, PHY), including encoding, interleaving, scrambling, modulation, power control/allocation, precoding, generation of physical layer control signaling, etc. The receiving processor 452 performs signal receiving processing functions of the L1 layer (that is, PHY), including decoding, de-interleaving, descrambling, demodulation, decoding, extraction of physical layer control signaling, etc. The transmitter 456 is configured to convert a baseband signal provided by the transmitting processor 455 into a radio-frequency signal and transmit the radio-frequency signal via the antenna 460. The receiver 456 is configured to convert a radio-frequency signal received via the antenna 460 into a baseband signal and provide the baseband signal to the receiving processor 452.

[00189] In Downlink (DL) transmission, a packet DL-SCH from a higher layer, which includes the first radio signal, the second radio signal and the second signaling in the present disclosure, is provided to the controller/processor 440. The controller/processor 440 performs functions of a layer 2. In downlink transmission, the controller/processor 440 provides header compression, encryption, packet segmentation and reordering, multiplexing between a logical channel and a transport channel, and radio resource allocation for the UE 450 based on various priorities. The controller/processor 440 is also in charge of HARQ operation, retransmission of a lost packet, and a signaling to the UE450. The transmitting processor 415 performs signal processing functions of the layer 1, including the generation of the first signaling in the present disclosure. The generation of the second signaling and the generation of the physical layer signals of the first radio signal and second radio signal are accomplished at the transmitting processor 415. The signal processing function includes decoding and interleaving, so as to ensure an FEC (Forward Error Correction) and a demodulation corresponding to a modulation scheme (i.e., BPSK, QPSK, etc.) at the UE 450 side. The modulated signals are divided into parallel streams. Each of the parallel streams is mapped into a corresponding subcarrier of multi-carriers and/or multi-carrier symbol. Then the transmitting processor 415 maps the parallel stream into the antenna 420 via the transmitter 416 to as to transmit the parallel stream in the form of Radio Frequency (RF) signals. At the receiving side, every receiver 456 receives a radio frequency signal via the corresponding antenna 460. Every receiver 456 recovers the baseband information modulated to the RF carrier and provides the baseband information to the receiving processor 452. The receiving processor 452 performs signal receiving processing functions of the layer 1, including the detection of the first signaling in the present disclosure, the receiving of the first radio signal and the second radio signal, the receiving of the physical layer signal of the second

signaling, etc. Demodulation is conducted corresponding to a modulation scheme (i.e., BPSK, QPSK, etc.) through the multi-carrier symbol in the multi-carrier symbol stream, then decoding and de-interleaving are conducted to recover the data or control signal transmitted by the gNB 410 on the physical channel, and then the data and control signal are provided to the controller/processor 490. The controller/processor 490 performs functions of the layer 2. The controller/processor can be connected to a memory 480 that stores program code and data. The memory 480 is a computer readable media.

[00190] In one embodiment, the UE 450 corresponds to the UE in the present disclosure.

[00191] In one embodiment, the gNB 410 corresponds to the base station device in the present disclosure.

[00192] In one embodiment, the UE 450 device includes at least one processor and at least one memory. The at least one memory includes computer program codes. The at least one memory and the computer program codes are configured to be used in collaboration with the at least one processor. The UE 450 device at least monitors a first signaling in X time intervals and receives a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00193] In one embodiment, the UE 450 includes a memory that stores a computer readable instruction program. The computer readable instruction program generates an action when executed by at least one processor. The action includes monitoring a first signaling in X time intervals and receiving a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for

determining the X time intervals.

[00194] In one embodiment, the gNB 410 device includes at least one processor and at least one memory. The at least one memory includes computer program codes. The at least one memory and the computer program codes are configured to be used in collaboration with the at least one processor. The gNB 410 at least transmits a first signaling in a positive integer number of time intervals of X time intervals and transmits a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00195] In one embodiment, the gNB 410 device includes a memory that stores a computer readable instruction program. The computer readable instruction program generates an action when executed by at least one processor. The action includes transmitting a first signaling in a positive integer number of time intervals of X time intervals and transmitting a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain. At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00196] In one embodiment, the receiver 456 (including the antenna 460) and the receiving processor 452 are configured to monitor the first signaling in the present disclosure.

[00197] In one embodiment, the receiver 456 (including the antenna 460), the receiving processor 452 and the controller/processor 490 are configured to receive the first radio signal in the present disclosure.

[00198] In one embodiment, the receiver 456 (including the antenna 460), the receiving processor 452 and the controller/processor 490 are configured to receive the second radio signal in the present disclosure.

[00199] In one embodiment, the receiver 456 (including the antenna 460), the receiving processor 452 and the controller/processor 490 are configured to monitor the second signaling in the present disclosure.

[00200] In one embodiment, the transmitter 416 (including the antenna 420) and the transmitting processor 415 are configured to transmit the first signaling in the present disclosure.

[00201] In one embodiment, the transmitter 416 (including the antenna 420), the transmitting processor 415 and the controller/processor 440 are configured to transit the first radio signal in the present disclosure.

[00202] In one embodiment, the transmitter 416 (including the antenna 420), the transmitting processor 415 and the controller/processor 440 are configured to transit the second radio signal in the present disclosure.

[00203] In one embodiment, the transmitter 416 (including the antenna 420), the transmitting processor 415 and the controller/processor 440 are configured to transit the second signaling in the present disclosure.

[00204] Embodiment 5

[00205] Embodiment 5 illustrates an example of a flowchart for the transmission of a radio signal according to an embodiment of the present disclosure, as shown in FIG. 5. In FIG. 5, the base station N1 is a maintenance base station for a serving cell of the UE U2. Steps marked in a dotted box are optional.

[00206] The base station N1 transmits a second radio signal in S11, transmits a second signaling in S12, transmits a first signaling in a positive integer number of time intervals of X time intervals in S13, and transmits a first radio signal in S14.

[00207] The UE U2 receives the second radio signal in S21, receives the second signaling in S22, monitors the first signaling in X time intervals in S23, and receives the first radio signal in S24.

[00208] In Embodiment 5, X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency

domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals; The second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}; The second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; A feature ID of a monitor of the first signaling is used for determining the first subband in the Q subbands.

[00209] In one embodiment, any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; The feature ID of the monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00210] In one embodiment, the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00211] In one embodiment, the paging message includes a feature ID of a paged UE.

[00212] In one embodiment, the MCS includes one of {QPSK, 16QAM, 64QAM, 256QAM, 1024QAM}.

[00213] In one embodiment, the subcarrier spacing is equal to 15kHz multiplied by 2 to the Kth power. K is an integer.

[00214] In one embodiment, the first subband includes a positive integer multiple of 12 subcarriers.

[00215] In one embodiment, all subcarriers included in the first subband have an equal subcarrier spacing.

[00216] In one embodiment, the location of the first subband in frequency domain refers to the location of the first subband in a carrier where the first subband is located.

[00217] In one embodiment, the location of the first subband in frequency domain refers to the location of a carrier where the first subband is located in frequency domain.

[00218] In one embodiment, the location of the first subband in frequency domain refers to a

subband index of the first subband in a carrier where the first subband is located.

[00219] In one embodiment, the location of the first subband in frequency domain refers to the location of the first subband in a frequency resource corresponding to a band where the first subband is located.

[00220] In one embodiment, the second signaling is a high layer signaling.

[00221] In one embodiment, the second signaling is a physical layer signaling.

[00222] In one embodiment, the second signaling is transmitted through a BCH.

[00223] In one embodiment, the second signaling is transmitted through a PBCH.

[00224] In one embodiment, the second signaling is transmitted through a PDSCH.

[00225] In one embodiment, the second signaling is an RRC signaling.

[00226] In one embodiment, the second signaling is an SIB.

[00227] In one embodiment, the second signaling is transmitted through a DCI.

[00228] Embodiment 6

[00229] Embodiment 6 illustrates an example of a diagram for a relationship between Z time windows and Q subbands according to one embodiment of the present disclosure, as shown in FIG. 6. In FIG. 6, the horizontal axis represents time, the vertical axis represents frequency, each rectangle represents a time interval, the rectangles filled by oblique lines represent X1 time intervals monitored by a UE#1 in a time window #a, the rectangles filled by cross lines represent X2 time intervals monitored by a UE#2 in a time window #b, the rectangles filled by crossed oblique lines represent X3 time intervals monitored by a UE#3 in a time window #c.

[00230] In embodiment 6, the UE#1 monitors a first signaling in X1 time intervals respectively. The frequency domain resource used for transmitting the first signaling belongs to the subband #1. The subband #1 includes a positive integer number of consecutive subcarriers in frequency domain. At least one of {location of the subband #1 in frequency domain, subcarrier spacing of subcarriers included in the subband #1} is used for determining the X1 time intervals. Any one of the X1 time intervals belongs to the time window #a in time domain. The time length of the time window #a is predefined. The time window #a is divided into Y1 time intervals. The X1 time intervals are X1 time intervals of the Y1 time intervals, Y1 being a positive integer not smaller than X1. The subcarrier spacing of subcarriers included in the subband #1 is used for determining Y1. A feature ID of the UE#1 is used for determining the X1 time intervals in the Y1 time intervals. The time window #a belongs to one of Z time windows, Z being an integer

greater than 1. Z is predefined, or Z is configurable. Any two of the Z time windows have an equal time length. The feature ID of the UE#1 is used for determining the time window #a in the Z time windows. The subband #1 belongs to one of the Q subbands, Q being a positive integer. Any one of the Q subbands includes a positive integer number of consecutive subcarriers. The feature ID of the UE#1 is used for determining the subband #1 in the Q subbands.

[00231] In one embodiment, Z is equal to 10.

[00232] In one embodiment, any two of the Z time windows are orthogonal in time domain.

[00233] In one embodiment, any one of the Z time windows is a subframe. Z is equal to 10,

[00234] In one embodiment, any one of the Z time windows is a radio frame. Z is equal to the number of radio frames included in a DRX cycle.

[00235] In one embodiment, any one of the Z time windows is a radio frame. The time window #a is obtained by the following formula.

[00236] SFN mod Z= (Z div N)*(UE_ID mod N)

[00237] Herein, SFN is a frame number of a radio frame corresponding to the time window #a, N= min(Z,nB), nB is equal to one of {4Z, 2Z, Z, Z/2, Z/4, Z/8, Z/16, Z/32, Z/64, Z/128, Z/256, Z/512, Z/1024}.

[00238] In one embodiment, in any one of the Q subbands, all the included subcarriers have an equal subcarrier spacing.

[00239] In one embodiment, in any two of the Q subbands, the subcarriers have different subcarrier spacings.

[00240] In one embodiment, in two of the Q subbands, the subcarriers have an equal subcarrier spacing .

[00241] In one embodiment, any two of the Q subbands have an equal frequency domain width.

[00242] In one embodiment, two of the Q subbands have different frequency domain widths.

[00243] In one embodiment, the Q subbands all belong to one same carrier.

[00244] In one embodiment, two of the Q subbands belong to different carriers.

[00245] Embodiment 7

[00246] Embodiment 7 illustrates an example of a diagram for a relationship between a first time window and X time intervals according to one embodiment of the present disclosure, as

shown in FIG. 7. FIG. 7 lists the index of X=1 time interval in the first time window according to different Y values and different UE feature IDs.

[00247] In embodiment 7, the UE monitors a first signaling in X time intervals respectively. Any one of the X time intervals belongs to a first time window in time domain. The time length of the first time window is predefined. The first time window is divided into Y time intervals. The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X. The subcarrier spacing of subcarriers included in the first subband is used for determining Y. The feature ID of the UE is used for determining the X time intervals in the Y time intervals.

[00248] In one embodiment, the first signaling is detected P times at most in each one of the X time intervals. P is a positive integer.

[00249] In one embodiment, any two of the X time intervals have an equal time length.

[00250] In one embodiment, two of the X time times have different time lengths.

[00251] In one embodiment, any one of the X time intervals is a slot.

[00252] In one embodiment, any two of the X time intervals have an equal time length, and the time length of each one of the X time intervals is correlated to the subcarrier spacing of subcarriers included in the first subband.

[00253] In one embodiment, any one of the X time intervals is M OFDM symbols. M is a positive integer smaller than 14.

[00254] In one embodiment, any one of the X time intervals is M OFDM symbols. M is a positive integer smaller than 7.

[00255] In one embodiment, any two of the X time intervals are orthogonal in time domain. The orthogonality refers that there is no time unit that belongs to any two of the X time intervals simultaneously.

[00256] In one embodiment, two of the X time intervals are discrete in time domain.

[00257] In one embodiment, the time length of the first time window is fixed.

[00258] In one embodiment, the first time window includes a positive integer number of consecutive multi-carrier symbols.

[00259] In one embodiment, the multi-carrier symbol includes a data symbol and a CP.

[00260] In one embodiment, the first time window has a time length of 1 millisecond.

[00261] In one embodiment, the first time window has a time length of 10 milliseconds.

[00262] In one embodiment, the first time window is a subframe.

[00263] In one embodiment, the first time window is a radio frame.

[00264] In one embodiment, any two of the Y time intervals have an equal time length.

[00265] In one embodiment, Y is proportional to the subcarrier spacing of subcarriers included in the first subband.

[00266] In one embodiment, the feature ID refers to an IMSI.

[00267] In one embodiment, the feature ID refers to a remainder when the IMSI is divided by 1024.

[00268] In one embodiment, the feature ID refers to a remainder when the IMSI is divided by 4096.

[00269] In one embodiment, the feature ID refers to a remainder when the IMSI is divided by 16384.

[00270] In one embodiment, the feature ID refers to a C-RNTI.

[00271] Embodiment 8

[00272] Embodiment 8 illustrates an example of a diagram for a relationship among a first signaling, a first radio signal and a second radio signal according to one embodiment of the present disclosure, as shown in FIG. 8. In FIG. 8, the horizontal axis represents time, the vertical axis represents frequency, the rectangle filled by oblique lines represents a time-frequency resource occupied by the second radio signal, the rectangle filled by cross lines represents a time-frequency resource occupied by the first signaling, the rectangle filled by crossed oblique lines represents a time-frequency resource occupied by the first radio signal, and the dotted arrow represents a specific usage relationship.

[00273] In embodiment 8, the first signaling is used for determining scheduling information for the first radio signal. The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}.The frequency domain resource used for transmitting the first signaling belongs to a first subband. The first subband includes a positive integer number of consecutive subcarriers in frequency domain. The second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00274] In one embodiment, the first signaling is a physical layer signaling.

[00275] In one embodiment, the first signaling is DCI.

[00276] In one embodiment, the first signaling is transmitted through an NR-PDCCH.

[00277] In one embodiment, the first signaling is transmitted through a PDCCH. The PDCCH has a CRC scrambled by a P-RNTI.

[00278] In one embodiment, the first radio signal is transmitted through a DL-SCH.

[00279] In one embodiment, the first radio signal is transmitted through a PDSCH.

[00280] In one embodiment, a first bit block is subjected to a modulation mapper, a layer mapper, precoding, a resource element mapper and OFDM single generation in sequence to obtain the first radio signal. The first bit block includes the output obtained after a code block is subjected to channel coding. In one subembodiment, the code block is a TB. In one subembodiment, the code block is one part of a TB.

[00281] In one embodiment, the second radio signal includes a PSS.

[00282] In one embodiment, the second radio signal includes an SSS.

[00283] In one embodiment, the second radio signal is transmitted through a BCH.

[00284] In one embodiment, the second radio signal is transmitted through a PBCH.

[00285] In one embodiment, the second radio signal carries MIB information.

[00286] In one embodiment, the second radio signal carries SIB information.

[00287] In one embodiment, the information carried by the second radio signal is transmitted cyclically.

[00288] In one embodiment, the information carried by the second radio signal is transmitted on-demand.

[00289] In one embodiment, the second radio signal carries first information. The first information is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00290] In one embodiment, the second radio signal carries first information. The first information indicates at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00291] Embodiment 9

[00292] Embodiment 9 illustrates an example of a structure block diagram for a processing device in a UE, as shown in FIG. 9. In FIG. 9, the processing device 900 for the UE is mainly

composed of a first receiver module 901 and a second receiver module 902. The first receiver module 901 includes the transmitter/receiver 456 (including the antenna 460), the receiving processor 452 and the controller/processor 490 shown in FIG. 4. The second receiver module 902 includes the transmitter/receiver 456 (including the antenna 460), the receiving processor 452 and the controller/processor 490 shown in FIG. 4.

[00293] In embodiment 9, the first receiver module 901 monitors a first signaling in X time intervals, and the second receiver module 902 receives a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00294] In one embodiment, any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00295] In one embodiment, the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00296] In one embodiment, the first receiver module 901 further receives a second radio signal; The second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00297] In one embodiment, the first receiver module 901 further receives a second signaling; The second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

[00298] Embodiment 10

[00299] Embodiment 10 illustrates an example of a structure block diagram for a processing device in a base station, as shown in FIG. 10. The processing device 1000 for the base station is mainly composed of a first transmitter module 1001 and a second transmitter module 1002. The first transmitter module 1001 includes the transmitter/receiver 416 (including the antenna 420), the transmitting processor 415 and the controller/processor 440 shown in FIG. 4. The second transmitter module 1002 is mainly composed of the transmitter/receiver 416 (including the antenna 420), the transmitting processor 415 and the controller/processor 440 shown in FIG. 4.

[00300] In embodiment 10, the first transmitter module 1001 transmits a first signaling in a positive integer number of time intervals of X time intervals, and the second transmitter module 1002 transmits a first radio signal, wherein X is a positive integer; The first signaling is used for determining scheduling information for the first radio signal; The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}; The first radio signal carries a paging message; The frequency domain resource used for transmitting the first signaling belongs to a first subband; The first subband includes a positive integer number of consecutive subcarriers in frequency domain; At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

[00301] In one embodiment, any one of the X time intervals belongs to a first time window in time domain; The time length of the first time window is predefined; The first time window is divided into Y time intervals; The X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; The subcarrier spacing of subcarriers included in the first subband is used for determining Y; A feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals.

[00302] In one embodiment, the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; Any two of the Z time windows have an equal time length; The feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

[00303] In one embodiment, the first transmitter module 1001 further transmits a second radio signal; The second radio signal is used for determining at least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband}.

[00304] In one embodiment, the first transmitter module 1001 further transmits a second

signaling; The second signaling is used for determining Q subbands, Q being a positive integer; The first subband belongs to one of the Q subbands; Any one of the Q subbands includes a positive integer number of consecutive subcarriers; The feature ID of the monitor of the first signaling is used for determining the first subband in the Q subbands.

[00305] The ordinary skill in the art may understand that all or part steps in the above method may be implemented by instructing related hardware through a program. The program may be stored in a computer readable storage medium, for example Read-Only Memory (ROM), hard disk or compact disc, etc. Optionally, all or part steps in the above embodiments also may be implemented by one or more integrated circuits. Correspondingly, each module unit in the above embodiment may be realized in the form of hardware, or in the form of software function modules. The present disclosure is not limited to any combination of hardware and software in specific forms. The UE and terminal in the present disclosure include but not limited to mobile phones, tablet computers, notebooks, network cards, low-power equipment, eMTC equipment, NB-IoT equipment, unmanned aerial vehicles, telecontrolled aircrafts, vehicle-mounted communication equipment and other wireless communication equipment. The base station in the present disclosure includes but not limited to macro-cellular base stations, micro-cellular base stations, home base stations, relay base station, eNB, gNB, TRP and other radio communication equipment.

[00306] The above are merely the preferred embodiments of the present disclosure and are not intended to limit the scope of protection of the present disclosure. Any modification, equivalent substitute and improvement made within the spirit and principle of the present disclosure are intended to be included within the scope of protection of the present disclosure.

CLAIMS

WHAT IS CLAIMED IS:

1. A method in a User Equipment (UE) for paging, comprising:

monitoring a first signaling in X time intervals; and

receiving a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises occupied time-frequency resource and adopted Modulation Coding Scheme (MCS); the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband is used for determining the X time intervals；all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH); the PDCCH is transmitted in a Common Search Space (CSS).

2. The method according to claim 1, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

3. The method according to claim 2, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

4. The method according to claim 3, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

5. The method according to claim 1, further comprising:

receiving a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

6. A method in a base station for paging, comprising:

transmitting a first signaling in a positive integer number of time intervals of X time intervals; and

transmitting a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises occupied time-frequency resource and adopted MCS; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband is used for determining the X time intervals； all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS).

7. The method according to claim 6, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

8. The method according to claim 7, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

9. The method according to claim 8, further comprising:

receiving a third signaling;

wherein, the third signaling is used for configuring Z.

10. The method according to claim 6, further comprising:

transmitting a second radio signal;

wherein the second radio signal is used for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

11. A UE for paging, comprising:

a first receiver, to monitor a first signaling in X time intervals; and

a second receiver, to receive a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises occupied time-frequency resource and adopted MCS; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband is used for determining the X time intervals; all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS).

12. The UE according to claim 11, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

13. The UE according to claim 12, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

14. The method according to claim 13, wherein the second receiver further receives a third signaling, the third signaling is used for configuring Z.

15. The UE according to claim 11, wherein the first receiver further receives a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

16. A base station for paging, comprising:

a first transmitter, to transmit a first signaling in a positive integer number of time intervals of X time intervals; and

a second transmitter, to transmit a first radio signal;

wherein X is a positive integer; the first signaling is used for determining scheduling information for the first radio signal; the scheduling information comprises occupied time-frequency resource and adopted MCS; the first radio signal carries a paging message; the frequency domain resource used for transmitting the first signaling belongs to

a first subband; the first subband comprises a positive integer number of consecutive subcarriers in frequency domain; and subcarrier spacing of subcarriers included in the first subband is used for determining the X time intervals； all subcarriers included in the first subband have an equal subcarrier spacing, any two of the X time intervals are orthogonal in time domain; the first signaling is transmitted through a PDCCH, the PDCCH has a Cyclic Redundancy Check (CRC) scrambled by a Paging Radio Network Temporary Identity (P-RNTI), the first radio signal is transmitted through a Physical Downlink Shared Channel (PDSCH) ; the PDCCH is transmitted in a Common Search Space (CSS).

17. The base station according to claim 16, wherein any one of the X time intervals belongs to a first time window in time domain; the time length of the first time window is predefined; the first time window is divided into Y time intervals; the X time intervals are X time intervals of the Y time intervals, Y being a positive integer not smaller than X; the subcarrier spacing of subcarriers included in the first subband is used for determining Y; and a feature ID of a monitor of the first signaling is used for determining the X time intervals in the Y time intervals, the feature ID refers to a remainder when an International Mobile Subscriber Identification Number (IMSI) is divided by 1024.

18. The base station according to claim 17, wherein the first time window belongs to one of Z time windows, Z being an integer greater than 1; Z is predefined, or Z is configurable; any two of the Z time windows have an equal time length, any two of the Z time windows are orthogonal in time domain, any one of the Z time windows is a radio frame, Z is equal to the number of radio frames included in a Discontinuous Reception (DRX) cycle; and the feature ID of the monitor of the first signaling is used for determining the first time window in the Z time windows.

19. The method according to claim 18, wherein the second transmitter further transmits a third signaling, the third signaling is used for configuring Z.

20. The base station according to claim 16, wherein the first transmitter further transmits a second radio signal; the second radio signal is for determining at least one of location of the first subband in frequency domain, or subcarrier spacing of subcarriers included in the first subband; the second radio signal carries Master Information Block (MIB) information, or the second radio signal carries System Information Block (SIB) information.

ABSTRACT

The present disclosure provides a method and a device in a User Equipment (UE) and a base station used for paging. The UE first monitors a first signaling in X time intervals respectively, and then receives a first radio signal. The first signaling is used for determining scheduling information for the first radio signal. The scheduling information includes at least one of {occupied time-frequency resource, adopted MCS, subcarrier spacing of subcarriers in occupied frequency domain resource}. The first radio signal carries a paging message. The frequency domain resource is used for transmitting the first signaling belongs to a first subband. The first subband includes a positive integer number of consecutive subcarriers in frequency domain. At least one of {location of the first subband in frequency domain, subcarrier spacing of subcarriers included in the first subband} is used for determining the X time intervals.

DECLARATION (37 CFR 1.63) FOR UTILITY OR DESIGN APPLICATION USING AN APPLICATION DATA SHEET (37 CFR 1.76)

Title of Invention	METHOD AND DEVICE IN UE AND BASE STATION USED FOR PAGING

As the below named inventor, I hereby declare that:

This declaration is directed to:

- [x] The attached application, or
- [ ] United States application or PCT international application number _____ filed on _____.

The above-identified application was made or authorized to be made by me.

I believe that I am the original inventor or an original joint inventor of a claimed invention in the application.

I hereby acknowledge that any willful false statement made in this declaration is punishable under 18 U.S.C. 1001 by fine or imprisonment of not more than five (5) years, or both.

WARNING:

Petitioner/applicant is cautioned to avoid submitting personal information in documents filed in a patent application that may contribute to identity theft. Personal information such as social security numbers, bank account numbers, or credit card numbers (other than a check or credit card authorization form PTO-2038 submitted for payment purposes) is never required by the USPTO to support a petition or an application. If this type of personal information is included in documents submitted to the USPTO, petitioners/applicants should consider redacting such personal information from the documents before submitting them to the USPTO. Petitioner/applicant is advised that the record of a patent application is available to the public after publication of the application (unless a non-publication request in compliance with 37 CFR 1.213(a) is made in the application) or issuance of a patent. Furthermore, the record from an abandoned application may also be available to the public if the application is referenced in a published application or an issued patent (see 37 CFR 1.14). Checks and credit card authorization forms PTO-2038 submitted for payment purposes are not retained in the application file and therefore are not publicly available.

LEGAL NAME OF INVENTOR

Inventor: XiaoBo ZHANG Date (Optional): Apr. 12 2018

Signature: XiaoBo ZHANG

Note: An application data sheet (PTO/AIA/14 or equivalent), including naming the entire inventive entity, must accompany this form. Use an additional PTO/SB/AIA01 form for each additional inventor.

This collection of information is required by 35 U.S.C. 115 and 37 CFR 1.63. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.11 and 1.14. This collection is estimated to take 1 minute to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.
