ELECTRONIC ACKNOWLEDGEMENT RECEIPT

APPLICATION #	RECEIPT DATE / TIME	ATTORNEY DOCKET #
17/950,726	**11/19/2023 10:47:29 PM Z ET**	**ZL0205-0004-US-CON3**

Title of Invention

METHOD AND DEVICE IN UE AND BASE STATION USED FOR PAGING

Application Information

APPLICATION TYPE	Utility - Nonprovisional Application under 35 USC 111(a)	PATENT #	-
CONFIRMATION #	6005	FILED BY	Jialin Zhong
PATENT CENTER #	63311403	FILING DATE	09/22/2022
CUSTOMER #	155075	FIRST NAMED INVENTOR	Xiaobo ZHANG
CORRESPONDENCE ADDRESS	-	AUTHORIZED BY	-

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

CERTIFICATION STATEMENT

Please see 37 CFR 1.97 and 1.98 to make the appropriate selection(s):

☐ That each item of information contained in the information disclosure statement was first cited in any communication from a foreign patent office in a counterpart foreign application not more than three months prior to the filing of the information disclosure statement. See 37 CFR 1.97(e)(1).

OR

☐ That no item of information contained in the information disclosure statement was cited in a communication from a foreign patent office in a counterpart foreign application, and, to the knowledge of the person signing the certification after making reasonable inquiry, no item of information contained in the information disclosure statement was known to any individual designated in 37 CFR 1.56(c) more than three months prior to the filing of the information disclosure statement. See 37 CFR 1.97(e)(2).

☐ See attached certification statement.

☒ The fee set forth in 37 CFR 1.17 (p) has been submitted herewith.

☒ A certification statement is not submitted herewith.

SIGNATURE

A signature of the applicant or representative is required in accordance with CFR 1.33, 10.18. Please see CFR 1.4(d) for the form of the signature.

This collection of information is required by 37 CFR 1.97 and 1.98. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 1 hour to complete, including gathering, preparing and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these record s.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

(54) METHOD, EQUIPMENT AND SYSTEM FOR COORDINATED MULTI-POINT TRANSMISSION/ RECEPTION

(57) A method, a device, and a system for CoMP coordinated multi-point transmission are disclosed, where the method includes: obtaining reference signal received power RSRP of a cell in a measurement set of a user equipment UE; determining that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold; and combining a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE, and performing coordinated multi-point transmission on the UE, thereby improving an effect of CoMP.

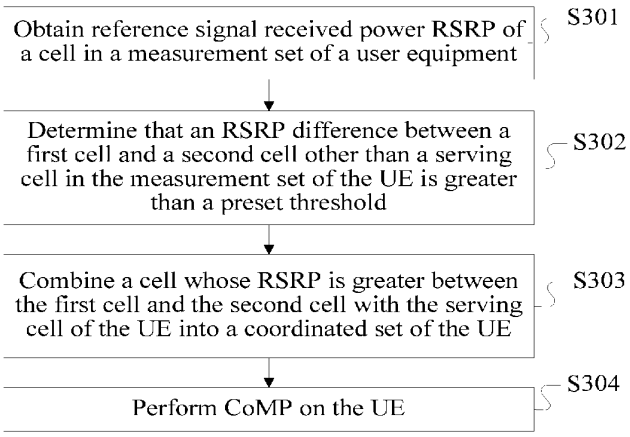

FIG. 3

Printed by Jouve, 75001 PARIS (FR)

EP 2 712 228 A1

Description

TECHNICAL FIELD

[0001] The present invention relates to the field of network technologies, and in particular, to a method, a device, and a system for coordinated multi-point transmission.

BACKGROUND

[0002] CoMP (Coordinated Multi-point Transission/reception, coordinated multi-point transmission) is one of key technologies of LTE-A (Long Term Evolution-Advanced, long term evolution-advanced), and is used to expand coverage of a high data rate and increase average throughput of a system, thereby improving performance of a cell edge user.

[0003] FIG. 1 is a schematic diagram of a CoMP technology. CoMP is a cooperative sending and receiving technology, where one base station (for example, eNodeB x in FIG. 1) is connected to several access points (for example, Point x in FIG. 1), and one access point may include one or more antennas. Multiple users (User Equipment, UE for short) (UE x) may be served by one or more access points located at one same base station or different base stations. A coordination center controller may obtain information from a distributed access point, and allocate a resource to meet a QoS (Quality of Service, quality of service) requirement of a user, thereby maximizing performance of an entire network.

[0004] In the CoMP technology, signals of a serving cell and multiple coordination cells may be simultaneously sent or received, which is equivalent to increasing the number of antennas at a transmit end or a receive end, and demodulation performance is improved through a multiple input multiple output (Multiple Input Multiple Output, MIMO for short) receiver.

[0005] A main principle of uplink-based intra-eNodeB (Intra-eNodeB) CoMP is that, antennas in different cells of one same base station are used for receiving a signal of a certain user, and a combined gain and an interference suppression gain of the signal received by the multiple antennas may be obtained at the same time, and the combined gain of the signal is greater for a user closer to a boundary between two cells. By taking FIG. 2 as an example, a user is located at a boundary between cells, a Cell 0 and a Cell 1, and the Cell 1 is a serving cell for the user. When the user is closer to the boundary of the cell Cell 0, power of a signal of the user received by the cell Cell 0 is greater, and a combined gain of the signal is higher.

[0006] However, it is very complicated to implement CoMP for all users. Due to a limitation on a processing capability of a device at present, it is very difficult to implement this solution in practice. In a case of joint reception for some cells with excessively low signal to interference plus noise ratios (SINR), performance may decrease instead due to the influence of channel estimation. Therefore, how to select a CoMP coordinated set and which UEs are to be selected, where CoMP is performed on the UEs for optimization in terms of performance and complexity, become very important.

[0007] Currently, a mainstream solution in the prior art is to determine whether to perform CoMP on a UE by using whether a difference between RSRP (Reference Signal Receiving Power, reference signal received power) of a serving cell and RSRP of another neighboring cell is greater than a predetermined threshold. However, this selection manner does not take an interference factor into consideration, and in practice, interference on the serving cell and interference on another cell are usually very different. Therefore, a UE selected according to an RSRP difference between the serving cell and the another cell is usually not a UE for which a highest gain is obtained when CoMP is performed, which reduces an effect of CoMP.

SUMMARY

[0008] In view of this, embodiments of the present invention provide a method, a device, and a system for coordinated multi-point transmission, which can select a user equipment located at a cell overlapping area to perform coordinated multi-point transmission, thereby improving an effect of coordinated multi-point transmission.

[0009] To achieve the foregoing objectives, in one aspect, the present invention provides a method for CoMP coordinated multi-point transmission, where the method includes:

obtaining reference signal received power RSRP of a cell in a measurement set of a user equipment UE;
determining that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold; and
combining a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE, and performing coordinated multi-point transmission on the UE.

[0010] In another aspect, the present invention further provides a device for coordinated multi-point transmission, where the device includes:

an RSRP obtaining unit, configured to obtain reference signal received power RSRP of all cells in a measurement set of a user equipment UE;
a determining unit, configured to determine that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold;
a coordinated set joining unit, configured to combine a cell whose RSRP is greater between the first cell

and the second cell with the serving cell of the UE into a coordinated set of the UE; and

a transmitting unit, configured to perform coordinated multi-point transmission on the UE.

[0011] In still another aspect, the present invention further provides a system, including the device for coordinated multi-point transmission.

[0012] It can be seen that, in the method, the device, and the system for coordinated multi-point transmission provided by the embodiments of the present invention, whether to perform CoMP on a UE is determined based on whether two cells whose RSRP difference is greater than a threshold exist in a measurement set of the UE other than a serving cell. In the embodiments of the present invention, a UE near a cell overlapping area can be selected, and a relatively high gain can be obtained for such UE during CoMP, thereby improving an effect of CoMP.

BRIEF DESCRIPTION OF DRAWINGS

[0013] To describe the technical solutions in the embodiments of the present invention or in the prior art more clearly, the following briefly introduces accompanying drawings required for describing the embodiments or the prior art. Apparently, the accompanying drawings in the following description show merely some embodiments of the present invention, and a person of ordinary skill in the art may still derive other drawings according to these accompanying drawings without creative efforts.

FIG. 1 is a schematic diagram of a CoMP technology in the prior art;

FIG. 2 is a schematic diagram of a cell of an Intra-eNodeB CoMP technology;

FIG. 3 is a schematic flow chart of a method for coordinated multi-point transmission according to an embodiment of the present invention;

FIG. 4 is a schematic flow chart of a method for coordinated multi-point transmission according to another embodiment of the present invention;

FIG. 5 is a schematic diagram of an application scenario for a method for coordinated multi-point transmission according to an embodiment of the present invention;

FIG. 6 is a schematic structural diagram of a device for coordinated multi-point transmission according to an embodiment of the present invention; and

FIG. 7 is a schematic structural diagram of a device for coordinated multi-point transmission according to another embodiment of the present invention.

DESCRIPTION OF EMBODIMENTS

[0014] To make the objectives, technical solutions, and advantages of the embodiments of the present invention more comprehensible, the following clearly and completely describes the technical solutions in the embodiments of the present invention with reference to the accompanying drawings in the embodiments of the present invention. Apparently, the embodiments to be described are merely a part rather than all of the embodiments of the present invention. All other embodiments obtained by a person of ordinary skill in the art based on the embodiments of the present invention without creative efforts shall fall within the protection scope of the present invention.

[0015] FIG. 3 is a schematic flow chart of a method for coordinated multi-point transmission according to an embodiment of the present invention. An embodiment of the present invention provides a method for coordinated multi-point transmission, where, as shown in FIG. 3, the method includes:

Step S301: Obtain reference signal received power RSRP of a cell in a measurement set of a user equipment (UE).

[0016] Specific implementation of obtaining RSRP may adopt the prior art, for example, a method defined in the 3GPP 36.214 protocol. The present invention does not limit implementation of obtaining RSRP.

[0017] In addition, the measurement set may be determined by using the following method: A base station of a serving cell of the UE delivers a periodic measurement configuration to the UE. After receiving the periodic measurement configuration, the UE measures all available cells of a configured frequency to obtain signal quality, and reports the signal quality to the base station of the serving cell. The base station adds a cell whose signal quality exceeds a threshold set on a network to the measurement set of the UE. It may also be stipulated that cells whose signal quality ranks in the top several places are added to the measurement set of the UE, which is not limited by the present invention. Cells in the measurement set may belong to different base stations, or may belong to one same base station.

Step S302: Determine that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold. Subtraction may be performed on RSRP values of every two cells other than the serving cell in the measurement set of the UE to obtain an absolute value of an RSRP difference between two cells other than the serving cell in the measurement set, and the absolute value of the difference is compared with a threshold preset in advance.

[0018] For example, when there are two cells other than the serving cell of the UE in the measurement set, subtraction is performed on RSRP of the two cells for comparison with a preset threshold. It is assumed that there are three cells other than the serving cell of the UE

in the measurement set cell 1, cell 2, and cell 3. Subtraction is performed on RSRP values of every two cells of cell 1, cell 2, and cell 3 to obtain |RSRP cell 1 - RSRP cell 2|, |RSRP cell 1 - RSRP cell 3|, and |RSRP cell 3 - RSRP cell 2|, and the three values are compared with the preset threshold. As long as there is one of the three values which is greater than the preset threshold (or greater than or equal to the preset threshold, which is not limited in the present invention), CoMP may be performed on the UE.

When a first cell and a second cell that meet the foregoing condition exist, it indicates that the UE is located at an overlapping area of the serving cell and another cell, and a relatively high gain is obtained for the UE during CoMP.

Step S303: Combine a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE, and perform CoMP on the UE. A specific method for coordinated multi-point transmission may also be implemented through the prior art.

[0019] In the method provided by the embodiment, whether to perform CoMP on a UE is determined based on whether two cells whose RSRP difference is greater than a threshold exist in a measurement set of the UE other than a serving cell. Interference between cells other than the serving cell is usually close. Therefore, a UE near a cell overlapping area can be selected more accurately, and a relatively high gain can be obtained for such UE during CoMP, thereby improving an effect of CoMP.

[0020] FIG. 4 is a schematic flow chart of a method for coordinated multi-point transmission according to another embodiment of the present invention. As shown in FIG. 4, the method for coordinated multi-point transmission in embodiment 1 includes:

Step S401: Obtain reference signal received power (RSRP) of a cell in a measurement set of a UE.

[0021] For a specific method, reference may be similarly made to step S301 in the foregoing embodiment.

Step S402: Determine that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold.

For a specific method, reference may be similarly made to step S302 in the foregoing embodiment.

Step S403: Combine a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE.

For a specific method, reference may be similarly made to step S303 in the foregoing embodiment.

Step S404: After step S403, obtain a gain between a post-SINR (Posted-SINR) of the UE in the coordinated set and a post-SINR of the UE in the serving cell.

In a scenario where coverage is limited, a relative gain may be used as the gain in step S404. The relative gain may be determined according to the following formula:

$$\frac{\log_2(1+SINR_1)-\log_2(1+SINR_0)}{\log_2(1+SINR_0)},$$

where $SINR_0$ is the post-SINR of the UE in the serving cell of the UE, and $SINR_1$ is a post-SINR of the UE in a cell other than the serving cell in the coordinated set of the UE, where the cell other than the serving cell in the coordinated set of the UE may also be called a coordination cell of the UE; and

$\log_2(1+SINR_1)$ is throughput which is of the UE in the coordinated set of the UE and is determined according to the Shannon's formula, and $\log_2(1+SINR_0)$ is throughput which is of the UE in the serving cell of the UE and is determined according to the Shannon's formula.

[0022] In a scenario where a capacity is limited, an absolute gain may be used as the gain in step S404.

[0023] The absolute gain may be determined according to the following formula:

$$\log_2(1+SINR_1)-\log_2(1+SINR_0),$$

where $SINR_0$ is the post-SINR of the UE in the serving cell of the UE, and $SINR_1$ is the post-SINR of the UE in the cell other than the serving cell in the coordinated set of the UE; and

$\log_2(1+SINR_1)$ is the throughput which is of the UE in the coordinated set of the UE and is determined according to the Shannon's formula, and $\log_2(1+SINR_0)$ is the throughput which is of the UE in the serving cell of the UE and is determined according to the Shannon's formula.

Step S405: Perform CoMP on a UE whose gain is greater than the preset threshold.

In practice, alternatively, UEs may also be sorted according to gains obtained through calculation in step S404, and a UE with a highest gain is selected preferably for performing CoMP, until a processing resource is used up.

[0024] In the embodiment, by taking a case that a hardware resource is limited into consideration, it is possible that CoMP can be performed on only a part of UEs. After UEs near a cell overlapping area are selected through

step S401 to step S403, these UEs are sorted according to their gains, and CoMP is preferably performed on a UE with a highest gain, so that efficiency of CoMP may be fully improved with a limited resource.

[0025] It should be noted that, in the embodiment, the step for obtaining the gains of the UEs may be performed in each transmission time interval (TTI), or may be performed on each resource block (RB). Certainly, a granularity implemented in the step for obtaining the gains of the UEs may be divided according to another granularity.

[0026] In each of the foregoing embodiments, cells in the measurement set of the UE may belong to one same base station, or at least two cells may belong to different base stations.

[0027] If cells in the measurement set of the UE belong to one same base station, intra-eNodeB CoMP (Intra-eNodeB CoMP) is implemented when CoMP is performed on the UE.

[0028] If at least two cells in the measurement set of the UE belong to different base stations and the coordinated set of the UE also includes cells that belong to at least two base stations, inter-eNodeB CoMP is implemented when CoMP is performed on the UE.

[0029] Specific implementation of the method for coordinated multi-point transmission in the present invention is described in detail in the following through several specific examples.

[0030] Example 1: As shown in FIG. 5, it is assumed that a serving cell of a UE is Cell 0. In a measurement set of the UE, three cells are included, namely, a serving cell of the UE Cell0 and two other neighboring cells Cell 1 and Cell 2.

[0031] First, RSRP of Cell 0, Cell 1, and Cell 2 are obtained, and are marked as RSRP0, RSRP1, and RSRP2, respectively.

[0032] When it is determined that an absolute value of a difference between the RSRP1 and the RSRP2 is greater than a preset threshold, it indicates that the UE is located at a cell overlapping area. In FIG. 5, the UE is located at an overlapping area between cells Cell 0 and Cell 1, and a cell corresponding to a greater RSRP value between the RSRP1 and the RSRP2 and the serving cell Cell 0 are included in a coordinated set of the UE. For example, when the absolute value of the difference between the RSRP1 and the RSRP2 is greater than the preset threshold, and it may be measured that RSRP1> RSRP2 due to a fact the UE is closer to Cell1 than to Cell2, Cell 0 and Cell 1 are included in the coordinated set of the UE. Next, CoMP is performed on the UE.

[0033] Example 2: It is assumed that there are three UEs, which may be marked as UE1, UE2, and UE3 respectively, Cell0 is a serving cell of all the three UEs, and measurement sets all include Cell0 and other two neighboring cells Cell 1 and Cell 2.

[0034] First, a process as described in the foregoing example 1 for obtaining of RSPR and formation of a coordinated set of each UE is separately implemented for UE1, UE2, and UE3.

[0035] Next, a gain between a post-SINR of UE1 in the coordinated set of UE1 and a post-SINR of UE1 in the serving cell Cell0 of UE1 is calculated, and is marked as D1. A gain between a post-SINR of UE2 in the coordinated set of UE2 and a post-SINR of UE2 in the serving cell Cell0 of UE2 is calculated, and is marked as D2. A gain between a post-SINR of UE3 in the coordinated set of UE3 and a post-SINR of UE3 in the serving cell Cell0 of UE3 is calculated, and is marked as D3.

[0036] It is assumed that D2>D1>D3, and UE1, UE2, and UE3 are sorted according to order of their gains as follows: UE2, UE1, UE3.

[0037] CoMP is preferably performed on UE2, and then UE1. If a processing resource is used up after CoMP is performed on UE1, CoMP is not performed on UE3.

[0038] In addition, there may be multiple first cells and second cells that meet a condition in the foregoing embodiments, for example, in a scenario such as that a UE is located at a cell overlapping area between base stations, or a base station is divided into six cells. It is assumed that in a measurement set of a UE, five cells are included, namely, Cell 0, Cell 1, Cell 2, Cell 3, and Cell 4. Cell 0 is a serving cell of the UE. After measurement, RSRP of Cell 1, Cell 2, Cell 3, and Cell 4 are RSRP1, RSRP2, RSRP3, and RSRP4, respectively.

[0039] It is found through comparison that: An absolute value of a difference between the RSRP1 and the RSRP2 is greater than a preset threshold; an absolute value of a difference between the RSRP3 and the RSRP4 is also greater than the preset threshold. In a case that a hardware resource is sufficient, a cell whose RSRP is greater in each pair of cells whose RSRP difference is greater than the preset threshold and that meet a condition may be used as a coordination cell of the UE, and the coordination cell of the UE and the serving cell of the UE are included in a coordinated set of the UE. It is assumed that, in the foregoing example, there are two pairs of cells that meet the condition, namely, {cell1, cell2} and {cell3, cell4}, RSRP corresponding to the two pairs of cells may be respectively marked as {RSRP1, RSRP2} and {RSRP3, RSRP4}. It is assumed that, |RSRP1-RSRP2| and |RSRP3-RSRP4| are both greater than the preset threshold, and RSRP1>RSRP2 and RSRP3>RSRP4. In this case, RSRP1 and RSRP3 may both be used as coordination cells of the UE. In this way, the coordinated set of the UE includes Cell 0, Cell1, and Cell3.

[0040] However, sometimes, in a case that the hardware resource is insufficient, the number of coordination cells in the coordinated set of the UE is limited. In this case, cells whose RSRP is greater in each pair of the cells whose RSRP difference is greater than the preset threshold and that meet the condition need to be compared, and a cell whose RSRP is greater is preferably selected as the coordination cell of the UE. Alternatively, whether RSRP of a cell whose RSRP is greater among the cells whose RSRP difference is greater than the preset threshold is also greater than the preset threshold is determined through comparison, and then the cell whose

RSRP is greater is used as the coordination cell of the UE. For example, in the foregoing example, it is further assumed that, a difference between the RSRP1 and the RSRP3 of two first cells is also greater than the threshold. Then, only Cell1 whose RSRP is greater is used as the coordination cell of the UE. In this case, the coordinated set of the UE includes only Cell 0 and Cell1.

[0041] FIG. 6 is a schematic structural diagram of a device for coordinated multi-point transmission according to an embodiment of the present invention. As shown in FIG. 6, the device for coordinated multi-point transmission includes:

An RSRP obtaining unit 601 is configured to obtain reference signal received power RSRP of all cells in a measurement set of a user equipment UE.

[0042] A determining unit 602 is configured to determine that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold.

[0043] A transmitting unit 603 is configured to combine a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE, and perform coordinated multi-point transmission on the UE.

[0044] In practice, the device for coordinated multi-point transmission in the embodiment may be a base station.

[0045] Specific implementation of obtaining RSRP by the RSRP obtaining unit 601 may adopt the prior art, for example, a method defined in the 3GPP 36.214 protocol. The present invention does not limit implementation of obtaining RSRP. Cells in the measurement set may belong to different base stations or may belong to one same base station.

[0046] The determining unit 602 may perform subtraction on RSRP values of every two cells other than the serving cell in the measurement set of the UE to obtain an absolute value of an RSRP difference between two cells other than the serving cell in the measurement set, and compare the absolute value of the difference with the threshold preset in advance.

[0047] FIG. 7 is a schematic structural diagram of a device for coordinated multi-point transmission according to another embodiment of the present invention. As shown in FIG. 7, the device for coordinated multi-point transmission includes:

An RSRP obtaining unit 701 is configured to obtain reference signal received power RSRP of all cells in a measurement set of a user equipment UE. Specific implementation of obtaining RSRP by the RSRP obtaining unit 701 may adopt the prior art, for example, a method defined in the 3GPP 36.214 protocol. The present invention does not limit implementation of obtaining RSRP. Cells in the measurement set may belong to different base stations or may belong to one same base station.

[0048] A determining unit 702 is configured to determine that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold. The determining unit 702 may perform subtraction on RSRP values of every two cells other than the serving cell in the measurement set of the UE to obtain an absolute value of an RSRP difference between two cells other than the serving cell in the measurement set, and compare the absolute value of the difference with the threshold preset in advance.

[0049] A gain obtaining unit 703 is further included, where the gain obtaining unit 703 is configured to obtain a gain between a post-SINR of the UE in the coordinated set of the UE and a post-SINR of the UE in the serving cell of the UE.

[0050] Specifically, in a scenario where coverage is limited, the gain obtained by the gain obtaining unit 703 may be a relative gain, where the relative gain may be determined according to the following formula:

$$\frac{\log_2(1+SINR_1)-\log_2(1+SINR_0)}{\log_2(1+SINR_0)},$$

where $SINR_0$ is the post-SINR of the UE in the serving cell of the UE, and $SINR_1$ is a post-SINR of the UE in a cell other than the serving cell in the coordinated set of the UE, where the cell other than the serving cell in the coordinated set of the UE may also be called a coordination cell of the UE; and

$\log_2(1 + SINR_1)$ is throughput which is of the UE in the coordinated set of the UE and is determined according to the Shannon's formula, and $\log_2(1+SINR_0)$ is throughput which is of the UE in the serving cell of the UE and is determined according to the Shannon's formula.

[0051] In a scenario where a capacity is limited, the gain obtained by the gain obtaining unit 604 may be an absolute gain.

[0052] The absolute gain may be determined according to the following formula:

$$\log_2(1+SINR_1)-\log_2(1+SINR_0),$$

where $SINR_0$ is the post-SINR of the UE in the serving cell of the UE, and $SINR_1$ is the post-SINR of the UE in the cell other than the serving cell in the coordinated set of the UE; and

$\log_2(1 + SINR_1)$ is the throughput which is of the UE in the coordinated set of the UE and is determined according to the Shannon's formula, and

$\log_2(1+SINR_0)$ is the throughput which is of the UE in the serving cell of the UE and is determined according to the Shannon's formula.

[0053] A process of obtaining gains of UEs by the gain obtaining unit 703 may be performed in each transmission time interval (TTI), or may be performed on each resource block (RB). Certainly, a granularity implemented in the step for obtaining the gains of the UEs may be divided according to another granularity.

[0054] A transmitting unit 704 is specifically configured to select a UE whose gain is greater than a preset threshold to perform coordinated multi-point transmission.

[0055] The device for coordinated multi-point transmission in the embodiment may be a base station.

[0056] In addition, an embodiment of the present invention further provides a system, where the system includes the device for coordinated multi-point transmission in the foregoing device embodiments.

[0057] Exemplary implementation manners of the present invention are described in the foregoing. It should be noted that, a person of ordinary skill in the art may further make several modifications and variations without departing from the principle of the present invention, and these modifications and variations should also be construed as falling within the protection scope of the present invention.

Claims

1. A method for CoMP coordinated multi-point transmission, comprising:

   obtaining reference signal received power RSRP of a cell in a measurement set of a user equipment UE;
   determining that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold; and
   combining a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE, and performing coordinated multi-point transmission on the UE.

2. The method according to claim 1, further comprising:

   obtaining a gain between a post-SINR of the UE in the coordinated set and a post-SINR of the UE in the serving cell; wherein
   the performing coordinated multi-point transmission on the UE comprises:

   selecting the UE whose gain is greater than a preset threshold to perform coordinated multi-point transmission.

3. The method according to claim 2, wherein the gain is a relative gain or an absolute gain.

4. The method according to claim 2 or 3, wherein the obtaining a gain between a post-SINR of the UE in the coordinated set and a post-SINR of the UE in the serving cell comprises:

   obtaining, in each transmission time interval (TTI), the gain between the post-SINR of the UE in the coordinated set and the post-SINR of the UE in the serving cell.

5. The method according to claim 2 or 3, wherein the obtaining a gain between a post-SINR of the UE in the coordinated set and a post-SINR of the UE in the serving cell comprises:

   obtaining, on each resource block (RB), the gain between the post-SINR of the UE in the coordinated set and the post-SINR of the UE in the serving cell.

6. The method according to any one of claims 1 to 5, wherein,
   cells in the measurement set of the UE belong to one same base station, or
   at least two of cells in the measurement set of the UE belong to different base stations.

7. A device for coordinated multi-point transmission, comprising:

   an RSRP obtaining unit, configured to obtain reference signal received power RSRP of all cells in a measurement set of a user equipment UE;
   a determining unit, configured to determine that an RSRP difference between a first cell and a second cell other than a serving cell in the measurement set of the UE is greater than a preset threshold; and
   a transmitting unit, configured to combine a cell whose RSRP is greater between the first cell and the second cell with the serving cell of the UE into a coordinated set of the UE, and perform coordinated multi-point transmission on the UE.

8. The device according to claim 7, further comprising:

   a gain obtaining unit, configured to obtain a gain between a post-SINR of the UE in the coordinated set and a post-SINR of the UE in the serving cell; wherein
   the transmitting unit is specifically configured to select the UE whose gain is greater than a preset threshold to perform coordinated multi-point transmission.

9. The device according to claim 7, wherein the gain obtaining unit is specifically configured to obtain, in each transmission time interval (TTI), the gain between the post-SINR of the UE in the coordinated set and the post-SINR of the UE in the serving cell; or the gain obtaining unit is specifically configured to obtain, on each resource block (RB), the gain between the post-SINR of the UE in the coordinated set and the post-SINR of the UE in the serving cell.

10. The device according to any one of claims 7 to 9, wherein the device is a base station.

11. A system, comprising the device for coordinated multi-point transmission according to any one of claims 7 to 9.

(54) Title: ENODEB REFERENCE SIGNAL REDUCTION

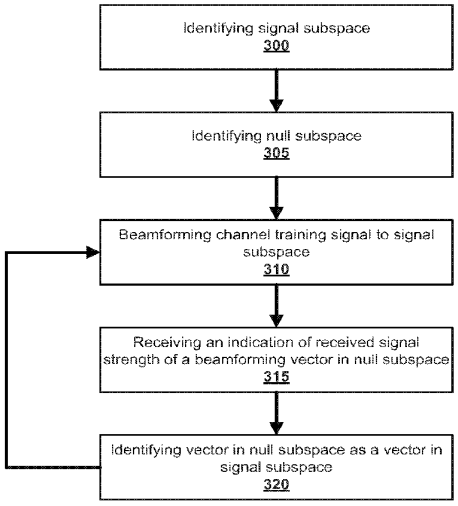

Figure 3

(57) Abstract: In embodiments, apparatuses, methods, and storage media may be described for reducing the overhead associated with the transmission of channel training signals from an eNodeB (eNB) of a wireless network. Specifically, the eNB may receive feedback from a user equipment (UE) regarding the received signal energy of a first and second beamformed signal produced with a first and second beamforming vector, respectively. The eNB may identify, based on the feedback of the received signal energy, a signal subspace and a null subspace. The eNB may then transmit a channel training signal to the signal subspace.

ENODEB REFERENCE SIGNAL REDUCTION

Cross Reference to Related Application

The present application claims priority to U.S. Provisional Patent Application No. 61/806,821, filed March 29, 2013, entitled "Advanced Wireless Communication Systems and Techniques," the entire disclosure of which is hereby incorporated by reference in its entirety.

Field

Embodiments of the present invention relate generally to the technical field of channel training signals in wireless systems.

Background

The background description provided herein is for the purpose of generally presenting the context of the disclosure. Work of the presently named inventors, to the extent it is described in this background section, as well as aspects of the description that may not otherwise qualify as prior art at the time of filing, are neither expressly nor impliedly admitted as prior art against the present disclosure. Unless otherwise indicated herein, the approaches described in this section are not prior art to the claims in the present disclosure and are not admitted to be prior art by inclusion in this section.

Full dimension multiple-input-multiple-output (FD-MIMO) is a study item for the upcoming Release 12 of the third generation partnership project (3GPP) long term evolution (LTE) specifications. In FD-MIMO systems, the eNodeB (eNB) may have 16 or more different antenna elements that are configured for beamforming on one or more antenna ports to user equipment (UEs). Ideally, the throughput of the eNB in FD-MIMO systems may be expected to significantly increase with a large number of antenna elements.

However, in frequency division duplex (FDD) mode, beamforming may require channel training signals. Specifically, channel training signals may be reference signals that are sent by the eNB to each UE. The UE(s) may then respond with channel feedback based on the received channel training signals. This feedback may be used to identify the resources used to beamform one or more additional signals to the UE. Currently, the overhead associated with transmitting the channel training signals may increase linearly with the number of antenna elements. For large antenna arrays having, for example, 30 antenna elements, the overhead associated with transmitting the channel training signals may become prohibitive because the throughput gains realized through use of FD-MIMO

may be offset by the overhead incurred through transmission of the channel training signals.

Brief Description of the Drawings

Embodiments will be readily understood by the following detailed description in conjunction with the accompanying drawings. To facilitate this description, like reference numerals designate like structural elements. Embodiments are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings.

Figure 1 schematically illustrates a high-level example of a network system comprising a UE and an eNB, in accordance with various embodiments.

Figure 2 depicts an example of different subspaces for FD-MIMO transmissions from an eNodeB (eNB) to a plurality of user equipment (UEs), in accordance with various embodiments.

Figure 3 depicts an example of a process flow for transmitting channel training signals, in accordance with various embodiments.

Figure 4 schematically illustrates an example system that may be used to practice various embodiments described herein.

Detailed Description

Apparatuses, methods, and storage media are described herein for reducing the overhead associated with the transmission of channel training signals such as the channel state information reference signal (CSI-RS). As described above, the number of antenna ports of an eNB may linearly increase with an increase in the number of antenna elements used by the eNB. This increase in antenna ports may increase transmissions of channel training signals, which in turn may increase resource overhead of the eNB.

The channel training signals may be shared between the antenna ports in order to reduce the resource overhead of the eNB. However, time sharing of the channel training signals may introduce latency or delay to transmissions of the eNB. As noted above, the channel training signals may be transmitted from the eNB, and the UE may feed back information related to the channel training signals, and more specifically the radio resources used to transmit the channel training signals. Based on the fed back information, the eNB may identify radio resources that should be used for further communication with the UE.

However, the latency introduced by time sharing of the channel training signals may be detrimental because the latency may be such that the radio resources in the cell may have changed significantly between the transmission of the channel training signal

and the identification of the channel resources to use to transmit further signals using the feedback based on the transmission of the channel training signal. In other words, the fed back information from a UE receiving the channel training signals may not necessarily correspond to the radio resources of the cell at the time of transmission of the additional signal(s) from the eNB. This change may be due to interference caused by multiple UEs, the UE moving, or other reasons. Therefore, time sharing of the channel training signals may reduce overall performance of the cell.

By contrast, the present disclosure may relate to selectively transmitting one or more channel training signals to particular signal subspaces. Specifically, the channel training signals may be beamformed to those signal subspaces. Typically, beamforming may include multiplying a signal by an antenna-specific or antenna-port specific weighting vector, which may be referred to as a beamforming vector. The beamforming vector may affect the phase of the signal, the amplitude of the signal, or some other characteristic of the signal. The weighted signal produced by this weighting may be referred to as a beamformed signal. By multiplying one or more antenna transmissions by the weighting vector, the beamformed signal may only be transmitted to a specific signal subspace.

Specifically, a signal subspace may be a vector space defined by a subset of the possible beamforming vectors. In other words, transmissions of the signal to the signal subspace may include weighting the signal by one or more beamforming vectors of the possible beamforming vectors to produce a beamformed signal, and transmitting the beamformed signal from the eNB. The signal subspace may be identified by identifying the beamforming vectors with which the UEs receive the signal with a relatively high signal energy. Specifically, as noted above, the eNB may initially transmit one or more training signals to one or more UEs, and receive feedback information from the UEs regarding the received signal. For example, the feedback may include information regarding strength or magnitude of the received signal energy, or the phase of the received signal. Based on that fedback information, the eNB may be able to identify the beamforming vectors that produce a relatively high amount of signal energy at the UEs. The identified beamforming vectors that produce a relatively high amount of signal energy at the UEs may then be used to identify the signal subspace on which the channel training signals should be transmitted. The eNB may then transmit the channel training signals to that signal subspace using the identified beamforming vectors.

The null subspace may then be identified as the remainder of the beamforming vectors that are not used for the beamforming signal transmission to the signal subspace.

In some embodiments an additional channel training signal may be beamformed to only a portion of the null subspace, as explained in greater detail below. In embodiments, the number of beamforming vectors used to generate a beamformed signal for the signal subspace may be significantly less than the number of beamforming vectors in the null subspace. Therefore, the transmission overhead of the eNB may be significantly reduced. For example, the dimension of the null space may be several times that of the signal subspace that is useful for data communications. Therefore, skipping the channel training in the entire null space may reduce the training overhead by multiple times. For example, simulations indicate that by not transmitting the channel training signal to the entire null subspace, the resource overhead of the cell may be reduced by up to 50% while the throughput of an FD-MIMO eNB with 16 antenna elements may only be reduced by 5%. The overhead reduction may be expected to increase significantly for eNBs with antenna arrays of 64 or 128 antenna elements. For example, an eNB with 128 antenna elements transmitting data to 10 UEs may need up to 128 antenna ports in legacy systems, while only needing up to 10 antennas ports (one antenna port per UE) in wireless cells of the present disclosure.

In some embodiments, and as described in further detail below, one or both of the signal and/or null subspaces may vary over time due to mobile channel variation. Because the eNB may identify or update the signal subspace and null subspace according to the feedback indications of training signals that were beamformed by the previous beamforming vectors, the currently updated signal subspace and null subspaces may not be exactly the same as the previous signal and null subspaces where the previous beamforming vectors are located. Therefore, in some embodiments, the newly identified subspace may not fully include the previous beamforming vector. However, since the channel variation may be relatively slow in many embodiments such that the subspaces are substantially correlated in time, i.e. very alike, the previous and the current signal and null subspace may be substantially the same.

In the following detailed description, reference is made to the accompanying drawings which form a part hereof wherein like numerals designate like parts throughout, and in which is shown by way of illustration embodiments that may be practiced. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope of the present disclosure. Therefore, the following detailed description is not to be taken in a limiting sense.

Various operations may be described as multiple discrete actions or operations in

turn, in a manner that is most helpful in understanding the claimed subject matter. However, the order of description should not be construed as to imply that these operations are necessarily order dependent. In particular, these operations may not be performed in the order of presentation. Operations described may be performed in a different order than the described embodiment. Various additional operations may be performed and/or described operations may be omitted in additional embodiments.

For the purposes of the present disclosure, the phrases "A and/or B" and "A or B" mean (A), (B), or (A and B). For the purposes of the present disclosure, the phrase "A, B, and/or C" means (A), (B), (C), (A and B), (A and C), (B and C), or (A, B and C).

The description may use the phrases "in an embodiment," or "in embodiments," which may each refer to one or more of the same or different embodiments. Furthermore, the terms "comprising," "including," "having," and the like, as used with respect to embodiments of the present disclosure, are synonymous.

Figure 1 schematically illustrates a wireless communication network 100 in accordance with various embodiments. The wireless communication network 100 (hereinafter "network 100") may be an access network of a 3GPP LTE network such as evolved universal terrestrial radio access network (E-UTRAN). The network 100 may include an eNodeB (eNB, also referred to as an evolved NodeB) 105, configured to wirelessly communicate with a UE 110.

As shown in Figure 1, the UE 110 may include a transceiver module 120. The transceiver module 120 may be coupled with one or more of a plurality of antenna elements 125 of the UE 110 for communicating wirelessly with other components of the network 100, e.g., eNB 105 or another UE. The antenna elements 125 may be powered by a power amplifier 130 which may be a component of the transceiver module 120, as shown in Figure 1, or may be a separate component of the UE 110. In one embodiment, the power amplifier 130 provides the power for all transmissions on the antenna elements 125. In other embodiments, there may be multiple power amplifiers on the UE 110. The use of multiple antenna elements 125 may allow for the UE 110 to use transmit diversity techniques such as spatial orthogonal resource transmit diversity (SORTD), MIMO, or FD-MIMO. In certain embodiments the transceiver module 120 may contain both transmitter circuitry 155 and receiver circuitry 160. Specifically, the transmitter circuitry 155 may be configured to transmit a signal from the UE 110, for example using antenna elements 125. Similarly, the receiver circuitry 160 may be configured to receive a signal at the UE 110. Although Figure 1 depicts the transceiver module 120 including both the

transmitter circuitry 155 and the receiver circuitry 160, in other embodiments, the transceiver module 120 may be replaced by transmitter circuitry and receiver circuitry which are separate from one another (not shown). In other embodiments, the transceiver module 120 may be coupled with processor circuitry configured to alter, process, or transform signals or data received from, or sent to, the transceiver module 120 (not shown).

Similarly to the UE 110, the eNB 105 may include a transceiver module 140. The transceiver module 140 may be further coupled with one or more of a plurality of antenna elements 135 of the eNB 105 for communicating wirelessly with other components of the network 100, e.g., UE 110. The antenna elements 135 may be powered by a power amplifier 145 which may be a component of the transceiver module 140, as shown in Figure 1, or may be a separate component of the eNB 105. In one embodiment, the power amplifier 145 provides the power for all transmissions on the antenna elements 135. In other embodiments, there may be multiple power amplifiers on the eNB 105. The use of multiple antenna elements 135 may allow for the eNB 105 to use transmit diversity techniques such as SORTD, MIMO, or FD-MIMO. In certain embodiments the transceiver module 140 may contain both transmitter circuitry 165 and receiver circuitry 170 which may be similar to the transmitter circuitry 155 and receiver circuitry 160 described above. In other embodiments, the transceiver module 140 may be replaced by transmitter circuitry and receiver circuitry which are separate from one another (not shown). In other embodiments, the transceiver module 140 may be coupled with processor circuitry configured to alter, process, or transform signals or data received from, or sent to, the transceiver module 120 (not shown).

As noted above, an eNB such as eNB 105 may have a plurality of antenna ports, and each antenna port may correspond to one or more of the antenna elements 135. In embodiments the transceiver module 140 may additionally include, or otherwise be coupled with, a subspace identifier 150. As will be explained in additional detail below, the subspace identifier 150 may be configured to identify signal subspaces and/or null subspace(s) in the cell.

In embodiments, an antenna port may be perceived by a UE 110 over the air interface between the UE 110 and the eNB 105. In embodiments, one antenna port may be associated with one set of channel training symbols, for example the CSI-RS as described above. As will be described in further detail below, the UE 110 may measure the channel response of one or multiple antenna ports to generate feedback or make decisions. For

example, the UE 110 may measure the received power of antenna port 0 during a handover situation.

Therefore, in embodiments an antenna port may be the air interface perceived by UE 110. In embodiments herein, each antenna port may be formed by the eNB 105 using one or more (or all) antenna elements 135, with a beamforming weight assigned to each antenna element. In some embodiments, each antenna port may be associated with a set of beamforming weights, as described in further detail below. In embodiments described as examples below, the eNB 105 may form eight antenna ports using eight sets of weights, i.e. eight beamforming vectors. The eNB 105 may then let UEs in the cell know how the antenna ports are configured such that the UE can identify the resource in frequency and time allocated for the port.

In some embodiments, the eNB 105 may include a directional antenna with a narrow downtilt angle that uses multiple antenna elements with relatively fixed or constant beamforming weights. In the present disclosure, this directional antenna may be considered a single antenna element of the antenna elements 135 because the beamforming weights of the different antenna elements of the directional antenna may remain constant. Specifically, one or more of the antenna elements 135 may be omni-directional or unidirectional, and a directional antenna element of the antenna elements 135 may be physically implemented using multiple antenna elements with constant antenna weights.

Figure 2 depicts an example of a network 200 including an eNB 205, which may be similar to eNB 105, and UEs 210, 215, and 220, which may be similar to UE 110. Some of the UEs, for example UEs 210 and 220, may only include a single antenna element, while other UEs such as UE 215 may include two or more antenna elements. As can be seen, the eNB 205 may include a plurality of antenna elements 225 configured to transmit signals to, or receive signals from, UEs 210, 215, and 220. In the embodiment shown in Figure 2, the plurality of antenna elements 225 may include a first antenna element 230 through a sixteenth antenna element 235. In other embodiments, the eNB 205 may have more or less antenna elements in the plurality of antenna elements 225.

As used herein, "spaces" may refer to the vector spaces spanned by the antenna ports. For example, eNB 205 may have 16 antennas element in the plurality of antenna elements. If one antenna port is assigned to each antenna element in the plurality of antenna elements 225, then 16 antenna ports may be perceived by UEs 210, 215, and 220, and the dimension of the whole space may be 16. The 16 antenna ports may form a 16 by

1 vector space in linear algebra. The signal subspace may then be the "location" of the UEs in the whole space.

For example, the vector channel from the 16 antenna elements at the eNB to UE 210 may be denoted as $a = \begin{bmatrix} a_1 \\ \vdots \\ a_{16} \end{bmatrix}$, where a_i represents the channel response from the *i*th antenna element in the plurality of antenna elements 225 of eNB 205 to the receive antenna element of the UE 210. Similarly, the UE 215 may be equipped with two receive antenna elements and have two vector channels $b = \begin{bmatrix} b_1 \\ \vdots \\ b_{16} \end{bmatrix}$ and $c = \begin{bmatrix} c_1 \\ \vdots \\ c_{16} \end{bmatrix}$; and the UE 220 may have a vector channel $d = \begin{bmatrix} d_1 \\ \vdots \\ d_{16} \end{bmatrix}$. Because UE 215 has multiple vector channels, UE215 may have a matrix channel $\begin{bmatrix} b_1 & c_1 \\ \vdots & \vdots \\ b_{16} & c_{16} \end{bmatrix}$.

The signal subspace may be computed as follows as an example. Let the aggregated channel matrix of the active vector channels be $H = \begin{bmatrix} a_1 & b_1 & c_1 & d_1 \\ \vdots & \vdots & \vdots & \vdots \\ a_{16} & b_{16} & c_{16} & d_{16} \end{bmatrix}^T$. Let the singular value decomposition (SVD) of H be $H = U \begin{bmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \sigma_3 & \\ & & & \sigma_4 \end{bmatrix} [v_1 \quad v_2 \quad v_3 \quad v_4]^H$, where σ_i represents the singular value of the ith eigen-mode; v_i is the corresponding beamforming vector of *i*th eigen-mode; and v_i is a 16 by 1 vector with complex values.

In this embodiment, the singular values may be ordered. Specifically, σ_i may be greater than or equal to σ_j for any $i < j$. If the eNB 205 is attempting to send a relatively high amount of signal to the aggregated UE side, which in this example may consist of the antenna elements of all three of the UEs 210, 215, and 220, using one antenna beam or one beamforming vector, then v_1 may be the beamforming vector because it corresponds to the largest singular value σ_1.

For this example, the dimension of the whole space may be 16 because there are 16 antenna elements in the plurality of antenna elements 225 of the eNB 200 and correspondingly 16 linearly independent channels to the receive antenna elements of each UE 210, 215, and 220. If the eNB 205 is configured to only use one antenna port for

channel training, then in this embodiment the eNB 205 may use the beamforming vector (or weight) v_1 for the antenna port. Namely, the *i*th entry of v_1 may be the beamforming weight for the *i*th antenna element of the eNB 205. Using v_1, the three UEs 210, 215, and 220 may receive the greatest amount of signal energy from the eNB 220 in total. Because in this example there may only be one beamformed signal, the three UEs 210, 215, and 220 may have to time share the beam. Similarly, if the eNB 205 is configured to use two antenna ports, then v_1 and v_2 or the linear combination of the two can be used as beamforming vectors for the two antenna ports for channel training.

The linear space spanned by vectors v_1 and v_2 within the whole space may be referred to as "subspace" or "signal subspace." If the eNB 205 sends two data streams over two beams, then there may exist two beamforming vectors within the signal subspace that can send the most energy to the aggregated UE side consisting of UEs 210, 215, and 220. The linear space within the whole space that is spanned by all the vectors orthogonal to the vectors in the signal subspace may be referred to as the null space (of the signal subspace). In this example, if eNB 205 uses two antenna ports, then the signal subspace may be spanned by v_1 and v_2 and any beamforming vectors orthogonal to v_1 and v_2 may be in the null space that may have 16-2=14 orthogonal vectors or dimensions. In other words, the null space may depend on the selection of the signal subspace. Note that in the example above v_3 and v_4 may be in the null space of v_1 and v_2 even though v_3 and v_4 may send energy to the aggregated UE side.

In the example above, the signal subspace is described with respect to beamforming vectors v_1 and v_2. However, as noted above in other embodiments the signal subspace may be described with respect to linear combinations of beamforming vectors v_1 and v_2. Specifically, as noted above beamforming vector v_1 may deliver the greatest amount of signal energy to UEs 210, 215, and 220. Beamforming vector v_2 may deliver the next greatest amount of signal energy to UEs 210, 215, and 220. In some embodiments, it may be desirable for one or more of UEs 210, 215, and 220 to perceive a relatively equal amount of signal energy from beamforming vectors v_1 and v_2. Therefore, in some embodiments beamforming vectors v_1 and v_2 may be added or subtracted from one another to produce one or more alternative beamforming vectors which may still be within the signal subspace defined by beamforming vectors v_1 and v_2, but produce a relatively equal amount of signal energy at one or more of UEs 210, 215, and 220.

Figure 3 depicts an example process 300 for identifying signal subspaces within a cell, and beamforming the channel training signal to the signal subspaces. Initially, the

signal subspace(s) may be identified at 300. In embodiments, and as described above, a signal subspace may be identified at 300 based on previous feedback(s) from the UEs 210, 215, and 220. Specifically, the eNB such as eNB 205 may transmit a pilot signal using each possible beamforming vector in the space. Each UE, for examples UEs 210, 215, and 220, may calculate the channel response of each beamforming vector as seen by the UE. The UE may then quantize the channel responses of all received beamforming vectors using vector or scalar quantization. To continue the example above with reference to Figure 2, four beamforming vectors (v_1, v_2, v_3, and v_4) may be selected by the eNB 205. Four pilot signals, one for each beamforming vector, may be transmitted from the eNB. If the UE has one receive antenna element, for example UEs 210 or 220, the channel response, which may indicate the received signal power of each beamformed pilot signal, of the eNB's four antenna ports may be a 4 by 1 vector with complex entries. The UE may then quantizes the 4 by 1 vector jointly using vector quantization i.e. codebook quantization. The index of the quantization codeword may then be fed back to the eNB.

If the UE has *m* receive antenna elements, for example UE 215 with two receive antenna elements, then the channel response of the four antenna ports may be a 4 by *m* matrix. The UE may select a desirable *k*-dimensional subspace of the 4 by *m* matrix, for example by using SVD. In embodiments, *k* may represent the number of spatial streams or rank that the UE desires. This *k*-dimensional subspace may in some embodiments be the best *k*-dimensional subspace, and may be based on the UE stepping through the available numbers of spatial streams for identifying the spatial stream that may maximize the throughput of the signal received by the UE from the eNB. The selected *k*-dimensional subspace may be quantized to produce a quantization index, and the quantization index may be fed back to the eNB. Additionally or alternatively, the eNB may be able to identify feedback information based on, for example, downlink or uplink sounding in time-division duplexing (TDD) mode. In some embodiments the feedback may be part of or associated with a rank indicator and/or precoding matrix indicator transmission of each UE.

In some embodiments the feedback may be based on an averaging function, a summation function, or some other mathematical function performed by the UE on a pilot or beamformed signal received from the eNB. As will be explained in greater detail below, in some embodiments the signal subspace may change based on changing conditions in the cell. Therefore, it may be desirable for the fedback information from the UE to be based only on one or more signals in a given time period such as a frame, a subframe, a plurality of frames, or some other time period in which the signal subspace is constant. Otherwise,

an averaging or summation function that spans a plurality of different signal subspaces may not be accurate.The combination of vectors received from the plurality of UEs may be used by the eNB to build the aggregated channel matrix *H* described above with respect to Figure 2.

The principal signal subspaces may be identified as corresponding to large singular values in the singular value decomposition of the fedback beamforming vectors. Specifically, as described above, the signal subspace may be identified as the signal subspace formed by the beamforming vectors that are capable of delivering the most signal power from the eNB to the UEs. A set of beamforming vectors that sufficiently covers the selected signal subspace may then be identified for additional transmissions of channel training signals from the eNB to the one or more UEs. In embodiments, each beamforming vector may be used for beamforming one channel training signal, for example a CSI-RS signal, using a given antenna port. In some embodiments, the beamforming vectors may or may not be orthogonal to one another. In some embodiments, set selection may be designed for feedback accuracy, a given feedback codebook, or based on the detection of channel variation.

Concurrently with, or subsequent to, the identification of the signal subspace at 300, the null subspace may be identified based on the singular value decomposition of the matrix formed by the fed back beamforming vectors received at the eNB from the UE. Specifically, the null subspace may be identified based on low singular values in the singular value decomposition formed by the fed back beamforming vectors received at the eNB from the UEs. Specifically, the null subspaces may correspond to beamforming vectors that produce relatively low signal power at the UEs. The eNB may then beamform one or more channel training signals, for example the CSI-RS, to the signal subspace at 310.

In some embodiments, after the signal subspace is identified at 300 and the null subspace is identified at 305, the strength of signals beamformed to the signal subspace may change. Specifically, a beamforming vector that produces a relatively high amount of signal energy at the UEs in the cell may instead begin to produce a relatively low amount of signal energy at the UEs. This may occur, for example, if a UE such as a mobile phone, personal digital assistant (PDA), laptop, or some other type of UE moves. Additionally or alternatively, the cell may experience a change in signal reflection, propagation, or interference. Based on this change in the strength of beamforming vectors, it may be desirable for the eNB to track variation in the channel or the cell. Specifically, UEs may

continuously provide feedback to the eNB, and it may be useful for the eNB to be able to dynamically modify this change in signal conditions in the cell based on the feedback from the UEs.

If the channel variation of a UE is within the signal subspace spanned by the current set of channel training signals, then the normal channel feedback procedures may be able to identify this change in the signal subspace. However, if a beamforming vector in the null subspace increases in strength, for example above the strength of a beamforming vector in the signal subspace, then there may be no feedback information from a UE that indicates this change in the beamforming vector of the null subspace because if the eNB is only beamforming signals to the signal subspace, then there may be no transmissions to the entire null subspace, or certain portions of the null subspace, by which the UE can feedback information to the eNB with regards to beamforming vectors in the null subspace.

In some embodiments it may therefore be desirable to identify whether the beamforming vectors of the signal subspace and the null subspace have changed. Therefore, in some embodiments, the eNB may receive an indication from a UE of a relatively high received signal strength of a beamforming vector in the null subspace at 315. Specifically, the eNB may occasionally beamform one or more channel training signals to the null subspace, and then analyze the singular values in the singular value decomposition formed by the fed back beamforming vectors received at the eNB from the UEs, as will be described in greater detail below. In some embodiments, because channel variation may usually be slow, the eNB may give processing priority to the beamforming feedback related to the signal subspace. Therefore, the channel training signals transmitted to the null subspace, for example by beamforming, may time share a single or a relatively low number of antenna ports so that the overhead that may result from the transmission of the channel training signals is reduced.

Based on the tracking the variation in the cell at 315, if the eNB receives feedback from one or more UEs that a transmission of a channel training signal using a beamforming vector in the null subspace has greater energy than a channel training signal beamformed using a beamforming vector in the signal subspace, then the eNB may identify the beamforming vector in the null subspace as part of the signal subspace at 320. The eNB may then return to beamforming the channel training signals in the signal subspace at 310.

To illustrate the process depicted in Figure 3 in more detail, the following specific

example may be useful. It will be understood that the following is merely an example and in other embodiments other values, equations, variables, or processes may be used. Generally, during the initial training phase, an eNB such as eNB 205 may receive feedback from one or more UEs in the cell. Based on that feedback, the signal subspace, which may contain almost all of the signal energy of the fed-back signals, and the null subspaces, which may contain a low amount or no signal energy of the fed-back signals, may be calculated at 300 and 305, respectively. The calculated information may then be used to configure future downlink training and reduce the signaling overhead by scanning the signal subspace for information from UEs with greater frequency than the null subspaces, as described above.

Initially, the variable k may represent the kth UE in a cell. t may represent a given orthogonal frequency division multiplexing (OFDM) symbol, and n may represent a subcarrier in the channel. Using this notation, the channel from an eNB to the kth UE may be written as $H_k[n,t] = \sum_{m=1}^{M} h_{k,m}[n,t]e_m = \sum_{m=1}^{M} g_{k,m}[n,t]w_m$. H_k may be, for example, a 16x1 vector in cells where the eNB includes 16 antenna elements, and there is only a single UE, and it may represent the spatial signature from the eNB to the UE that is obtained through uplink feedback. M may be the dimensionality of the channel, i.e. the number of subspaces in the cell. $h_{k,m}[n,t]$ may be the estimated channel, i.e. the channel response, for the kth UE on a given subcarrier n in OFDM symbol t. e_m may be a vector equal to, for example (0, 0, . . ., 0, 1, 0, 0, . . ., 0) with the 1 in the mth position and zeroes elsewhere, and represent the unit vector pointing to the mth direction. $g_{k,m}[n,t]$ may represent the channel coefficient for the kth UE in the mth dimension in OFDM symbol t and subcarrier n. w_m my represent the unit norm vector for the mth dimension, i.e. the normalization weighting factor.

As noted above, M may represent the dimensionality of the channel, i.e. the total number of subspaces in the cell. It may be desirable to compress the channel and reduce the dimensionality from M to $D < M$. In other words, all of the subspaces in the cell may have a dimensionality M, and the signal subspace may have a dimensionality $D < M$. In order to reduce the dimensionality of the channel, it may be desirable to find the optimal basis $w_1, \ldots, w_m$ such that $g_{k,m}[n]$ is approximately equal to 0 when $m > D$. Then, for $d = 1, 2, \ldots, D$, coefficients $g_{k,m}[n,t]$ may be given by $g_{k,d}[n,t] = w_d^H H_k[n,t]$.

One result of reducing the dimensionality from M to $D < M$ may be that, instead of

utilizing M reference signals to estimate the channel in the original M-dimensional space and feeding back that information, the eNB may only employ D reference signals. By beamforming these reference signals with the weights $w_1, \ldots, w_D$, each UE may estimate the coefficient $g_{k,m}[n]$ directly and send that information to the eNB.

By allowing the UE to estimate the coefficient $g_{k,m}[n]$ directly, the overhead of transmitting the channel training signals may be reduced by a factor of D/M. Additionally, because UEs may not need to actually know the beamforming vectors used to generate the beamformed signals in order to receive the beamformed signals, the process of reducing the dimensionality of the channel from M to D may be completely transparent to the UEs. In other words, the UEs may not receive an indication that channel training signals are being beamformed only to the signal subspace rather than to the full space of the cell. However, as described in further detail below, in some embodiments it may be useful for one or more of the UEs to receive an antenna port configuration schedule from the eNB so that the UE is able to identify, for feedback purposes, when the subspace configuration may remain relatively constant.

After receiving the feedback from the UE, the eNB may identify the signal and null subspaces in the cell. Specifically, the channel covariance matrix may be estimated at the end of the qth training phase (that is, the qth time that the channel training signals are transmitted from the eNB) as

$$R_q \approx \frac{1}{KTN}\sum_{k=1}^{K}\sum_{t=(q-1)T+1}^{qT}\sum_{n=1}^{N}\left(\frac{\hat{H}_k[t,n]}{\left\|\hat{H}_k[t,n]\right\|}\right)\left(\frac{\hat{H}_k[t,n]}{\left\|\hat{H}_k[t,n]\right\|}\right)^{H} = U_q \Lambda_q U_q^{H}$$

where R_q is the channel covariance matrix in the qth training phase. T may be the length of the training period for sample covariance matrix calculations at the eNB in terms of OFDM symbols. $\hat{H}_k$ may be the estimated channel for the kth UE. K may be the total number of UEs in the cell. N may be the total number of subcarriers used by the eNB. Superscript H may represent the transpose conjugate mathematical operation. U_q may be an M x M unitary matrix, and Λ_q may be a diagonal matrix of eigenvalues $\lambda_{q,1}, \ldots, \lambda_{q,D}$. In general, $U_q \Lambda_q U_q^{H}$ may be referred to as the SVD of the matrix formed by the fedback beamforming vectors received by the eNB from the UEs, and the eigenvalues may be the singular value corresponding to each eigenvector direction. An eigenvector may be a specific example of a beamforming vector. In other words, the eigenvalues from $\lambda_{q,1}$ to $\lambda_{q,D}$ may represent the strength of the signal received from signals beamformed using beamforming vectors in the signal subspaces, and the eigenvalues $\lambda_{q,D+1}$ to $\lambda_{q,M}$ may represent the strength of the

signals, or lack thereof, received from signals beamformed using beamforming vectors in the null subspaces. Without loss of generality, it may be assumed that $\lambda_{q,1} \geq \ldots \geq \lambda_{q,D} \geq \lambda_{q,D+1}$ which may be approximately equal to λ_M, which may be approximately equal to 0. Therefore, the basis for each signal subspace in the D-dimensional channel may be $\{u_{q,1}, \ldots, u_{q,D}\}$ where $u_{q,D}$ is the dth column of the unitary matrix U_q, that is the eigenvector corresponding to the dth strongest eigenvalue. These strongest eigenvectors may now be used to beamform reference signals to the signal subspace at 310.

However, as mentioned before, the signal subspace may change and one or more beamforming vectors in the null subspace may produce a better channel response than one or more beamforming vectors in the signal subspace. In order to track these movements, and the resultant changes in the channel, it may be desirable to occasionally scan at 315 one or more null subspaces that are orthogonal to the D-dimension signal subspace to identify new beamforming vector or vectors with components in the null subspaces that produce a better channel response than one or more beamforming vectors in the signal subspace. Specifically, the new beamforming vector may include two components. The first component may be in the existing subspace spanned by one or more vectors of the signal subspace. The other component may be in the null space, and may be viewed as a correction or adjustment to the component in the existing subspace. In embodiments, the correction component may be smaller than the component in the signal subspace. Because the basis for each signal subspace in the D-dimensional channel may be $\{u_{q,1}, \ldots, u_{q,D}\}$, the basis for each null subspace in the M-dimensional channel may be $\{u_{q,D+1}, \ldots, u_{q,M}\}$.

In order to scan the null subspaces, the eNB may beamform D-r reference signals with $u_{q,1}, \ldots, u_{q,D-r}$ and the remaining r reference signals may be beamformed with r vectors selected from $u_{q,D-r+1}, \ldots, u_{q,M}$ in order to cover the null subspaces of the M-dimensional space. UEs that receive one or more of the r reference signals may estimate and quantize their channel direction in the new space as $\tilde{g}_{k,d}[n,t] = \frac{u_{q,d}^{H} H_k[n,t]}{\left\| u_{q,d}^{H} H_k[n,t] \right\|}$ where $d = 1, 2, \ldots, D$. The estimated and quantized channel direction may be transmitted from the UE to the eNB along with a channel quality indicator (CQI) transmission (which may represent a signal to interference plus noise ratio (SINR)) to the eNB. The eNB may reconstruct the channel direction in the original M dimensional space as $\tilde{H}_k[t,n] \approx \sqrt{SINR_k[t,n]} \sum_{d=1}^{D-1} \tilde{g}_{k,d}[n,t] u_{k,d}$ to identify the relative strength of signals

received in the null subspace at 315. Based on these reconstructed channel directions, the eNB may be able to identify one or more of the beamforming vectors in the null subspaces as part of the signal subspace at 320.

Results of a simulated test using one embodiment of the present disclosure are presented below in Tables 1 and 2. In these simulations, it was assumed that an eNB such as eNB 205 included 16 antenna elements with eight antenna ports. The first seven antenna ports were selected to transmit channel training signals to the signal subspace, while the eighth antenna port was selected to periodically beamform a channel training signal to the null subspace. Specifically, the transmissions of the first seven channel training signals were weighted with the seven eigenvectors corresponding to the seven strongest eigenvalues to produce beamformed channel training signals. These seven eigenvectors may be considered to be in the signal subspace. The seven beamformed channel training signals were then respectively transmitted using the first seven antenna ports of the eNB. The eighth port was selected to time share the nine remaining eigenvectors, i.e. the beamforming vectors in the null subspace, that were orthogonal to the seven eigenvectors used to produce the beamformed channel training signals. Every five to ten frames, the eNB would update the first seven beamforming vectors, while the eighth eigenvector for tracking would be updated more often for time sharing the single port. In other words, while the first seven antenna ports transmitted the beamformed seven channel training signals produced by the seven strongest eigenvectors in each frame, the eighth port would sequentially transmit beamformed channel training signals produced using the ninth through sixteenth eigenvectors one at a time in respective frames (i.e. through time sharing of the eighth port).

Tables 1 and 2, below, depict simulated sample results for a 4x4 antenna configuration and a 16x1 antenna configuration, respectively. Specifically, Tables 1 and 2 depict the average cell throughput in Megabits per second (Mbps) and cell edge user throughput in kilobits per second per UE (kbps/UE). Tables 1 and 2 depicts results for a baseline measurement where the process of Figure 3 is not performed, a subspace tracking (SS) process with scalar quantization wherein the channel direction is quantized by a scalar quantizer with 3 bits per real dimension, an SS singular value decomposition (SVD) process wherein the channel direction is obtained by SVD, and a frequency division (FD) zero-forcing beamforming (ZFBF) process based on the instantaneous values of the effective channel where no channel compression is performed.

	Average Cell Throughput (Mbps)	Cell edge User Throughput (kbps/UE)
Baseline	19.57	671
SS, Scalar Quant.	23.29	757
SS, SVD	26.43	810
FD ZFBF, SVD	27.41	852

Table 2: Simulation Results for 16x1 Antenna Configuration

In some embodiments, the process described above with respect to Figures 2 and 3 may cause the channel training signals to vary with time. For example, the channel reference signal (CRS) and CSI-RS may be beamformed on a vector that may vary with time. Therefore, in embodiments it may be useful for the UE to know the time boundary when the beamforming vectors of the channel training signals transmitted from the eNB in the signal subspace change. By knowing this time boundary, the UE may avoid providing feedback to the eNB regarding an average of the channel training signal across two different periods with two differently beamformed channel training signals.

Specifically, as noted above in some embodiments the signal subspace may change based on variations in the cell, positions of the UEs in the cell, or other factors.

Additionally, as described above the signal subspace may be constructed based on information fedback from UEs in the cell. However, if the signal conditions in the cell are changing, then based on this feedback the beamforming vectors in the signal subspace and the null subspace may change.

As noted above, in some embodiments the feedback may be based on one or more averaging, summation or some other mathematical operations of a UE of signals received from the eNB. However, in some embodiments if the beamforming vectors in the signal subspace and null subspace change, then information averaged over the change in signal subspace may not be desirable. Therefore, it may be useful for the UEs in the cell to not perform averaging or other mathematical operations that span two different signal subspace configurations. Specifically, in some embodiments the signal subspace may change with each radio frame, radio subframe, or plurality of radio frames, or according to some other time period. Therefore, an averaging, summation, or other mathematical operation of a UE may be limited to only a single time period rather than a plurality of time periods.

Therefore, in some embodiments the eNB may transmit an antenna port configuration schedule to one or more UEs. In some embodiments, the eNB may beamform the antenna port configuration schedule to one or more of the UEs, while in other embodiments the eNB may omnicast the antenna port configuration schedule to UEs in the cell. In some embodiments, the antenna port configuration schedule may include one or more of a start time at which the signal subspace configuration may remain constant, a duration at which the signal subspace configuration may remain constant, and/or an end time at which the signal subspace configuration may remain constant. In some embodiments the antenna port configuration schedule may be demarcated according to specific times, while in other embodiments the antenna port configuration schedule may indicate one or more known periods such as radio frames, subframes, etc. In some embodiments, the antenna port configuration schedule may include one or more of a start time at which the antenna port for the null space configuration may remain constant, a duration at which the null space configuration may remain constant, and/or an end time at which the null space may remain constant. In addition, the configuration information about how the large null space is stepped through by a small number of antenna ports may be sent by the eNB. By knowing the port scheduling of the null space, the UE may not average signals across two differently beamformed ports for the null space.

Embodiments of the present disclosure may be implemented into a system using

any suitable hardware and/or software to configure as desired. Figure 4 schematically illustrates an example system 400 that may be used to practice various embodiments described herein. Figure 4 illustrates, for one embodiment, an example system 400 having one or more processor(s) 405, system control module 410 coupled to at least one of the processor(s) 405, system memory 415 coupled to system control module 410, non-volatile memory (NVM)/storage 420 coupled to system control module 410, and one or more communications interface(s) 425 coupled to system control module 410.

In some embodiments, the system 400 may be capable of functioning as the UEs 110, 210, 215, or 220 as described herein. In other embodiments, the system 400 may be capable of functioning as the eNB 105 or 205 depicted in Figures 1 or 2 or any one of the other described embodiments. In some embodiments, the system 400 may include one or more computer-readable media (e.g., system memory or NVM/storage 420) having instructions and one or more processors (e.g., processor(s) 405) coupled with the one or more computer-readable media and configured to execute the instructions to implement a module to perform actions described herein.

System control module 410 for one embodiment may include any suitable interface controllers to provide for any suitable interface to at least one of the processor(s) 405 and/or to any suitable device or component in communication with system control module 410.

System control module 410 may include memory controller module 430 to provide an interface to system memory 415. The memory controller module 430 may be a hardware module, a software module, and/or a firmware module.

System memory 415 may be used to load and store data and/or instructions, for example, for system 400. System memory 415 for one embodiment may include any suitable volatile memory, such as suitable DRAM, for example. In some embodiments, the system memory 415 may include double data rate type four synchronous dynamic random-access memory (DDR4 SDRAM).

System control module 410 for one embodiment may include one or more input/output (I/O) controller(s) to provide an interface to NVM/storage 420 and communications interface(s) 425.

The NVM/storage 420 may be used to store data and/or instructions, for example. NVM/storage 420 may include any suitable non-volatile memory, such as flash memory, for example, and/or may include any suitable non-volatile storage device(s), such as one or more hard disk drive(s) (HDD(s)), one or more compact disc (CD) drive(s), and/or one or

more digital versatile disc (DVD) drive(s), for example.

The NVM/storage 420 may include a storage resource physically part of a device on which the system 400 may be installed or it may be accessible by, but not necessarily a part of, the device. For example, the NVM/storage 420 may be accessed over a network via the communications interface(s) 525.

Communications interface(s) 425 may provide an interface for system 400 to communicate over one or more network(s) and/or with any other suitable device. The system 400 may wirelessly communicate with the one or more components of the wireless network in accordance with any of one or more wireless network standards and/or protocols. In some embodiments the communications interface(s) 425 may include the transceiver module 140 and/or subspace identifier 150 of Figure 1.

For one embodiment, at least one of the processor(s) 405 may be packaged together with logic for one or more controller(s) of system control module 410, e.g., memory controller module 430. For one embodiment, at least one of the processor(s) 405 may be packaged together with logic for one or more controllers of system control module 410 to form a System in Package (SiP). For one embodiment, at least one of the processor(s) 405 may be integrated on the same die with logic for one or more controller(s) of system control module 410. For one embodiment, at least one of the processor(s) 405 may be integrated on the same die with logic for one or more controller(s) of system control module 410 to form a System on Chip (SoC).

In some embodiments the processor(s) 405 may include or otherwise be coupled with one or more of a graphics processor (GPU) (not shown), a digital signal processor (DSP) (not shown), wireless modem (not shown), digital camera or multimedia circuitry (not shown), sensor circuitry (not shown), display circuitry (not shown), and/or GPS circuitry (not shown).

In various embodiments, the system 400 may be, but is not limited to, a server, a workstation, a desktop computing device, or a mobile computing device (e.g., a laptop computing device, a handheld computing device, a tablet, a netbook, a smart phone, a gaming console, etc.). In various embodiments, the system 400 may have more or less components, and/or different architectures. For example, in some embodiments, the system 400 includes one or more of a camera, a keyboard, liquid crystal display (LCD) screen (including touch screen displays), non-volatile memory port, multiple antenna elements, graphics chip, application-specific integrated circuit (ASIC), and speakers.

Methods and apparatuses are provided herein for Example 1 may include an eNodeB (eNB) comprising: a plurality of antenna ports with a plurality of antenna elements; subspace identification circuitry coupled with the plurality of antenna elements, the subspace identification circuitry to: identify, based on feedback information, a plurality of beamforming weights for one or multiple antenna ports wherein a number of the antenna ports is less than a number of the plurality of antenna elements; and assign a beamforming weight in the plurality of beamforming weights to an antenna in the plurality of antenna elements; and transmitter circuitry coupled with the subspace identification circuitry, the transmitter circuitry to: beamform a channel training signal allocated for the antenna port with the beamforming weights; and transmit an antenna port configuration schedule from the plurality of antennas.

Example 2 may include the eNB of example 1, wherein the feedback information is based on downlink sounding, or uplink sounding, or a signal received from a user equipment (UE).

Example 3 may include the eNB of example 1, wherein the antenna port configuration schedule includes an indication of a time period where the beamforming weights will not change.

Example 4 may include the eNB of any of examples 1-3, wherein: the feedback information includes a first indication of a magnitude or phase of a first received signal of a first beamformed signal produced with a first beamforming vector and a second indication of a magnitude or phase of a second received signal of a second beamformed signal produced with a second beamforming vector; the subspace identification circuitry is further to identify a signal subspace that substantially includes the first beamforming vector based at least in part on the first indication, and a null subspace that substantially includes the second beamforming vector based at least in part on the second indication; and the transmitter circuitry is further to beamform the channel training signal to the signal subspace.

Example 5 may include the eNB of example 4, wherein the first received signal energy is higher than the second received signal energy.

Example 6 may include the eNB of example 4, wherein the channel training signal is a first channel training signal and the transmitter circuitry is further to beamform a second channel training signal to only a portion of the null subspace.

Example 7 may include the eNB of example 6, further comprising receiver circuitry coupled with the transmitter circuitry, the receiver circuitry to receive, in

response to the transmission of the additional training signal in the null subspace, a second feedback that includes a third indication of a magnitude or phase of a third received signal of a third beamformed signal produced with a third beamforming vector in the null subspace.

Example 8 may include the eNB of example 6, wherein the signal subspace is a first signal subspace and the subspace identification circuitry is further to identify a second signal subspace based at least in part on the third indication, wherein the second signal subspace includes the third beamforming vector.

Example 9 may include a method comprising: identifying, by an eNodeB (eNB), a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the first signal subspace, the first signal subspace substantially including the first beamforming vector; identifying, by the eNB, a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using a second beamforming vector in the null subspace, the null subspace substantially including the second beamforming vector; and beamforming, from an antenna port of the eNB, a channel training signal to the first signal subspace.

Example 10 may include the method of example 9, further comprising: receiving, by the eNB after the beamforming of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and identifying, by the eNB, a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

Example 11 may include the method of example 10, wherein the channel training signal is a first channel training signal and the third indication is based at least in part on beamforming, by the eNB, a second channel training signal to at least a portion of the null subspace.

Example 12 may include the method of example 9, wherein the first signal subspace is based at least in part on a singular value decomposition of the first indication.

Example 13 may include the method of example 9, wherein the first received signal strength is greater than the second received signal strength.

Example 14 may include the method of any of examples 9-13, wherein the first indication, second indication, and third indication are received by the eNB from a user equipment (UE).

Example 15 may include the method of any of examples 9-13, wherein the antenna port includes a plurality of antenna elements of the eNB.

Example 16 may include the method of any of examples 9-13, wherein the channel training signal is a channel state information-reference signal (CSI-RS) signal.

Example 17 may include one or more computer readable media comprising instructions which, when executed by one or more processors of an eNodeB (eNB), cause the eNB to: identify a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the signal subspace, the first signal subspace substantially including a first beamforming vector; identify a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using a second beamforming vector in the null subspace, the null subspace substantially including the second beamforming vector; and beamform a channel training signal to the first signal subspace.

Example 18 may include the one or more computer readable media of example 17, further comprising instructions to: obtain, after the beamform of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and identify a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

Example 19 may include the one or more computer readable media of examples 17 or 18, wherein the first received signal strength is greater than the second received signal strength.

Example 20 may include an eNodeB comprising: the one or more computer readable media of any of examples 17-19; and one or more processors coupled with the one or more computer-readable media and configured to execute the instructions.

Example 21 may include a method comprising: identifying, by an eNodeB (eNB) based on feedback information, a plurality of beamforming weights for one or multiple antenna ports, wherein the one or multiple antenna ports have a plurality of antenna elements, and a number of the antenna ports is less than a number of the plurality of antenna elements; assigning, by the eNB, a beamforming weight in the plurality of beamforming weights to an antenna in the plurality of antenna elements; beamforming, from the eNB, a channel training signal allocated for the antenna port with the

beamforming weights; and transmitting, from the eNB, an antenna port configuration schedule from the plurality of antennas.

Example 22 may include the method of example 21, wherein the feedback information is based on downlink sounding, or uplink sounding, or a signal received from a user equipment (UE).

Example 23 may include the method of example 21, wherein the antenna port configuration schedule includes an indication of a time period where the beamforming weights will not change.

Example 24 may include the method of any of examples 21-23, wherein the feedback information includes a first indication of a magnitude or phase of a first received signal of a first beamformed signal produced with a first beamforming vector and a second indication of a magnitude or phase of a second received signal of a second beamformed signal produced with a second beamforming vector and the method further comprises: identifying, by the eNB, a signal subspace that substantially includes the first beamforming vector based at least in part on the first indication, and a null subspace that substantially includes the second beamforming vector based at least in part on the second indication; and beamforming, from the eNB, the channel training signal to the signal subspace.

Example 25 may include the method of example 24, wherein the first received signal energy is higher than the second received signal energy.

Example 26 may include the method of example 24, wherein the channel training signal is a first channel training signal and the method further comprises beamforming, from the eNB, a second channel training signal to only a portion of the null subspace.

Example 27 may include the method of example 26, further comprising receiving, by the eNB and in response to the transmission of the additional training signal in the null subspace, a second feedback that includes a third indication of a magnitude or phase of a third received signal of a third beamformed signal produced with a third beamforming vector in the null subspace.

Example 28 may include the method of example 26, wherein the signal subspace is a first signal subspace and the method further comprising identifying, by the eNB, a second signal subspace based at least in part on the third indication, wherein the second signal subspace includes the third beamforming vector.

Example 29 may include an apparatus comprising: means to identify, based on feedback information, a plurality of beamforming weights for one or multiple antenna

ports, wherein the one or multiple antenna ports have a plurality of antenna elements, and a number of the antenna ports is less than a number of the plurality of antenna elements; means to assign a beamforming weight in the plurality of beamforming weights to an antenna in the plurality of antenna elements; means to beamform a channel training signal allocated for the antenna port with the beamforming weights; and means to transmit an antenna port configuration schedule from the plurality of antennas.

Example 30 may include the apparatus of example 29, wherein the feedback information is based on downlink sounding, or uplink sounding, or a signal received from a user equipment (UE).

Example 31 may include the apparatus of example 29, wherein the antenna port configuration schedule includes an indication of a time period where the beamforming weights will not change.

Example 32 may include the apparatus of any of examples 29-31, wherein the feedback information includes a first indication of a magnitude or phase of a first received signal of a first beamformed signal produced with a first beamforming vector and a second indication of a magnitude or phase of a second received signal of a second beamformed signal produced with a second beamforming vector and the apparatus further comprises: means to identify a signal subspace that substantially includes the first beamforming vector based at least in part on the first indication, and a null subspace that substantially includes the second beamforming vector based at least in part on the second indication; and means to beamform the channel training signal to the signal subspace.

Example 33 may include the apparatus of example 32, wherein the first received signal energy is higher than the second received signal energy.

Example 34 may include the apparatus of example 32, wherein the channel training signal is a first channel training signal and the apparatus further comprises means to beamform a second channel training signal to only a portion of the null subspace.

Example 35 may include the apparatus of example 34, further comprising means to receive, in response to the transmission of the additional training signal in the null subspace, a second feedback that includes a third indication of a magnitude or phase of a third received signal of a third beamformed signal produced with a third beamforming vector in the null subspace.

Example 36 may include the apparatus of example 34, wherein the signal subspace is a first signal subspace and the apparatus further comprises means to identify a second

signal subspace based at least in part on the third indication, wherein the second signal subspace includes the third beamforming vector.

Example 37 may include one or more computer readable media comprising instructions configured, upon execution of the instructions by a processor, to: identify, based on feedback information, a plurality of beamforming weights for one or multiple antenna ports, wherein the one or multiple antenna ports have a plurality of antenna elements, and a number of the antenna ports is less than a number of the plurality of antenna elements; assign a beamforming weight in the plurality of beamforming weights to an antenna in the plurality of antenna elements; beamform a channel training signal allocated for the antenna port with the beamforming weights; and transmit an antenna port configuration schedule from the plurality of antennas.

Example 38 may include the one or more computer readable media of example 37, wherein the feedback information is based on downlink sounding, or uplink sounding, or a signal received from a user equipment (UE).

Example 39 may include the one or more computer readable media of example 37, wherein the antenna port configuration schedule includes an indication of a time period where the beamforming weights will not change.

Example 40 may include the one or more computer readable media of any of examples 37-39, wherein the feedback information includes a first indication of a magnitude or phase of a first received signal of a first beamformed signal produced with a first beamforming vector and a second indication of a magnitude or phase of a second received signal of a second beamformed signal produced with a second beamforming vector and further comprising instructions to: identify a signal subspace that substantially includes the first beamforming vector based at least in part on the first indication, and a null subspace that substantially includes the second beamforming vector based at least in part on the second indication; and beamform the channel training signal to the signal subspace.

Example 41 may include the one or more computer readable media of example 40, wherein the first received signal energy is higher than the second received signal energy.

Example 42 may include the one or more computer readable media of example 40, wherein the channel training signal is a first channel training signal and further comprising instructions to beamform a second channel training signal to only a portion of the null subspace.

Example 43 may include the one or more computer readable media of example 42, further comprising instructions to receive, in response to the transmission of the additional training signal in the null subspace, a second feedback that includes a third indication of a magnitude or phase of a third received signal of a third beamformed signal produced with a third beamforming vector in the null subspace.

Example 44 may include the one or more computer readable media of example 42, wherein the signal subspace is a first signal subspace and further comprising instructions to identify a second signal subspace based at least in part on the third indication, wherein the second signal subspace includes the third beamforming vector.

Example 45 may include an apparatus comprising: means to identify a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the first signal subspace, the first signal subspace substantially including the first beamforming vector; means to identify a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using a second beamforming vector in the null subspace, the null subspace substantially including the second beamforming vector; and means to beamform, from an antenna port, a channel training signal to the first signal subspace.

Example 46 may include the apparatus of example 45, further comprising: means to receive, after the beamforming of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and means to identify a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

Example 47 may include the apparatus of example 46, wherein the channel training signal is a first channel training signal and the third indication is based at least in part on a beamforming, by the eNB, of a second channel training signal to at least a portion of the null subspace.

Example 48 may include the apparatus of example 45, wherein the first signal subspace is based at least in part on a singular value decomposition of the first indication.

Example 49 may include the apparatus of example 45, wherein the first received signal strength is greater than the second received signal strength.

Example 50 may include the apparatus of any of examples 45-49, wherein the first indication, second indication, and third indication are received from a user equipment (UE).

Example 51 may include the apparatus of any of examples 45-49, wherein the antenna port includes a plurality of antenna elements of the eNB.

Example 52 may include the apparatus of any of examples 45-49, wherein the channel training signal is a channel state information-reference signal (CSI-RS) signal.

Example 53 may include an eNode B (eNB) comprising: subspace identification circuitry to: identify a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the first signal subspace, the first signal subspace substantially including the first beamforming vector; and identify a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using a second beamforming vector in the null subspace, the null subspace substantially including the second beamforming vector; and transmitter circuitry coupled with the subspace identification circuitry, the transmitter circuitry to beamform, from an antenna port of the eNB, a channel training signal to the first signal subspace.

Example 54 may include the eNB of example 53, further comprising: receiver circuitry coupled with the transmitter circuitry, the receiver circuitry to receive, after the beamforming of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and the subspace identification circuitry is further to identify a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

Example 55 may include the eNB of example 54, wherein the channel training signal is a first channel training signal and the third indication is based at least in part on a beamforming, by the eNB, of a second channel training signal to at least a portion of the null subspace.

Example 56 may include the eNB of example 53, wherein the first signal subspace is based at least in part on a singular value decomposition of the first indication.

Example 57 may include the eNB of example 53, wherein the first received signal strength is greater than the second received signal strength.

Example 58 may include the eNB of any of examples 53-57, wherein the first indication, second indication, and third indication are received from a user equipment (UE).

Example 59 may include the eNB of any of examples 53-57, wherein the antenna port includes a plurality of antenna elements of the eNB.

Example 60 may include the eNB of any of examples 53-57, wherein the channel training signal is a channel state information-reference signal (CSI-RS) signal.

Although certain embodiments have been illustrated and described herein for purposes of description, this application is intended to cover any adaptations or variations of the embodiments discussed herein. Therefore, it is manifestly intended that embodiments described herein be limited only by the claims.

Where the disclosure recites "a" or "a first" element or the equivalent thereof, such disclosure includes one or more such elements, neither requiring nor excluding two or more such elements. Further, ordinal indicators (e.g., first, second or third) for identified elements are used to distinguish between the elements, and do not indicate or imply a required or limited number of such elements, nor do they indicate a particular position or order of such elements unless otherwise specifically stated.

Claims

What is claimed is:

1. An eNodeB (eNB) comprising:

a plurality of antenna ports with a plurality of antenna elements;

subspace identification circuitry coupled with the plurality of antenna elements, the subspace identification circuitry to:

identify, based on feedback information, a plurality of beamforming weights for one or multiple antenna ports wherein a number of the antenna ports is less than a number of the plurality of antenna elements; and

assign a beamforming weight in the plurality of beamforming weights to an antenna in the plurality of antenna elements; and

transmitter circuitry coupled with the subspace identification circuitry, the transmitter circuitry to:

beamform a channel training signal allocated for the antenna port with the beamforming weights; and

transmit an antenna port configuration schedule from the plurality of antennas.

2. The eNB of claim 1, wherein the feedback information is based on downlink sounding, or uplink sounding, or a signal received from a user equipment (UE).

3. The eNB of claim 1, wherein the antenna port configuration schedule includes an indication of a time period where the beamforming weights will not change.

4. The eNB of any of claims 1-3, wherein:

the feedback information includes a first indication of a magnitude or phase of a first received signal of a first beamformed signal produced with a first beamforming vector and a second indication of a magnitude or phase of a second received signal of a second beamformed signal produced with a second beamforming vector;

the subspace identification circuitry is further to identify a signal subspace that substantially includes the first beamforming vector based at least in part on the first indication, and a null subspace that substantially includes the second beamforming vector based at least in part on the second indication; and

the transmitter circuitry is further to beamform the channel training signal to the signal subspace.

5. The eNB of claim 4, wherein the first received signal energy is higher than the second received signal energy.

6. The eNB of claim 4, wherein the channel training signal is a first channel training signal and the transmitter circuitry is further to beamform a second channel training signal to only a portion of the null subspace.

7. The eNB of claim 6, further comprising receiver circuitry coupled with the transmitter circuitry, the receiver circuitry to receive, in response to the transmission of the additional training signal in the null subspace, a second feedback that includes a third indication of a magnitude or phase of a third received signal of a third beamformed signal produced with a third beamforming vector in the null subspace.

8. The eNB of claim 6, wherein the signal subspace is a first signal subspace and the subspace identification circuitry is further to identify a second signal subspace based at least in part on the third indication, wherein the second signal subspace includes the third beamforming vector.

9. A method comprising:

identifying, by an eNodeB (eNB), a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the first signal subspace, the first signal subspace substantially including the first beamforming vector; and

identifying, by the eNB, a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using a second beamforming vector in the null subspace, the null subspace substantially including the second beamforming vector; and

beamforming, from an antenna port of the eNB, a channel training signal to the first signal subspace.

10. The method of claim 9, further comprising:

receiving, by the eNB after the beamforming of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and

identifying, by the eNB, a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

11. The method of claim 10, wherein the channel training signal is a first channel training signal and the third indication is based at least in part on beamforming, by the eNB, a second channel training signal to at least a portion of the null subspace.

12. The method of claim 9, wherein the first signal subspace is based at least in part on a singular value decomposition of the first indication.

13. The method of claim 9, wherein the first received signal strength is greater than the second received signal strength.

14. The method of any of claims 9-13, wherein the first indication, second indication, and third indication are received by the eNB from a user equipment (UE).

15. The method of any of claims 9-13, wherein the antenna port includes a plurality of antenna elements of the eNB.

16. The method of any of claims 9-13, wherein the channel training signal is a channel state information-reference signal (CSI-RS) signal.

17. One or more computer readable media comprising instructions which, when executed by one or more processors of an eNodeB (eNB), cause the eNB to:

identify a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the signal subspace, the first signal subspace substantially including a first beamforming vector;

identify a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using

a second beamforming vector in the null subspace, the null subspace substantially including the second beamforming vector; and

beamform a channel training signal to the first signal subspace.

18. The one or more computer readable media of claim 17, further comprising instructions to:

obtain, after the beamform of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and

identify a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

19. The one or more computer readable media of claims 17 or 18, wherein the first received signal strength is greater than the second received signal strength.

20. An eNodeB comprising:

the one or more computer readable media of any of claims 17-19; and

one or more processors coupled with the one or more computer-readable media and configured to execute the instructions.

AMENDED CLAIMS
received by the International Bureau on 13 May 2014 (13.05.2014)

1. An eNodeB (eNB) comprising:

a plurality of antenna ports with a plurality of antenna elements;

subspace identification circuitry coupled with the plurality of antenna elements, the subspace identification circuitry to:

identify, based on feedback information, a plurality of beamforming weights for one or multiple antenna ports wherein a number of the antenna ports is less than a number of the plurality of antenna elements; and

assign a beamforming weight in the plurality of beamforming weights to an antenna in the plurality of antenna elements; and

transmitter circuitry coupled with the subspace identification circuitry, the transmitter circuitry to:

beamform a channel training signal allocated for the antenna port with the beamforming weights; and

transmit an antenna port configuration schedule from the plurality of antennas.

2. The eNB of claim 1, wherein the feedback information is based on downlink sounding, or uplink sounding, or a signal received from a user equipment (UE).

3. The eNB of claim 1, wherein the antenna port configuration schedule includes an indication of a time period where the beamforming weights will not change.

4. The eNB of any of claims 1-3, wherein:

the feedback information includes a first indication of a magnitude or phase of a first received signal of a first beamformed signal produced with a first beamforming vector and a second indication of a magnitude or phase of a second received signal of a second beamformed signal produced with a second beamforming vector;

the subspace identification circuitry is further to identify a signal subspace that includes the first beamforming vector based at least in part on the first indication, and a null subspace that includes the second beamforming vector based at least in part on the second indication; and

the transmitter circuitry is further to beamform the channel training signal to the signal subspace.

5. The eNB of claim 4, wherein the first received signal magnitude is higher than the second received signal magnitude.

AMENDED SHEET (ARTICLE 19)

6. The eNB of claim 4, wherein the channel training signal is a first channel training signal and the transmitter circuitry is further to beamform a second channel training signal to only a portion of the null subspace.

7. The eNB of claim 6, further comprising receiver circuitry coupled with the transmitter circuitry, the receiver circuitry to receive, in response to the transmission of the additional training signal in the null subspace, a second feedback that includes a third indication of a magnitude or phase of a third received signal of a third beamformed signal produced with a third beamforming vector in the null subspace.

8. The eNB of claim 6, wherein the signal subspace is a first signal subspace and the subspace identification circuitry is further to identify a second signal subspace based at least in part on the third indication, wherein the second signal subspace includes the third beamforming vector.

9. A method comprising:

identifying, by an eNodeB (eNB), a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the first signal subspace, the first signal subspace including the first beamforming vector; and

identifying, by the eNB, a null subspace in the space based at least in part on a second indication of a magnitude or a phase of a second received signal of a second beamforming signal using a second beamforming vector in the null subspace, the null subspace including the second beamforming vector; and

beamforming, from an antenna port of the eNB, a channel training signal to the first signal subspace.

10. The method of claim 9, further comprising:

receiving, by the eNB after the beamforming of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and

identifying, by the eNB, a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

11. The method of claim 10, wherein the channel training signal is a first channel training signal and the third indication is based at least in part on beamforming, by the eNB, a second channel training signal to at least a portion of the null subspace.

12. The method of claim 9, wherein the first signal subspace is based at least in part on a singular value decomposition of the first indication.

13. The method of claim 9, wherein the first received signal magnitude is greater than the second received signal magnitude.

14. The method of any of claims 9-13, wherein the first indication, second indication, and third indication are received by the eNB from a user equipment (UE).

15. The method of any of claims 9-13, wherein the antenna port includes a plurality of antenna elements of the eNB.

16. The method of any of claims 9-13, wherein the channel training signal is a channel state information-reference signal (CSI-RS) signal.

17. One or more computer readable media comprising instructions which, when executed by one or more processors of an eNodeB (eNB), cause the eNB to:

identify a first signal subspace in a space based at least in part on a first indication of a magnitude or a phase of a first received signal of a first beamforming signal using a first beamforming vector in the signal subspace, the first signal subspace including a first beamforming vector;

including the second beamforming vector; and

beamform a channel training signal to the first signal subspace.

18. The one or more computer readable media of claim 17, further comprising instructions to:

obtain, after the beamform of the channel training signal, a third indication of a magnitude or a phase of a third received signal of a third beamforming signal using a third beamforming vector in the null subspace, the null subspace including a third beamforming vector; and

identify a second signal subspace based at least in part on the third indication, the second signal subspace including the third beamforming vector.

19. The one or more computer readable media of claims 17 or 18, wherein the first received signal magnitude is greater than the second received signal magnitude.

20. An eNodeB comprising:

the one or more computer readable media of claims 17 or 18; and

one or more processors coupled with the one or more computer-readable media and configured to execute the instructions.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US2013/075463

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☒ Claims Nos.: 20
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required addtional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of any additional fees.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
☐ No protest accompanied the payment of additional search fees.

(54) **Title**: DEVICE, SYSTEM AND METHOD EMPLOYING UNIFIED FLEXIBLE 5G AIR INTERFACE

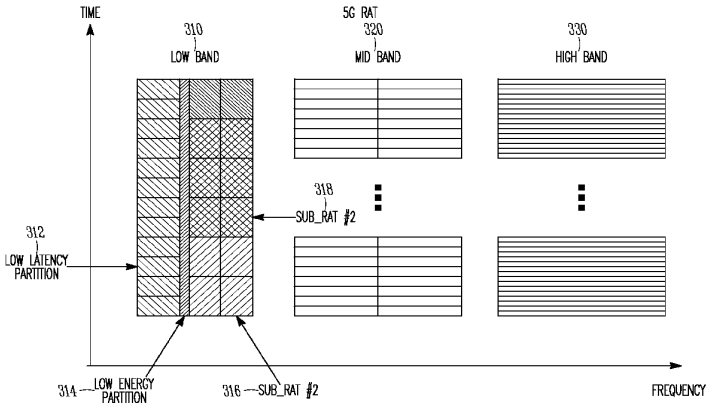

FIG. 3

(57) **Abstract**: An eNodeB (eNB), user equipment (UE) and method of providing a flexible Radio Access Technology (FRAT) are generally described. The information (resource allocation, partition information and numerology) of at least one of a plurality of RATs used by the eNB is provided to a UE. Each RAT has a flexible subcarrier spacing and symbol duration, which are integer multiples of a base subcarrier spacing and symbol duration, and is associated with at least one of different temporal and frequency resources. The symbol and/or frame structure of each RAT are independent. A Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration. The information of the RATs is provided either via a different RAT than the RAT used by the UE for communication or via a dedicated carrier in the RAT used by the UE for communication.

WO 2016/130175 A1

DEVICE, SYSTEM AND METHOD EMPLOYING UNIFIED FLEXIBLE 5G AIR INTERFACE

PRIORITY CLAIM

[0001] This application claims the benefit of priority to United States Provisional Patent Application Serial No. 62/114,733, filed February 11, 2015, and entitled "UNIFIED FLEXIBLE 5G NEW AIR INTERFACE DESIGN," which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

[0002] Embodiments pertain to radio access networks. Some embodiments relate to a unified communication framework using Radio Access Technologies (RAT) in 5th generation (5G) cellular networks.

BACKGROUND

[0003] The use of personal communication devices has increased astronomically over the last several decades. The penetration of mobile devices in modern society has continued to drive demand for a wide variety of networked devices in a number of disparate environments. The variety of available applications, especially video-related applications, has led to a concomitant increase in demand for increased bandwidth beyond that provided by Third Generation Partnership Project Long Term Evolution (3GPP LTE) and LTE advanced (LTE-A) systems.

[0004] The next generation wireless communication system, 5G, may provide access to information and sharing of data using a network that may be required to meet vastly different and sometimes conflicting performance dimensions and services driven by different services and use cases. It is therefore desirable that the next generation communication system be flexible and capable of providing high speed communications services for a wide ambit of devices under a multiplicity of circumstances.

BRIEF DESCRIPTION OF THE FIGURES

[0005] In the figures, which are not necessarily drawn to scale, like numerals may describe similar components in different views. Like numerals having different letter suffixes may represent different instances of similar components. The figures illustrate generally, by way of example, but not by way of limitation, various embodiments discussed in the present document.

[0006] FIG. 1 is a functional diagram of a 3GPP network in accordance with some embodiments.

[0007] FIG. 2 is a block diagram of a 3GPP device in accordance with some embodiments.

[0008] FIG. 3 illustrates one embodiment of a flexible Radio Access Technology (FRAT) of a 5G system in accordance with some embodiments.

[0009] FIG. 4 illustrates a unified frame structure in accordance with some embodiments.

[0010] FIG. 5 illustrates a Transmission Time Interval (TTI) boundary alignment in accordance with some embodiments.

[0011] FIG. 6 illustrates a symbol structure in accordance with some embodiments.

[0012] FIG. 7 illustrates frame structures within a TTI in accordance with some embodiments.

[0013] FIGS. 8A and 8B illustrate flowcharts of a uniform framework utilization method in accordance with some embodiments.

DETAILED DESCRIPTION OF THE INVENTION

[0014] The following description and the drawings sufficiently illustrate specific embodiments to enable those skilled in the art to practice them. Other embodiments may incorporate structural, logical, electrical, process, and other changes. Portions and features of some embodiments may be included in, or substituted for, those of other embodiments. Embodiments set forth in the claims encompass all available equivalents of those claims.

[0015] FIG. 1 is a functional diagram of a 3GPP network in accordance with some embodiments. The network may comprise a radio access network (RAN) (e.g., as depicted, the E-UTRAN or evolved universal terrestrial radio

access network) 100 and the core network 120 (e.g., shown as an evolved packet core (EPC)) coupled together through an S1 interface 115. For convenience and brevity sake, only a portion of the core network 120, as well as the RAN 100, is shown.

[0016] The core network 120 includes mobility management entity (MME) 122, serving gateway (serving GW) 124, and packet data network gateway (PDN GW) 126. The RAN 100 includes eNBs 104 (which may operate as base stations) for communicating with UE 102. The eNBs 104 may include macro eNBs and low power (LP) eNBs.

[0017] The MME is similar in function to the control plane of legacy Serving GPRS Support Nodes (SGSN). The MME manages mobility aspects in access such as gateway selection and tracking area list management. The serving GW 124 terminates the interface toward the RAN 100, and routes traffic packets (such as data packets or voice packets) between the RAN 100 and the core network 120. In addition, it may be a local mobility anchor point for inter-eNB handovers and also may provide an anchor for inter-3GPP mobility. Other responsibilities may include lawful intercept, charging, and some policy enforcement. The serving GW 124 and the MME 122 may be implemented in one physical node or separate physical nodes. The PDN GW 126 terminates a SGi interface toward the packet data network (PDN). The PDN GW 126 routes traffic packets between the EPC 120 and the external PDN, and may be a key node for policy enforcement and charging data collection. It may also provide an anchor point for mobility with non-LTE accesses. The external PDN can be any kind of IP network, as well as an IP Multimedia Subsystem (IMS) domain. The PDN GW 126 and the serving GW 124 may be implemented in one physical node or separated physical nodes.

[0018] The eNBs 104 (macro and micro) terminate the air interface protocol and may be the first point of contact for a UE 102. The eNBs 104 may communicate both with UEs 102 in a normal coverage mode and UEs 104 in one or more enhanced coverage modes. In some embodiments, an eNB 104 may fulfill various logical functions for the RAN 100 including but not limited to RNC (radio network controller functions) such as radio bearer management, uplink and downlink dynamic radio resource management and traffic packet

scheduling, and mobility management. In accordance with some embodiments, UEs 102 may be configured to communicate via orthogonal multiple access (OMA) communications such as Time Division Multiple Access (TDMA), Frequency Division Multiple Access (FDMA) Orthogonal FDMA (OFDMA), SC-FDMA or other communication signals with an eNB 104 over a multicarrier communication channel in accordance with the appropriate communication technique. The OFDM signals may comprise a plurality of orthogonal subcarriers. In accordance with some embodiments, UEs 102 may be configured to communicate via non-orthogonal multiple access (NOMA) signals.

[0019] The S1 interface 115 is the interface that separates the RAN 100 and the EPC 120. It is split into two parts: the S1-U, which carries traffic packets between the eNBs 104 and the serving GW 124, and the S1-MME, which is a signaling interface between the eNBs 104 and the MME 122.

[0020] With cellular networks, LP cells are typically used to extend coverage to indoor areas where outdoor signals do not reach well, or to add network capacity in areas with very dense phone usage, such as train stations. As used herein, the term low power (LP) eNB refers to any suitable relatively low power eNB for implementing a narrower cell (narrower than a macro cell) such as a femtocell, a picocell, or a micro cell. Femtocell eNBs are typically provided by a mobile network operator to its residential or enterprise customers. A femtocell is typically the size of a residential gateway or smaller and generally connects to the user's broadband line. Once plugged in, the femtocell connects to the mobile operator's mobile network and provides extra coverage in a range of typically 30 to 50 meters for residential femtocells. Thus, a LP eNB might be a femtocell eNB since it is coupled through the PDN GW 126. Similarly, a picocell is a wireless communication system typically covering a small area, such as in-building (offices, shopping malls, train stations, etc.), or more recently in-aircraft. A picocell eNB can generally connect through the X2 link to another eNB such as a macro eNB through its base station controller (BSC) functionality. Thus, LP eNB may be implemented with a picocell eNB since it is coupled to a macro eNB via an X2 interface. Picocell eNBs or other LP eNBs may incorporate some or all functionality of a macro eNB. In some cases, this may be referred to as an access point base station or enterprise femtocell.

[0021] As indicated in more detail below, communication over a 4G LTE network may be split up into 10ms frames, each of which may contain ten 1ms subframes. Each subframe of the frame, in turn, may contain two slots of 0.5ms. The eNB may schedule uplink and downlink transmissions over a variety of frequency bands. The allocation of resources in subframes used in one frequency band and may differ from those in another frequency band. Each slot of the subframe may contain 6-7 symbols, depending on the system used. In some embodiments, the subframe may contain 12 or 24 subcarriers. A resource grid may be used for downlink and uplink transmissions between an eNB and a UE. The resource grid may be a time-frequency grid, which is the physical resource in each slot. The smallest time-frequency unit in a resource grid may be denoted as a resource element (RE). Each column and each row of the resource grid may correspond to one OFDM symbol and one OFDM subcarrier, respectively. The resource grid may contain resource blocks (RBs) that describe the mapping of physical channels to resource elements and physical RBs (PRBs). A PRB may be the smallest unit of resources that can be allocated to a UE in the current 3GPP standard. A resource block may be 180 kHz wide in frequency and 1 slot long in time. In frequency, resource blocks may be either 12 x 15 kHz subcarriers or 24 x 7.5 kHz subcarriers wide. For most channels and signals, 12 subcarriers may be used per resource block, dependent on the system bandwidth. The duration of the resource grid in the time domain corresponds to one subframe or two resource blocks. Each resource grid may comprise 12 (subcarriers) *14 (symbols) =168 resource elements for normal cyclic prefix (CP) case. Several different physical channels may be conveyed using such resource blocks. As discussed in more detail below, in a 5G network, the sizes of the resource blocks, resource elements, and symbols, among others, may vary.

[0022] There may be several different physical downlink channels that are conveyed using such resource blocks, including the physical downlink control channel (PDCCH) and the physical downlink shared channel (PDSCH). Each subframe may contain a PDCCH, physical hybrid-ARQ indicator channel (PHICH), physical control format indicator channel (PCFICH) and the PDSCH. The PDCCH may normally occupy the first up to three symbols (four in the case

of narrow bandwidths of 1.4MHz) of each subframe and carry, among other things, information about the transport format and resource allocations related to the PDSCH channel and uplink scheduling grants for a physical uplink shared channel (PUSCH) transmission. The PHICH may be used to signal HARQ information in response to a PUSCH transmission. The PCFICH may inform the UE the control region size (e.g. one, two or three OFDM symbols) in each downlink subframe. The PDSCH may carry user data and higher layer signaling to a particular UE and occupy the remainder of the downlink subframe to avoid the resources in which downlink control channels (PDCCH/PHICH/PCFICH) are transmitted. Typically, downlink scheduling (assigning control and shared channel resource blocks to UEs within a cell) may be performed at the eNB based on channel quality information provided by the UEs, and then the downlink resource assignment information may be sent to a scheduled UE on the PDCCH used for (assigned to) PDSCH reception of the UE.

[0023] The PDCCH may contain downlink control information (DCI) in one of a number of formats that tell the UE where to find and how to decode the data, transmitted on PDSCH in the same subframe, from the resource grid. The DCI may provide details such as the number of resource blocks, resource allocation type, modulation scheme, transport block, redundancy version, coding rate etc. Each DCI format may have a cyclic redundancy code (CRC) and be scrambled with a Radio Network Temporary Identifier (RNTI) that identifies the target UE for which the PDSCH is intended. Use of the RNTI, which may be UE-specific, may limit decoding of the DCI information (and hence the corresponding PDSCH) to only the intended UE. The PDCCH may be located in any of a number of frequency/temporal regions, depending on whether the PDCCH is UE-Specific or common, as well as the aggregation level. The set of possible candidate locations for the PDCCH is defined in terms of search spaces. A search space is defined by a set of Control Channel Element (CCE) candidates with a number of aggregation level $L \in \{1,2,4,8\}$ where the UE may monitor to find its PDCCHs. A common search space may carry DCIs that are common for all UEs; for example, system information (using the SI-RNTI), paging (P-RNTI), PRACH responses (RA-RNTI), or UL TPC commands (TPC-PUCCH/PUSCH-RNTI). A UE-specific search space may carry DCIs for UE-

specific allocations using a Cell Radio-Network Temporary Identifier (C-RNTI) assigned to the UE, a semi-persistent scheduling (SPS C-RNTI), or an initial allocation (temporary C-RNTI). When configuring an SPS (either uplink or downlink), the SPS C-RNTI is provided by the eNB and the UE is configured by higher layers to decode a PDCCH with a CRC scrambled by the SPS C-RNTI. The UE may monitor the PDCCH having a CRC scrambled by the SPS C-RNTI in every subframe as the eNB can activate/re-activate/release the SPS at any time using a DCI format with a CRC scrambled by an SPS C-RNTI. The received DCI format with a CRC scrambled by the SPS C-RNTI can be a grant/assignment for a retransmission or for activation/re-activation/release of the SPS. 3GPP Technical Specification 36.213 has tabulated the validation procedure for activation/re-activation/release of SPS.

[0024] In addition to the PDCCH, an enhanced PDCCH (EPDCCH) may be used by the eNB and UE. The PDSCH may thus contain data in some of the resource blocks (RBs) and then EPDCCH contains the downlink control signals in others of the RBs of the bandwidth supported by the UE. Different UEs may have different EPDCCH configurations. The sets of RBs corresponding to EPDCCH may be configured, for example, by higher layer signaling such as Radio Resource Control (RRC) signaling for EPDCCH monitoring.

[0025] The Physical Uplink Control Channel (PUCCH) may be used by the UE to send Uplink Control Information (UCI) to the eNB. The PUCCH may be mapped to an UL control channel resource defined by an orthogonal cover code and two resource blocks (RBs), consecutive in time, with hopping potentially at the boundary between adjacent slots. The PUCCH may take several different formats, with the UCI containing information dependent on the format. Specifically, the PUCCH may contain a scheduling request (SR), acknowledgement responses/retransmission requests (ACK/NACK) or a Channel Quality Indication (CQI)/Channel State Information (CSI). The CQI/CSI may indicate to the eNB an estimate of the current downlink channel conditions as seen by the UE to aid channel-dependent scheduling and, if one MIMO transmission mode is configured to the UE, may include MIMO-related feedback (e.g. Precoder matrix indication, PMI).

[0026] FIG. 2 is a functional diagram of a 3GPP device in accordance with some embodiments. The device may be a UE or eNB, for example. In some embodiments, the eNB may be a stationary non-mobile device. The 3GPP device 200 may include physical layer circuitry 202 for transmitting and receiving signals using one or more antennas 201. The 3GPP device 200 may also include medium access control layer (MAC) circuitry 204 for controlling access to the wireless medium. The 3GPP device 200 may also include processing circuitry 206 and memory 208 arranged to perform the operations described herein.

[0027] In some embodiments, mobile devices or other devices described herein may be part of a portable wireless communication device, such as a personal digital assistant (PDA), a laptop or portable computer with wireless communication capability, a web tablet, a wireless telephone, a smartphone, a wireless headset, a pager, an instant messaging device, a digital camera, an access point, a television, a medical device (e.g., a heart rate monitor, a blood pressure monitor, etc.), or other device that may receive and/or transmit information wirelessly. In some embodiments, the mobile device or other device can be a UE 102 or eNB 104 configured to operate in accordance with 3GPP standards. In some embodiments, the mobile device or other device may be configured to operate according to other protocols or standards, including IEEE 802.11 or other IEEE standards. In some embodiments, the mobile device or other device may include one or more of a keyboard, a display, a non-volatile memory port, multiple antennas, a graphics processor, an application processor, speakers, and other mobile device elements. The display may be an LCD screen including a touch screen.

[0028] The antennas 201 may comprise one or more directional or omnidirectional antennas, including, for example, dipole antennas, monopole antennas, patch antennas, loop antennas, microstrip antennas or other types of antennas suitable for transmission of RF signals. In some multiple-input multiple-output (MIMO) embodiments, the antennas 201 may be effectively separated to take advantage of spatial diversity and the different channel characteristics that may result.

[0029] Although the 3GPP device 200 is illustrated as having several separate functional elements, one or more of the functional elements may be combined and may be implemented by combinations of software-configured elements, such as processing elements including digital signal processors (DSPs), and/or other hardware elements. For example, some elements may comprise one or more microprocessors, DSPs, field-programmable gate arrays (FPGAs), application specific integrated circuits (ASICs), radio-frequency integrated circuits (RFICs) and combinations of various hardware and logic circuitry for performing at least the functions described herein. In some embodiments, the functional elements may refer to one or more processes operating on one or more processing elements.

[0030] Embodiments may be implemented in one or a combination of hardware, firmware and software. Embodiments may also be implemented as instructions stored on a computer-readable storage device, which may be read and executed by at least one processor to perform the operations described herein. A computer-readable storage device may include any non-transitory mechanism for storing information in a form readable by a machine (e.g., a computer). For example, a computer-readable storage device may include read-only memory (ROM), random-access memory (RAM), magnetic disk storage media, optical storage media, flash-memory devices, and other storage devices and media. Some embodiments may include one or more processors and may be configured with instructions stored on a computer-readable storage device.

[0031] The term "machine readable medium" may include a single medium or multiple media (e.g., a centralized or distributed database, and/or associated caches and servers) configured to store one or more instructions. The term “machine readable medium” may include any medium that is capable of storing, encoding, or carrying instructions for execution by the 3GPP device 200 and that cause it to perform any one or more of the techniques of the present disclosure, or that is capable of storing, encoding or carrying data structures used by or associated with such instructions. The term “transmission medium” shall be taken to include any intangible medium that is capable of storing, encoding or carrying instructions for execution, and includes digital or analog

communications signals or other intangible medium to facilitate communication of such software.

[0032] As above, the upcoming 5G wireless communications technology systems may have a number of unique challenges, including carrying the inherent ability to provide different performances requirements for numerous different types of wireless devices. Higher data rates in particular may continue to drive network development and evolution for 5G system. It may be desirable for a 5G system to support a peak data rate of more than 10Gps and a minimum guaranteed user data rate of at least 100Mbps. In addition, it may be desirable for the 5G system to support the huge increase in variety and number of Internet of Things (IoT) and Machine-Type Communication (MTC)-type devices. MTC devices have been increasingly employed for different applications, using low operational power consumption and infrequent small burst transmissions. Moreover, it may be desirable for the 5G system to provide an extremely high level of reliable connectivity with guaranteed low latency, availability and reliability-of-service for mission critical MTC use cases.

[0033] In general, 5G systems may use a plurality of Radio Access Technologies (RATs), unlike previous 2G, 3G and 4G, systems. For example, an enormous amount of spectrum may be available through the use of higher frequency bands. In one example, the use of millimeter wave (mmWave) frequency bands ranging from 30 to 300GHz may provide the desired scalability, capacity and density for the 5G system. In this case, a new RAT may be defined for the mmWave band to achieve low latency and higher peak data rate. The RAT for mmWave band communications may differ from the RAT for one or more of the other frequency bands used to provide communication services. In some embodiments, the RATs may be used simultaneously by a single eNB for communications with different UEs.

[0034] In some embodiments, a 5G system may be provided that contains multiple RATs in a unified framework to support diverse applications, use cases and services and inter-networking in multiple frequency bands, including both licensed and unlicensed frequency bands. The RATs used in the licensed and unlicensed may be independent of each other. In some embodiments, flexible subcarrier spacing and symbol duration (i.e., configurable

numerology) may be provided across the frequency bands used in the 5G system. In addition, the 5G system may include mechanisms to multiplex multiple RATs, sub-RATs and other partitions in different or the same frequency resource or frequency bands.

[0035] The inter-networking in the unified frame structure may include, in some embodiments, a Transmission Time Interval (TTI) boundary alignment between multiple RATs may be provided to allow seamless scheduling, fallback and support of different RATs. In some embodiments, a TTI is the smallest unit of time in which the eNB is capable of scheduling any UE for uplink or downlink transmission. In some embodiments, the TTI boundary alignment may occur at a subframe or frame boundary. As used herein, a unified RAT with flexible air interface for the 5G system is referred to as a flexible Radio Access Technology (FRAT). A UE that communicates with an eNB operating using the FRAT may remain using a single air interface technology (i.e., RAT) or may switch between different RATs.

[0036] In some embodiments, a unified RAT with configurable numerologies may be used in the 5G system in which a base subcarrier spacing (Δf) and symbol duration (T) can be defined in the FRAT. In one example, to maintain the backward compatibility for existing LTE and LTE-Advanced systems, a base subcarrier spacing and symbol duration can be specified as Δf = 15KHz and T=66.7μs. Moreover, for convenience in some embodiments a single oscillator may be used, with the subcarrier spacing and symbol duration for different RATs specified as an integer number of the base subcarrier spacing and symbol duration, respectively.

[0037] Similarly, when a low latency use case and service is desired, a shortened symbol duration may be employed to reduce the latency by using larger subcarrier spacing. The subcarrier spacing and symbol duration may in this case be defined as $\Delta f_i = K*\Delta f$ and $T_i=(1/K)*T$. In one example, for frequency band between 6GHz and 30GHz, K can be chosen as 10, leading to a subcarrier spacing and symbol duration of 150KHz and 6.67μs, respectively. This may result in a 0.1ms TTI for low latency use case. In another example, for frequency bands below 6GHz, which includes the current LTE frequency range,

K can be selected by the network to be 2 or 4, and the corresponding subcarrier spacing and symbol duration changed proportional to the selected K value. Alternatively, the same subcarrier spacing and symbol duration can be defined for frequency bands below 6GHz (i.e., K =1), but a shorter TTI can be considered, e.g., with a fewer number of symbols, to support low latency use cases.

[0038] To efficiently support a massive number of MTC devices used in the 5G network, in other embodiments, the subcarrier spacing and symbol duration can be defined as $\Delta f_i = (1/K)*\Delta f$ and $T_i=K*T$. In such embodiments, K can be selected to be 10, and the subcarrier spacing and symbol duration 1.5KHz and 667μs, respectively. In this case, the subframe duration for MTC use cases can be defined to be 10ms, in the current generation LTE systems the length of a typical frame, rather than the typical 1ms. This may reduce the power consumption of MTC UEs by reducing the amount of time the MTC UE is active, thereby increasing the battery life of the MTC UEs.

[0039] A UE may be initially assigned the appropriate RAT by the eNB or other network device (such as the MME). In some embodiments, the UE may be configurable to communicate using any of the RATs, as indicated via the eNB, and can configure the subcarrier spacing and symbol duration accordingly. In some embodiments, the UE may be limited to communicating only using a subset of the RATs, and perhaps only a single RAT, e.g., when the UE is an MTC UE having a limited bandwidth and capabilities. The RAT may depend on the type of UE as well as the operating mode of the UE. For example, some UEs may change mode between a normal mode and an enhanced coverage mode in situations in which the link budget to the nearest serving eNB is worse than a typical link budget value in the network and additional link budget is to be obtained without increasing transmission power. Enhanced coverage mode may be employed by a variety of UEs, including a normal UE (e.g., a smartphone or the like), a machine-to-machine (M2M) UE or a stationary wireless UE (i.e., a UE that remains indefinitely in a single location) using MTC. The UE may determine whether additional link budget is desired, as well as how much additional link budget is desired, and enter an appropriate enhanced coverage mode (that provides the appropriate additional link budget). The different

enhanced coverage modes may correspond to different RATs. Some UEs, such as low cost, low complexity MTC UEs, further may be band limited and operate in a narrow bandwidth of e.g., to 1.4 MHz, for both control and data channels, leading to the ability to operate, e.g., in a single RAT unless the RAT is modified by the network.

[0040] FIG. 3 illustrates one embodiment of a FRAT of a 5G system in accordance with some embodiments. The FRAT 300 may contain one or more partitions in different frequency band regions 310, 320, 330. In one example, the low frequency band 310 may include frequencies used in 4G systems (up to 6 GHz), the mid-frequency band 320 may include higher frequencies (e.g., 6-30 GHz) and the high frequency band 330 may include the highest frequencies in the 5G system (e.g., mmWave, above 30 GHz). Although the RATs of only a low frequency band 310, a mid-frequency band 320, and a high frequency band 330 are shown, any number of RATs of different frequency bands may exist. The various RATs in frequency bands may each have a subcarrier spacing and symbol duration that is independent of the subcarrier spacing and symbol duration of another RAT in another frequency band (i.e., the RATs have configurable numerologies). Moreover, within each frequency band, one or more sub-RATs and partitions 312, 314, 316, 318 may be present with each sub-RAT or partition 312, 314, 316, 318 having a subcarrier spacing and symbol duration independent of the subcarrier spacing and symbol duration of another sub-RAT or partition 312, 314, 316, 318 and independent of the RAT in other frequency bands. As shown in FIG. 3, the sub_RATs 316, 318 in the low frequency band 310 may have the same subcarrier spacing and symbol duration and may be separated by frequency and/or time, while partitions 312, 314 may have different subcarrier spacings and symbol durations from each other and the sub_RATs 316, 318 and may be separated by frequency and/or time. Although the low frequency band 310 is shown as having multiple partitions 312, 314 and sub_RATs 316, 318, the mid frequency band 320 is shown as having two sub_RATs and the high frequency band 330 is shown as having no sub_RATs, the eNB may establish the number and type of RATs used within a particular frequency band differently.

[0041] In some embodiments, RATs and sub-RATs with same or different numerologies can be multiplexed. The multiplexing may be via Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), code-division multiplex (CDM), spatial division multiplex (SDM), other possible orthogonal or non-orthogonal multiplexing schemes, or any combination thereof. For example, multiple RATs, sub-RATs or partitions with same or different numerologies can be multiplexed in a TDM manner. Each RAT, sub-RAT and partition may have a numerology, access scheme and modulation scheme that is independent of the numerology, access scheme and modulation scheme of the other RATs, sub-RATs and partitions. The numerologies, resource allocation and partition information in the time domain can be predefined or configured by higher layer signaling, e.g. via a Master Information Block (MIB), System Information Block (SIB) or UE-specific dedicated RRC signaling. If a MIB is used to indicate the partition configuration for multiple RATs, sub-RATs or partitions, the resource for the transmission physical broadcast channel (PBCH) used to carry the MIB may be predefined and known at the UEs. In some embodiments, the PBCH may be transmitted in a predetermined RAT, independent of the UE or number of RATs, sub-RATs or partitions supported. Once the UE receives the configuration information via the PBCH on the predetermined RAT, the UE may use a different RAT for further control and data communications; that is, the predetermined RAT and the RAT used by the UE to communicate may be independent.

[0042] In some embodiments, multiple RATs, sub-RATs or partitions with same or different numerologies can be multiplexed in a FDM manner. To minimize the interference between multiple RATs, sub-RATs or partitions with different numerologies, guard bands may be inserted at the edge of frequency resources allocated for the RATs, sub-RATs or partitions. Similar to the above, the numerologies and/or resource partition for multiple RATs, sub-RATs or partitions may be predefined or configured by high layer signaling via a MIB, SIB or UE-specific dedicated RRC signaling.

[0043] In embodiments in which numerologies and/or resource partition for multiple RATs, sub-RATs or partitions is predefined or dedicated carriers are allocated for different RATs, a dedicated downlink synchronization signal and

PBCHs may be transmitted on each RAT, sub-RAT or partition. In embodiments in which the numerologies and/or resource partition for multiple RATs, sub-RATs or partitions is configured using a MIB or SIB, a single MIB or SIB may be transmitted on one of the RAT, sub-RAT or partition. After successfully decoding the MIB or SIB, the UEs may be able to derive the resource information or numerologies for other RATs, sub-RATs or partitions. Thus, information provided from the eNB to the UE via a single transmission in a particular RAT, sub-RAT or partition may enable communications using different RATs, sub-RATs or partitions.

[0044] Particular RATs/sub-RATs/partitions may be used for different types of communications, with each having independently sized resource blocks. For example, as shown, the resources in a first partition 312 may be used for low-latency communications while the resources in a second partition 314 may be used for low energy communications. The first and second partitions 312, 314 may be multiplexed, as shown, using FDM such that the first and second partitions 312, 314 occupy the same time but different frequency resources. The first partition 312 may be associated with low latency communications in which the UE operates in a low latency mode and may have a short symbol duration and TTI, while the second partition 314 may be associated with low energy communications in which the UE operates in a low energy mode and may have a long symbol duration and TTI.

[0045] Other sub-RATs 316, 318 may similarly be FDM multiplexed with the first and second partitions 312, 314 and TDM multiplexed with each other. The sub-RATs 316, 318 may have a symbol duration and TTI between those associated with the first and second partitions 312, 314.

[0046] The RATs 320, 330 for the mid- and high- frequency band may be supported simultaneously with each other and the RAT 310 for low frequency band, while maintaining TTI boundary alignment between the different RATs 310, 320, 330. The RATs 320, 330 may similarly be FDM multiplexed with the first and second partitions 312, 314 and sub-RATs 316, 318. The RATs 320, 330 may have a symbol duration and TTI smaller than those associated with the first partition 312. As shown in FIG. 3, in some embodiments, the amount of temporal and/or frequency resources associated with the different RATs, sub-

RATs and partitions may differ among the different types, and the same type may be associated either with different amounts of temporal and/or frequency resources (e.g., as partitions 312, 314) or the same amount of temporal and/or frequency resources (e.g., as sub-RATs 316, 318). A given frequency and temporal range may be associated with a particular frame and symbol structure (as well as subcarrier spacing and symbol duration), with the frame and symbol structures of the frequency and temporal range independent of the frame and symbol structures of other frequency and temporal ranges.

[0047] FIG. 4 illustrates a unified frame structure in accordance with some embodiments. The unified frame structure contains frames 400, subframes 410, slots 420 and symbols 430. More specifically, each frame 400 may contain L subframes of equal duration and have an overall duration of X ms. Each subframe 410 may similarly comprise N slots of equal duration and have an overall duration of Y ms. Each slot may, in turn, comprise M symbols of equal duration. The slot and symbol durations may be different between subframes of different RATs depending on specific use cases, frequency bands and deployment scenarios. The frame structure of each of RAT may be independent of the frame structure of the other RATs. Thus, a particular RAT may have one or more of different L, N and/or M values, as well as different X and/or Y values, as the other RATs. This may also apply to the sub-RATs and partitions shown in FIG. 3.

[0048] FIG. 5 illustrates a Transmission Time Interval (TTI) boundary alignment in accordance with some embodiments. In some embodiments of the unified frame structure, it may be beneficial from a simplified design standpoint to periodically align the TTI boundary 530 between different RATs 510, 520, e.g., at a particular subframe or frame boundary after a predetermined number of subframes or frames. Thus, in some embodiments an integral number of TTIs 540 of a RAT 510 having a smaller TTI duration (low latency RAT) may be disposed within a single TTI 550 of a RAT 520 having a larger TTI duration. In the example shown in FIG. 5, the smaller TTI duration RAT 510 may have a TTI 540 of 0.1ms while the larger TTI RAT 520 may have a TTI 550 of 1ms. By implementing a TTI of 1ms, a low latency RAT TTI may align with the existing LTE specification TTI boundary. Having a common TTI boundary may support

cross-carrier/RAT scheduling for high frequency band RATs from low frequency band RATs based an anchor booster architecture. This is to say that, in some embodiments for cross-carrier/RAT scheduling, as shown a common PDCCH may be used to schedule other RATs, with the UE switching to a particular RAT to obtain the scheduling and then switching to another RAT to communicate and perhaps to obtain further scheduling information using that RAT. In some embodiments, the other RAT may contain a PDCCH for additional scheduling, while in other embodiments the other RAT may not contain a PDCCH, in which case the UE may periodically switch to the scheduling RAT to obtain scheduling information for the other RAT. In some embodiments, a UE may obtain initial scheduling information (e.g., when it initially powers on or otherwise accesses the eNB) from the initial RAT (e.g., a conventional 4G system RAT) and from then on, after switching to its assigned RAT, obtains scheduling information using that RAT. In other embodiments, each RAT may contain a PDCCH and scheduling is performed for the UE operating on the RAT. A licensed low frequency band RAT may provide reliable coverage for control signaling as an anchor cell, using the PDCCH shown in FIG. 5, while a high frequency band RAT may provide opportunistic boosting in data rate when channel conditions are favorable as booster cell.

[0049] FIG. 6 illustrates a symbol structure in accordance with some embodiments. FIG. 6 shows an OFDM symbol 610 and a unique word (UW) OFDM symbol 620. Each OFDM symbol 610 may contain a cyclic prefix (CP) 612 that comprises a replication of the initial portion of the OFDM symbol 610. The CP 612 may range in size from 1/4 to 1/32 of the symbol period 614. The CP 612 may be disposed at the end of the symbol or outside the symbol, depending on specific waveform, thereby creating a guard between the symbol and the adjacent symbol. In some embodiments, when OFDM downlink and SC-FDMA uplink waveforms are selected for a 5G RAT, the CP 612 may be inserted outside the symbol 610. In embodiments in which a UW OFDM symbol 620 or UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM) symbol is used, the UW 622 may be inserted within one symbol duration 624. The symbol structure may be independent for each of the RATs, such that whether or not a particular RAT a

CP or UW and whether the CP or UW is outside or within a symbol is independent of the symbol structure of any other RAT.

[0050] As shown in FIG. 6, the UW-OFDM 620 may be used to support different UW lengths based on different channel delay spreads while maintaining the same symbol duration (or FFT size). This enables both shorter UW 622 and longer UW 626 to be used in the same size symbol 624 as the UW 622, 624 is inserted within the FFT instead of being adding after the FFT size. The ability to maintain the same symbol duration may provide a greater flexibility to support a unified RAT design. In one example, using an OFDM symbol for a low frequency band (below 6GHz), a subcarrier spacing of 60KHz (i.e., K = 4, Δf =60KHz) may be used to achieve a 0.1ms TTI. This translates to OFDM symbols of T=16.7μs (66.7μs/K). Thus, 5 OFDM symbols may be able to be accommodated within one subframe (83.5μs) with a CP length of approximately 3.3μs (0.1ms - 83.5μs =16.5μs/5 CPs).

[0051] FIG. 7 illustrates frame structures within a TTI in accordance with some embodiments. In FIG. 7, various TTIs 710, 720, 730, 740 are illustrated in which the TTIs 710, 720, 730, 740 comprise UW-OFDM waveforms. The first TTI 710 shown in FIG. 7 may comprise a UW 712 and symbol 714 of typical length. In this example, the subcarrier spacing may be 15KHz and the symbol duration 716 may be 66.7μs. A total of 3 OFDM symbols 716 may be present in a TTI 710 of 200μs.

[0052] The second TTI 720 shown in FIG. 7 may comprise a low latency TTI 720 with short symbol duration. Such a TTI 720 can be used for use cases such as mission critical MTC applications and Vehicle–to-Vehicle applications, among others. The UW 722 and symbol 724 may each be smaller than the first TTI 710. In this example, the subcarrier spacing may be 30KHz and the symbol duration 726 may be 33.3μs. For a TTI 720 of the same length as the first TTI (e.g., 200μs), a total of 6 short OFDM symbols 726 may be present.

[0053] The third TTI 730 shown in FIG. 7 may comprise another low latency TTI 730 similar to the low latency TTI 720. The UW 732 and symbol 734 may each be smaller than the first TTI 710, the subcarrier spacing may be 30KHz and the symbol duration 736 may be 33.3μs. However, in this example

the TTI 730 may only be half the length as the first TTI (i.e., 100μs), corresponding to a total of 3 short OFDM symbols 736.

[0054] The fourth TTI 740 shown in FIG. 7 may comprise a low energy TTI 740, e.g., for use by MTC UEs. The UW 742 and symbol 744 may each have a longer duration smaller than the first TTI 710. In one example, the subcarrier spacing may be 5KHz and the symbol duration 746 may be 200μs. In this example, the TTI 740 may be 1ms, corresponding to a total of 5 long OFDM symbols 746.

[0055] The above TTIs 710, 720, 730, 740 may be FDM or TDM multiplexed based on the FRAT design. One or more of the UW-OFDM waveforms may be replaced by other waveforms so long as the same symbol duration is maintained. Other examples of OFDM waveforms may include ZT-OFDM and UW-DFTs-OFDM, among others. When different waveforms are used in the same carrier, multi-RATs can be supported where each RAT may have different waveform design. In some embodiments, existing LTE waveforms may be reused, i.e., OFDM waveforms may be used for downlink and SC-FDMA waveforms may be used for uplink communications. In some embodiments, OFDM may be used both downlink and uplink communications. In some embodiments, UW-based waveforms may be used both downlink and uplink communications. For example, UW-OFDM waveforms may be used for downlink communications and UW-DFT-s-OFDM waveforms may be used for uplink communications or either UW-OFDM or UW-DFT-s-OFDM waveforms may be used for both downlink and uplink communications. In some embodiment, filtered OFDM and filter-bank multiple carrier (FBMC) may be used. FBMC waveforms are produced using a nonrectangular sub-channel pulse shape in the time domain during OFDM-offset quadrature amplitude modulation (OQAM) transmission (in which the real part of QAM symbols are mapped to ½ of the multi-carrier symbols and the imaginary parts are mapped to an interlaced 1/2 of the multi-carrier symbols) and may lack a CP.

[0056] Tables 1-3 below illustrate various examples of 5G numerology.

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform

<3GHz (low power or MTC)	1.5KHz	10ms	OFDM	SC-FDMA
<3GHz	15KHz	1ms	OFDM	SC-FDMA
[3-6]GHz	75KHz	0.2ms	UW-OFDM	UW-DFT-s-OFDM
[6-30]GHz	480KHz	0.1ms	UW-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	DFT-s-OFDM	DFT-s-OFDM

Table 1: First 5G numerology example

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform
<3GHz (low power or MTC)	1.5KHz	10ms	UW-OFDM	UW-OFDM
<3GHz	15KHz	1ms	UW-OFDM	UW-OFDM
[3-6]GHz	75KHz	0.2ms	UW-OFDM	UW-OFDM
[6-30]GHz	480KHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	OFDM	OFDM

Table 2: Second 5G numerology example

Frequency Band	Subcarrier spacing	TTI	DL waveform	UL waveform
<3GHz (low power or MTC)	1.5KHz	10ms	OFDM	OFDM
<3GHz	15KHz	1ms	OFDM	OFDM
[3,6]GHz	75KHz	0.2ms	OFDM	OFDM
[6,30]GHz	480KHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM
>30GHz	1.5MHz	0.1ms	UW-DFT-s-OFDM	UW-DFT-s-OFDM

Table 3: Third 5G numerology example

[0057] FIGS. 8A and 8B illustrate flowcharts of a uniform framework utilization method in accordance with some embodiments. FIG. 8A in particular illustrates a flowchart of a uniform framework utilization method of an eNB such as the eNB shown in FIGS. 1 or 2 in accordance with some embodiments. As shown in FIG. 8A, the eNB may determine the unified framework at operation 802. The unified framework may include access scheme, modulation

scheme, frame structure, symbol structure, and configurable numerology including subcarrier spacing and symbol duration. The different frame and symbol structures may be associated with different temporal and/or frequency resources multiplexed respectively in a TDM or FDM manner.

[0058] At operation 804, the eNB may communicate specific unified framework configuration information of a particular RAT to one or more UEs serviced by the eNB. Different RAT information may be provided to different UEs attached to the eNB, in which different RATs may be associated with different frequency bands and/or time spans. The eNB may determine the configuration information to be provided to a particular UE based on the device type and/or data to be communicated between the UE and the eNB. The frequency bands may include both licensed and unlicensed frequency bands. The RAT information may include access and modulation scheme, frame and symbol structure, as well as numerology. The RAT information may also include resource allocation and partition information. The unified framework configuration information provided to each UE may be independent of the unified framework configuration information provided to any other UE. The RAT indicated by the eNB to the UE may be dependent on the type and/or operating mode of the UE.

[0059] The eNB may communicate with the UE at operation 806 using the RAT provided at operation 804. The information may include data and/or control information. For example, downlink communications from the eNB to the UE may include paging or control signals for channel estimation on the PDCCH and voice or video data from another UE on the PDSCH. The RAT information may be provided using a dedicated RAT that is different from the RAT used for communication with the UE or using a dedicated carrier on the RAT used for communication with the UE.

[0060] The eNB may, subsequent to communicating with the UE, receive an indication from the UE of a change of operating state of the UE at operation 808. The UE may, for example, be configured to operate in one or more of a normal mode, a low latency and low energy mode. The eNB may, at operation 804, assign the RAT to the UE based on the initial mode of the UE and

determine that an update of the operation mode of the UE has occurred at operation 808.

[0061] In response to determining at operation 808 that an update of the operation mode of the UE has occurred, the eNB may determine a new RAT and transmit the updated unified framework configuration information of the new RAT to the UE at operation 810. The new RAT may include a different frame and/or symbol structure and use a different frequency spectrum and/or time range. The eNB may then continue to communicate with the UE at operation 806.

[0062] FIG. 8B illustrates a uniform framework utilization method as performed by a UE in accordance with some embodiments. The UE may be the UE shown in FIGS. 1 or 2 and may attach to the eNB prior to communicating data. During the attachment, the UE may transmit the initial operation conditions to the eNB at operation 812. In particular, the UE may provide a UE type and/or operating mode during attachment. For example, the UE may be a MTC UE. The UE may moreover be configured to operate in a low latency and/or low energy mode. In some embodiments, a MTC UE may operate in an enhanced coverage, low energy mode.

[0063] In response to transmitting the operating conditions, unified framework configuration (RAT) information may be received by a particular UE at operation 814. The RAT information may be dependent on the type and/or operating mode of the UE. The RAT may be associated with a particular frequency band and/or time range. For example, when the UE operates in the low latency mode, a larger subcarrier spacing and shorter symbol duration may be indicated by the unified framework configuration information; while when the UE operates in the low energy mode, a smaller subcarrier spacing and longer symbol duration may be indicated by the unified framework configuration information.

[0064] Once the RAT received by the UE, the UE may then communicate using the RAT at operation 816. The UE may, for example, adjust FFT operating conditions and processing to meet the RAT information provided at operation 814. The UE may communicate with the eNB or may communicate directly with other UEs using device-to-device communication (D2D)

communication. The information may include uplink and downlink data and/or control information. For example, the information may include uplink communications of voice or video data for another UE or measurements of control signals for channel estimation.

[0065] The UE may, subsequent to communicating with the eNB, determine that a change of operating conditions is warranted at operation 818. For example, the UE may transition between the normal and enhanced coverage/low energy mode dependent on UE location, or between the normal and low latency mode dependent on the type of communication to transmit.

[0066] In response to determining that a change of operating conditions is warranted at operation 818, at operation 820 the UE may transmit an indication to the eNB indicating the change of operating state of the UE. The UE may instead determine that a change of operating conditions is desired at operation 820 and wait to change operating state until a new RAT is assigned to the UE.

[0067] In response to transmitting the indication at operation 820, the UE may return to operation 814 and receive a new RAT at operation 810. The new RAT may include a different frame and/or symbol structure and use a different frequency spectrum and/or time range. The eNB may then continue to communicate with the UE at operation 816.

[0068] Various examples of the disclosure are provided below. These examples are not intended to in any way limit the disclosure herein. In Example 1, user equipment (UE) may comprise processing circuitry configured to: configure a transceiver to receive a resource allocation from a network using a first Radio Access Technology (RAT), the first RAT selected from a plurality of RATs of a flexible RAT (FRAT) employed by the network, the plurality of RATs of the FRAT each comprising configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resources, the transceiver configurable to communicate using the plurality of RATs and configure the subcarrier spacing and symbol duration based on the numerology; and configure the transceiver to communicate using the first RAT.

[0069] In Example 2, the subject matter of Example 1 can optionally include that the processing circuitry is further configured to configure the transceiver to receive from an enhanced NodeB (eNB) higher layer signaling associated with the FRAT, the higher layer signaling indicating numerologies, resource allocation and partition information in at least one of a time and frequency domain.

[0070] In Example 3, the subject matter of one or any combination of Examples 1-2 can optionally include that the FRAT comprises a base subcarrier spacing and symbol duration, and at least one of the subcarrier spacing and symbol duration for different RATs of the FRAT is respectively specified as an integer number of the base subcarrier spacing or symbol duration.

[0071] In Example 4, the subject matter of one or any combination of Examples 1-3 can optionally include that the UE is a Machine-Type Communication (MTC) UE configured to operate in at least one of a low latency and low energy mode, and the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode.

[0072] In Example 5, the subject matter of one or any combination of Examples 1-4 can optionally include that at least one of the plurality of RATs of the FRAT comprises at least one of a plurality of sub-RATs and partitions, each of the at least one of the plurality of sub-RATs and partitions comprising an independent configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resource, and the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using at least one of a Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), Code-Division Multiplexing (CDM), and Spatial Division Multiplexing (SDM).

[0073] In Example 6, the subject matter of one or any combination of Examples 1-6 can optionally include that the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using TDM, and numerologies, resource allocation and partition information in a time domain are at least one of predefined or configured by higher-layer signaling via Master

Information Block (MIB), System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling, or the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using FDM, guard bands are inserted at an edge of frequency resources allocated for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions, and at least one of numerologies and resource partition for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are at least one of predefined or configured by the higher-layer signaling.

[0074] In Example 7, the subject matter of one or any combination of Examples 1-6 can optionally include that a Transmission Time Interval (TTI) boundary between different RATs of the plurality of RATs is common, and the plurality of RATs comprise a common reference TTI duration.

[0075] In Example 8, the subject matter of one or any combination of Examples 1-7 can optionally include that a symbol structure of each of the plurality of RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the plurality of RATs is independent of the symbol structure of the other RATs. ‘

[0076] In Example 9, the subject matter of one or any combination of Examples 1-8 can optionally include that the processing circuitry is further configured to configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

[0077] In Example 10, the subject matter of one or any combination of Examples 1-9 can optionally include that a frame structure in each of the plurality of RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and the frame structure of each of the plurality of RATs is independent of the frame structure of the other RATs.

[0078] In Example 11, the subject matter of one or any combination of Examples 1-10 can optionally include that the processing circuitry is further configured to configure the transceiver to receive numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[0079] In Example 12, the subject matter of one or any combination of Examples 1-11 can optionally include that the processing circuitry is configured to configure the transceiver to receive numerologies, resource allocation and partition information via a dedicated carrier in the first RAT, a dedicated carrier allocated for each of the plurality of RATs, and a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the plurality of RATs.

[0080] In Example 13, the subject matter of one or any combination of Examples 1-12 can optionally include an antenna configured to transmit and receive communications between the transceiver and the eNB.

[0081] Example 14 comprises an apparatus of an eNode B (eNB) comprising processing circuitry configured to: configure a transceiver to transmit resource allocations for different Radio Access Technologies (RATs) to a plurality of user equipment (UE), at least two of the UEs associated with a different RAT, each RAT comprising an independent subcarrier spacing, symbol duration, frame structure and symbol structure; and configure the transceiver to communicate with each UE using the RAT associated with the UE.

[0082] In Example 15, the subject matter of Example 14 can optionally include that the processing circuitry is configured to configure the transceiver to transmit higher layer signaling indicating numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a same RAT to each of the plurality of UEs.

[0083] In Example 16, the subject matter of one or any combination of Examples 14-15 can optionally include that the processing circuitry is

configured to configure the transceiver to transmit numerologies, resource allocation and partition information via a dedicated carrier allocated for each of the RATs, and a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the RATs.

[0084] In Example 17, the subject matter of one or any combination of Examples 14-16 can optionally include that at least one of the subcarrier spacing and symbol duration for each of the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration.

[0085] In Example 18, the subject matter of one or any combination of Examples 14-17 can optionally include that the RATs comprise a first RAT comprising a larger subcarrier spacing and shorter symbol duration configured for a UE operating in a low latency mode and a second RAT comprising a smaller subcarrier spacing and longer symbol duration configured for a UE operating in a low energy mode.

[0086] In Example 19, the subject matter of one or any combination of Examples 14-18 can optionally include that a Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration.

[0087] In Example 20, the subject matter of one or any combination of Examples 14-19 can optionally include that a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the RATs is independent of the symbol structure of the other RATs.

[0088] In Example 21, the subject matter of one or any combination of Examples 14-20 can optionally include that the processing circuitry is configured to at least one of: configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

[0089] In Example 22 a non-transitory computer-readable storage medium that stores instructions for execution by one or more processors of a user equipment (UE) to configure the UE to communicate with an enhanced Node B (eNB), the one or more processors to configure the UE to: receive resource allocation, partition information and numerology, including subcarrier spacing and symbol duration, for a first Radio Access Technology (RAT) of a plurality of RATs used by the eNB, the UE configurable to configure the subcarrier spacing and symbol duration based on the numerology and to communicate using the plurality of RATs; and communicate using the first RAT.

[0090] In Example 23, the subject matter of Example 22 can optionally include that at least one of: a) at least one of the subcarrier spacing and symbol duration for the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration, b) the UE is configured to operate in at least one of a low latency and low energy mode, and the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode, and c) a Transmission Time Interval (TTI) boundary between the RATs is common, and the RATs comprise a common reference TTI duration.

[0091] In Example 24, the subject matter of one or any combination of Examples 22-23 can optionally include that at least one of: a) a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and the symbol structure of each of the RATs is independent of the symbol structure of the other RATs, and b) a frame structure in each of the RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and the frame structure of each of the RATs is independent of the frame structure of the other RATs.

[0092] In Example 25, the subject matter of one or any combination of Examples 22-24 can optionally include that the numerology, resource allocation and partition information is received via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

[0093] Although an embodiment has been described with reference to specific example embodiments, it will be evident that various modifications and changes may be made to these embodiments without departing from the broader spirit and scope of the present disclosure. Accordingly, the specification and drawings are to be regarded in an illustrative rather than a restrictive sense. The accompanying drawings that form a part hereof show, by way of illustration, and not of limitation, specific embodiments in which the subject matter may be practiced. The embodiments illustrated are described in sufficient detail to enable those skilled in the art to practice the teachings disclosed herein. Other embodiments may be utilized and derived therefrom, such that structural and logical substitutions and changes may be made without departing from the scope of this disclosure. This Detailed Description, therefore, is not to be taken in a limiting sense, and the scope of various embodiments is defined only by the appended claims, along with the full range of equivalents to which such claims are entitled.

[0094] Such embodiments of the inventive subject matter may be referred to herein, individually and/or collectively, by the term “invention” merely for convenience and without intending to voluntarily limit the scope of this application to any single invention or inventive concept if more than one is in fact disclosed. Thus, although specific embodiments have been illustrated and described herein, it should be appreciated that any arrangement calculated to achieve the same purpose may be substituted for the specific embodiments shown. This disclosure is intended to cover any and all adaptations or variations of various embodiments. Combinations of the above embodiments, and other embodiments not specifically described herein, will be apparent to those of skill in the art upon reviewing the above description.

[0095] In this document, the terms "a" or "an" are used, as is common in patent documents, to include one or more than one, independent of any other instances or usages of "at least one" or "one or more." In this document, the term "or" is used to refer to a nonexclusive or, such that "A or B" includes "A but not B," "B but not A," and "A and B," unless otherwise indicated. In this document, the terms "including" and "in which" are used as the plain-English equivalents of the respective terms "comprising" and "wherein." Also, in the following claims, the

terms "including" and "comprising" are open-ended, that is, a system, UE, article, composition, formulation, or process that includes elements in addition to those listed after such a term in a claim are still deemed to fall within the scope of that claim. Moreover, in the following claims, the terms "first," "second," and "third," etc. are used merely as labels, and are not intended to impose numerical requirements on their objects.

[0096] The Abstract of the Disclosure is provided to comply with 37 C.F.R. §1.72(b), requiring an abstract that will allow the reader to quickly ascertain the nature of the technical disclosure. It is submitted with the understanding that it will not be used to interpret or limit the scope or meaning of the claims. In addition, in the foregoing Detailed Description, it can be seen that various features are grouped together in a single embodiment for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed embodiments require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter lies in less than all features of a single disclosed embodiment. Thus the following claims are hereby incorporated into the Detailed Description, with each claim standing on its own as a separate embodiment.

CLAIMS

What is claimed is:

1. User equipment (UE) comprising:

processing circuitry configured to:

configure a transceiver to receive a resource allocation from a network using a first Radio Access Technology (RAT), the first RAT selected from a plurality of RATs of a flexible RAT (FRAT) employed by the network, the plurality of RATs of the FRAT each comprising configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resources, the transceiver configurable to communicate using the plurality of RATs and configure the subcarrier spacing and symbol duration based on the numerology; and

configure the transceiver to communicate using the first RAT.

2. The UE of claim 1, wherein the processing circuitry is configured to:

configure the transceiver to receive from an enhanced NodeB (eNB) higher layer signaling associated with the FRAT, the higher layer signaling indicating numerologies, resource allocation and partition information in at least one of a time and frequency domain.

3. The UE of claim 1, wherein:

the FRAT comprises a base subcarrier spacing and symbol duration, and

at least one of the subcarrier spacing and symbol duration for different RATs of the FRAT is respectively specified as an integer number of the base subcarrier spacing or symbol duration.

4. The UE of claim 3, wherein:

the UE is a Machine-Type Communication (MTC) UE configured to operate in at least one of a low latency and low energy mode, and

the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller

subcarrier spacing and longer symbol duration when the UE operates in the low energy mode.

5. The UE of claim 1, wherein:

at least one of the plurality of RATs of the FRAT comprises at least one of a plurality of sub-RATs and partitions, each of the at least one of the plurality of sub-RATs and partitions comprising an independent configurable numerology with flexible subcarrier spacing and symbol duration and associated with at least one of different temporal and frequency resource, and

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using at least one of a Time-Division Multiplexing (TDM), Frequency-Division Multiplexing (FDM), Code-Division Multiplexing (CDM), and Spatial Division Multiplexing (SDM).

6. The UE of claim 5, wherein one of:

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using TDM, and numerologies, resource allocation and partition information in a time domain are at least one of predefined or configured by higher-layer signaling via Master Information Block (MIB), System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling, or

the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are combined using FDM, guard bands are inserted at an edge of frequency resources allocated for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions, and at least one of numerologies and resource partition for the plurality of RATs and the at least one of the plurality of sub-RATs and partitions are at least one of predefined or configured by the higher -layer signaling.

7. The UE of claim 1, wherein:

a Transmission Time Interval (TTI) boundary between different RATs of the plurality of RATs is common, and

the plurality of RATs comprise a common reference TTI duration.

8. The UE of claim 1, wherein:

a symbol structure of each of the plurality of RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the plurality of RATs is independent of the symbol structure of the other RATs.

9. The UE of claim 1, wherein the processing circuitry is configured to at least one of:

configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and

configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

10. The UE of claim 1, wherein:

a frame structure in each of the plurality of RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and

the frame structure of each of the plurality of RATs is independent of the frame structure of the other RATs.

11. The UE of claim 1, wherein the processing circuitry is configured to:

configure the transceiver to receive numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

12. The UE of claim 1, wherein:

the processing circuitry is configured to configure the transceiver to receive numerologies, resource allocation and partition information via a dedicated carrier in the first RAT, a dedicated carrier allocated for each of the plurality of RATs, and

a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the plurality of RATs.

13. The UE of claim 1, further comprising an antenna configured to transmit and receive communications between the transceiver and the eNB.

14. An apparatus of an eNode B (eNB) comprising:

processing circuitry configured to:

configure a transceiver to transmit resource allocations for different Radio Access Technologies (RATs) to a plurality of user equipment (UE), at least two of the UEs associated with a different RAT, each RAT comprising an independent subcarrier spacing, symbol duration, frame structure and symbol structure; and

configure the transceiver to communicate with each UE using the RAT associated with the UE.

15. The apparatus of claim 14, wherein the processing circuitry is configured to:

configure the transceiver to transmit higher layer signaling indicating numerologies, resource allocation and partition information via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a same RAT to each of the plurality of UEs.

16. The apparatus of claim 14, wherein the processing circuitry is configured to:

configure the transceiver to transmit numerologies, resource allocation and partition information via a dedicated carrier allocated for each of the RATs, and

a dedicated downlink synchronization signal and physical broadcast channel (PBCH) is able to be received on each of the RATs.

17. The apparatus of claim 14, wherein:

at least one of the subcarrier spacing and symbol duration for each of the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration.

18. The apparatus of claim 14, wherein:

the RATs comprise a first RAT comprising a larger subcarrier spacing and shorter symbol duration configured for a UE operating in a low latency mode and a second RAT comprising a smaller subcarrier spacing and longer symbol duration configured for a UE operating in a low energy mode.

19. The apparatus of claim 14, wherein:

a Transmission Time Interval (TTI) boundary between the RATs is common, and

the RATs comprise a common reference TTI duration.

20. The apparatus of claim 14, wherein:

a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the RATs is independent of the symbol structure of the other RATs.

21. The apparatus of claim 14, wherein the processing circuitry is configured to at least one of:

configure the transceiver to communicate using Orthogonal Frequency-Division Multiplexing (OFDM) for downlink communications and one of Single Carrier Frequency-Division Multiple Access (SC-FDMA) and OFDM for uplink communications, and

configure the transceiver to communicate using at least one of UW-OFDM and UW Discrete Fourier transform-Spread-Orthogonal Frequency Division Multiplexing (UW-DFT-s-OFDM).

22. A non-transitory computer-readable storage medium that stores instructions for execution by one or more processors of a user equipment (UE) to configure the UE to communicate with an enhanced Node B (eNB), the one or more processors to configure the UE to:

receive resource allocation, partition information and numerology, including subcarrier spacing and symbol duration, for a first Radio Access Technology (RAT) of a plurality of RATs used by the eNB, the UE configurable to configure the subcarrier spacing and symbol duration based on the numerology and to communicate using the plurality of RATs; and

communicate using the first RAT.

23. The medium of claim 22, wherein at least one of:

a) at least one of the subcarrier spacing and symbol duration for the RATs is respectively specified as an integer number of a base subcarrier spacing or symbol duration,

b) the UE is configured to operate in at least one of a low latency and low energy mode, and

the first RAT comprises a larger subcarrier spacing and shorter symbol duration when the UE operates in the low latency mode and comprises a smaller subcarrier spacing and longer symbol duration when the UE operates in the low energy mode, and

c) a Transmission Time Interval (TTI) boundary between the RATs is common, and

the RATs comprise a common reference TTI duration.

24. The medium of claim 22, wherein at least one of:

a) a symbol structure of each of the RATs comprises a cyclic prefix (CP) or unique word (UW) outside or within a symbol, and

the symbol structure of each of the RATs is independent of the symbol structure of the other RATs, and

b) a frame structure in each of the RATs comprises a frame comprising L subframes, each subframe comprising N slots, each slot comprising M symbols, and

the frame structure of each of the RATs is independent of the frame structure of the other RATs.

25. The medium of claim 22, wherein:

the numerology, resource allocation and partition information is received via Master Information Block (MIB) carried by a physical broadcast channel (PBCH), a System Information Block (SIB) or UE-specific dedicated Radio Resource Control (RRC) signaling in a second RAT, the first and second RATs being different.

(54) Title: METHOD AND USER EQUIPMENT FOR RECEIVING DOWNLINK CONTROL INFORMATION, AND METHOD AND BASE STATION FOR TRANSMITTING DOWNLINK CONTROL INFORMATION

(57) Abstract: A search space (hereinafter, CSS) for a control channel for scheduling a random access response may be configured by a system information block. A user equipment (UE) may attempt to receive a control channel for a random access response on the assumption that CSS is configured in accordance with a configuration based on the system information block. The UE may attempt to receive the control channel within a UE-specific search space (USS) by assuming that the USS is configured in accordance with the configuration of the CSS until a configuration for the USS is received.

Description

Title of Invention: METHOD AND USER EQUIPMENT FOR RECEIVING DOWNLINK CONTROL INFORMATION, AND METHOD AND BASE STATION FOR TRANSMITTING DOWNLINK CONTROL INFORMATION

Technical Field

[1] The present invention relates to a wireless communication system, and more particularly, to a method for transmitting or receiving downlink control information and a device therefor.

Background Art

[2] With appearance and spread of machine-to-machine (M2M) communication and a variety of devices such as smartphones and tablet PCs and technology demanding a large amount of data transmission, data throughput needed in a cellular network has rapidly increased. To satisfy such rapidly increasing data throughput, carrier aggregation technology, cognitive radio technology, etc. for efficiently employing more frequency bands and multiple input multiple output (MIMO) technology, multi-base station (BS) cooperation technology, etc. for raising data capacity transmitted on limited frequency resources have been developed.

[3] A general wireless communication system performs data transmission/reception through one downlink (DL) band and through one uplink (UL) band corresponding to the DL band (in case of a frequency division duplex (FDD) mode), or divides a prescribed radio frame into a UL time unit and a DL time unit in the time domain and then performs data transmission/reception through the UL/DL time unit (in case of a time division duplex (TDD) mode). A base station (BS) and a user equipment (UE) transmit and receive data and/or control information scheduled on a prescribed time unit basis, e.g. on a subframe basis. The data is transmitted and received through a data region configured in a UL/DL subframe and the control information is transmitted and received through a control region configured in the UL/DL subframe. To this end, various physical channels carrying radio signals are formed in the UL/DL subframe. In contrast, carrier aggregation technology serves to use a wider UL/DL bandwidth by aggregating a plurality of UL/DL frequency blocks in order to use a broader frequency band so that more signals relative to signals when a single carrier is used can be simultaneously processed.

[4] In addition, a communication environment has evolved into increasing density of nodes accessible by a user at the periphery of the nodes. A node refers to a fixed point

capable of transmitting/receiving a radio signal to/from the UE through one or more antennas. A communication system including high-density nodes may provide a better communication service to the UE through cooperation between the nodes.

Disclosure of Invention

Technical Problem

[5] Due to introduction of new radio communication technology, the number of user equipments (UEs) to which a BS should provide a service in a prescribed resource region increases and the amount of data and control information that the BS should transmit to the UEs increases. Since the amount of resources available to the BS for communication with the UE(s) is limited, a new method in which the BS efficiently receives/transmits uplink/downlink data and/or uplink/downlink control information using the limited radio resources is needed.

[6] The technical objects that can be achieved through the present invention are not limited to what has been particularly described hereinabove and other technical objects not described herein will be more clearly understood by persons skilled in the art from the following detailed description.

Solution to Problem

[7] A search space (hereinafter, CSS_RAR) for a control channel for scheduling a random access response may be configured by a system information block. A user equipment (UE) may attempt to receive a control channel for a random access response by assuming that CSS_RAR is configured in accordance with a configuration based on the system information block. If the UE receives the control channel for a random access response, the UE may receive the random access response to a random access preamble transmitted therefrom in accordance with control information carried by the control channel. The UE may attempt to receive a control channel within a UE-specific search space (hereinafter, USS) by assuming that the USS is configured in accordance with the configuration of the CSS until a configuration for the USS is received.

[8] In an aspect of the present invention, provided herein is a method for receiving, by a user equipment (UE), downlink control information (DCI) for the UE. The method comprises: receiving, by the UE, a common search space configuration for a common search space; receiving, by the UE, a first physical downlink control channel (PDCCH) scheduling a random access response; and receiving, by the UE, a second PDCCH carrying the DCI for the UE. The UE can monitor first PDCCH candidates of the common search space according to the common search space configuration in order to receive the first PDCCH. The UE can monitor second PDCCH candidates of a UE-specific search space in order to receive the second PDCCH. The UE can assume that configuration of the UE-specific search space is the same as that of the common search

space until the UE receives a UE-specific search space configuration.

[9] In another aspect of the present invention, provided herein is a method for transmitting, by a base station (BS), downlink control information (DCI) for a user equipment (UE). The method comprises: transmitting, by the BS, common search space configuration for a common search space; transmitting, by the BS to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response; and transmitting, by the BS to the UE, a second PDCCH carrying the DCI for the UE. The BS can transmit the first PDCCH by using one of first PDCCH candidates of the common search space according to the common search space configuration. The BS can transmit the second PDCCH by using one of second PDCCH candidates of a UE-specific search space. The BS can configure the UE-specific search space according to the same configuration as the common search space configuration until the BS transmits a UE-specific search space configuration to the UE.

[10] In still another aspect of the present invention, provided herein a user equipment (UE) for receiving downlink control information (DCI) for the UE. The UE comprises a radio frequency (RF) unit and a processor connected to the RF unit. The processor can be configured to control the RF unit to receive common search space configuration for a common search space; control the RF unit to receive a first physical downlink control channel (PDCCH) scheduling a random access response; and control the RF unit to receive a second PDCCH carrying the DCI for the UE. The processor can be configured to monitor first PDCCH candidates of the common search space according to the common search space configuration in order to detect the firs PDCCH. The processor can be configured to monitor second PDCCH candidates of a UE-specific search space in order to detect the second PDCCH. The processor can be configured to assume that configuration of the UE-specific search space is the same as that of the common search space until the UE receives a UE-specific search space configuration.

[11] In a further aspect of the present invention, provided herein a base station (BS) for transmitting downlink control information (DCI) for a user equipment (UE). The BS comprises a radio frequency (RF) unit and a processor connected to the RF unit. The processor can be configured to control the RF unit to transmit common search space configuration for a common search space; control the RF unit to transmit a first physical downlink control channel (PDCCH) scheduling a random access response; and control the RF unit to transmit a second PDCCH carrying the DCI for the UE. The processor can be configured to control the RF unit to transmit the first PDCCH using one of first PDCCH candidates of the common search space according to the common search space configuration. The processor can be configured to control the RF unit to transmit the second PDCCH using one of second PDCCH candidates of a UE-specific search space. The processor can configure the UE-specific search space according to

the same as that of the common search space until the BS transmits a UE-specific search space configuration.

[12] In each aspect of the present invention, the common search space configuration can include information on a narrowband for the common search space. The second PDCCH candidates of the UE-specific search space can be configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[13] In each aspect of the present invention, the common search space configuration can include information on a maximum number of repetitions for the first common search space. The second PDCCH candidates of the UE-specific search space can be configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.

[14] In each aspect of the present invention, the common search space configuration can include information on a first physical resource block (PRB) set for transmitting the first PDCCH. The same physical resource block set as the first PRB set can be used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE

[15] In each aspect of the present invention, the first PDCCH candidates of the common search space can be configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, whereas the second PDCCH candidates of the UE-specific search space can be configured according to the plurality of aggregation levels.

[16] In each aspect of the present invention, the UE can transmit a random access preamble using a physical random access channel (PRACH) resource. The UE can monitor the first PDCCH candidates in response to transmission of the random access preamble. The UE can receive the random access response according to control information carried by the first PDCCH. The BS can receive a random access preamble using a physical random access channel (PRACH) resource. The BS can transmit the first PDCCH in response to reception of the random access preamble. The BS can transmit the random access response according to control information carried by the first PDCCH.

[17] The above technical solutions are merely some parts of the embodiments of the present invention and various embodiments into which the technical features of the present invention are incorporated can be derived and understood by persons skilled in the art from the following detailed description of the present invention.

Advantageous Effects of Invention

[18] According to the present invention, uplink/downlink signals can be efficiently transmitted/received. Therefore, overall throughput of a radio communication system can be improved.

[19] According to one embodiment of the present invention, a low cost/complexity UE can perform communication with a BS at low cost while maintaining compatibility with a legacy system.

[20] According to one embodiment of the present invention, the UE can be implemented at low cost/complexity.

[21] According to one embodiment of the present invention, coverage can be enhanced.

[22] According to one embodiment of the present invention, the UE and the BS can perform communication with each other at a narrowband.

[23] It will be appreciated by persons skilled in the art that that the effects that can be achieved through the present invention are not limited to what has been particularly described hereinabove and other advantages of the present invention will be more clearly understood from the following detailed description.

Brief Description of Drawings

[24] The accompanying drawings, which are included to provide a further understanding of the invention, illustrate embodiments of the invention and together with the description serve to explain the principle of the invention.

[25] FIG. 1 illustrates the structure of a radio frame used in a wireless communication system.

[26] FIG. 2 illustrates the structure of a downlink (DL)/uplink (UL) slot in a wireless communication system.

[27] FIG. 3 illustrates a radio frame structure for transmission of a synchronization signal (SS).

[28] FIG. 4 illustrates the structure of a DL subframe used in a wireless communication system.

[29] FIG. 5 illustrates the structure of a UL subframe used in a wireless communication system.

[30] FIG. 6 illustrates an example of a signal band for MTC.

[31] FIG. 7 illustrates repeated transmission of a channel for coverage enhancement.

[32] FIG. 8 illustrates a configuration of a common search space (CSS) for paging according to the present invention.

[33] FIG. 9 illustrates a configuration of a common search space (CSS) for random access response (RAR) according to the present invention.

[34] FIG. 10 illustrates the example of the monitoring time region of USS and CSS.

[35] FIG. 11 illustrates a procedure of configuring a search space according to the present

invention.

[36] FIG. 12 illustrates a configuration of M-PDCCH repeated transmission according to the present invention.

[37] FIG. 13 is a block diagram illustrating elements of a transmitting device 10 and a receiving device 20 for implementing the present invention.

Mode for the Invention

[38] Reference will now be made in detail to the exemplary embodiments of the present invention, examples of which are illustrated in the accompanying drawings. The detailed description, which will be given below with reference to the accompanying drawings, is intended to explain exemplary embodiments of the present invention, rather than to show the only embodiments that can be implemented according to the invention. The following detailed description includes specific details in order to provide a thorough understanding of the present invention. However, it will be apparent to those skilled in the art that the present invention may be practiced without such specific details.

[39] In some instances, known structures and devices are omitted or are shown in block diagram form, focusing on important features of the structures and devices, so as not to obscure the concept of the present invention. The same reference numbers will be used throughout this specification to refer to the same or like parts.

[40] The following techniques, apparatuses, and systems may be applied to a variety of wireless multiple access systems. Examples of the multiple access systems include a code division multiple access (CDMA) system, a frequency division multiple access (FDMA) system, a time division multiple access (TDMA) system, an orthogonal frequency division multiple access (OFDMA) system, a single carrier frequency division multiple access (SC-FDMA) system, and a multicarrier frequency division multiple access (MC-FDMA) system. CDMA may be embodied through radio technology such as universal terrestrial radio access (UTRA) or CDMA2000. TDMA may be embodied through radio technology such as global system for mobile communications (GSM), general packet radio service (GPRS), or enhanced data rates for GSM evolution (EDGE). OFDMA may be embodied through radio technology such as institute of electrical and electronics engineers (IEEE) 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802.20, or evolved UTRA (E-UTRA). UTRA is a part of a universal mobile telecommunications system (UMTS). 3rd generation partnership project (3GPP) long term evolution (LTE) is a part of evolved UMTS (E-UMTS) using E-UTRA. 3GPP LTE employs OFDMA in DL and SC-FDMA in UL. LTE-advanced (LTE-A) is an evolved version of 3GPP LTE. For convenience of description, it is assumed that the present invention is applied to 3GPP LTE/LTE-A. However, the

technical features of the present invention are not limited thereto. For example, although the following detailed description is given based on a mobile communication system corresponding to a 3GPP LTE/LTE-A system, aspects of the present invention that are not specific to 3GPP LTE/LTE-A are applicable to other mobile communication systems.

[41] For example, the present invention is applicable to contention based communication such as Wi-Fi as well as non-contention based communication as in the 3GPP LTE/LTE-A system in which an eNB allocates a DL/UL time/frequency resource to a UE and the UE receives a DL signal and transmits a UL signal according to resource allocation of the eNB. In a non-contention based communication scheme, an access point (AP) or a control node for controlling the AP allocates a resource for communication between the UE and the AP, whereas, in a contention based communication scheme, a communication resource is occupied through contention between UEs which desire to access the AP. The contention based communication scheme will now be described in brief. One type of the contention based communication scheme is carrier sense multiple access (CSMA). CSMA refers to a probabilistic media access control (MAC) protocol for confirming, before a node or a communication device transmits traffic on a shared transmission medium (also called a shared channel) such as a frequency band, that there is no other traffic on the same shared transmission medium. In CSMA, a transmitting device determines whether another transmission is being performed before attempting to transmit traffic to a receiving device. In other words, the transmitting device attempts to detect presence of a carrier from another transmitting device before attempting to perform transmission. Upon sensing the carrier, the transmitting device waits for another transmission device which is performing transmission to finish transmission, before performing transmission thereof. Consequently, CSMA can be a communication scheme based on the principle of "sense before transmit" or "listen before talk". A scheme for avoiding collision between transmitting devices in the contention based communication system using CSMA includes carrier sense multiple access with collision detection (CSMA/CD) and/or carrier sense multiple access with collision avoidance (CSMA/CA). CSMA/CD is a collision detection scheme in a wired local area network (LAN) environment. In CSMA/CD, a personal computer (PC) or a server which desires to perform communication in an Ethernet environment first confirms whether communication occurs on a network and, if another device carries data on the network, the PC or the server waits and then transmits data. That is, when two or more users (e.g. PCs, UEs, etc.) simultaneously transmit data, collision occurs between simultaneous transmission and CSMA/CD is a scheme for flexibly transmitting data by monitoring collision. A transmitting device using CSMA/CD adjusts data transmission thereof by sensing data transmission performed by another

device using a specific rule. CSMA/CA is a MAC protocol specified in IEEE 802.11 standards. A wireless LAN (WLAN) system conforming to IEEE 802.11 standards does not use CSMA/CD which has been used in IEEE 802.3 standards and uses CA, i.e. a collision avoidance scheme. Transmission devices always sense carrier of a network and, if the network is empty, the transmission devices wait for determined time according to locations thereof registered in a list and then transmit data. Various methods are used to determine priority of the transmission devices in the list and to re-configure priority. In a system according to some versions of IEEE 802.11 standards, collision may occur and, in this case, a collision sensing procedure is performed. A transmission device using CSMA/CA avoids collision between data transmission thereof and data transmission of another transmission device using a specific rule.

[42] In the present invention, a user equipment (UE) may be a fixed or mobile device. Examples of the UE include various devices that transmit and receive user data and/or various kinds of control information to and from a base station (BS). The UE may be referred to as a terminal equipment (TE), a mobile station (MS), a mobile terminal (MT), a user terminal (UT), a subscriber station (SS), a wireless device, a personal digital assistant (PDA), a wireless modem, a handheld device, etc. In addition, in the present invention, a BS generally refers to a fixed station that performs communication with a UE and/or another BS, and exchanges various kinds of data and control information with the UE and another BS. The BS may be referred to as an advanced base station (ABS), a node-B (NB), an evolved node-B (eNB), a base transceiver system (BTS), an access point (AP), a processing server (PS), etc. In describing the present invention, a BS will be referred to as an eNB.

[43] In the present invention, a node refers to a fixed point capable of transmitting/ receiving a radio signal through communication with a UE. Various types of eNBs may be used as nodes irrespective of the terms thereof. For example, a BS, a node B (NB), an e-node B (eNB), a pico-cell eNB (PeNB), a home eNB (HeNB), a relay, a repeater, etc. may be a node. In addition, the node may not be an eNB. For example, the node may be a radio remote head (RRH) or a radio remote unit (RRU). The RRH or RRU generally has a lower power level than a power level of an eNB. Since the RRH or RRU (hereinafter, RRH/RRU) is generally connected to the eNB through a dedicated line such as an optical cable, cooperative communication between RRH/ RRU and the eNB can be smoothly performed in comparison with cooperative communication between eNBs connected by a radio line. At least one antenna is installed per node. The antenna may mean a physical antenna or mean an antenna port, a virtual antennIn the present invention, a cell refers to a prescribed geographical area to which one or more nodes provide a communication service. Accordingly, in the present invention, communicating with a specific cell may mean communicating with an eNB

or a node which provides a communication service to the specific cell. In addition, a DL/UL signal of a specific cell refers to a DL/UL signal from/to an eNB or a node which provides a communication service to the specific cell. A node providing UL/DL communication services to a UE is called a serving node and a cell to which UL/DL communication services are provided by the serving node is especially called a serving cell. Furthermore, channel status/quality of a specific cell refers to channel status/ quality of a channel or communication link formed between an eNB or node which provides a communication service to the specific cell and a UE. The UE may measure DL channel state received from a specific node using cell-specific reference signal(s) (CRS(s)) transmitted on a CRS resource and/or channel state information reference signal(s) (CSI-RS(s)) transmitted on a CSI-RS resource, allocated by antenna port(s) of the specific node to the specific node. Detailed CSI-RS configuration may be understood with reference to 3GPP TS 36.211 and 3GPP TS 36.331 documents.

[44] Meanwhile, a 3GPP LTE/LTE-A system uses the concept of a cell in order to manage radio resources and a cell associated with the radio resources is distinguished from a cell of a geographic region.

[45] A "cell" of a geographic region may be understood as coverage within which a node can provide service using a carrier and a "cell" of a radio resource is associated with bandwidth (BW) which is a frequency range configured by the carrier. Since DL coverage, which is a range within which the node is capable of transmitting a valid signal, and UL coverage, which is a range within which the node is capable of receiving the valid signal from the UE, depends upon a carrier carrying the signal, the coverage of the node may be associated with coverage of the "cell" of a radio resource used by the node. Accordingly, the term "cell" may be used to indicate service coverage of the node sometimes, a radio resource at other times, or a range that a signal using a radio resource can reach with valid strength at other times. The "cell" of the radio resource will be described later in more detail.

[46] 3GPP LTE/LTE-A standards define DL physical channels corresponding to resource elements carrying information derived from a higher layer and DL physical signals corresponding to resource elements which are used by a physical layer but which do not carry information derived from a higher layer. For example, a physical downlink shared channel (PDSCH), a physical broadcast channel (PBCH), a physical multicast channel (PMCH), a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), and a physical hybrid ARQ indicator channel (PHICH) are defined as the DL physical channels, and a reference signal and a synchronization signal are defined as the DL physical signals. A reference signal (RS), also called a pilot, refers to a special waveform of a predefined signal known to both a BS and a UE. For example, a cell-specific RS (CRS), a UE-specific RS (UE-RS), a po-

sitioning RS (PRS), and channel state information RS (CSI-RS) may be defined as DL RSs. Meanwhile, the 3GPP LTE/LTE-A standards define UL physical channels corresponding to resource elements carrying information derived from a higher layer and UL physical signals corresponding to resource elements which are used by a physical layer but which do not carry information derived from a higher layer. For example, a physical uplink shared channel (PUSCH), a physical uplink control channel (PUCCH), and a physical random access channel (PRACH) are defined as the UL physical channels, and a demodulation reference signal (DM RS) for a UL control/data signal and a sounding reference signal (SRS) used for UL channel measurement are defined as the UL physical signals.

[47] In the present invention, a physical downlink control channel (PDCCH), a physical control format indicator channel (PCFICH), a physical hybrid automatic retransmit request indicator channel (PHICH), and a physical downlink shared channel (PDSCH) refer to a set of time-frequency resources or resource elements (REs) carrying downlink control information (DCI), a set of time-frequency resources or REs carrying a control format indicator (CFI), a set of time-frequency resources or REs carrying downlink acknowledgement (ACK)/negative ACK (NACK), and a set of time-frequency resources or REs carrying downlink data, respectively. In addition, a physical uplink control channel (PUCCH), a physical uplink shared channel (PUSCH) and a physical random access channel (PRACH) refer to a set of time-frequency resources or REs carrying uplink control information (UCI), a set of time-frequency resources or REs carrying uplink data and a set of time-frequency resources or REs carrying random access signals, respectively. In the present invention, in particular, a time-frequency resource or RE that is assigned to or belongs to PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH is referred to as PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH RE or PDCCH/PCFICH/PHICH/PDSCH/PUCCH/PUSCH/PRACH time-frequency resource, respectively. Therefore, in the present invention, PUCCH/PUSCH/PRACH transmission of a UE is conceptually identical to UCI/uplink data/random access signal transmission on PUSCH/PUCCH/PRACH, respectively. In addition, PDCCH/PCFICH/PHICH/PDSCH transmission of an eNB is conceptually identical to downlink data/DCI transmission on PDCCH/PCFICH/PHICH/PDSCH, respectively.

[48] Hereinafter, OFDM symbol/subcarrier/RE to or for which CRS/DMRS/CSI-RS/SRS/UE-RS/TRS is assigned or configured will be referred to as CRS/DMRS/CSI-RS/SRS/UE-RS/TRS symbol/carrier/subcarrier/RE. For example, an OFDM symbol to or for which a tracking RS (TRS) is assigned or configured is referred to as a TRS symbol, a subcarrier to or for which the TRS is assigned or configured is referred to as a TRS subcarrier, and an RE to or for which the TRS is

assigned or configured is referred to as a TRS RE. In addition, a subframe configured for transmission of the TRS is referred to as a TRS subframe. Moreover, a subframe in which a broadcast signal is transmitted is referred to as a broadcast subframe or a PBCH subframe and a subframe in which a synchronization signal (e.g. PSS and/or SSS) is transmitted is referred to a synchronization signal subframe or a PSS/SSS subframe. OFDM symbol/subcarrier/RE to or for which PSS/SSS is assigned or configured is referred to as PSS/SSS symbol/subcarrier/RE, respectively.

[49] In the present invention, a CRS port, a UE-RS port, a CSI-RS port, and a TRS port refer to an antenna port configured to transmit a CRS, an antenna port configured to transmit a UE-RS, an antenna port configured to transmit a CSI-RS, and an antenna port configured to transmit a TRS, respectively. Antenna ports configured to transmit CRSs may be distinguished from each other by the locations of REs occupied by the CRSs according to CRS ports, antenna ports configured to transmit UE-RSs may be distinguished from each other by the locations of REs occupied by the UE-RSs according to UE-RS ports, and antenna ports configured to transmit CSI-RSs may be distinguished from each other by the locations of REs occupied by the CSI-RSs according to CSI-RS ports. Therefore, the term CRS/UE-RS/CSI-RS/TRS ports may also be used to indicate a pattern of REs occupied by CRSs/UE-RSs/CSI-RSs/TRSs in a predetermined resource region. In the present invention, both a DMRS and a UE-RS refer to RSs for demodulation and, therefore, the terms DMRS and UE-RS are used to refer to RSs for demodulation.

[50] FIG. 1 illustrates the structure of a radio frame used in a wireless communication system.

[51] Specifically, FIG. 1(a) illustrates an exemplary structure of a radio frame which can be used in frequency division multiplexing (FDD) in 3GPP LTE/LTE-A and FIG. 1(b) illustrates an exemplary structure of a radio frame which can be used in time division multiplexing (TDD) in 3GPP LTE/LTE-A.

[52] Referring to FIG. 1, a 3GPP LTE/LTE-A radio frame is 10ms ($307,200T_s$) in duration. The radio frame is divided into 10 subframes of equal size. Subframe numbers may be assigned to the 10 subframes within one radio frame, respectively. Here, T_s denotes sampling time where T_s=1/(2048*15kHz). Each subframe is 1ms long and is further divided into two slots. 20 slots are sequentially numbered from 0 to 19 in one radio frame. Duration of each slot is 0.5ms. A time interval in which one subframe is transmitted is defined as a transmission time interval (TTI). Time resources may be distinguished by a radio frame number (or radio frame index), a subframe number (or subframe index), a slot number (or slot index), and the like.

[53] A radio frame may have different configurations according to duplex modes. In FDD mode for example, since DL transmission and UL transmission are discriminated

according to frequency, a radio frame for a specific frequency band operating on a carrier frequency includes either DL subframes or UL subframes. In TDD mode, since DL transmission and UL transmission are discriminated according to time, a radio frame for a specific frequency band operating on a carrier frequency includes both DL subframes and UL subframes.

[54] Table 1 shows an exemplary UL-DL configuration within a radio frame in TDD mode.

[55] [Table 1]

DL-UL configuration	Downlink-to-Uplink Switch-point periodicity	Subframe number									
		0	1	2	3	4	5	6	7	8	9
0	5ms	D	S	U	U	U	D	S	U	U	U
1	5ms	D	S	U	U	D	D	S	U	U	D
2	5ms	D	S	U	D	D	D	S	U	D	D
3	10ms	D	S	U	U	U	D	D	D	D	D
4	10ms	D	S	U	U	D	D	D	D	D	D
5	10ms	D	S	U	D	D	D	D	D	D	D
6	5ms	D	S	U	U	U	D	S	U	U	D

[56] In Table 1, D denotes a DL subframe, U denotes a UL subframe, and S denotes a special subframe. The special subframe includes three fields, i.e. downlink pilot time slot (DwPTS), guard period (GP), and uplink pilot time slot (UpPTS). DwPTS is a time slot reserved for DL transmission and UpPTS is a time slot reserved for UL transmission. Table 2 shows an example of the special subframe configuration.

[57] [Table 2]

Special subframe configuration	Normal cyclic prefix in downlink			Extended cyclic prefix in downlink		
	DwPTS	UpPTS		DwPTS	UpPTS	
		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink
0	$6592 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$	$7680 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$
1	$19760 \cdot T_s$			$20480 \cdot T_s$		
2	$21952 \cdot T_s$			$23040 \cdot T_s$		
3	$24144 \cdot T_s$			$25600 \cdot T_s$		
4	$26336 \cdot T_s$			$7680 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$
5	$6592 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$	$20480 \cdot T_s$		
6	$19760 \cdot T_s$			$23040 \cdot T_s$		
7	$21952 \cdot T_s$			$12800 \cdot T_s$		
8	$24144 \cdot T_s$			-	-	-
9	$13168 \cdot T_s$			-	-	-

[58] FIG. 2 illustrates the structure of a DL/UL slot structure in a wireless communication system.

[59] Referring to FIG. 2, a slot includes a plurality of orthogonal frequency division multiplexing (OFDM) symbols in the time domain and includes a plurality of resource blocks (RBs) in the frequency domain. The OFDM symbol may refer to one symbol duration. Referring to FIG. 2, a signal transmitted in each slot may be expressed by a resource grid including $N^{DL/UL}_{RB} * N^{RB}_{sc}$ subcarriers and $N^{DL/UL}_{symb}$ OFDM symbols. N^{DL}_{RB} denotes the number of RBs in a DL slot and N^{UL}_{RB} denotes the number of RBs in a UL slot. N^{DL}_{RB} and N^{UL}_{RB} depend on a DL transmission bandwidth and a UL transmission bandwidth, respectively. N^{DL}_{symb} denotes the number of OFDM symbols in a DL slot, N^{UL}_{symb} denotes the number of OFDM symbols in a UL slot, and N^{RB}_{sc} denotes the number of subcarriers configuring one RB.

[60] An OFDM symbol may be referred to as an OFDM symbol, a single carrier frequency division multiplexing (SC-FDM) symbol, etc. according to multiple access schemes. The number of OFDM symbols included in one slot may be varied according to channel bandwidths and CP lengths. For example, in a normal cyclic prefix (CP) case, one slot includes 7 OFDM symbols. In an extended CP case, one slot includes 6

OFDM symbols. Although one slot of a subframe including 7 OFDM symbols is shown in FIG. 2 for convenience of description, embodiments of the present invention are similarly applicable to subframes having a different number of OFDM symbols. Referring to FIG. 2, each OFDM symbol includes $N^{DL/UL}_{RB} * N^{RB}_{sc}$ subcarriers in the frequency domain. The type of the subcarrier may be divided into a data subcarrier for data transmission, a reference signal (RS) subcarrier for RS transmission, and a null subcarrier for a guard band and a DC component. The null subcarrier for the DC component is unused and is mapped to a carrier frequency f_0 in a process of generating an OFDM signal or in a frequency up-conversion process. The carrier frequency is also called a center frequency f_c.

[61] One RB is defined as $N^{DL/UL}_{symb}$ (e.g. 7) consecutive OFDM symbols in the time domain and as N^{RB}_{sc} (e.g. 12) consecutive subcarriers in the frequency domain. For reference, a resource composed of one OFDM symbol and one subcarrier is referred to a resource element (RE) or tone. Accordingly, one RB includes $N^{DL/UL}_{symb} * N^{RB}_{sc}$ REs. Each RE within a resource grid may be uniquely defined by an index pair (k, l) within one slot. k is an index ranging from 0 to $N^{DL/UL}_{RB} * N^{RB}_{sc}$—1 in the frequency domain, and l is an index ranging from 0 to $N^{DL/UL}_{symb}$—1 in the time domain.

[62] Meanwhile, one RB is mapped to one physical resource block (PRB) and one virtual resource block (VRB). A PRB is defined as N^{DL}_{symb} (e.g. 7) consecutive OFDM or SC-FDM symbols in the time domain and N^{RB}_{sc} (e.g. 12) consecutive subcarriers in the frequency domain. Accordingly, one PRB is configured with $N^{DL/UL}_{symb} * N^{RB}_{sc}$ REs. In one subframe, two RBs each located in two slots of the subframe while occupying the same N^{RB}_{sc} consecutive subcarriers are referred to as a physical resource block (PRB) pair. Two RBs configuring a PRB pair have the same PRB number (or the same PRB index).

[63] FIG. 3 illustrates a radio frame structure for transmission of a synchronization signal (SS). Specifically, FIG. 3 illustrates a radio frame structure for transmission of an SS and a PBCH in frequency division duplex (FDD), wherein FIG. 3(a) illustrates transmission locations of an SS and a PBCH in a radio frame configured as a normal cyclic prefix (CP) and FIG. 3(b) illustrates transmission locations of an SS and a PBCH in a radio frame configured as an extended CP.

[64] If a UE is powered on or newly enters a cell, the UE performs an initial cell search procedure of acquiring time and frequency synchronization with the cell and detecting a physical cell identity N^{cell}_{ID} of the cell. To this end, the UE may establish synchronization with the eNB by receiving synchronization signals, e.g. a primary synchronization signal (PSS) and a secondary synchronization signal (SSS), from the eNB and obtain information such as a cell identity (ID).

[65] An SS will be described in more detail with reference to FIG. 3. An SS is categorized

into a PSS and an SSS. The PSS is used to acquire time-domain synchronization of OFDM symbol synchronization, slot synchronization, etc. and/or frequency-domain synchronization and the SSS is used to acquire frame synchronization, a cell group ID, and/or CP configuration of a cell (i.e. information as to whether a normal CP is used or an extended CP is used). Referring to FIG. 3, each of a PSS and an SSS is transmitted on two OFDM symbols of every radio frame. More specifically, SSs are transmitted in the first slot of subframe 0 and the first slot of subframe 5, in consideration of a global system for mobile communication (GSM) frame length of 4.6 ms for facilitation of inter-radio access technology (inter-RAT) measurement. Especially, a PSS is transmitted on the last OFDM symbol of the first slot of subframe 0 and on the last OFDM symbol of the first slot of subframe 5 and an SSS is transmitted on the second to last OFDM symbol of the first slot of subframe 0 and on the second to last OFDM symbol of the first slot of subframe 5. A boundary of a corresponding radio frame may be detected through the SSS. The PSS is transmitted on the last OFDM symbol of a corresponding slot and the SSS is transmitted on an OFDM symbol immediately before an OFDM symbol on which the PSS is transmitted. A transmit diversity scheme of an SS uses only a single antenna port and standards therefor are not separately defined. That is, a single antenna port transmission scheme or a transmission scheme transparent to a UE (e.g. precoding vector switching (PVS), time switched transmit diversity (TSTD), or cyclic delay diversity (CDD)) may be used for transmit diversity of an SS.

[66] Upon detecting a PSS, a UE may discern that a corresponding subframe is one of subframe 0 and subframe 5 because the PSS is transmitted every 5ms but the UE cannot discern whether the subframe is subframe 0 or subframe 5. Accordingly, the UE cannot recognize the boundary of a radio frame only by the PSS. That is, frame synchronization cannot be acquired only by the PSS. The UE detects the boundary of a radio frame by detecting an SSS which is transmitted twice in one radio frame with different sequences.

[67] The UE, which has determined time and frequency parameters necessary for demodulating a DL signal and transmitting a UL signal at an accurate time by performing a cell search procedure using PSS/SSS, can communicate with the eNB only after acquiring system information necessary for system configuration of the UE from the eNB.

[68] The system information is configured by a master information block (MIB) and system information blocks (SIBs). Each SIB includes a set of functionally associated parameters and is categorized into an MIB, SIB Type 1 (SIB 1), SIB Type 2 (SIB2), and SIB3 to SIB17 in accordance with the parameters.

[69] The MIB includes most frequently transmitted parameters which are essential for

initial access of the UE to a network of the eNB. The UE may receive the MIB through a broadcast channel (e.g. PBCH). The MIB includes a DL bandwidth (BW), PHICH configuration, and a system frame number (SFN). Accordingly, the UE may be explicitly aware of information about the DL BW, SFN, and PHICH configuration by receiving the MIB. Meanwhile, information which may be implicitly recognized by the UE through reception of the PBCH includes the number of transmit antenna ports of the eNB. Information about the number of transmit antennas of the eNB is implicitly signaled by masking (e.g. XOR operation) a sequence corresponding to the number of transmit antennas to a 16-bit cyclic redundancy check (CRC) used for error detection of the PBCH.

[70] The SIB1 includes parameters needed to determine if a specific cell is suitable for cell selection, as well as information about time-domain scheduling of the other SIBs. The SIB1 is received by the UE through broadcast signaling or dedicated signaling.

[71] DL carrier frequency and corresponding system bandwidth may be acquired by the MIB carried by the PBCH. UL carrier frequency and corresponding system bandwidth may be acquired by system information which is a DL signal. The UE which has received the MIB applies a DL BW value within the MIB to a UL-bandwidth (UL BW) until system information block type 2 (SystemInformationBlockType2, SIB2) is received if there is no valid system information stored in a corresponding cell. For example, the UE may identify a full UL system band, which may be used by itself for UL transmission, through UL-carrier frequency and UL-bandwidth information within the SIB2 by acquiring system information block type 2 (SystemInformationBlockType2, SIB2).

[72] In the frequency domain, a PSS/SSS and a PBCH are transmitted only in a total of 6 RBs, i.e. a total of 72 subcarriers, irrespective of actual system BW, wherein 3 RBs are in the left and the other 3 RBs are in the right centering on a DC subcarrier on corresponding OFDM symbols. Therefore, the UE is configured to detect or decode the SS and the PBCH irrespective of DL BW configured for the UE.

[73] After initial cell search, the UE may perform a random access procedure to complete access to the eNB. To this end, the UE may transmit a preamble through a physical random access channel (PRACH) and receive a response message to the preamble through a PDCCH and a PDSCH. In contention based random access, the UE may perform additional PRACH transmission and a contention resolution procedure of a PDCCH and a PDSCH corresponding to the PDCCH.

[74] After performing the aforementioned procedure, the UE may perform PDDCH/PDSCH reception and PUSCH/PUCCH transmission as general uplink/downlink transmission procedures.

[75] The random access procedure is also called RACH (random access channel)

procedure. The random access procedure is used for initial access, uplink synchronization adjustment, resource assignment, handover, etc. The random access procedure is classified into a contention-based process and a dedicated (i.e. non-contention-based) process. The contention-based random access procedure includes initial access and is normally used, whereas the dedicated random access procedure is limitedly used for handover. In the contention-based random access procedure, a UE randomly select a RACH preamble sequence. Accordingly, a plurality of UEs can simultaneously transmit the same RACH preamble sequence and thus a contention resolution procedure is not needed. In the dedicated random access procedure, a UE uses a RACH preamble sequence uniquely allocated thereto by an eNB. Accordingly, the UE can perform the random access procedure without colliding with other UEs.

[76] The contention-based random access procedure has the following four steps. Hereinafter, messages transmitted in steps 1 to 4 may be respectively referred to as Msg 1 to Msg 4.

[77] - Step 1: RACH preamble (via PRACH) (UE to eNB)

[78] - Step 2: Random access response (RAR) (via PDCCH and PDSCH) (eNB to UE)

[79] - Step 3: Layer 2/Layer 3 message (via PUSCH) (UE to eNB)

[80] - Step 4: Contention resolution message (eNB to UE)

[81] The dedicated random access procedure includes the following three steps. Hereinafter, uplink transmission (i.e. step 3) corresponding to a RAR may be performed as a part of the random access procedure. The dedicated random access procedure can be triggered using a PDCCH (hereinafter, referred to as PDCCH order) used for an eNB to command RACH preamble transmission.

[82] - Step 0: PACH preamble allocation through dedicated signaling (eNB to UE)

[83] - Step 1: RACH preamble (via PRACH) (UE to eNB)

[84] - Step 2: RAR (via PDCCH and PDSCH) (eNB to UE)

[85] After transmission of RACH preamble, the UE attempts to receive a random access response (RAR) within a predetermined time window. Specifically, the UE attempts to detect a PDCCH (hereinafter, referred to as RA-RNTI PDCCH) having an RA-RNTI (Random Access RNTI) (e.g., CRC is masked with RA-RNTI in the PDCCH) within the time window. The UE checks whether a RAR therefor is present in a PDSCH corresponding to the RA-RNTI PDCCH during RA-RNTI PDCCH detection. The RAR includes timing advance (TA) information indicating timing offset information for UL synchronization, UL resource allocation information (UL grant information), a temporary UE identifier (e.g., temporary cell-RNTI, TC-RNTI), etc. The UE can perform UL transmission (e.g., Msg3) in accordance with resource allocation information and TA value in the RAR. HARQ is applied to UL transmission corresponding to the RAR. Accordingly, the UE can receive acknowledgement information

(e.g., PHICH) corresponding to Msg 3 after transmission of Msg 3.

[86] The random access preamble, i.e., RACH preamble consists of a cyclic prefix of length T_{CP} and a sequence part of length T_{SEQ} in the physical layer. T_{CP} and T_{SEQ} depend on the frame structure and the random access configuration. The preamble format is controlled by higher layers. The following table shows examples of T_{CP} and T_{SEQ}.

[87] [Table 3]

Preamble format	T_{CP}	T_{SEQ}
0	$3168 \cdot T_s$	$24576 \cdot T_s$
1	$21024 \cdot T_s$	$24576 \cdot T_s$
2	$6240 \cdot T_s$	$2 \cdot 24576 \cdot T_s$
3	$21024 \cdot T_s$	$2 \cdot 24576 \cdot T_s$
4(see NOTE)	$448 \cdot T_s$	$4096 \cdot T_s$
NOTE: Frame structure type 2 and special subframe configuration with UpPTS lengths $4384 \cdot T_s$ and $5120 \cdot T_s$ only.		

[88] The random access preamble is transmitted in UL subframe(s). The transmission of a random access preamble is restricted to certain time and frequency resources. These resources are called PRACH resources. The PRACH resources, are enumerated in increasing order of the subframe number within the radio frame and the PRBs in the frequency domain such that index 0 correspond to the lowest numbered PRB and subframe within the radio frame. PRACH resources within the radio frame are indicated by a PRACH configuration index.

[89] For frame structure type 1 with preamble format 0-3, for each of the PRACH configurations there is at most one random access resource per subframe. The following table shows examples of the preamble formats and the subframes in which random access preamble transmission is allowed for a given configuration in frame structure type 1. The PRACH configuration index is given by a higher layer signal (transmitted by an eNB).

[90] [Table 4]

PRACH Configuration Index	Preamble Format	SFN	Subframe number	PRACH Configuration Index	Preamble Format	SFN	Subframe number
0	0	Even	1	32	2	Even	1
1	0	Even	4	33	2	Even	4
2	0	Even	7	34	2	Even	7
3	0	Any	1	35	2	Any	1
4	0	Any	4	36	2	Any	4
5	0	Any	7	37	2	Any	7
6	0	Any	1,6	38	2	Any	1,6
7	0	Any	2,7	39	2	Any	2,7

30	N/A	N/A	N/A	62	N/A	N/A	N/A
31	1	Even	9	63	3	Even	9

[91] In Table 4, SFN denotes a system frame number.

[92] The first PRB, n^{RA}_{PRB}, allocated to the PRACH opportunity considered for preamble formats 0, 1, 2 and 3 is defined by $n^{RA}_{PRB}=n^{RA}_{PRBoffset}$, where the PRACH frequency offset $n^{RA}_{PRBoffset}$ is a PRB configured by higher layers and satisfies $0\leq n^{RA}_{PRBoffset}\leq N^{UL}_{RB}-6$.

[93] In case of frame structure type 2 with preamble formats 0 to 4, a plurality of random access resources may exist within UL subframe (or UpPTS for preamble format 4) in accordance with UL/DL configuration. The random access resources for the frame structure type 2 are defined in accordance with PRACH configuration index (see 3GPP TS 36.211 standard document).

[94] FIG. 4 illustrates the structure of a DL subframe used in a wireless communication system.

[95] Referring to FIG. 4, A DL subframe is divided into a control region and a data region in the time domain. Referring to FIG. 4, a maximum of 3 (or 4) OFDM symbols located in a front part of a first slot of a subframe corresponds to the control region. Hereinafter, a resource region for PDCCH transmission in a DL subframe is referred to as a PDCCH region. OFDM symbols other than the OFDM symbol(s) used in the control region correspond to the data region to which a physical downlink shared channel (PDSCH) is allocated. Hereinafter, a resource region available for PDSCH transmission in the DL subframe is referred to as a PDSCH region.

[96] Examples of a DL control channel used in 3GPP LTE include a physical control format indicator channel (PCFICH), a physical downlink control channel (PDCCH), a physical hybrid ARQ indicator channel (PHICH), etc.

[97] The PCFICH is transmitted in the first OFDM symbol of a subframe and carries information about the number of OFDM symbols available for transmission of a control channel within a subframe. The PCFICH notifies the UE of the number of OFDM symbols used for the corresponding subframe every subframe. The PCFICH is located at the first OFDM symbol. The PCFICH is configured by four resource element groups (REGs), each of which is distributed within a control region on the basis of cell ID. One REG includes four REs.

[98] A set of OFDM symbols available for the PDCCH at a subframe is given by the following Table.

[99] [Table 5]

Subframe	Number of OFDM symbols for PDCCH when $N^{DL}_{RB}>10$	Number of OFDM symbols for PDCCH when $N^{DL}_{RB}\leq 10$
Subframe 1 and 6 for frame structure type 2	1, 2	2
MBSFN subframes on a carrier supporting PDSCH, configured with 1 or 2 cell-specfic antenna ports	1, 2	2
MBSFN subframes on a carrier supporting PDSCH, configured with 4 cell-specific antenna ports	2	2
Subframes on a carrier not supporting PDSCH	0	0
Non-MBSFN subframes (except subframe 6 for frame structure type 2) configured with positioning reference signals	1, 2, 3	2, 3
All other cases	1, 2, 3	2, 3, 4

[100] A subset of downlink subframes within a radio frame on a carrier for supporting PDSCH transmission may be configured as MBSFN subframe(s) by a higher layer. Each MBSFN subframe is divided into a non-MBSFN region and an MBSFN region. The non-MBSFN region spans first one or two OFDM symbols, and its length is given by Table 5. The same CP as cyclic prefix (CP) used for subframe 0 is used for transmission within the non-MBSFN region of the MBSFN subframe. The MBSFN region within the MBSFN subframe is defined as OFDM symbols which are not used in the non-MBSFN region.

[101] The PCFICH carries a control format indicator (CFI), which indicates any one of values of 1 to 3. For a downlink system bandwidth $N^{DL}_{RB}>10$, the number 1, 2 or 3 of OFDM symbols which are spans of DCI carried by the PDCCH is given by the CFI. For a downlink system bandwidth $N^{DL}_{RB}\leq 10$, the number 2, 3 or 4 of OFDM symbols which are spans of DCI carried by the PDCCH is given by CFI+1. The CFI is coded in accordance with the following Table.

[102] [Table 6]

CFI	CFI code word<b_0, b_1, ..., b_{31}>
1	<0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1>
2	<1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0>
3	<1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1>
4(Reserved)	<0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0>

[103] The PHICH carries a HARQ (Hybrid Automatic Repeat Request) ACK/NACK (acknowledgment/negative-acknowledgment) signal as a response to UL transmission. The PHICH includes three REGs, and is scrambled cell-specifically. ACK/NACK is indicated by 1 bit, and the ACK/NACK of 1 bit is repeated three times. Each of the repeated ACK/NACK bits is spread with a spreading factor (SF) 4 or 2 and then mapped into a control region.

[104] The control information transmitted through the PDCCH will be referred to as downlink control information (DCI). The DCI includes resource allocation information for a UE or UE group and other control information. Transmit format and resource allocation information of a downlink shared channel (DL-SCH) are referred to as DL scheduling information or DL grant. Transmit format and resource allocation information of an uplink shared channel (UL-SCH) are referred to as UL scheduling information or UL grant. The size and usage of the DCI carried by one PDCCH are varied depending on DCI formats. The size of the DCI may be varied depending on a coding rate. In the current 3GPP LTE system, various formats are defined, wherein formats 0 and 4 are defined for a UL, and formats 1, 1A, 1B, 1C, 1D, 2, 2A, 2B, 2C, 3 and 3A are defined for a DL. Combination selected from control information such as a hopping flag, RB allocation, modulation coding scheme (MCS), redundancy version (RV), new data indicator (NDI), transmit power control (TPC), cyclic shift, cyclic shift demodulation reference signal (DM RS), UL index, channel quality information (CQI) request, DL assignment index, HARQ process number, transmitted precoding matrix indicator (TPMI), precoding matrix indicator (PMI) information is transmitted to the UE as the DCI. The following table shows examples of DCI formats.

[105] [Table 7]

DCI format	Description
0	Resource grants for the PUSCH transmissions (uplink)
1	Resource assignments for single codeword PDSCH transmissions
1A	Compact signaling of resource assignments for single codeword PDSCH
1B	Compact signaling of resource assignments for single codeword PDSCH
1C	Very compact resource assignments for PDSCH (e.g. paging/broadcast system information)
1D	Compact resource assignments for PDSCH using multi-user MIMO
2	Resource assignments for PDSCH for closed-loop MIMO operation
2A	Resource assignments for PDSCH for open-loop MIMO operation
2B	Resource assignments for PDSCH using up to 2 antenna ports with UE-specific reference signals
2C	Resource assignment for PDSCH using up to 8 antenna ports with UE-specific reference signals
3/3A	Power control commands for PUCCH and PUSCH with 2-bit/1-bit power adjustments
4	Scheduling of PUSCH in one UL Component Carrier with multi-antenna port transmission mode

[106] Other DCI formats in addition to the DCI formats defined in Table 7 may be defined.

[107] A plurality of PDCCHs may be transmitted within a control region. A UE may monitor the plurality of PDCCHs. An eNB determines a DCI format depending on the DCI to be transmitted to the UE, and attaches cyclic redundancy check (CRC) to the DCI. The CRC is masked (or scrambled) with an identifier (for example, a radio network temporary identifier (RNTI)) depending on usage of the PDCCH or owner of the PDCCH. For example, if the PDCCH is for a specific UE, the CRC may be masked with an identifier (for example, cell-RNTI (C-RNTI)) of the corresponding UE. If the PDCCH is for a paging message, the CRC may be masked with a paging identifier (for example, paging-RNTI (P-RNTI)). If the PDCCH is for system information (in more detail, system information block (SIB)), the CRC may be masked with system information RNTI (SI-RNTI). If the PDCCH is for a random access response, the CRC may be masked with a random access RNTI (RA-RNTI). For example, CRC masking

(or scrambling) includes XOR operation of CRC and RNTI at the bit level.

[108] Generally, a DCI format, which may be transmitted to the UE, is varied depending on a transmission mode configured for the UE. In other words, certain DCI format(s) corresponding to the specific transmission mode not all DCI formats may only be used for the UE configured to a specific transmission mode.

[109] For example, a transmission mode is semi-statically configured for the UE by a higher layer so that the UE may receive a PDSCH transmitted in accordance with one of a plurality of transmission modes which are previously defined. The UE attempts to decode a PDCCH using DCI formats only corresponding to its transmission mode. In other words, in order to maintain UE operation load according to blind decoding attempt, at a certain level or less, all DCI formats are not searched by the UE at the same time. Table 8 illustrates transmission modes for configuring multi-antenna technology and DCI formats for allowing a UE to perform blind decoding at the corresponding transmission mode. Particularly, Table 8 illustrates a relation between PDCCH and PDSCH configured by C-RNTI (Cell RNTI(Radio Network Temporary Identifier)).

[110] [Table 8]

Transmission mode	DCI format	Search Space	Transmission scheme of PDSCH corresponding to PDCCH
Mode 1	DCI format 1A	Common andUE specific by C-RNTI	Single-antenna port, port 0
	DCI format 1	UE specific by C-RNTI	Single-antenna port, port 0
Mode 2	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1	UE specific by C-RNTI	Transmit diversity
Mode 3	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 2A	UE specific by C-RNTI	Large delay CDD or Transmit diversity
Mode 4	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 2	UE specific by C-RNTI	Closed-loop spatial multiplexing or Transmit diversity
Mode 5	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1D	UE specific by C-RNTI	Multi-user MIMO
Mode 6	DCI format 1A	Common andUE specific by C-RNTI	Transmit diversity
	DCI format 1B	UE specific by C-RNTI	Closed-loop spatial multiplexing using a single transmission layer
Mode 7	DCI format	Common andUE	If the number of PBCH antenna ports

	1A	specific by C-RNTI	is one, Single-antenna port, port 0 is used, otherwise Transmit diversity
	DCI format 1	UE specific by C-RNTI	Single-antenna port, port 5
Mode 8	DCI format 1A	Common andUE specific by C-RNTI	If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity
	DCI format 2B	UE specific by C-RNTI	Dual layer transmission, port 7 and 8 or single-antenna port, port 7 or 8
Mode 9	DCI format 1A	Common andUE specific by C-RNTI	Non-MBSFN subframe: If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity.MBSFN subframe: Single-antenna port, port 7
	DCI format 2C	UE specific by C-RNTI	Up to 8 layer transmission, ports 7-14 or single-antenna port, port 7 or 8
Mode 10	DCI format 1A	Common andUE specific by C-RNTI	Non-MBSFN subframe: If the number of PBCH antenna ports is one, Single-antenna port, port 0 is used, otherwise Transmit diversity.MBSFN subframe: Single-antenna port, port 7
	DCI format 2D	UE specific by C-RNTI	Up to 8 layer transmission, ports 7-14 or single antenna port, port 7 or 8

[111] Although transmission modes 1 to 10 are listed in Table 8, other transmission modes in addition to the transmission modes defined in Table 8 may be defined.

[112] Referring to Table 8, a UE configured to a transmission mode 9, for example, tries to decode PDCCH candidates of a UE-specific search space (USS) to a DCI format 1A, and tries to decode PDCCH candidates of a common search space (CSS) and the USS to a DCI format 2C. The UE may decode a PDSCH in accordance with DCI based on the DCI format successfully decoded. If DCI decoding from one of a plurality of PDCCH candidates to the DCI format 1A is successfully performed, the UE may decode the PDSCH by assuming that up to 8 layers from antenna ports 7 to 14 are transmitted thereto through the PDSCH, or may decode the PDSCH by assuming that a single layer from the antenna port 7 or 8 is transmitted thereto through the PDSCH.

[113] The PDCCH is allocated to first m number of OFDM symbol(s) within a subframe.

In this case, m is an integer equal to or greater than 1, and is indicated by the PCFICH.

[114] The PDCCH is transmitted on an aggregation of one or a plurality of continuous control channel elements (CCEs). The CCE is a logic allocation unit used to provide a coding rate based on the status of a radio channel to the PDCCH. The CCE corresponds to a plurality of resource element groups (REGs). For example, one CCE corresponds to nine resource element groups (REGs), and one REG corresponds to four REs. Four QPSK symbols are mapped to each REG. A resource element (RE) occupied by the reference signal (RS) is not included in the REG. Accordingly, the number of REGs within given OFDM symbols is varied depending on the presence of the RS. The REGs are also used for other downlink control channels (that is, PCFICH and PHICH).

[115] Assuming that the number of REGs not allocated to the PCFICH or the PHICH is N_{REG}, the number of available CCEs in a DL subframe for PDCCH(s) in a system is numbered from 0 to N_{CCE}—1, where $N_{CCE} = \text{floor}(N_{REG}/9)$.

[116] A PDCCH format and the number of DCI bits are determined in accordance with the number of CCEs. The CCEs are numbered and consecutively used. To simplify the decoding process, a PDCCH having a format including n CCEs may be initiated only on CCEs assigned numbers corresponding to multiples of n. The number of CCEs used for transmission of a specific PDCCH is determined by a network or the eNB in accordance with channel status. For example, one CCE may be required for a PDCCH for a UE (for example, adjacent to eNB) having a good downlink channel. However, in case of a PDCCH for a UE (for example, located near the cell edge) having a poor channel, eight CCEs may be required to obtain sufficient robustness. Additionally, a power level of the PDCCH may be adjusted to correspond to a channel status.

[117] In a 3GPP LTE/LTE-A system, a set of CCEs on which a PDCCH can be located for each UE is defined. A CCE set in which the UE can detect a PDCCH thereof is referred to as a PDCCH search space or simply as a search space (SS). An individual resource on which the PDCCH can be transmitted in the SS is called a PDCCH candidate. A set of PDCCH candidates that the UE is to monitor is defined in terms of SSs, where a search space $S^{(L)}_k$ at aggregation level $L \in \{1,2,4,8\}$ is defined by a set of PDCCH candidates. SSs for respective PDCCH formats may have different sizes and a dedicated SS and a common SS are defined. The dedicated SS is a UE-specific SS (USS) and is configured for each individual UE. The common SS (CSS) is configured for a plurality of UEs.

[118] The following table shows an example of aggregation levels for defining SS.

[119] [Table 9]

Search space $S^{(L)}_k$			Number of PDCCH candidates $M^{(L)}$
Type	Aggregation level L	Size [in CCEs]	
UE-specific	1	6	6
	2	12	6
	4	8	2
	8	16	2
Common	4	16	4
	8	16	2

[120] For each serving cell on which PDCCH is monitored, the CCEs corresponding to PDCCH candidates m of the search space $S^{(L)}_k$ are configured by "$L*\{Y_k+m'\}$ mod floor($N_{CCE,k}/L\}+i$", where i=0,...,L—1. For the common search space $m'=m$. For the PDCCH UE specific search space, for the serving cell on which PDCCH is monitored, if the monitorng UE is configured with carrier indicator field then $m'=m+M^{(L)}*n_{CI}$ where n_{CI} is the carrier indicator field (CIF) value, else if the monitoring UE is not configured with carrier indicator field then $m'=m$, where m=0,1,...,$M^{(L)}$—1. $M^{(L)}$ is the number of PDCCH candidates to monitor at aggregation level L in the given search space. The carrier indication field value can be the same as a serving cell index (*Serv-CellIndex*). For the common search space, Y_k is set to 0 for the two aggregation levels L=4 and L=8. For the UE-specific search space $S^{(L)}_k$ at aggregation level D, the variable Y_k is defined by "$Y_k = (A\cdot Y_{k-1})$ mod D", where $Y_{-1}=n_{RNTI}\neq 0$, A=39827, D=65537 and k =floor(n_s/2). n_s is the slot number within a radio frame.

[121] The eNB transmits an actual PDCCH (DCI) on a PDCCH candidate in a search space and the UE monitors the search space to detect the PDCCH (DCI). Here, monitoring implies attempting to decode each PDCCH in the corresponding SS according to all monitored DCI formats. The UE may detect a PDCCH thereof by monitoring a plurality of PDCCHs. Basically, the UE does not know the location at which a PDCCH thereof is transmitted. Therefore, the UE attempts to decode all PDCCHs of the corresponding DCI format for each subframe until a PDCCH having an ID thereof is detected and this process is referred to as blind detection (or blind decoding (BD)).

[122] For example, it is assumed that a specific PDCCH is CRC-masked with a radio network temporary identity (RNTI) 'A' and information about data transmitted using a radio resource 'B' (e.g. frequency location) and using transport format information 'C' (e.g. transmission block size, modulation scheme, coding information, etc.) is transmitted in a specific DL subframe. Then, the UE monitors the PDCCH using RNTI

information thereof. The UE having the RNTI 'A' receives the PDCCH and receives the PDSCH indicated by 'B' and 'C' through information of the received PDCCH.

[123] FIG. 5 illustrates the structure of a UL subframe used in a wireless communication system.

[124] Referring to FIG. 5, a UL subframe may be divided into a data region and a control region in the frequency domain. One or several PUCCHs may be allocated to the control region to deliver UCI. One or several PUSCHs may be allocated to the data region of the UE subframe to carry user data.

[125] In the UL subframe, subcarriers distant from a direct current (DC) subcarrier are used as the control region. In other words, subcarriers located at both ends of a UL transmission BW are allocated to transmit UCI. A DC subcarrier is a component unused for signal transmission and is mapped to a carrier frequency f_0 in a frequency up-conversion process. A PUCCH for one UE is allocated to an RB pair belonging to resources operating on one carrier frequency and RBs belonging to the RB pair occupy different subcarriers in two slots. The PUCCH allocated in this way is expressed by frequency hopping of the RB pair allocated to the PUCCH over a slot boundary. If frequency hopping is not applied, the RB pair occupies the same subcarriers.

[126] The PUCCH may be used to transmit the following control information.

[127] - Scheduling request (SR): SR is information used to request a UL-SCH resource and is transmitted using an on-off keying (OOK) scheme.

[128] - HARQ-ACK: HARQ-ACK is a response to a PDCCH and/or a response to a DL data packet (e.g. a codeword) on a PDSCH. HARQ-ACK indicates whether the PDCCH or PDSCH has been successfully received. 1-bit HARQ-ACK is transmitted in response to a single DL codeword and 2-bit HARQ-ACK is transmitted in response to two DL codewords. A HARQ-ACK response includes a positive ACK (simply, ACK), negative ACK (NACK), discontinuous transmission (DTX), or NACK/DRX. HARQ-ACK is used interchangeably with HARQ ACK/NACK and ACK/NACK.

[129] - Channel state information (CSI): CSI is feedback information for a DL channel. CSI may include channel quality information (CQI), a precoding matrix indicator (PMI), a precoding type indicator, and/or a rank indicator (RI). In the CSI, MIMO-related feedback information includes the RI and the PMI. The RI indicates the number of streams or the number of layers that the UE can receive through the same time-frequency resource. The PMI is a value reflecting a space characteristic of a channel, indicating an index of a preferred precoding matrix for DL signal transmission based on a metric such as an SINR. The CQI is a value of channel strength, indicating a received SINR that can be obtained by the UE generally when the eNB uses the PMI.

[130] A general wireless communication system performs data transmission/reception through one downlink (DL) band and through one uplink (UL) band corresponding to

the DL band (in case of a frequency division duplex (FDD) mode), or divides a prescribed radio frame into a UL time unit and a DL time unit in the time domain and then performs data transmission/reception through the UL/DL time unit (in case of a time division duplex (TDD) mode). Recently, to use a wider frequency band in recent wireless communication systems, introduction of carrier aggregation (or BW aggregation) technology that uses a wider UL/DL BW by aggregating a plurality of UL/DL frequency blocks has been discussed. A carrier aggregation (CA) is different from an orthogonal frequency division multiplexing (OFDM) system in that DL or UL communication is performed using a plurality of carrier frequencies, whereas the OFDM system carries a base frequency band divided into a plurality of orthogonal subcarriers on a single carrier frequency to perform DL or UL communication. Hereinbelow, each of carriers aggregated by carrier aggregation will be referred to as a component carrier (CC).

[131] For example, three 20MHz CCs may be aggregated on each of a UL and a DL to support a bandwidth of 60MHz. The respective CCs may be contiguous or non-contiguous in the frequency domain. For convenience, although it has been described that the bandwidth of UL CC and the bandwidth of DL CC are the same as each other and symmetric to each other, the bandwidth of each CC may be independently determined. Asymmetrical carrier aggregation in which the number of UL CCs is different from the number of DL CCs may be implemented. DL/UL CC limited to a specific UE may be referred to as a serving UL/DL CC configured for the specific UE.

[132] Meanwhile, the 3GPP LTE-A standard uses the concept of a cell to manage radio resources. The "cell" associated with the radio resources is defined by combination of downlink resources and uplink resources, that is, combination of DL CC and UL CC. The cell may be configured by downlink resources only, or may be configured by downlink resources and uplink resources. If carrier aggregation is supported, linkage between a carrier frequency of the downlink resources (or DL CC) and a carrier frequency of the uplink resources (or UL CC) may be indicated by system information. For example, combination of the DL resources and the UL resources may be indicated by linkage of system information block type 2 (SIB2). In this case, the carrier frequency means a center frequency of each cell or CC. A cell operating on a primary frequency may be referred to as a primary cell (Pcell) or PCC, and a cell operating on a secondary frequency may be referred to as a secondary cell (Scell) or SCC. The carrier corresponding to the Pcell on downlink will be referred to as a downlink primary CC (DL PCC), and the carrier corresponding to the Pcell on uplink will be referred to as an uplink primary CC (UL PCC). A Scell means a cell that may be configured after completion of radio resource control (RRC) connection establishment and used to provide additional radio resources. The Scell may form a set of serving cells for the UE

together with the Pcell in accordance with capabilities of the UE. The carrier corresponding to the Scell on the downlink will be referred to as downlink secondary CC (DL SCC), and the carrier corresponding to the Scell on the uplink will be referred to as uplink secondary CC (UL SCC). Although the UE is in RRC-CONNECTED state, if it is not configured by carrier aggregation or does not support carrier aggregation, a single serving cell configured by the Pcell only exists.

[133] The eNB may activate all or some of the serving cells configured in the UE or deactivate some of the serving cells for communication with the UE. The eNB may change the activated/deactivated cell, and may change the number of cells which is/are activated or deactivated. If the eNB allocates available cells to the UE cell-specifically or UE-specifically, at least one of the allocated cells is not deactivated unless cell allocation to the UE is fully reconfigured or unless the UE performs handover. Such a cell which is not deactivated unless CC allocation to the UE is fully reconfigured will be referred to as Pcell, and a cell which may be activated/deactivated freely by the eNB will be referred to as Scell. The Pcell and the Scell may be discriminated from each other on the basis of the control information. For example, specific control information may be set to be transmitted and received through a specific cell only. This specific cell may be referred to as the Pcell, and the other cell(s) may be referred to as Scell(s).

[134] A configured cell refers to a cell in which carrier aggregation is performed for a UE based on measurement report from another eNB or UE among cells of an eNB and is configured per UE. The cell configured for the UE may be a serving cell in terms of the UE. For the cell configured for the UE, i.e. the serving cell, resources for ACK/NACK transmission for PDSCH transmission are reserved in advance. An activated cell refers to a cell configured to be actually used for PDSCH/PUSCH transmission among cells configured for the UE and CSI reporting and SRS transmission for PDSCH/PUSCH transmission are performed in the activated cell. A deactivated cell refers to a cell configured not to be used for PDSCH/PUSCH transmission by the command of an eNB or the operation of a timer and, if a cell is deactivated, CSI reporting and SRS transmission are also stopped in the cell.

[135] For reference, a carrier indicator (CI) denots a serving cell index (*ServCellIndex*), CI=0 is applied to Pcell. The serving cell index is a short ID used to identify a serving cell. For example, any one of integers from 0 to 'maximum number of carrier frequencies which can be configured for the UE at a time - 1' may be allocated to one serving cell as the serving cell index. That is, the serving cell index may be a logical index used to identify a specific serving cell among cells allocated to the UE rather than a physical index used to identify a specific carrier frequency among all carrier frequencies.

[136] Meanwhile, the 3GPP LTE-A standard uses the concept of a cell to manage radio

resources.

[137] The cell mentioned in the present invention means a cell of carrier aggregation which is combination of UL CC and DL CC unless specifically noted.

[138] Meanwhile, since one serving cell is only present in case of communication based on a single carrier, a PDCCH carrying UL/DL grant and corresponding PUSCH/PDSCH are transmitted on one cell. In other words, in case of FDD under a single carrier environment, a PDCCH for a DL grant for a PDSCH, which will be transmitted on a specific DL CC, is transmitted on the specific CC, and a PDCCH for a UL grant for a PUSCH, which will be transmitted on a specific UL CC, is transmitted on a DL CC linked to the specific UL CC. In case of TDD under a single carrier environment, a PDCCH for a DL grant for a PDSCH, which will be transmitted on a specific DL CC, is transmitted on the specific CC, and a PDCCH for a UL grant for a PUSCH, which will be transmitted on a specific UL CC, is transmitted on the specific CC.

[139] On the contrary, since a plurality of serving cells may be configured in a multi-carrier system, transmission of UL/DL grant through a serving cell having a good channel status may be allowed. In this way, if a cell carrying UL/DL grant which is scheduling information is different from a cell where UL/DL transmission corresponding to the UL/DL grant is performed, this will be referred to as cross-carrier scheduling.

[140] Hereinafter, the case where the cell is scheduled from itself and the case where the cell is scheduled from another cell will be referred to as self-CC scheduling and cross-CC scheduling, respectively.

[141] For data transmission rate enhancement and stable control signaling, the 3GPP LTE/LTE-A may support aggregation of a plurality of CCs and a cross carrier-scheduling operation based on the aggregation.

[142] If cross-carrier scheduling (or cross-CC scheduling) is applied, a PDCCH for downlink allocation for a DL CC B or DL CC C, that is, carrying a DL grant may be transmitted through a DL CC A, and a corresponding PDSCH may be transmitted through the DL CC B or DL CC C. For cross-CC scheduling, a carrier indicator field (CIF) may be introduced. The presence or absence of the CIF within the PDCCH may be semi-statically and UE-specifically (or UE-group-specifically) configured by higher layer signaling (e.g., RRC signaling).

[143] Meanwhile, if RRH technology, cross-carrier scheduling technology, etc. are introduced, the amount of PDCCH which should be transmitted by the eNB is gradually increased. However, since a size of a control region within which the PDCCH may be transmitted is the same as before, PDCCH transmission acts as a bottleneck of system throughput. Although channel quality may be improved by the introduction of the aforementioned multi-node system, application of various communication schemes, etc., the introduction of a new control channel is required to apply the legacy commu-

nication scheme and the carrier aggregation technology to a multi-node environment. Due to the need, a configuration of a new control channel in a data region (hereinafter, referred to as PDSCH region) not the legacy control region (hereinafter, referred to as PDCCH region) has been discussed. Hereinafter, the new control channel will be referred to as an enhanced PDCCH (hereinafter, referred to as EPDCCH).

[144] The EPDCCH may be configured within rear OFDM symbols starting from a configured OFDM symbol, instead of front OFDM symbols of a subframe. The EPDCCH may be configured using continuous frequency resources, or may be configured using discontinuous frequency resources for frequency diversity. By using the EPDCCH, control information per node may be transmitted to a UE, and a problem that a legacy PDCCH region may not be sufficient may be solved. For reference, the PDCCH may be transmitted through the same antenna port(s) as that(those) configured for transmission of a CRS, and a UE configured to decode the PDCCH may demodulate or decode the PDCCH by using the CRS. Unlike the PDCCH transmitted based on the CRS, the EPDCCH is transmitted based on the demodulation RS (hereinafter, DMRS). Accordingly, the UE decodes/demodulates the PDCCH based on the CRS and decodes/demodulates the EPDCCH based on the DMRS. The DMRS associated with EPDCCH is transmitted on the same antenna port $p \in \{107,108,109,110\}$ as the associated EPDCCH physical resource, is present for EPDCCH demodulation only if the EPDCCH transmission is associated with the corresponding antenna port, and is transmitted only on the PRB(s) upon which the corresponding EPDCCH is mapped. For example, the REs occupied by the UE-RS(s) of the antenna port 7 or 8 may be occupied by the DMRS(s) of the antenna port 107 or 108 on the PRB to which the EPDCCH is mapped, and the REs occupied by the UE-RS(s) of antenna port 9 or 10 may be occupied by the DMRS(s) of the antenna port 109 or 110 on the PRB to which the EPDCCH is mapped. In other words, a certain number of REs are used on each RB pair for transmission of the DMRS for demodulation of the EPDCCH regardless of the UE or cell if the type of EPDCCH and the number of layers are the same as in the case of the UE-RS for demodulation of the PDSCH.

[145] For each serving cell, higher layer signalling can configure a UE with one or two EPDCCH-PRB-sets for EPDCCH monitoring. The PRB-pairs corresponding to an EPDCCH-PRB-set are indicated by higher layers. Each EPDCCH-PRB-set consists of set of ECCEs numbered from 0 to $N_{ECCE,p,k}$—1, where $N_{ECCE,p,k}$ is the number of ECCEs in EPDCCH-PRB-set p of subframe k. Each EPDCCH-PRB-set can be configured for either localized EPDCCH transmission or distributed EPDCCH transmission.

[146] The UE shall monitor a set of EPDCCH candidates on one or more activated serving cells as configured by higher layer signaling for control information.

[147] The set of EPDCCH candidates to monitor are defined in terms of EPDCCH UE-

specific search spaces. For each serving cell, the subframes in which the UE monitors EPDCCH UE-specific search spaces are configured by higher layers.

[148] An EPDCCH UE-specific search space $ES^{(L)}_k$ at aggregation level $L \in \{1,2,4,8,16,32\}$ is defined by a set of EPDCCH candidates.

[149] For an EPDCCH-PRB-set p, the ECCEs corresponding to EPDCCH candidate m of the search space $ES^{(L)}_k$ are given by the following equation.

[150] [Math.1]

$$L\left\{ (Y_{p,k} + \left\lfloor \frac{m \cdot N_{ECCE,p,k}}{L \cdot M_p^{(L)}} \right\rfloor + b) \bmod \lfloor N_{\mathrm{ECCE},p,k} / L \rfloor \right\} + i$$

[151] where $i=0,\ldots,L-1$. $b=n_{CI}$ if the UE is configured with a carrier indicator field for the serving cell on which EPDCCH is monitored, otherwise $b=0$. n_{CI} is the carrier indicator field (CIF) value, which is the same as a serving cell index (*ServCellIndex*). $m=0,1,\ldots,$ $M^{(L)}_p-1$, $M^{(L)}_p$ is the number of EPDCCH candidates to monitor at aggregation level L in EPDDCH-PRB-set p. The variable $Y_{p,k}$ is defined by '$Y_{p,k} = (A_p \cdot Y_{p,k-1}) \bmod D$', where $Y_{p,-1}=n_{RNTI} \neq 0$, $A_0=39827$, $A_0=39829$,$D=65537$ and $k=\mathrm{floor}(n_s/2)$. n_s is the slot number within a radio frame.

[152] A UE is not expected to monitor an EPDCCH candidate, if an ECCE corresponding to that EPDCCH candidate is mapped to a PRB pair that overlaps in frequency with a transmission of either PBCH or PSS/SSS in the same subframe.

[153] An EPDCCH is transmitted using an aggregation of one or several consecutive enhanced control channel elements (ECCEs). Each ECCE consists of multiple enhanced resource element groups (EREGs). EEREGs are used for defining the mapping of enhanced control channels to resource elements. There are 16 EREGs, numbered from 0 to 15, per physical resource block (PRB) pair. Number all resource elements (REs), except resource elements carrying DMRS (hereinafter EPDCCH DMRS) for demoduation of the EPDCCH, in a physical resource-block pair cyclically from 0 to 15 in an increasing order of first frequency, then time. Therefore all the REs, except REs carrying the EPDCCH DMRS, in the PRB pair has any one of numbers 0 to 15. All REs with number i in that PRB pair constitutes EREG number i.As described above, it is noted that EREGs are distributed on frequency and time axes within the PRB pair and an EPDCCH transmitted using aggregation of one or more ECCEs, each of which includes a plurality of EREGs, is also distributed on frequency and time axes within the PRB pair.

[154] The number of ECCEs used for one EPDCCH depends on the EPDCCH format as given by Table 10, the number of EREGs per ECCE is given by Table 11. Table 10 shows an example of supported EPDCCH formats, and Table 11 shows an example of

the number of EREGs per ECCE, N^{EREG}_{ECCE}. Both localized and distributed transmission is supported.

[155] [Table 10]

EPDCCH format	Number of ECCEs for one EPDCCH, N^{ECCE}_{EPDCCH}			
	Case A		Case B	
	Localized transmission	Distributed transmission	Localized transmission	Distributed transmission
0	2	2	1	1
1	4	4	2	2
2	8	8	4	4
3	16	16	8	8
4	-	32	-	16

[156] [Table 11]

Normal cyclic prefix			Extended cyclic prefix	
Normal subframe	Special subframe,configuration3, 4, 8	Special subframe,configuration1, 2, 6, 7, 9	Normal subframe	Special subframe,configuration1, 2, 3, 5, 6
4		8		

[157] An EPDCCH can use either localized or distributed transmission, differing in the mapping of ECCEs to EREGs and PRB pairs. One or two sets of PRB pairs which a UE shall monitor for EPDCCH transmissions can be configured. All EPDCCH candidates in EPDCCH set S_p (i.e., EPDCCH-PRB-set) use either only localized or only distributed transmission as configured by higher layers. Within EPDCCH set S_p in subframe k, the ECCEs available for transmission of EPDCCHs are numbered from 0 to $N_{ECCE,p,k}$—1. ECCE number n is corresponding to the following EREG(s):

[158] - EREGs numbered $(n \bmod N^{ECCE}_{RB})+jN^{ECCE}_{RB}$ in PRB index floor(n/N^{ECCE}_{RB}) for localized mapping, and

[159] - EREGs numbered floor $(n/N^{Sm}_{RB})+jN^{ECCE}_{RB}$ in PRB indices $(n+j\max(1,N^{Sp}_{RB}/N^{EREG}_{ECCE}))\bmod N^{Sp}_{RB}$ for distributed mapping,

[160] where $j=0,1,\ldots,N^{EREG}_{ECCE}-1$, N^{EREG}_{ECCE} is the number of EREGs per ECCE, and $N^{ECCE}_{RB}=16/N^{EREG}_{ECCE}$ is the number of ECCEs per RB pair. The PRB pairs constituting EPDCCH set S_p are assumed to be numbered in ascending order from 0 to $N^{Sp}_{RB}-1$.

[161] Case A in Table 10 applies when:

[162] - DCI formats 2, 2A, 2B, 2C or 2D is used and $N^{DL}_{RB}\geq 25$, or

[163] - any DCI format when n_{EPDCCH}<104 and normal cyclic prefix is used in normal subframes or special subframes with configuration 3, 4, 8.

[164] Otherwise case B is used. The quantity n_{EPDCCH} for a particular UE is defined as the number of downlink resource elements (k,l) in a PRB pair configured for possible EPDCCH transmission of EPDCCH set S_0 and and fulfilling all of the following criteria,

[165] - they are part of any one of the 16 EREGs in the physical resource-block pair,

[166] - they are assumed by the UE not to be used for CRSs or CSI-RSs,

[167] - the index l in a subframe fulfils $l \geq l_{EPDCCHStart}$.

[168] where $l_{EPDCCHStart}$ is given based on higher layer signaling '*epdcch*-StartSymbol-r11', higher layer signaling '*pdsch*-Start-r11', or CFI value carried by PCFICH.

[169] The mapping to resource elements (k,l) on antenna port p meeting the criteria above is in increasing order of first the index k and then the index l, starting with the first slot and ending with the second slot in a subframe.

[170] For localized transmission, the single antenna port p to use is given by Table 12 with $n' = n_{ECCE,low} \bmod N^{ECCE}_{RB} + n_{RNTI} \bmod \min(N^{ECCE}_{EPDCCH}, N^{ECCE}_{RB})$, where $n_{ECCE,low}$ is the lowest ECCE index used by this EPDCCH transmission in the EPDCCH set, n_{RNTI} corresponds to the RNTI associated with the EPDCCH transmission, and N^{ECCE}_{EPDCCH} is the number of ECCEs used for this EPDCCH.

[171] [Table 12]

n'	Normal cyclic prefix		Extended cyclic prefix
	Normal subframes,Special subframes,configurations3, 4, 8	Special subframes, configurations1, 2, 6, 7, 9	Any subframe
0	107	107	107
1	108	109	108
2	109	-	-
3	110	-	-

[172] For distributed transmission, each resource element in an EREG is associated with one out of two antenna ports in an alternating manner where $p \in \{107,109\}$ for normal cyclic prefix and $p \in \{107,108\}$ for extended cyclic prefix.

[173] Recently, machine type communication (MTC) has come to the fore as a significant communication standard issue. MTC refers to exchange of information between a machine and an eNB without involving persons or with minimal human intervention. For example, MTC may be used for data communication for measurement/

sensing/reporting such as meter reading, water level measurement, use of a surveillance camera, inventory reporting of a vending machine, etc. and may also be used for automatic application or firmware update processes for a plurality of UEs. In MTC, the amount of transmission data is small and UL/DL data transmission or reception (hereinafter, transmission/reception) occurs occasionally. In consideration of such properties of MTC, it would be better in terms of efficiency to reduce production cost and battery consumption of UEs for MTC (hereinafter, MTC UEs) according to data transmission rate. Since the MTC UE has low mobility, the channel environment thereof remains substantially the same. If an MTC UE is used for metering, reading of a meter, surveillance, and the like, the MTC UE is very likely to be located in a place such as a basement, a warehouse, and mountain regions which the coverage of a typical eNB does not reach. In consideration of the purposes of the MTC UE, it is better for a signal for the MTC UE to have wider coverage than the signal for the conventional UE (hereinafter, a legacy UE).

[174] When considering the usage of the MTC UE, there is a high probability that the MTC UE requires a signal of wide coverage compared with the legacy UE. Therefore, if the eNB transmits a PDCCH, a PDSCH, etc. to the MTC UE using the same scheme as a scheme of transmitting the PDCCH, the PDSCH, etc. to the legacy UE, the MTC UE has difficulty in receiving the PDCCH, the PDSCH, etc. Therefore, the present invention proposes that the eNB apply a coverage enhancement scheme such as subframe repetition (repetition of a subframe with a signal) or subframe bundling upon transmission of a signal to the MTC UE having a coverage issue so that the MTC UE can effectively receive a signal transmitted by the eNB. For example, the PDCCH and PDSCH may be transmitted to the MTC UE having the coverage issue in a plurality of subframes (e.g. about 100 subframes).

[175] FIG. 6 illustrates an example of signals band for MTC.

[176] As one method for reducing the cost of the MTC UE, an operation of the MTC UE may be performed at a reduced UE downlink and uplink bandwidth of 1.4 MHz, for example, regardless of an operating system bandwidth of a cell. At this time, a subband (narrowband) for operating the MTC UE may always be located at the center (e.g., 6 center PRBs) of a cell as shown in FIG. 6(a), or several subbands for MTC may be provided for one subframe to multiplex MTC UEs as shown in FIG. 6(b), whereby the UEs may use their respective subbands different from each other or the UEs use the same subband not the subband of 6 center PRBs.

[177] In this case, the MTC UE cannot receive a legacy PDCCH transmitted through a full system band normally, and transmission of PDCCH for the MTC UE from an OFDM symbol region within which the legacy PDCCH is transmitted may not be preferable due to multiplexing issue with a PDCCH transmitted to another UE. As one method for

solving this, it is required to introduce a control channel transmitted within a subband where MTC is operated for the MTC UE. As a downlink control channel for such a low-complexity MTC UE, the legacy EPDCCH may be used as it is. Or, M-PDCCH for the MTC UE which is a control channel of a modified type of the legacy PDCCH/ EPDCCH may be introduced. Hereinafter, in the present invention, the legacy EPDCCH or M-PDCCH for the low-complexity MTC UE or normal complexity MTC UE will be referred to as M-PDCCH. Also, MTC-EPDCCH is hereinafter used to refer to M-PDCCH.

[178] A data channel (e.g., PDSCH, PUSCH) and/or a control channel (e.g., M-PDCCH, PUCCH, PHICH) may be transmitted for coverage enhancement (CE) of the UE by using a repetition or TTI bundling scheme through multiple subframes. The control/ data channel may be transmitted by additionally using cross-subframe channel estimation and frequency (narrowband) hopping for CE. In this case, cross-subframe channel estimation means a channel estimation method means channel estimation using a reference signal within a subframe of a corresponding channel and a reference signal within neighboring subframe(s).

[179] The MTC UE may need CE of 15dB, for example. However, all MTC UEs do not exist in an environment that CE is needed. Also, the same requirements of QoS are not applied to all MTC UEs. For example, since devices such as sensor and meter have low mobility and are likely to be located in a shaded area even while having a small amount of data transmission and reception, the devices may need high CE. However, wearable devices such as smart watch may have mobility and are likely to be located in a place not a shaded area while having a relatively large amount of data transmission and reception. Therefore, all MTC UEs do not need CE of high level, and their requirement capability may be varied depending on their type.

[180] In the present invention, an operation for monitoring M-PDCCH by means of an MTC UE (which needs coverage enhancement (CE)) will be suggested. Hereinafter, M-PDCCH monitoring, search space monitoring, or M-PDCCH candidates monitoring may mean that reception or detection of M-PDCCH is attempted within a corresponding search space or from one of M-PDCCH candidates configuring the corresponding search space.

[181] In the following embodiments, the expression "assume" may mean that an entity for transmitting a channel transmits the channel to be suitable for the corresponding "assumption". An entity for receiving the channel may receive or decode the channel to be suitable for the corresponding "assumption" provided that the channel has been transmitted to be suitable for the corresponding "assumption".

[182] FIG. 7 illustrates repeated transmission of a channel for coverage enhancement.

[183] A search space for M-PDCCH may be configured over a plurality of downlink

subframes. For example, M-PDCCH search space having an aggregation level L and a repetition level R is defined by a set of M-PDCCH candidates. In this case, each M-PDCCH candidate may be repeated within a set of R number of consecutive downlink subframes. Referring to FIG. 7, in an example of maximum repetitions R_{max}=8 and a possible repetition level of $R \in \{1, 2, 4, 0\}$, a UE may attempt decoding of M-PDCCH by assuming that repetition of M-PDCCH (transmitted at an aggregation level L) exists in each of R number of consecutive downlink subframes. For example, the UE may attempt decoding of M-PDCCH by regarding signals received from each of 8 subframes as those of the same M-PDCCH in case of a repetition level $R = 8$ and attempt decoding of different M-PDCCHs in each of 8 subframes in case of a repetition level $R = 1$.

[184] In FIG. 7, repetition of a channel is performed over consecutive downlink subframes. However, a data channel and/or a control channel (hereinafter, data/control channel) transmitted to/from the MTC UE which needs CE may be transmitted by being repeated through non-consecutive subframes. For example, the control/data channel for a specific MTC UE may not be in all downlink subframes but may be restricted to some downlink subframes. Non-consecutive downlink subframes available at the MTC UE may be configured in such a manner that a downlink subframe group comprised of one or more consecutive downlink subframes is repeated with a periodicity greater than the number of subframes within the downlink subframe group. In other words, the data/control channel may be transmitted not in physically consecutive subframes, but transmitted in transmitted in each of physically non-consecutive subframes (excluding uplink subframes in case of downlink transmission, downlink subframes in case of uplink transmission, and/or subframes except subframe used for other purpose of use and cannot be used for data/control channel transmission). Use of non-consecutive (downlink or uplink) subframes for repeated transmission of the data/control channel of the MTC UE may increase transmission/reception latency. However, as time diversity effect is obtained in the time domain by use of non-consecutive subframes, the number of repetitions or the number of subframes used for channel transmission may be reduced as compared with transmission based on consecutive subframes. Therefore, overall system throughput may be increased. The embodiments of the present invention, which will be described later, suggest UE operation and transmission subframe during transmission/reception of a corresponding channel when a data/control channel transmitted from MTC UE is transmitted with repetition through consecutive subframes or non-consecutive subframes.

[185] In the following embodiments, each search space within an interval where a UE monitors M-PDCCH (CSS and/or USS) may be configured over one or more (consecutive or non-consecutive) downlink subframes. That is, a search space for

reception of the same M-PDCCH may be configured in each of one or more downlink subframes.

[186] For example, referring to FIG. 8, in case of no CE or CE having a repetition level = 1, each of CSSs of FIG. 8 may be CSS on which a respective M-PDCCH can be transmitted. At this time, a CSS starting subframe may mean a first subframe of paging occasions for allowing a UE to monitor M-PDCCH for a paging message. As another example, referring to FIG. 9, in case of no CE or CE having a repetition level = 1, each of CSSs of FIG. 9 may be CSS on which a respective M-PDCCH can be transmitted. At this time, a CSS starting subframe may mean a first subframe of a RAR window for allowing a UE to monitor M-PDCCH for scheduling RAR.

[187] In case of coverage enhancement (CE), M-PDCCH may be transmitted by being repeated once or multiple times. Therefore, a search space where M-PDCCH (hereinafter, paging M-PDCCH) will be monitored may be configured repeatedly over a plurality of downlink subframes, and a UE may attempt repeated reception of M-PDCCH within search spaces within the plurality of downlink subframes. If CE having a repetition level greater than 1 is applied, for example, each CSS shown in FIG. 8 may be a plurality of consecutive subframes that may have repetitions of M-PDCCH. If CE having a repetition level greater than 1 is applied, as another example, a plurality of CSSs within the same paging occasion shown in FIG. 8 may be CSSs for repetitions of the same M-PDCCH. If CE having a repetition level greater than 1 is applied, as still another example, a plurality of CSSs over a plurality of paging occasions shown in FIG. 8 may be CSSs for repetitions of the same M-PDCCH.

[188] ■ Section 1. M-PDCCH CSS for paging message scheduling

[189] In Section 1, details on M-PDCCH CSS for paging message scheduling are discussed.

[190] The paging message is used to notify UE(s) under RRC_IDLE and UE(s) under RRC_CONNECTED of system information modification.

[191] An eNB initiates a paging process by transmitting the paging message at a paging occasion of a UE. The eNB may address a plurality of UEs within the paging message by including a paging record (*PagingRecord*) per UE. The paging record may include information indicating NAS (non-access stratum) identifier of a UE which is paged and information indicating the origin of paging. One paging occasion means a subframe having P-RNTI transmitted on PDCCH/M-PDCCH addressing the paging message. A paging frame (PF) means one radio frame that includes one or a plurality of paging occasion(s).

[192] The UE may use discontinuous reception (DRX) in an idle mode to reduce power consumption. If DRX is used, the UE monitors only one paging occasion per DRX cycle.

[193] The paging message may be transmitted through a PDSCH, and the PDSCH carrying the paging message may be scheduled by PDCCH/M-PDCCH.

[194] For paging message scheduling, multiple narrowbands can be configured by eNB. Then, a narrowband location for a paging occasion monitoring of a UE is determined by at least UE ID at least for paging record(s). However, the narrowband location and paging occasion for common signal transmission (e.g., SI update, earthquake and tsunami warning system (ETWS), and/or commercial mobile alert system (CMAS)) is not determined yet. To reduce UE complexity, it would be beneficial to apply the same paging occasion and narrowband location for paging record(s) reception and other information reception such as SI update, ETWS, and CMAS. For example, the UE may attempt reception of M-PDCCH for scheduling the paging message on the same narrowband at the same paging occasion for SI update and reception of ETWS and CMAS instead of monitoring different paging occasions and/or different narrowbands for SI update and reception of ETWS and CMAS.

[195] FIG. 8 illustrates a configuration of a common search space (CSS) for paging according to the present invention.

[196] Under the assumption that a paging occasion is a time region for M-PDCCH monitoring for paging message scheduling, a UE can monitor a common search space (CSS) within a paging occasion to check paging message transmission. Depending on duration of paging occasion and period of CSS starting subframe, there can be multiple CSS monitoring opportunities within a paging occasion as shown in FIG. 8. The period and offset of CSS starting subframe location can be configured by eNB. In this case, offset k_{offset} of the CSS starting subframe may mean a difference from a reference subframe n (e.g., subframe 0) to a subframe $n+k_{offset}$ in which the CSS starting subframe is first applied.

[197] The composition of decoding candidates (i.e. M-PDCCH candidates) and a subset of $\{L, R\}$ for CSS for paging should be composed to supports all UEs with different CE levels. In this case, L indicates an aggregation level, and M-PDCCH of the aggregation level L is transmitted using aggregation of L number of M-CCEs. ECCE may be used as M-CCE, and CCE for MTC UE may newly be defined as M-CCE for MTC UE.

[198] To transmit paging message adapt to the target CE level, a subset of $\{L, R\}$ of CSS for paging needs to be composed to cover all range of CE levels or all range of repetition numbers. One simple configuration is $\{8, R1\}$, $\{16, R1\}$, $\{24, R1\}$, $\{24, R2\}$, $\{24, R3\}$, $\{24, R4\}$ where $R1 = 1$ and $R4$ is the maximum repetition level.

[199] In the present invention, a paging occasion may be defined as an interval where a UE monitors a paging M-PDCCH. For example, the UE may attempt reception of (same) paging M-PDCCH (or M-PDCCH scrambled by P-RNTI) within CSS(s) existing in the paging occasion or paging M-PDCCH search space(s) as shown in FIG. 8. Since the

paging M-PDCCH may be transmitted in any one of CSS(s) within the paging occasion, the UE continuously monitors the CSS(s) within the paging occasion. If the paging M-PDCCH (or M-PDCCH scrambled by P-RNTI) is received within the corresponding interval, the UE may receive a PDSCH carrying the corresponding paging message even though a paging message scheduled by the corresponding M-PDCCH, that is, a PDSCH carrying paging is transmitted outside a paging occasion interval.

[200] A duration of the paging occasion may be configured to be a multiple of the number of subframes configuring CSSs or search spaces on which the paging M-PDCCH is transmitted. For example, if the paging M-PDCCH search space is configured in each of R number of (consecutive or non-consecutive) downlink subframes, the paging occasion may be configured to have a duration of R*X number of subframes (where X is a positive integer).

[201] ■ Section 2. M-PDCCH CSS for RAR scheduling

[202] FIG. 9 illustrates a configuration of a common search space (CSS) for RAR according to the present invention.

[203] There would be multiple narrowbands for CSS for RAR scheduling, and the narrowband location of a UE for RAR monitoring is determined by PRACH resource set.

[204] After transmitting PRACH, a UE would try to receive RAR. Similar to paging occasion, there can be multiple CSS regions within a RAR window as depicted in Figure 9. So, the UE can monitor M-PDCCH scheduling RAR in CSS region(s) within the RAR window.

[205] A subset of $\{L, R\}$ and composition of decoding candidates of CSS for RAR can depend on CE level of corresponding PRACH resource set. For example, for each CE level, PRACH resource set(s) and available repetition level(s) may be configured. In this case, the UE may monitor a CSS, that is, M-PDCCH in accordance with a set of $\{L, R\}$ configured for a CE level associated with a PRACH resource used for a successful RACH procedure. Regardless of CSS and USS, same composition of decoding candidates and same subset of $\{L, R\}$ can be used for same CE level of the search space. For example, the UE may monitor a CSS and a USS in accordance with $\{L, R\}$ of the same set with respect to the same CE level.

[206] The present invention suggests that a RAR window interval should be defined as an interval where a UE monitor M-PDCCH (hereinafter, RAR M-PDCCH) for scheduling RAR. That is, as shown in FIG. 9, the UE may attempt reception of RAR M-PDCCH (e.g., M-PDCCH scheduled by RA-RNTI) on CSS(s) existing within a RAR window or a search space(s) (hereinafter, RAR M-PDCCH search space) on which RAR M-PDCCH is transmitted. If the UE receives RAR M-PDCCH within the corresponding interval, the UE may receive a PDSCH through which the corresponding RAR is

transmitted, even though RAR (e.g., PDSCH carrying RAR) scheduled by the corresponding M-PDCCH is transmitted outside the RAR window interval.

[207] A duration of the RAR window may be configured to become a multiple of the number of subframes configuring CSSs or RAR M-PDCCH search spaces. For example, if RAR M-PDCCH search space is configured in each of R number of (consecutive or non-consecutive) downlink subframes, the RAR window may be configured to have a duration of R*X number of subframes (in this case, X is a positive integer).

[208] ■ Section 3. M-PDCCH CSS for other purposes

[209] M-PDCCH CSS can be used to transmit DCIs for other purposes except paging message and RAR scheduling. For example, M-PDCCH CSS can be used for transmission of DCI for unicast data, DCI for TPC, DCI for enhanced interference management and traffic adaptation (eIMTA), and DCI for enhanced PHICH (EPHICH). If CSS is used to transmit these DCIs, the narrowband location, monitoring subframe location, and decoding candidates composition need to be specified. Hereinafter, the CSS will be referred to as CSS_regular or CSS_others.

[210] CSS for these purposes (i.e. CSS_regular) can be located in the same narrowband to USS. Then, a UE does not need to re-tune its operating frequency to monitor this CSS.

[211] To reconfigure CE level of a UE, the CSS needs to support the maximum CE level of the cell considering CE level reconfiguration message can be transmitted by this CSS. Therefore, CE level or a subset of $\{L, R\}$ composing the CSS should support all CE level of the cell.

[212] FIG. 10 illustrates the example of the monitoring time region of USS and CSS.

[213] Period of starting subframe for M-PDCCH USS monitoring and CSS monitoring can be configured independently. The period of CSS monitoring can be longer than the period of USS, since CE level of USS and CSS can be different and CSS can be occurred sparsely to reduce UE complexity.

[214] Referring to Math Figure 1 which is a hashing function, it is noted that $Y_{p,k}$ is varied depending on n_{RNTI} which is UE ID. In this way, CCE(s) or ECCE(s) configuring decoding candidates in the USS is(are) determined UE-specifically to be monitored by a specific UE. M-PDCCH CSS can be monitored by a group of MTC UEs. Therefore, for CSS, there should not be a hashing function to randomize the starting ECCE location composing a search space UE-specifically.

[215] ■ Section 4. Coverage enhancement level of CSS

[216] For transmission of a broadcast PDSCH (e.g., paging, RAR), CSSs for other purposes such as unicast data, TPC, eIMTA DCI and EPHICH may exist, and USS where a UE monitors unicast data may exist. Hereinafter, a coverage enhancement level of corresponding search spaces will be described.

[217] The present invention suggests that a plurality of SS types exist as follows in accordance with a coverage enhancement level supported by a search space or repetitions of M-PDCCH.

[218] - Method 1.

[219] In view of the UE, two types of search spaces (SSs) may exist as follows:

[220] * SS type 1: SS supporting all coverage enhancement levels or all repetitions of M-PDCCH, and

[221] * SS type 2: SS where the number of repetitions of M-PDCCH which is supported is varied depending on a coverage enhancement level of the UE.

[222] In this case, the UE may assume that CSS for paging and/or CSS_regular has SS type 1, and CSS and/or USS for RAR has SS type 2.

[223] Alternatively, as SS monitored by the UE, one SS having SS type 1 and one SS having SS type 2 may exist. CSS for paging and/or CSS_regular may be the same as SS having SS type 1, and CSS and/or USS for RAR may be the same as SS having SS type 2.

[224] - Method 2.

[225] When N number of coverage enhancement levels (or the number of repetitions of M-PDCCH) supported by a cell exist, in view of the cell, a plurality of SS types may exist as follows:

[226] * SS type 1: SS supporting coverage enhancement level 1 (or the number of repetitions R_1 of M-PDCCH),

[227] * SS type 2: SS supporting coverage enhancement level 2 (or the number of repetitions R_2 of M-PDCCH),

[228] ...

[229] * SS type N: SS supporting coverage enhancement level N (or the number of repetitions R_N of M-PDCCH),

[230] * SS type N+1: SS supporting all coverage enhancement levels (or all repetitions for M-PDCCH).

[231] In this case, SS supporting the coverage enhancement level n may mean SS supporting the coverage enhancement levels 1 to n or the maximum number of repetitions R_n of M-PDCCH.

[232] In this case, the UE may assume that the CSS for paging and CSS_regular has SS type N+1, and the CSS for RAR and/or USS has SS type k if the coverage enhancement level of the UE is k.

[233] ■ Section 5. Relationship between search spaces

[234] **CSS for paging (i.e., CSS_paging)**

[235] It is a CSS for paging monitoring in RRC_IDLE state. Since UEs in different CE levels monitor the same CSS for paging scheduling, it should be designed to cover all

the CE levels. CSS_paging are configured by SIB. In other words, the configuration of CSS_paging may be transmitted through SIB. The UE may identify the configuration of CSS_paging by reading SIB. The UE may monitor M-PDCCH candidates of CSS within subframe(s) and/or narrowband(s) according to the CSS_paging configuration.

[236] **CSS for** RAR corresponding to initial RACH procedure (i.e., CSS_RAR)

[237] Using CSS for RAR, a UE can monitor RAR, Msg3 (for retransmission), and Msg4. Though it can be considered to allow separate SS configurations for Msg3 re-transmission and Msg4 scheduling M-PDCCH from the SS configuration for RAR, given that those (i.e. RAR, Msg3 and Msg4) will be used only for initial access, the present invention proposes that the same configuration is used for initial RACH procedure. Required configurations for CSS_RAR can be configured by SIB per CE level. Then, in a UE perspective, configurations for CSS_RAR can be determined based on the CE level of PRACH resource set used for the latest PRACH transmission.

[238] **CSS for others (i.e., CSS_others or CSS_regular)**

[239] M-PDCCH CSS can be used to transmit DCIs for other purposes except paging message and initial RAR scheduling. For example, CSS is required to transmit TPC, unicast data for reconfiguration (such as CE level, transmission mode, USS recon-figuration), a DCI transmitting multiple HARQ-ACK corresponding to PUSCH to multiple UEs (if supported), transmit RAR corresponding to PRACH triggered by M-PDCCH order. CSS for these purposes can be located in the same narrowband to USS once a UE is connected to the network. Then, a UE does not need to re-tune its operating frequency to monitor this CSS. A UE can monitor CSS_others (i.e., CSS_regular) and USS simultaneously.

[240] If there is a complexity issue, TDM of CSS and USS monitoring can be considered. In other words, CSS and USS are time-division multiplexed, whereby the CSS and the USS may not be monitored at the same time.

[241] If CSS for other purposes are not defined, legacy PUCCH TPC via DCI format 3/3A cannot be supported. Then, if downlink traffic is occurred sparsely, it could be difficult to adopt PUCCH power since PUCCH TPC is accomplished by accumulated way. So, other way to handle this issue needs to be considered such as absolute PUCCH TPC via DL grant or unicast DCI for PUCCH TPC transmitted by USS. Thus, at least for CE mode A (for TCP and reconfiguration), CSS_others needs to be supported.

[242] **USS**

[243] USS is a search space for unicast data scheduling. Configurations for USS can be configured by SIB and Msg4. If necessary, reconfiguration can be utilized by radio resource control (RRC) layer (i.e. RRC signal). Configurations for USS also can be applied for CSS_others. In this case, individual configurations for CSS_others and USS may not be required.

[244] FIG. 11 illustrates a procedure of configuring a search space according to the present invention.

[245] Referring to FIG. 11, the UE may receive a list of search space (SS) configurations per CE level for RAR through SIB (S1101). The UE may transmit RACH preamble through PRACH by using a PRACH resource. PRACH resource(s) per CE level may be configured by SIB. The UE may monitor M-PDCCH for scheduling a response to the RACH preamble transmitted therefrom, that is, a response to transmission of the PRACH in a search space (S1103). The UE may assume that a search space for M-PDCCH scheduling the RAR depends on SS configuration (e.g., CSS_RAR configuration) received through the SIB. The UE which has received RAR M-PDCCH may receive RAR in accordance with DCI carried by the RAR M-PDCCH (S1105).

[246] Initial configuration for RAR, Msg3 and/or Msg4 may depend on SS configuration per CE level received (S1101) through SIB (S1121). The UE may monitor M-PDCCH for scheduling Msg4, which includes CSS configuration/reconfiguration and/or USS configuration/reconfiguration parameters, in the SS according to initial configuration through SIB (S1121). For example, the UE may monitor Msg4 M-PDCCH by assuming that the maximum number of repetitions, narrowband, PRB-set, etc. which are the same as those of CSS for RAR, are also applied to M-PDCCH (hereinafter, Msg4 M-PDCCH) for scheduling Msg4 (S1121). The UE which has received Msg4 M-PDCCH may receive Msg4 in accordance with DCI of the Msg4 M-PDCCH (S1123). The Msg4 may carry RRC message that includes UE-specific configuration for USS and/or CSS. In this case, the UE may monitor M-PDCCH by applying the UE-specific SS configuration instead of initial SS configuration (S1125).

[247] The UE may monitor M-PDCCH order within the CSS according to the UE-specific CSS configuration (S1141). The UE which has received the M-PDCCH order may receive RAR in accordance with scheduling information carried by the M-PDCCH order (S1143).

[248] The UE may monitor M-PDCCH for scheduling RRC message having UE-specific reconfiguration parameter(s) within the CSS according to the UE-specific CSS configuration (S1161). The UE-specific reconfiguration may include M-PDCCH configuration. The UE which has received the M-PDCCH may receive a PDSCH carrying the RRC message in accordance with scheduling information (that is, DCI) of the M-PDCCH (S1163). The UE may reconfigure M-PDCCH search space in accordance with the UE-specific reconfiguration.

[249] Table 13 illustrates parameters and configuration details required for search spaces. All or some of the parameters illustrated in Table 13 may be configured and/or reconfigured in accordance with Table 13.

[250] [Table 13]

Parameters	Configuration details				Description
	CSS_paging	CSS_RAR	CSS_others	USS	
Subset of L	Fixed to {8, 16, 24}			{1, 2, 4, 8, 16, 24}	
R_{max}	Configurable by SIB.	Configured by SIB per CE level (configuration can be shared for CSS_RAR, CSS_others, USS).For CSS_others/USS, it can be reconfigured by RRC.			Subset of repetition numbers is determined based on R_{max}. Details are described in Subsection 5.1.
PRB-sets	Configured by SIB.	Configured by SIB per CE level specific and cell-specific.	Alt 1. Configured by Msg4 per UE.Alt 2. Configured by SIB per CE level (in this case, same configuration for CSS_RAR, CSS_others, USS).It can be reconfigured by RRC.		This configuration includes the number of PRB-sets, PRB size/ location of each PRB-set.
Transmission type	Configured by SIB per PRB-set.	Configured by SIB per PRB-set.	Alt 1. Configured by Msg4 per UE (the network ensures the same type is used beween CSS_others and USS in case both are monitored at the same time).Alt 2. Configured by SIB per CE level (in this case, same configuration for CSS_RAR, CSS_others, USS).It can be reconfigured by RRC.		
Narrowband	Determined	Based on	Default value can be		

	by UE ID among paging narrowbands configured by SIB.	PRACH resource set where RAR narrowband corresponding to each PRACH resource set is configured by SIB.	CSS_RAR's narrowband location. Configurable by Msg 4 per UEIt can be reconfigured by RRC.	
M-PDCCH monitoring starting	Alt 1. Configured by SIB per CE level.Alt 2. Configured by SIB regardless of CE level (one maximum value to reset monitoring starting subframe).			See FIG. 7 and Subsection 5.1.
M-PDCCH starting subframe	Determined by repetition number R per repetition number R.	Alt 1. Determined by R_{max} for CE Mode A, determined by repetition number R per repetition number R for CE Mode B.Alt 2. Determined by repetition number R per repetition number R.		See FIG. 7 and Subsection 5.1.

[251] In Table 13, a merged cell means that the configuration can be shared by corresponding search spaces, so individual configuration is not needed for each search space. For example, referring to Table 13, "Fixed to {8, 16, 24}" which is the description of a subset of an aggregation level L exists within a cell merged for CSS_paging, CSS_RAR and CSS_others (i.e., CSS_regular), and thus means that a corresponding parameter is not required to be configured individually for CSS_paging, CSS_RAR and CSS_others(i.e. CSS_reguar) and a common parameter is applied to CSS_paging, CSS_RAR and CSS_others. According to Table 13, the UE may attempt reception of M-PDCCH at an aggregation level $L\in\{8, 16, 24\}$ for CSS_paging, CSS_RAR and CSS_others, and may attempt reception of M-PDCCH at $L\in\{1, 2, 4, 8, 16, 24\}$ for the USS.

[252] Reconfigurable parameters in Table 13 mean that the same value as initial configuration or default configuration is applied until a corresponding parameter is reconfigured, whereby search space(s) is(are) configured.

[253] For example, referring to Table 13, the maximum number of repetitions R_{max} of M-PDCCH may be provided through SIB as a configuration for CSS_RAR. The UE may monitor CSS_RAR, CSS_others and/or USS by assuming that R_{max} included in the SIB is applied to CSS_RAR, CSS_others, and USS. That is, the UE may monitor rep-

etitions of M-PDCCH in SS within maximum R_{max} number of subframes. According to Table 13, since R_{max} for CSS_others and/or USS (hereinafter, CSS_others/USS) may be reconfigured, if R_{max} for CSS_others/USS is reconfigured by RRC signal, the UE may monitor CSS_others/USS in accordance with the reconfigured R_{max}. In other words, the UE may monitor CSS_others/USS in accordance with R_{max} for CSS_RAR until R_{max} for CSS_others/USS is received.

[254] For another example, referring to parameters of PRB-sets in Table 13, PRBs on which PRB-set(s) for CSS_RAR, that is, RAR M-PDCCH may be transmitted may be configured CE level-specifically and cell-specifically by SIB. Referring to Alt 2, these PRB-sets configured per CE level may be applied to CSS_others and USS by SIB. Since PRB-set parameter for CSS_others and USS may be reconfigured by RRC, the UE may monitor CSS_others/USS by applying PRB-set(s) for CSS_RAR until reconfiguration PRB-set parameter for CSS_others/USS is received, and may monitor CSS_others/USS by applying the reconfiguration PRB-set parameter if the reconfiguration PRB-set parameter for CSS_others/USS is received. For example, if PRB-set(s) of CSS_RAR are fixed to 6, the UE may monitor M-PDCCH USS by assuming all PRBs within a narrowband according to CSS_RAR configuration as PRB-set(s) for USS until configuration of separate PRB-set(s) for USS is received.

[255] For still another example, referring to a narrowband parameter of Table 13, a narrowband (hereinafter, RAR narrowband) having CSS_RAR may be determined based on a PRACH resource set. In this case, a corresponding RAR narrowband per PRACH resource set is configured by SIB. A default narrowband location of CSS_others and/or USS may be a narrowband location of CSS_RAR. A narrowband for CSS_others/USS may be configured per UE by Msg4, and may be reconfigured by RRC. Therefore, the UE may monitor CSS_others/USS on the same narrowband as that for CSS_RAR until a narrowband parameter for CSS_others/USS is received, and if Msg4 for CSS_others/USS or reconfiguration RRC message is received, may monitor CSS_others/USS on a narrowband according to the Msg4 or the RRC message.

[256] □ Subsection 5.1. Aggregation levels and repetition numbers

[257] Search space configuration parameters of Table 13 may be applied as follows in view of an aggregation level and the number of repetitions. For example, a subset (and/or starting subframe of M-PDCCH SS and/or starting subframe of M-PDCCH) of the number of repetitions R based on R_{max} may be determined in accordance with the following description.

[258] **CSS for paging (i.e., CSS_paging)**

[259] - Aggregation levels:

[260] Since data transmission scheduled by CSS is targeted to multicast/broadcast, similar

to PDCCH CSS, some high aggregation levels can be supported. Aggregation levels (ALs) {8, 16, 24} can be supported for normal CP and ALs {4, 8, 12} can be supported for extended CP.

[261] - Repetition numbers:

[262] A subset of R for CSS for paging monitoring depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB. To support wide range of repetition numbers, the subset of R monitored for CSS_paging can be {$R_{max}/64$, $R_{max}/16$, $R_{max}/4$, R_{max}}.

[263] **CSS for** RAR corresponding to initial RACH procedure (i.e., CSS_RAR)

[264] - Aggregation levels:

[265] Similar to CSS_paging, ALs $L \in \{8, 16, 24\}$ can be supported for normal CP and ALs $L \in \{4, 8, 12\}$ can be supported for extended CP.

[266] - Repetition numbers:

[267] For CSS scheduling RAR, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level. The subset of R monitored for CSS_RAR can be {$R_{max}/4$, $R_{max}/2$, R_{max}}.

[268] **CSS for others (i.e., CSS_others)**

[269] - Aggregation levels:

[270] Similar to CSS_paging, ALs $L \in \{8, 16, 24\}$ can be supported for normal CP and ALs $L \in \{4, 8, 12\}$ can be supported for extended CP.

[271] - Repetition numbers:

[272] For CSS_others, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level or Msg4. R_{max} can be reconfigured by RRC if necessary. The subset of R monitored for CSS_others can be {$R_{max}/4$, $R_{max}/2$, R_{max}}. Or, to reduce UE complexity, the subset of R monitored for CSS_others can be {$R_{max}/2$, R_{max}}.

[273] **USS**

[274] - Aggregation levels:

[275] For CE Mode A, ALs $L \in \{1, 2, 4, 8, 16, 24\}$ are supported for normal CP. ALs $L \in \{1, 2, 4, 8, 12\}$ are supported for extended CP. For CE Mode B, ALs $L \in \{8, 16, 24\}$ is supported for normal CP. ALs $L \in \{4, 8, 12\}$ are supported for extended CP.

[276] - Repetition numbers:

[277] For USS, the subset of R depends on the maximum R (i.e., R_{max}) where R_{max} is configured by SIB per CE level or Msg4. R_{max} can be reconfigured by RRC if necessary. The subset of R monitored for USS can be {$R_{max}/4$, $R_{max}/2$, R_{max}}. Or, to support higher R to CSS_others for CE level reconfiguration reliably, subset of R monitored for USS can be {$R_{max}/8$, $R_{max}/4$, $R_{max}/2$}.

[278] ■ Section 6. Collision of M-PDCCH(s)

[279] If there are some subframes not available for downlink transmission, M-

PDCCH/PDSCH transmission or repetitions can be postponed till the next available subframe. It can be applied in case unavailable subframes are aligned between eNB and UE.

[280] FIG. 12 illustrates a configuration of M-PDCCH repeated transmission according to the present invention.

[281] If a small interval (e.g., cycle of starting subframe of M-PDCCH search space) of M-PDCCH search space is configured or a large number of invalid subframes, which cannot have M-PDCCH, are provided between M-PDCCH search space starting subframes, M-PDCCH2 transmission may not end until next starting subframe of the search space, in the same manner as M-PDCCH2 transmission of FIG. 12. That is, the subframes configuring two search spaces may be overlapped with each other. In this case, the UE may be in the status that the UE should perform monitoring for M-PDCCH transmitted in a previous search space and monitoring for M-PDCCH transmitted in a next search space. However, this operation may not be preferable due to buffer size and complexity issue of the UE. In this case, the UE may perform reception of M-PDCCH as follows.

[282] - Method 1. If a starting time (hereinafter, subframe #n) of next search space occurs before reception of M-PDCCH is ended, the UE may assume that the M-PDCCH is transmitted up to subframe #n-1 and is not transmitted in subframe #n. In this case, the UE may attempt reception of the M-PDCCH by using repetitions smaller than the number of expected repetitions of M-PDCCH.

[283] - Method 2. If a starting time (hereinafter, subframe #n) of next search space occurs before reception of M-PDCCH is ended, the UE may determine that the M-PDCCH that the UE is receiving is invalid, and may not perform reception of the corresponding M-PDCCH.

[284] - Method 3. If subframe(s) configuring two search spaces are overlapped with each other, the UE may determine that a search space existing at an earlier time is invalid, and may not perform reception of M-PDCCH for one of the two search space, which is first started in a time domain.

[285] FIG. 13 is a block diagram illustrating elements of a transmitting device 10 and a receiving device 20 for implementing the present invention.

[286] The transmitting device 10 and the receiving device 20 respectively include Radio Frequency (RF) units 13 and 23 capable of transmitting and receiving radio signals carrying information, data, signals, and/or messages, memories 12 and 22 for storing information related to communication in a wireless communication system, and processors 11 and 21 operationally connected to elements such as the RF units 13 and 23 and the memories 12 and 22 to control the elements and configured to control the memories 12 and 22 and/or the RF units 13 and 23 so that a corresponding device may

perform at least one of the above-described embodiments of the present invention.

[287] The memories 12 and 22 may store programs for processing and controlling the processors 11 and 21 and may temporarily store input/output information. The memories 12 and 22 may be used as buffers.

[288] The processors 11 and 21 generally control the overall operation of various modules in the transmitting device and the receiving device. Especially, the processors 11 and 21 may perform various control functions to implement the present invention. The processors 11 and 21 may be referred to as controllers, microcontrollers, microprocessors, or microcomputers. The processors 11 and 21 may be implemented by hardware, firmware, software, or a combination thereof. In a hardware configuration, application specific integrated circuits (ASICs), digital signal processors (DSPs), digital signal processing devices (DSPDs), programmable logic devices (PLDs), or field programmable gate arrays (FPGAs) may be included in the processors 11 and 21. Meanwhile, if the present invention is implemented using firmware or software, the firmware or software may be configured to include modules, procedures, functions, etc. performing the functions or operations of the present invention. Firmware or software configured to perform the present invention may be included in the processors 11 and 21 or stored in the memories 12 and 22 so as to be driven by the processors 11 and 21.

[289] The processor 11 of the transmitting device 10 performs predetermined coding and modulation for a signal and/or data scheduled to be transmitted to the outside by the processor 11 or a scheduler connected with the processor 11, and then transfers the coded and modulated data to the RF unit 13. For example, the processor 11 converts a data stream to be transmitted into K layers through demultiplexing, channel coding, scrambling, and modulation. The coded data stream is also referred to as a codeword and is equivalent to a transport block which is a data block provided by a MAC layer. One transport block (TB) is coded into one codeword and each codeword is transmitted to the receiving device in the form of one or more layers. For frequency up-conversion, the RF unit 13 may include an oscillator. The RF unit 13 may include N_t (where N_t is a positive integer) transmit antennas.

[290] A signal processing process of the receiving device 20 is the reverse of the signal processing process of the transmitting device 10. Under control of the processor 21, the RF unit 23 of the receiving device 20 receives radio signals transmitted by the transmitting device 10. The RF unit 23 may include N_r (where N_r is a positive integer) receive antennas and frequency down-converts each signal received through receive antennas into a baseband signal. The processor 21 decodes and demodulates the radio signals received through the receive antennas and restores data that the transmitting device 10 intended to transmit.

[291] The RF units 13 and 23 include one or more antennas. An antenna performs a function for transmitting signals processed by the RF units 13 and 23 to the exterior or receiving radio signals from the exterior to transfer the radio signals to the RF units 13 and 23. The antenna may also be called an antenna port. Each antenna may correspond to one physical antenna or may be configured by a combination of more than one physical antenna element. The signal transmitted from each antenna cannot be further deconstructed by the receiving device 20. An RS transmitted through a corresponding antenna defines an antenna from the view point of the receiving device 20 and enables the receiving device 20 to derive channel estimation for the antenna, irrespective of whether the channel represents a single radio channel from one physical antenna or a composite channel from a plurality of physical antenna elements including the antenna. That is, an antenna is defined such that a channel carrying a symbol of the antenna can be obtained from a channel carrying another symbol of the same antenna. An RF unit supporting a MIMO function of transmitting and receiving data using a plurality of antennas may be connected to two or more antennas.

[292] In the embodiments of the present invention, a UE operates as the transmitting device 10 in UL and as the receiving device 20 in DL. In the embodiments of the present invention, an eNB operates as the receiving device 20 in UL and as the transmitting device 10 in DL. Hereinafter, a processor, an RF unit, and a memory included in the UE will be referred to as a UE processor, a UE RF unit, and a UE memory, respectively, and a processor, an RF unit, and a memory included in the eNB will be referred to as an eNB processor, an eNB RF unit, and an eNB memory, respectively.

[293] The eNB processor of the present invention may configure or reconfigure CSS_paging in accordance with section 1, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_paging, to the UE in accordance with section 1, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for scheduling a paging message within CSS_paging according to CSS_paging configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_paging from the eNB in accordance with section 1, section 5 and/or section 6. The UE may attempt reception of paging M-PDCCH from CSS_paging according to the CSS_paging configuration.

[294] The eNB processor of the present invention may configure or reconfigure CSS_RAR in accordance with section 2, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_RAR, to the UE in accordance with section 2, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for

scheduling RAR, Msg3 and/or Msg4 within a CSS according to CSS_RAR configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_RAR from the eNB in accordance with section 2, section 5 and/or section 6. The UE may attempt reception of RAR M-MPDCCH, Msg3 M-PDCCH and/or Msg4 M-PDCCH from the CSS according to the CSS_RAR configuration.

[295] The eNB processor of the present invention may configure or reconfigure CSS_others in accordance with section 3, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit SIB or RRC message, which includes configuration for CSS_others, to the UE in accordance with section 3, section 5 and/or section 6. The eNB processor may control the eNB RF unit to transmit M-PDCCH for other purpose within a CSS according to CSS_others configuration. The UE processor of the present invention may control the UE RF unit to receive configuration or reconfiguration information on CSS_others from the eNB in accordance with section 3, section 5 and/or section 6. The UE may attempt reception of M-PDCCH for other purpose from the CSS according to the CSS_others configuration.

[296] The eNB processor of the present invention may transmit initial configuration for CSS through SIB in accordance with section 6. The eNB processor may configure CSS and/or USS in accordance with the initial configuration until the other configuration (e.g., UE-specific configuration/reconfiguration) for SS is transmitted. The initial configuration may include a configuration (e.g., narrowband, PRB-set(s), starting subframe and/or period, and the number of maximum repetitions of SS) of time-frequency resources of SS. The eNB processor may transmit M-PDCCH in accordance with the initial configuration until the other configuration for SS is transmitted. For example, the eNB processor may control the eNB RF unit to transmit M-PDCCH by applying the number of repetitions R based on maximum R_{max} according to the initial configuration within the PRB-set according to the initial configuration on a narrowband according to the initial configuration. If the other configuration for SS is transmitted, the eNB processor may control the eNB RF unit to transmit M-PDCCH on the SS configured in accordance with the other configuration. The UE processor may receive the initial configuration for CSS through SIB in accordance with section 6. The UE processor may assume that CSS and/or USS is configured in accordance with the initial configuration until the other configuration (e.g., UE-specific configuration/reconfiguration) for SS is received. The UE processor may monitor M-PDCCH in accordance with the initial configuration until the other configuration for SS is transmitted. For example, the UE processor may control the UE RF unit to receive or monitor M-PDCCH by applying the number of repetitions R based on maximum R_{max} according to the initial configuration within the PRB-set according to the initial con-

figuration on a narrowband according to the initial configuration. If the other configuration for SS is received, the UE processor may control the UE RF unit to receive or monitor M-PDCCH on the SS configured in accordance with the other configuration.

[297] As described above, the detailed description of the preferred embodiments of the present invention has been given to enable those skilled in the art to implement and practice the invention. Although the invention has been described with reference to exemplary embodiments, those skilled in the art will appreciate that various modifications and variations can be made in the present invention without departing from the spirit or scope of the invention described in the appended claims. Accordingly, the invention should not be limited to the specific embodiments described herein, but should be accorded the broadest scope consistent with the principles and novel features disclosed herein.

Industrial Applicability

[298] The embodiments of the present invention are applicable to a BS, a UE, or other devices in a wireless communication system.

Claims

[Claim 1] A method for receiving, by a user equipment (UE), downlink control information (DCI) for the UE, the method comprising:
receiving, by the UE, a common search space configuration for a common search space;
receiving, by the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by monitoring first PDCCH candidates of the common search space according to the common search space configuration; and
receiving, by the UE, a second PDCCH carrying the DCI for the UE by monitoring second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are monitored according to the same configuration as the common search space configuration until the UE receives a UE-specific search space configuration.

[Claim 2] The method according to claim 1,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored on the same narrowband as the narrowband for the common search space until the UE receives a UE-specific search space configuration.

[Claim 3] The method according to claim 1 or 2,
wherein the common search space configuration includes information on a maximum number of repetitions for the common common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored based on the same number as the maximum number of repetitions for the common search space until the UE receives a UE-specific search space configuration.

[Claim 4] The method according to any one of claims 1 to 3,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for monitoring the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for monitoring the second PDCCH candidates until the UE receives a UE-specific search space configuration.

[Claim 5] The method according to any one of claims 1 to 4,
wherein the first PDCCH candidates of the common search space are monitored according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are monitored according to the plurality of aggregation levels.

[Claim 6] A method for transmitting, by a base station (BS), downlink control information (DCI) for a user equipment (UE), the method comprising:
transmitting, by the BS, common search space configuration for a common search space;
transmitting, by the BS to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by using one of first PDCCH candidates of the common search space according to the common search space configuration; and
transmitting, by the BS to the UE, a second PDCCH carrying the DCI for the UE by using one of second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are configured according to the same configuration as the common search space configuration until a UE-specific search space configuration is transmitted to the UE.

[Claim 7] The method according to claim 6,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 8] The method according to claim 6 or 7,
wherein the common search space configuration includes information on a maximum number of repetitions for the first common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 9] The method according to any one of claims 6 to 8,
wherein the common search space configuration includes information

on a first physical resource block (PRB) set for transmitting the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE.

[Claim 10] The method according to any one of claims 6 to 9,
wherein the first PDCCH candidates of the common search space are configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are configured according to the plurality of aggregation levels.

[Claim 11] A user equipment (UE) for receiving downlink control information (DCI) for the UE, the UE comprising:
a radio frequency (RF) unit, and
a processor connected to the RF unit, the processor configured to:
control the RF unit to receive common search space configuration for a common search space;
control the RF unit to receive a first physical downlink control channel (PDCCH) scheduling a random access response by monitoring first PDCCH candidates of the common search space according to the common search space configuration; and
control the RF unit to receive a second PDCCH carrying the DCI for the UE by monitoring second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are monitored according to the same configuration as the common search space configuration until the UE receives a UE-specific search space configuration.

[Claim 12] The UE according to claim 11,
wherein the common search space configuration includes information on a narrowband for the common search space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored on the same narrowband as the narrowband for the common search space until the UE receives a UE-specific search space configuration.

[Claim 13] The UE according to claim 11 or 12,
wherein the common search space configuration includes information on a maximum number of repetitions for the common common search

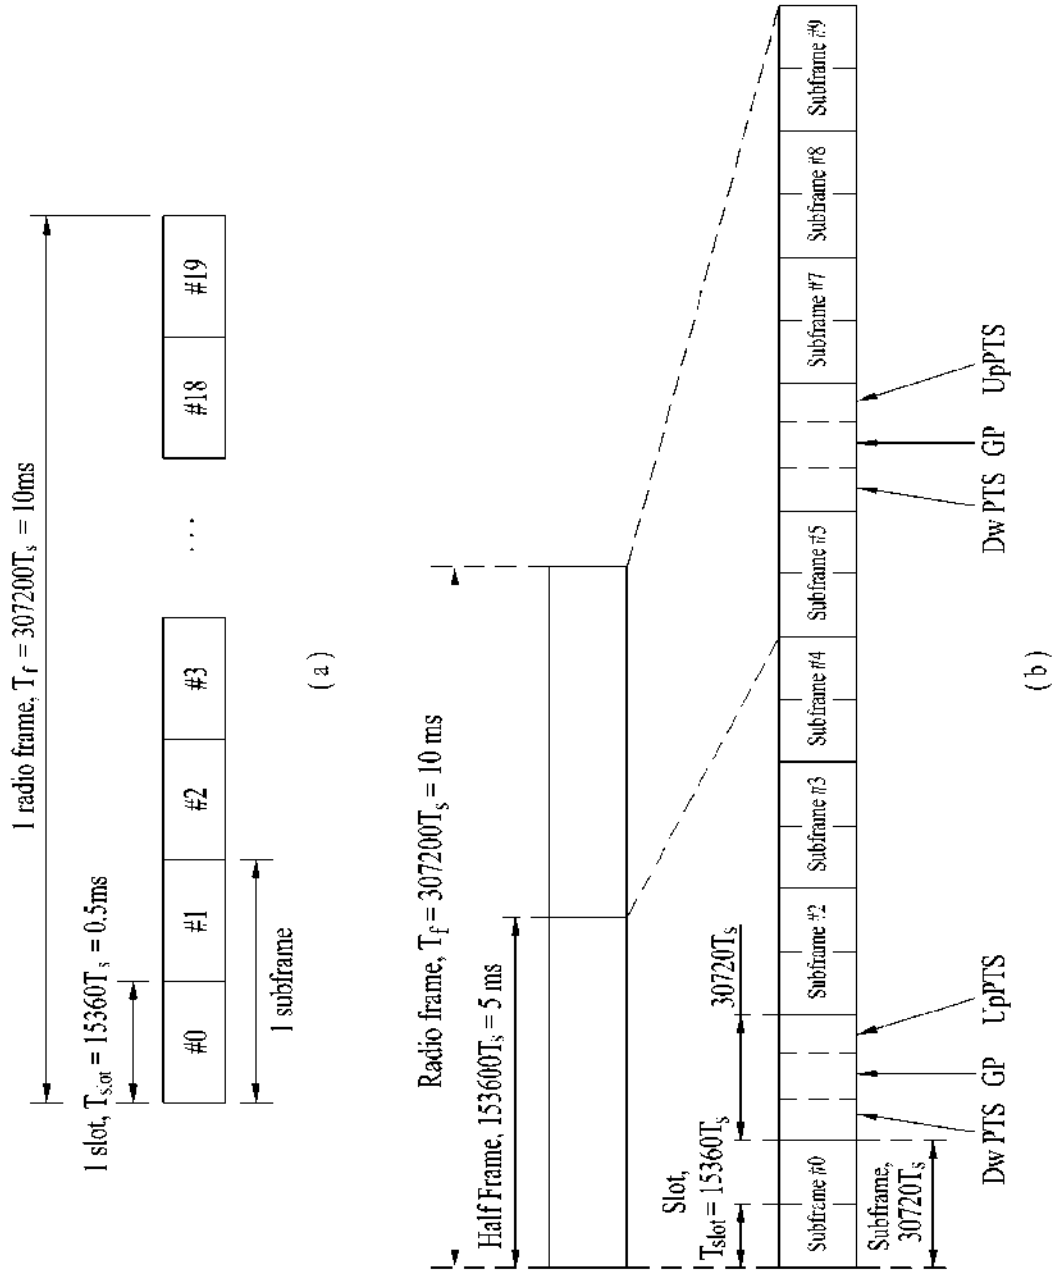
space, and
wherein the second PDCCH candidates of the UE-specific search space are monitored based on the same number as the maximum number of repetitions for the common search space until the UE receives a UE-specific search space configuration.

[Claim 14] The UE according to any one of claims 11 to 13,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for monitoring the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for monitoring the second PDCCH candidates until the UE receives a UE-specific search space configuration.

[Claim 15] The UE according to any one of claims 11 to 14,
wherein the first PDCCH candidates of the common search space are monitored according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are monitored according to the plurality of aggregation levels.

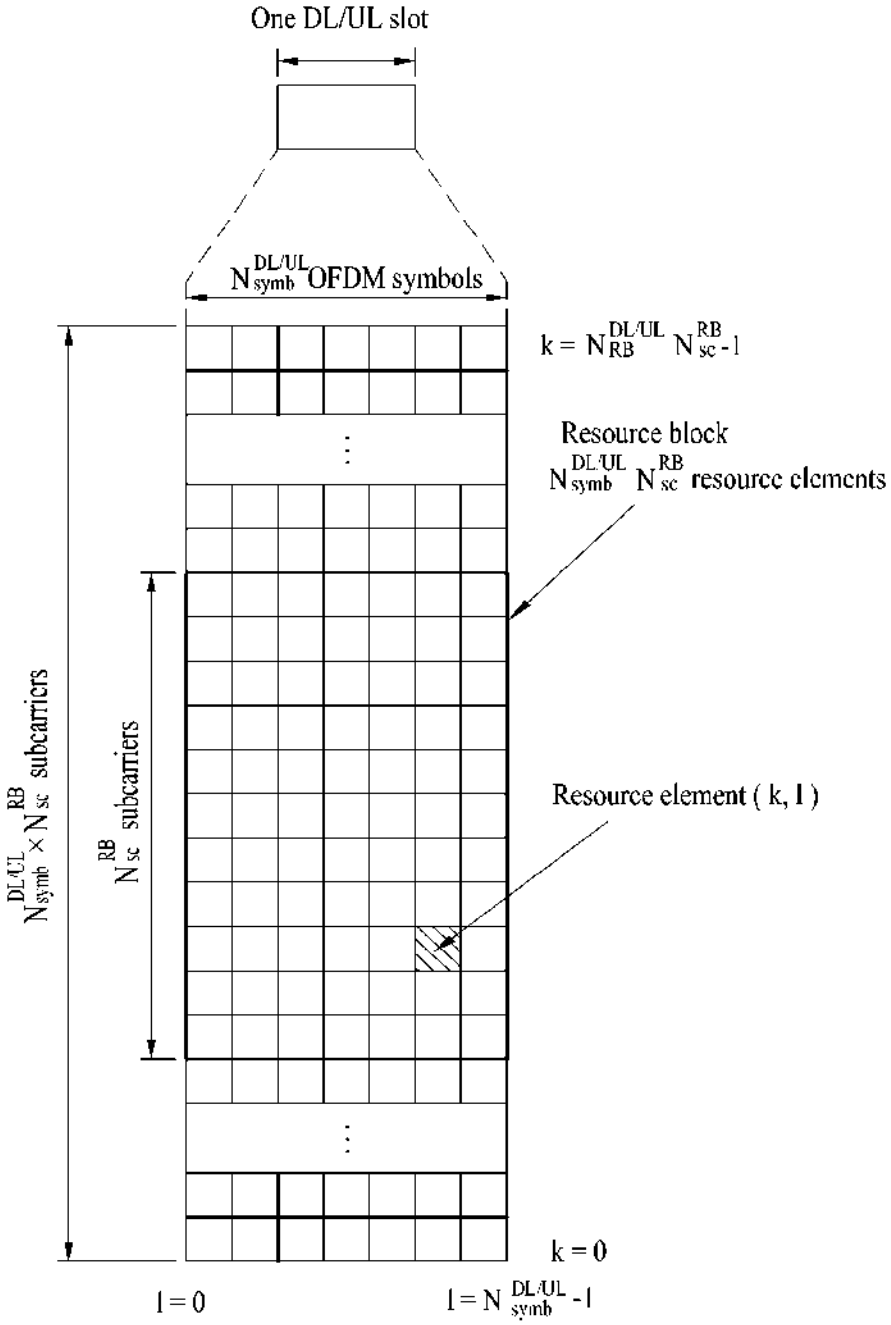
[Claim 16] A base station (BS) for transmitting downlink control information (DCI) to a user equipment (UE), the BS comprising:
a radio frequency (RF) unit, and
a processor connected to the RF unit, the processor configured to:
control the RF unit to transmit common search space configuration for a common search space;
control the RF unit to transmit, to the UE, a first physical downlink control channel (PDCCH) scheduling a random access response by using one of first PDCCH candidates of the common search space according to the common search space configuration; and
control the RF unit to transmit, to the UE, a second PDCCH carrying the DCI for the UE by using one of second PDCCH candidates of a UE-specific search space,
wherein the second PDCCH candidates of the UE-specific search space are configured according to the same configuration as the common search space configuration until a UE-specific search space configuration is transmitted to the UE.

[Claim 17] The BS according to claim 16,
wherein the common search space configuration includes information on a narrowband for the common search space, and



wherein the second PDCCH candidates of the UE-specific search space are configured on the same narrowband as the narrowband for the common search space until the UE-specific search space configuration is transmitted to the UE.

[Claim 18] The BS according to claim 16 or 17,
wherein the common search space configuration includes information on a maximum number of repetitions for the first common search space, and
wherein the second PDCCH candidates of the UE-specific search space are configured based on the same number as the maximum number of repetitions for the common search space until the UE-specific search space configuration is transmitted to the UE.



[Claim 19] The BS according to any one of claims 16 to 18,
wherein the common search space configuration includes information on a first physical resource block (PRB) set for transmitting the first PDCCH, and
wherein the same physical resource block set as the first PRB set is used for the second PDCCH candidates until the UE-specific search space configuration is transmitted to the UE.

[Claim 20] The BS according to any one of claims 16 to 19,
wherein the first PDCCH candidates of the common search space are configured according to aggregation levels larger than or equal to 8 among a plurality of aggregation levels, and the second PDCCH candidates of the UE-specific search space are configured according to the plurality of aggregation levels.

(54) Title: TRANSMISSION SCHEMES AND MODES AND FALLBACK SCHEMES FOR THE ACCESS LINK OF SYSTEMS OPERATING IN HIGHER FREQUENCY BANDS

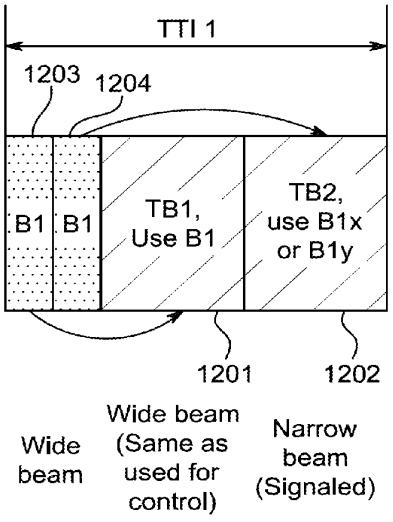

FIG. 12

(57) Abstract: A wireless transmit/receive unit (WTRU) configured to perform wireless communications in higher frequency bands (e.g., above 6 GHz) using a fallback scheme is provided. The WTRU includes a receiver configured to receive, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID, such that one of the at least one control signal indicates the second beam ID; and a processor configured to switch a receive beam of the receiver from the first beam to the second beam based on the second beam ID to receive the second data signal.

TRANSMISSION SCHEMES AND MODES AND FALLBACK SCHEMES FOR THE ACCESS LINK OF SYSTEMS OPERATING IN HIGHER FREQUENCY BANDS

CROSS REFERENCE TO RELATED APPLICATION

[0001] This application claims the benefit of U.S. provisional application No. 62/253,473 filed November 10, 2015, the content of which is hereby incorporated by reference herein.

BACKGROUND

[0002] In order to meet the high data rate required for next generation of cellular communication systems, the wireless industry and academia have been exploring ways to leverage the large bandwidths available at above-6 GHz frequencies (e.g., centimeter wave (cmW) and millimeter wave (mmW) frequencies). One challenge of using these above-6 GHz frequencies may be issues with signal propagation, which has been considered unfavorable for wireless communication, especially in an outdoor environment.

[0003] The propagation of higher frequencies, such as these, may experience higher free space path loss. Rainfall and atmospheric gasses (e.g., oxygen, nitrogen, and hydrogen) may add further attenuation for above-6 GHz frequencies. In addition, foliage may cause attenuation and depolarization. Penetration and diffraction attenuation may also become more severe. As a result, Non Line-Of-Sight (NLOS) propagation path loss may be significant at above-6 GHz frequencies. For example, at mmW frequencies NLOS path loss may be more than 20 dB higher than Line-Of-Sight (LOS) path loss.

[0004] Outdoor mmW cellular networks may be feasible through the use of beamforming techniques. In addition, a large number of reflected and scattered multipath components (MPC) may be utilized to facilitate the mmW coverage in NLOS conditions.

SUMMARY

[0005] Embodiments provide a system, method, and apparatus for transmitting data between a wireless transmit/receive unit (WTRU) and a base station at a high carrier frequency.

[0006] According to an embodiment, a WTRU is configured to perform wireless communications in higher frequency bands using a fallback scheme. The WTRU includes a receiver configured to receive, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID. At least one of the control signal(s) indicates the second beam ID. The WTRU further includes a processor configured to switch a receive beam of the receiver from the first beam to the second beam based on the second beam ID to receive the second data signal.

[0007] According to an embodiment, a method implemented by a WTRU includes receiving, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID. At least one of the control signal(s) indicates the second beam ID. The method further includes switching a receive beam of the WTRU from the first beam to the second beam based on the second beam ID to receive the second data signal.

[0008] According to an embodiment, a wireless communication device is configured to perform wireless communications in higher frequency bands using a fallback scheme. The wireless communication device includes a transmitter configured to transmit, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID. At least one of the control signal(s) indicates the second beam ID. The wireless

communication device further includes a processor configured to switch a transmit beam of the transmitter from the first beam to the second beam based on the second beam ID to transmit the second data signal to a WTRU.

[0009] According to an embodiment, a method implemented in a wireless communication device includes a transmitting, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID. At least one of the control signal(s) indicates the second beam ID. The method further includes switching a transmit beam of the wireless communication device from the first beam to the second beam based on the second beam ID to transmit the second data signal to a WTRU.

[0010] According to an embodiment, a WTRU is configured to perform wireless communications in higher frequency bands using a fallback scheme. The WTRU includes a receiver configured to receive, in a time transmission interval (TTI), at least one control signal, a first transport block and a second transport block. The at least one control signal and the first transport block are received using a first beam, and the second transport block is received using a second beam that has a beam width that is more narrow than a beam width of the first beam. In addition, the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block. The WTRU further includes a processor configured to switch a receive beam of the receiver from the first beam to the second beam, to receive the second transport block, based on beam information associated with the second beam received in one of the at least one control signal.

[0011] According to an embodiment, a method implemented by a WTRU includes receiving, in a time transmission interval (TTI), at least one control signal, a first transport block and a second transport block. The at least one control signal and the first transport block are received using a first beam, and

the second transport block is received using a second beam that has a beam width that is more narrow than a beam width of the first beam. In addition, the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block. The method further includes switching a receive beam of the WTRU from the first beam to the second beam, to receive the second transport block, based on beam information associated with the second beam received in one of the at least one control signal.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] A more detailed understanding may be had from the following description, given by way of example in conjunction with the accompanying drawings wherein:

[0013] FIG. 1A is a system diagram of an example communications system in which one or more disclosed embodiments may be implemented;

[0014] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used within the communications system illustrated in FIG. 1A;

[0015] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used within the communications system illustrated in FIG. 1A;

[0016] FIG. 2 shows a diagram of an orthogonal frequency-division multiplexing (OFDM) frame structure over a 1-GHz system bandwidth according to one or more embodiments;

[0017] FIG. 3 shows a diagram of a single carrier frame structure over a 2-GHz system bandwidth according to one or more embodiments;

[0018] FIG. 4 shows a diagram illustrating a fully digitized beamforming system according to one or more embodiments;

[0019] FIG. 5 shows a diagram illustrating an analog beamforming system with one phase antenna array (PAA) and one radio frequency (RF) chain according to one or more embodiments;

[0020] FIGS. 6A and 6B show a diagram illustrating an analog beamforming system with one PAA and two RF chains according to one or more embodiments;

[0021] FIG. 7 shows a diagram illustrating an analog beamforming system with two PAAs and two RF chains according to one or more embodiments;

[0022] FIG. 8 shows a diagram illustrating an analog beamforming system with two PAAs and a single RF chain according to one or more embodiments;

[0023] FIG. 9 shows a diagram illustrating of a semi-static association between the control transmit (Tx) beam and data Tx beam according to one or more embodiments;

[0024] FIG. 10 shows a diagram illustrating an intra-transmission time interval (TTI) downlink (DL) assignment with a guard period according to one or more embodiments;

[0025] FIG. 11 shows a diagram illustrating a cross-TTI DL assignment with narrow beam indication according to one or more embodiments;

[0026] FIG. 12 shows a diagram for a dual transport block (TB) transmission scheme according to one or more embodiments;

[0027] FIG. 13 shows a diagram illustrating a use of a dual TB transmission scheme for data fallback according to one or more embodiments;

[0028] FIG. 14 shows a diagram illustrating another example of using a dual TB transmission scheme for data fallback according to one or more embodiments;

[0029] FIG. 15 shows a diagram illustrating an example of fallback TTI and linkage between fallback downlink control information (DCI) and fallback data, where the mB supports one RF chain according to one or more embodiments;

[0030] FIG. 16 shows a diagram illustrating an example of fallback TTI and linkage between fallback DCI and fallback data, where the mB supports multiple RF chains according to one or more embodiments;

[0031] FIG. 17 shows a diagram of fallback DCI mapped to the data region, and linkage to fallback data according to one or more embodiments;

[0032] FIG. 18 shows a diagram illustrating fallback DCI mapped to the data region using narrow beam transmission according to one or more embodiments;

[0033] FIG. 19 shows a flow diagram utilizing a dual TB transmission scheme according to one or more embodiments; and

[0034] FIG. 20 shows a flow diagram utilizing a dual TB transmission scheme according to one or more embodiments.

DETAILED DESCRIPTION

[0035] Embodiments described herein may define transmission modes (including reference signals and channel state information (CSI) feedback) and transmission schemes for operation of highly directional beamformed systems. In addition, embodiments may define how to mitigate control and/or data channel performance loss due to narrow beam misalignment, for systems operating in higher frequency bands (e.g. above-6 GHz frequencies).

[0036] The latter problem can further be broken down into two different scenarios. In the first scenario, a change in the wireless transmit/receive unit (WTRU) orientation may be such that the data channel performance using a narrow beam pair may be significantly degraded, while the downlink (DL) wide beam control channel may still be received by the WTRU. In the second scenario, the WTRU orientation change may be such that both the data and the control channels may not be received by the WTRU.

[0037] Embodiments may include downlink/uplink (DL/UL) transmission schemes for the access link of beamformed systems operating in the high frequency bands (e.g., above 6 GHz) using one or multiple radio frequency (RF) chains. In addition embodiments may define DL/UL transmission modes and modes of operations.

[0038] In addition to presenting transmission schemes and transmission modes for above 6 GHz systems, embodiments described herein may include

various scenarios where significant degradation of the control and/or data channel performance may occur due to transmit-receive (Tx-Rx) beam misalignment. Embodiments may addresses techniques for control and data fallback to maintain connectivity until a transmission mode change or a beam change is performed.

[0039] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, such as voice, data, video, messaging, broadcast, etc., to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications systems 100 may employ one or more channel access methods, such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0040] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, 102d, a radio access network (RAN) 104, a core network 106, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include user equipment (UE), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0041] The communications systems 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to one or more communication networks, such as the core network 106, the Internet 110, and/or the other networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0042] The base station 114a may be part of the RAN 104, which may also include other base stations and/or network elements (not shown), such as a base station controller (BSC), a radio network controller (RNC), relay nodes, etc. The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, i.e., one for each sector of the cell. In another embodiment, the base station 114a may employ multiple-input multiple-output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0043] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 116, which may be any suitable wireless communication link (e.g., radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, etc.). The air interface 116 may be established using any suitable radio access technology (RAT).

[0044] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access

schemes, such as CDMA, TDMA, FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 104 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 116 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0045] In another embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 116 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0046] In other embodiments, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (i.e., Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), and the like.

[0047] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, such as a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In another embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet another embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (e.g., WCDMA, CDMA2000, GSM, LTE, LTE-A, etc.) to establish a picocell or

femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106.

[0048] The RAN 104 may be in communication with the core network 106, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106 may provide call control, billing services, mobile location-based services, pre-paid calling, Internet connectivity, video distribution, etc., and/or perform high-level security functions, such as user authentication. Although not shown in FIG. 1A, it will be appreciated that the RAN 104 and/or the core network 106 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 104 or a different RAT. For example, in addition to being connected to the RAN 104, which may be utilizing an E-UTRA radio technology, the core network 106 may also be in communication with another RAN (not shown) employing a GSM radio technology.

[0049] The core network 106 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, such as the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include another core network connected to one or more RANs, which may employ the same RAT as the RAN 104 or a different RAT.

[0050] One or more of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, i.e., the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for

communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0051] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment.

[0052] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip.

[0053] The transceiver 120, or any part thereof, may be configured to align its transmit beam, for transmitting an uplink transmission, with a receive beam of an eNode-B. Similarly, the transceiver 120, or any part thereof, may be configured to align its receive beam, for receiving a downlink transmission, with

a transmit beam of the eNode-B. The processor 118 may further be configured to determine a transmit beam and/or receive beam (e.g., based on received configuration or control information) for the transceiver 120 to use, and configure the transceiver 120 accordingly for communicating with the eNode-B.

[0054] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (e.g., the base station 114a) over the air interface 116. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In another embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet another embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0055] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the WTRU 102 may include two or more transmit/receive elements 122 (e.g., multiple antennas) for transmitting and receiving wireless signals over the air interface 116.

[0056] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, such as UTRA and IEEE 802.11, for example.

[0057] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (e.g., a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also

output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, such as the non-removable memory 130 and/or the removable memory 132. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In other embodiments, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, such as on a server or a home computer (not shown).

[0058] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (e.g., nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), etc.), solar cells, fuel cells, and the like.

[0059] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (e.g., longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 116 from a base station (e.g., base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the WTRU 102 may acquire location information by way of any suitable location-determination method while remaining consistent with an embodiment.

[0060] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For

example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0061] FIG. 1C is a system diagram of the RAN 104 and the core network 106 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 106.

[0062] The RAN 104 may include eNode-Bs 140a, 140b, 140c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 140a, 140b, 140c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 140a, 140b, 140c may implement MIMO technology. Thus, the eNode-B 140a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0063] Each of the eNode-Bs 140a, 140b, 140c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1C, the eNode-Bs 140a, 140b, 140c may communicate with one another over an X2 interface.

[0064] The core network 106 shown in FIG. 1C may include a mobility management entity gateway (MME) 142, a serving gateway 144, and a packet data network (PDN) gateway 146. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0065] The MME 142 may be connected to each of the eNode-Bs 140a, 140b, 140c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 142 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 142 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, such as GSM or WCDMA.

[0066] The serving gateway 144 may be connected to each of the eNode Bs 140a, 140b, 140c in the RAN 104 via the S1 interface. The serving gateway 144 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 144 may also perform other functions, such as anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0067] The serving gateway 144 may also be connected to the PDN gateway 146, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0068] The core network 106 may facilitate communications with other networks. For example, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 106 may include, or may communicate with, an IP gateway (e.g., an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 106 and the PSTN 108. In addition, the core network 106 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0069] Other network 112 may further be connected to an IEEE 802.11 based wireless local area network (WLAN) 160. The WLAN 160 may include an access router 165. The access router may contain gateway functionality. The access router 165 may be in communication with a plurality of access points (APs) 170a, 170b. The communication between access router 165 and APs 170a, 170b may be via wired Ethernet (IEEE 802.3 standards), or any type of wireless communication protocol. AP 170a is in wireless communication over an air interface with WTRU 102d.

[0070] It should be noted that although 3GPP LTE may be used for example purposes, the techniques described herein may be applied to any other system.

[0071] The following list of definitions, although not intended to be limiting, may be helpful in understanding the following embodiments.

[0072] A "beam" may be one lobe (e.g. main/side/grating) of a transmit radiation pattern and receive gain pattern of an antenna array. The beam may also denote a spatial direction that may be represented with a set beamforming weights. The beam may be identified or associated with a reference signal, an antenna port, a beam identity (ID), and/or a scrambling sequence number. The beam may be transmitted and/or received at a specific time, frequency, code, and/or spatial resource. The beam may be formed digitally, in an analog manner, or both (i.e., hybrid beamforming). The analog beamforming may be based on fixed code-book or continuous phase shifting.

[0073] A "beam-specific reference signal" (BSRS) may be a sequence associated with a transmit beam used for beam acquisition, timing and/or frequency synchronization, channel estimation for a physical downlink directional control channel (PDDCCH), fine beam tracking, beam measurement, etc. BSRS may carry (e.g., implicitly carry) beam identity information. There may be different types of BSRS. For example, there may be BSRS for an mmW sector and its member segments. The segment may be referred as a beam direction (e.g., a narrow beam direction or a wide beam direction).

[0074] A “data channel beam” may be used to transmit a data channel, a Physical Downlink Shared Channel (PDSCH), a mPDSCH, a mmW PDSCH, a mmW data channel, a directional PDSCH, a beamformed data channel, a spatial data channel, a data channel slice, or a high frequency data channel. The data channel beam may be identified or associated with a reference signal, an antenna port, a beam identity (ID), and/or a scrambling sequence number. The data channel beam may be transmitted and/or received at a specific time, frequency, code, and/or spatial resource.

[0075] A “control channel beam” may be used to transmit a control channel, a control channel beam, a PDCCH, an mPDCCH, an mmW PDCCH, an mmW control channel, a directional PDCCH, a beamformed control channel, a spatial control channel, a control channel slice or a high frequency control channel. A control channel beam may be identified or associated with a reference signal, an antenna port, a beam identity (ID), a scrambling sequence number and may be transmitted and/or received at a specific time and/or frequency and/or code and/or spatial resources.

[0076] A “measurement beam” may be used to transmit a signal or channel for beam measurement. This may include a beam reference signal, a beam measurement reference signal, Cell Specific Reference Signal (CRS), Channel State Information-Reference Signal (CSI-RS), CSI-interference measurement (CSI-IM), etc. The measurement beam may be identified or associated with a reference signal, an antenna port, a beam identity (ID), and/or a scrambling sequence number. The measurement beam may be transmitted and/or received at a specific time, frequency, code, and/or spatial resource.

[0077] A “control channel beam duration” may be the length of time, which may be referred to in units of OFDM symbols, used within a scheduling interval for the transmission of one control channel beam.

[0078] A “control region” may be the length in theof time domain, which may be referred to in units of OFDM symbols, used within a scheduling interval for the transmission of all the control channel beams in that scheduling interval.

For example, a control region may be the number of OFDM symbols in a TTI occupied by all the control channel beams transmitted in the TTI.

[0079] A "data region" may be part of the scheduling interval in time domain, which may be referred to in units of OFDM symbols, used for the transmission of all data channel beams in that scheduling interval.

[0080] A "data fallback" may be an alternate scheme for data transmission, that may be used dynamically, irrespective of the transmission mode, to maintain the data communication between the base station and the WTRU. Data fallback schemes may be used in either downlink (DL), or uplink (UL), or both.

[0081] A "control fallback" may be an alternate scheme for signaling the control channel, that may be used dynamically, irrespective of the transmission mode, to maintain the control signaling between the base station and the WTRU.

[0082] In some embodiments described herein, the terms base station, eNode-B (eNB), mmW eNB (mB), Small Cell mmW eNB (SCmB), cell, small cell, primary cell (Pcell), and secondary cell (Scell) may be used interchangeably. In some embodiments, the term operate may be used interchangeably with transmit and/or receive. In some embodiments, the terms component carrier, mmW carrier may be used interchangeably with serving cell.

[0083] In some embodiments, the mB may transmit and/or receive one or more mmW channels and/or signals in a licensed band and/or an unlicensed band. In some embodiments, the WTRU may be substituted for eNB and/or vice versa and still be consistent with this disclosure. In some embodiments, UL may be substituted for DL and/or vice versa and still be consistent with this disclosure.

[0084] In some embodiments, a channel may refer to a frequency band that may have a center, or carrier frequency, and a bandwidth. Licensed and/or unlicensed spectrum may include one or more channels which may or may not overlap. Channel, frequency channel, wireless channel, and mmW channel may be used interchangeably. Accessing a channel may be the same as using (e.g., transmitting and/or receiving on or using) the channel.

[0085] In some embodiments, a channel refers to a mmW channel or signal, such as an uplink or downlink physical channel or signal. Downlink channels and signals may include one or more of the following: mmW synchronization signal, mmW broadcast channel, mmW cell reference signal, mmW beam reference signal, mmW beam control channel, mmW beam data channel, mmW hybrid automatic repeat request (ARQ) indicator channel, mmW demodulation reference signal, primary synchronization signal (PSS), secondary synchronization signal (SSS), demodulation reference signal (DMRS), CRS, CSI-RS, Physical Broadcast Channel (PBCH), Physical downlink Control Channel (PDCCH), Physical Hybrid ARQ Indicator Channel (PHICH), Enhanced Physical Downlink Control Channel (EPDCCH), and PDSCH. Uplink channels and signals may include one or more of the following: mmW Physical Random Access Channel (PRACH), mmW control channel, mmW data channel, mmW beam reference signal, mmW demodulation reference signal, PRACH, Physical Uplink Control Channel (PUCCH), sounding reference signal (SRS), DMRS and Physical Uplink Shared Channel (PUSCH). Channel and mmW channel may be used interchangeably. Channels and signals may be used interchangeably.

[0086] In some embodiments data/control may mean data and/or control signals and/or channels. Control may include synchronization. The data/control may be mmW data/control. Data/control and data/control channels and/or signals may be used interchangeably. Channels and signals may be used interchangeably. The terms control channel, control channel beam, PDCCH, mPDCCH, mmW PDCCH, mmW control channel, directional PDCCH, beamformed control channel, spatial control channel, control channel slice, high frequency control channel may be used interchangeably. The terms data channel, data channel beam, PDSCH, mPDSCH, mmW PDSCH, mmW data channel, directional PDSCH, beamformed data channel, spatial data channel, data channel slice, and high frequency data channel may be used interchangeably.

[0087] In some embodiments, channel resources may be resources (e.g., 3GPP LTE or LTE-A resources) such as time, frequency, code, and/or spatial

resources, which may, at least sometimes, carry one or more channels and/or signals. In some embodiments, channel resources may be used interchangeably with channels and/or signals.

[0088] The terms mmW beam reference signal, mmW reference resource for beam measurement, mmW measurement reference signal, mmW channel state measurement reference signal, mmW demodulation reference signal, mmW sounding reference signal, reference signal, CSI-RS, CRS, DM-RS, DRS, measurement reference signal, reference resource for measurement, CSI-IM, and measurement RS may be used interchangeably. mmW cell, mmW small cell, SCell, secondary cell, license-assisted cell, unlicensed cell, and Licensed Assisted Access (LAA) cell may be used interchangeably. The terms mmW cell, mmW small cell, PCell, primary cell, LTE cell, and licensed cell may be used interchangeably.

[0089] The terms interference and interference plus noise may be used interchangeably.

[0090] Multiple above-6 GHz frequency bands have been evaluated for next generation cellular networks. For example, 10 GHz and 15 GHz bands have been evaluated at the cmW frequency band. In addition, 28 GHz, 39 GHz, 60 GHz and 73 GHz bands have been evaluated at the mmW frequency band. These higher frequency bands may be allocated as licensed, lightly licensed, and unlicensed spectrums.

[0091] Depending on the allocation of the spectrum and its propagation characteristics, the above-6 GHz frequency bands may be deployed in various cellular network configurations. For example, mmW frequencies may be used for a homogenous network with mmW stand-alone Macro-, Micro- and Small Cell base stations. A heterogeneous network may consist of a mmW stand-alone small cell network overlaid with a LTE Macro- and/or Micro- network at sub-6 GHz frequencies. In such a network, a network node may be connected to both above-6 GHz frequencies (e.g., a mmW system) and below-6 GHz frequencies (e.g., a 2 GHz LTE system), which may be referred as Dual Connectivity. Carrier

aggregation may be applied to combine above-6 GHz carriers (e.g., mmW) and sub-6 GHz carriers (e.g., 2 GHz LTE carriers).

[0092] Embodiments described herein may apply to any above-6 GHz cellular deployment.

[0093] Waveforms, such as, for example, orthogonal frequency-division modulation (OFDM), broad-band Single Carrier (SC), SC-OFDM, Generalized OFDM, Filter Bank Multicarrier (FBMC), and Multi-Carrier Code Division Multiple Access (MC-CDMA) may be used for above-6 GHz systems. Waveforms may have different Peak to Average Power Ratio (PAPR) performance, sensitivity to transmitter non-linearity, Bit Error Rate (BER) performance, resource channelization, and implementation complexity.

[0094] While frame structure may depend on the applied waveform, it may also be dimensioned to meet the above-6 GHz system requirement. For example, in order to achieve very low latency, a higher-frequency cellular system may have a subframe length of 100 μs.

[0095] Referring to FIG. 2, FIG. 2 shows a diagram of an OFDM frame structure 200 over a 1-GHz system bandwidth. According to the OFDM-based frame structure 200 shown in FIG. 2, a frame 202 includes 10 sub-frames, each sub-frame includes 10 slots, and each slot includes 24 symbols. The OFDM-based frame structure 200 may have, for example, a sub-carrier spacing of 300 kHz with a corresponding symbol length (T_{symbol}) of 3.33 μs. Considering a cyclic prefix (CP) length may span over the entire length of the channel time dispersion in order to eliminate the inter-symbol-interference, one example of CP for a T_{symbol} of 3.33 μs may be selected at 1/4 of T_{symbol} (i.e., at 0.833 μs). This example numerology may be used for a range of above-6 GHz system bandwidths (e.g., from 50 MHz to 2 GHz) with corresponding Fast Fourier Transform (FFT) length.

[0096] Referring now to FIG. 3, FIG. 3 shows a diagram of a single carrier frame structure 300 over a 2-GHz system bandwidth. Another frame structure may be based on single carrier over an entire system bandwidth. The system bandwidth may range from 50 MHz to 2 GHz. One such example may be based

on 2 GHz bandwidth. The sampling frequency F_s may be 1.536 GHz with a 1024-FFT. A subframe 302 may include 10 time slots each of which may be 100 μs and may have 150 single carrier (FFT) blocks. Each single carrier block may have 1024 symbols that can be used for synchronization, reference, control, data, cyclic prefix or other system purposes.

[0097] An above-6 GHz system (e.g., cmW and mmW systems) may apply any waveform and frame structure or combination thereof as discussed above. Procedures described in this disclosure may apply to all these waveform and frame structure selections.

[0098] Above-6 GHz systems may use Frequency Division Duplex (FDD), Time Division Duplex (TDD), Spatial Division Duplex (SDD) or any combination of them in conjunction with either half-duplex or full-duplex mechanisms.

[0099] A full-duplex FDD system may use a duplex filter to allow simultaneous downlink and uplink operation at different frequencies separated by a duplex distance. A half-duplex FDD system may not use a duplex filter, as the downlink and uplink operation may take place at different time instance in its dedicated frequency. A TDD system may have the downlink and uplink operate at the same frequency at different time instances. A SDD system, for example, in a beamformed system, may enable a network node to transmit and receive at a same frequency and time instance but at different outgoing and incoming spatial directions.

[0100] An above-6 GHz network may use Frequency Division Multiple Access (FDMA), Time Division Multiple Access (TDMA), Spatial Division Multiple Access (SDMA), Code Division Multiple Access (CDMA), Non-Orthogonal Multiple Access (NOMA), or any combination thereof. FDMA, TDMA, SDMA and CDMA may be applied in an orthogonal manner to avoid interference.

[0101] Multiple network nodes may be assigned to use different frequency resources simultaneously in a FDMA system, or to access the system frequency resources at different time instances in a TDMA system. Moreover the network nodes may access the same frequency resources at the same time, but may use a

different code in a CDMA system. A SDMA system may assign a spatial resource to network nodes to operate at same frequency, time, and code resource. In a beamformed network, WTRUs may use different beams.

[0102] In a NOMA system, multiple network nodes may be assigned overlapping or identical resources in frequency, time, code or spatial domain, but may apply additional mechanisms to remove interference caused by the non-orthogonal use of the resource between users. For example, two WTRUs may be located relatively far from each other, and the difference of their path loss to the base station may be large. They may be assigned with the same frequency resource in the same subframe with very different transport formats. Superposition coding and a Successive Interference Rejection (SIC) receiver may be used for a WTRU to remove the received signal intended for the other.

[0103] An above-6 GHz system (e.g., cmW and mmW systems) may apply any duplex scheme and multiple access or combination of them as discussed above. Embodiments described herein may apply to all these duplex schemes and multiple access schemes.

[0104] An above-6 GHz system may have a number of physical channels and signals for various system purposes. Certain signals may be used for multiple system procedures.

[0105] The following are examples of downlink physical channels and signals.

[0106] A synchronization signal may be a pre-defined signal that may be used for cell timing/frequency synchronization. It may be transmitted according to pre-defined periodicity. In a beamformed system, the signal may provide beam timing and frequency acquisition.

[0107] A physical broadcast channel may carry broadcast information, such as cell specific system information.

[0108] A downlink reference signal may be a pre-defined sequence transmitted to enable various system procedures (e.g., channel estimation for control channel, channel statement measurement, timing and frequency fine-

tuning, system measurement, and the like). There may be different types of reference signals. In a beamformed system, a downlink reference signal may be used for beam acquisition, beam pairing, beam tracking, beam switch, beam measurement, and the like.

[0109] A physical downlink control channel may carry data related control information to identify, demodulate and decode the associated data channel properly.

[0110] A physical downlink data channel may carry payload information in the form of Medium Access Control (MAC) Protocol Data Unit (PDU) from the MAC layer. The resource allocation of this channel may be carried in the scheduling information in the physical downlink control channel.

[0111] A data demodulation reference signal may have symbols that may be transmitted for channel estimation of downlink control or data channel. The symbols may be placed together with the associated control or data symbols in the time and frequency domain according to pre-defined pattern. This may ensure correct interpolation and reconstruction of the channel.

[0112] The following are examples of uplink physical channels and signals.

[0113] An uplink reference signal may be used for uplink channel sounding, uplink system measurement, etc. In a beamformed system, an uplink reference signal may be used for uplink beam acquisition, beam pairing, beam tracking, beam switch, beam measurement, etc.

[0114] A physical random access channel (PRACH) may carry a pre-defined sequence in connection with a random access procedure.

[0115] A physical uplink control channel may carry uplink control information, such as channel state information, data acknowledgement, scheduling request, etc.

[0116] A physical uplink data channel may carry payload information in the form of MAC PDU from a UE MAC layer. The resource allocation of this channel may be conveyed in the downlink control channel.

[0117] A data demodulation reference signal may have symbols that may be transmitted for channel estimation of uplink control or data channel. The symbols may be placed together with the associated data symbols in the time and frequency domain according to pre-defined pattern to ensure correct interpolation and reconstruction of the channel.

[0118] An above-6 GHz system (e.g., cmW and mmW systems) may deploy the signals and channels discussed above. Embodiments described herein may apply to these physical signals and channels.

[0119] Beamforming may be important in above-6 GHz systems. Outage studies conducted at 28 GHz and 38 GHz in an urban area using a steerable 10°-beamwidth and a 24.5-dBi horn antenna have shown a consistent coverage may be achieved with a cell-radius of up to 200 meters. Currently, LTE WTRUs are assumed to have an Omni-directional beam pattern and may perceive a superimposed channel impulse response over the entire angular domain. Thus an aligned beam pair e.g., at mmW frequencies may provide an additional degree of freedom in the angular domain compared with the current LTE system.

[0120] Conventional LTE WTRUs may have an Omni-directional beam pattern and may perceive a superimposed channel impulse response over the entire angular domain. Thus, an aligned beam pair at, for example, mmW frequencies, may provide an additional degree of freedom in the angular domain compared with conventional LTE systems.

[0121] Referring now to FIG. 4, FIG. 4 shows a diagram illustrating fully digitized beamforming system 400 according to one or more embodiments. A phase antenna array (PAA) may be used for beamforming with element spacing, e.g., at 0.5λ. The phase antenna may apply different beamforming algorithms. A fully digitized beamforming approach may have a dedicated RF chain including an RF processor 401 and an analog-to-digital converter (ADC) 402 for each antenna element 403. The signal 404 processed by each antenna element 403 may be controlled independently in phase and amplitude to optimize the channel

capacity. A baseband (BB) processor 405 is configured to perform BB processing on each dedicated RF chain based on the signals received from each ADC 402.

[0122] Referring now to FIG. 5, FIG. 5 shows a diagram illustrating analog beamforming system 500 according to one or more embodiments. In this embodiment, the analog beamforming may be with one PAA and one RF chain. The analog beamforming may apply one RF chain for a number of antenna elements 503 that process the signal 504. Each antenna element 503 may be connected to a phase shifter 506 that may be used to set the weight for beamforming and steering. The RF chain further includes an RF processor 501 and an ADC 502 which provides an output to a BB processor 505. The implemented number of RF chains may be significantly reduced as well as the energy consumption.

[0123] The phase shifting and combining may be implemented in different stages (e.g., at RF state, at BB analog stage, or at Local Oscillator (LO) stage). One example is a single-beam analog configuration. It may operate one beam at a time and the single beam may be placed at, for example, the strongest angular direction such as a LOS path obtained from beam measurement. A broad beam pattern may cover a range of angular directions at the expense of reduced beamforming gain.

[0124] A hybrid beamforming may combine digital precoding and analog beamforming. The analog beamforming may be performed over the phase array antenna elements each associated with a phase shifter and all connected to one RF chain. The digital precoding may be applied on the baseband signal of each RF chain.

[0125] Examples of system parameters of the hybrid beamforming may be number of data streams (N_{DATA}), number of RF chains TRX (N_{TRX}), number of antenna ports (N_{AP}), number of antenna elements (N_{AE}), and number of phase antenna arrays (N_{PAA}). The configuration of these parameters may impact on the system function and performance as discussed below.

[0126] Referring now to FIGS. 6A and 6B, FIGS. 6A and 6B show a diagram illustrating analog beamforming system 600 with one PAA and two RF chains. One antenna port may carry a beamformed reference signal uniquely associated with this antenna port that may be used to identify the antenna port. One PAA may be connected to one RF chain or multiple RF chains depending on the system requirement and configuration. In FIGS. 6A and 6B, one PAA of size 4x4 with 16 antenna elements 603, for receiving a signal 604, may be connected to two RF chains and each RF chain may have a set of 16 phase shifters 606a and 606b. The PAA may form two narrow beam patterns within a $+45^{o}$ and -45° coverage in an azimuth plane. In this configuration, $N_{PAA} < N_{AP} = N_{TRX} < N_{AE}$. Each RF chain further includes an RF processor 601a or 601b and an ADC 602a or 602b which provide an output to a BB processor 605.

[0127] Referring now to FIG. 7, FIG. 7 shows a diagram illustrating analog beamforming system 700 with two PAAs and two RF chains. In an embodiment, there may two PAAs having a set of antenna elements 703a and 703b, respectively, for receiving signals 704a and 704b. Each antenna element 703a, 703b may be connected to a phase shifter 706a, 706b, respectively. Each PAA may have a dedicated RF chain, i.e., $N_{PAA} = N_{AP} = N_{TRX} \leq N_{AE}$, including an RF processor 701a, 701b and an ADC 702a, 702b which provide an output to a BB processor 705. This configuration may allow spatial independence between the two simultaneous signals 704a and 704b by placing the PAAs at different orientations (e.g., in an azimuth plane). An aligned PAA arrangement may provide an aggregated larger coverage.

[0128] Both abovementioned example configurations with two RF chains may apply MIMO with two data streams.

[0129] Referring now to FIG. 8, FIG. 8 shows a diagram illustrating analog beamforming system 800 with two PAAs having a set of antenna elements 803a and 803b, respectively, for receiving signals 804a and 804b. Each antenna element 803a, 803b may be connected to a phase shifter 806a, 806b, respectively. The PAAs are connected to a single RF chain that includes a switch 808, an RF

processor 801 and an ADC 802 that provides an output to a BB processor 805. Multiple PAAs may be connected to a single RF chain by using the switch 808 (i.e., $N_{AE} > N_{PAA} > N_{AP} = N_{TRX}$). Each PAA may form a narrow beam pattern covering from +45° to -45° in an azimuth plane. They may be oriented separately so a single-beam network node may have a good coverage by using a beam at different direction at different time instances.

[0130] An above-6 GHz system may apply different beamforming techniques, such as analogue, hybrid and digital beamforming. Embodiments described herein may apply to these beamforming techniques.

[0131] One or more embodiments may address the transmission schemes and transmission modes for highly directional antenna systems, and define the BRS association, the resource allocation and configuration for the fallback schemes, as well as the necessary CSI feedback.

[0132] Another embodiment may address the scenario where the data channel may exhibit a significant degradation, while the control channel may still be received. This scenario may occur for several reasons. For example, the scenario may be due to a change in orientation of the mobile device, which causes misalignment of the previously paired Tx-Rx narrow beams for data transmissions. Embodiments addressing this issue may be based on the fact that the control channel may still be received, and therefore it may be used for the data transmission at a lower rate. In other words, a main principle may be the use of the active control wide beam for data fallback, which may include both DL and UL data. The embodiments may include, but are not limited to: fallback to wide beam (both DL & UL data), and/or fallback to dual transport block (TB) transmission using wide and narrow beams for UE data in the same transmission time interval (TTI).

[0133] Another embodiment may address the scenario where both the control and the data channels are lost due to the beam misalignment. In this case, a two-step solution may be needed: the first step may identify a fallback for the control channel, and once the control channel can be decoded, a fallback may

be determined for the data channel. The embodiments may include: fallback for the DL control and the associated DL/UL data, using fallback TTI.

[0134] The following may provide details for embodiments of DL/UL transmission schemes for one and multiple RF chains.

[0135] Transmission schemes for a system operating at a high carrier frequency (e.g., above 6 GHz) may be defined as mapping of the modulated baseband symbols to the allocated space/time/frequency resources, individual transmit antenna(s), and the associated reference symbols.

[0136] As indicated above, systems operating at high carrier frequency (e.g., above 6 GHz) may need to use beamforming (analog, digital or hybrid) to compensate for a 20-30 dB pathloss since it becomes more significant as the carrier frequency becomes higher. The beamforming may be used at the transmitter and/or at the receiver. The highest beamforming may be achieved when both transmitter and receiver use beamforming and the beam directions are aligned (e.g., transmitter and receiver beams are paired). The transmit and receive beam widths may be determined as a function of the type, size and number of antenna elements of the phased array antenna (PAA).

[0137] A normal transmission scheme may be defined as a transmission scheme used when a transmitter and/or a receiver may control beams properly based on the current channel condition (e.g., wide or narrow transmit and/or receive beam pairing is complete). The system may operate within the expected SNR range. In a system, one or more normal transmission schemes may be defined.

[0138] A fallback transmission scheme may be defined as a transmission scheme used for one or more of following cases. A fallback transmission scheme may be used when the performance of the normal transmission scheme is significantly degraded. For example, a significant loss in SNR may occur due to a change of the WTRU orientation with respect to the mB or due to blocking. A fallback transmission scheme may be used when the channel status information (CSI) ages faster than a feedback cycle, so that a transmitter may not rely on the

reported CSI. A fallback transmission scheme may be used when a CSI is not available at the transmitter. Fallback transmission schemes may be defined for data channels, and for control channels. The transmission schemes in this disclosure may be not limited to a system with a high carrier frequency and may be used for a system with any carrier frequency.

[0139] A normal transmission scheme may use a single transmit RF chain or multiple transmit RF chains. If a single transmit RF chain is used, the normal transmission scheme may use analog beamforming. On the other hand, if multiple RF chains are used, the normal transmission scheme may use analog, digital, or hybrid beamforming. Although the beamforming capability is determined based on the number of RF chain and/or number of antenna element, embodiments described herein may be used for a system with any number of transmit/receive RF chains and/or antenna elements and still be consistent with this disclosure.

[0140] The beamforming capability described herein may include one or more of following: a number of beams supported, a beamwidth, a beam control ability (e.g., analog, digital, and hybrid), and a beam measurement/reporting. The number of beams may be interchangeably used as a number of beam steering vectors and a number of precoding vectors. The beamwidth may be interchangeably used as a beam steering vector and as a precoding vector.

[0141] A normal transmission scheme may use analog beamforming and may operate using either wide or narrow beams, with or without channel state information (CSI) feedback from the receiver (i.e., closed loop or open loop transmission schemes).

[0142] In an example, a WTRU may not have a receiver beamforming capability and an analog beamforming may be used only at the transmitter. Therefore, the beam pairing between transmitter beam and receiver beam may not be used. A transmission scheme may be defined without a beam pairing process. Therefore, a transmitter may not provide a transmit beam information

(e.g., the transmit beam ID) for a downlink transmission when a transmission scheme which may not support beam pairing process may be used.

[0143] In another example, a WTRU may have receiver beamforming capability and the analog beamforming may be used at both transmitter and receiver. A beam pairing scheme/process between transmitter beam and receiver beam may be used. A transmission scheme with beam pairing process may use one or more following methods. A downlink control channel may indicate the transmit beam information for the associated data channel. The downlink control channel may be, but is not limited to, a physical downlink control channel, MAC control message, higher layer radio resource control (RRC) signaling, or a broadcasting channel. A downlink control channel may indicate a receive beam information for the associated data channel. Therefore, a WTRU may use the receiver beam indicated from the downlink control channel. A transmitter may request a preferred transmit beam information from a receiver, or a receiver may be configured to report a preferred transmit beam information regularly.

[0144] The receiver beamforming may be indicated as a WTRU capability and a transmission scheme may be determined as a function of the receiver beamforming capability. For example, if a WTRU indicates no receiver beamforming support, a transmission scheme without beam pairing process may be used. On the other hand, if a WTRU indicates receiver beamforming support, a transmission scheme with beam pairing process may be used. For the transmission scheme determination according to the WTRU receiver beamforming capability, one or more of following operations may apply. Existence of a bit field in a downlink control channel may be used to indicate the transmit beamforming information may be determined as a function of the WTRU receiver beamforming capability. A downlink control information (DCI) format may be determined as a function of the WTRU receiver beamforming capability. A channel status information (CSI) reporting type may be determined as a function of the WTRU receiver beamforming capability. A downlink control type may be determined as a function of the WTRU receiver beamforming

capability. The relative timing between a downlink control channel and the associated data channel may be determined as a function of the WTRU beamforming capability.

[0145] Referring now to FIG. 9, FIG. 9 illustrates a diagram of a semi-static association between the control transmit (Tx) beam and data Tx beam. While the beams shown in FIG. 9 are described in the context of Tx beams used by a transmitter, it will be appreciated that a receiver uses a corresponding Rx beam in a similar manner. Therefore, Tx and Rx may be used interchangeably in the context of a transmitter or a receiver, respectively.

[0146] In FIG. 9, two TTIs 901 and 902 are shown. In TTI 901, a normal control Tx beam B1 (i.e., wide beam) is associated with a normal data Tx beam B1, which is a wide beam. In TTI 902, normal control Tx beams B1 and B2 (i.e., wide beams) are associated with normal data Tx beams B1 and B2, respectively, where the normal data Tx beams B1 and B2 are wide beams. A transmission scheme may use an implicit beam association between control channel and data channel, where a same transmit beam may be used for both the control channel and the associated data channel, as illustrated in FIG. 9. A WTRU or receiver may assume that a same transmit beam is used for the control channel and the associated data channel. A WTRU may use the same receiver beam for the control channel and the associated data channel as a WTRU may assume the same transmit beam is used. A WTRU may determine a preferred receiver beam during the control channel reception and use the determined receiver beam for the associated data channel.

[0147] For a transmission scheme which may use the same transmit beam for a control channel and the associated data channel, or may require the same receiver beam for a control channel and the associated data channel, the transmit beam information may not be indicated from the control channel. The transmit beam may be adapted either semi-statically or dynamically without the downlink beam indication. The beam may be changed semi-statically and the beam information may be transparent to a WTRU. The beam information for the

control channel and/or the associated data channel may be indicated via higher layer signaling. The beam may be changed dynamically without beam indication in the downlink control channel. The beam information for the control channel and/or the associated data channel may be determined based on the search space of the control channel. The beam information for the control channel and/or the associated data channel may be determined as a function of the location of the control channel within a search space. A beam index may be determined as a function of the starting control channel element (CCE) or enhanced control channel element (ECCE) index of the control channel. A beam index may be determined as a function of BRS used to demodulation the control channel.

[0148] A transmission scheme may use explicit beam association between control channel and the associated data channel, where the transmit beam for the control channel and the associated data channel may be determined independently (or separately). The transmit beam used for the data channel may be explicitly indicated from the corresponding control channel. The transmit beam described herein may include one or more of following parameters:, Tx or Rx beam width (e.g., beam subgroup), Tx or Rx beam direction (e.g., beam index) within the beam width, and a time-frequency resource associated with the beam. The beam index may be indicated as antenna port or reference signal sequence.

[0149] In an example, the transmission scheme using explicit beam association may dynamically switch the Tx beam within a TTI from the wide beam used for control channel to a narrow beam used for the associated data channel. The narrow beam may reside within the wide beam as a subset of the wide beam. As the transmit node dynamically switches from a wide to a narrow beam within a TTI, the receive node may need to also steer its receive beam to ensure that it can receive the narrow Tx beam correctly from the transmitter (e.g., mB). That is, the receiver configures its receive beam to be aligned with the narrow transmit beam. The DCI in the control channel may carry one or more of following parameters for the transmission scheme using explicit beam association: HARQ process number, transport block information, antenna

configuration (as needed), downlink assignment index (DAI), and/or power control indicator.

[0150] The DCI in the control channel may carry a beam ID or a beam index for the data channel. The beam ID or beam index may be interpreted differently according to the beam used for the control channel. For example, one or more wide beams may be used for the control channel. Additionally, a group of narrow beams, which may be associated with a wide beam, may be used for the associated data channel. Therefore, according to the wide beam used for the control channel, the narrow beam ID or beam index for the associated data channel may be different. The beam ID or beam index may be an index of a narrow beam within the group of narrow beams associated with the wide beam.

[0151] The wide beam for the control channel may be determined in a semi-static manner. For example, a higher layer signaling may be used to determine the wide beam and, based on the higher layer configured wide beam for control channel, the group of the narrow beam may be determined. The wide beam for the control channel may be determined as a function of the location of a WTRU-specific search space and/or location within the search space. The wide beam for the control channel may be determined during initial access procedure, random access procedure, and/or cell (re)selection procedure.

[0152] The DCI in the control channel may carry a bit field to request preferred beam reporting. If a WTRU receives an indication of preferred beam reporting, the WTRU may report a preferred narrow beam index in the corresponding uplink resource.

[0153] The DCI in the control channel may carry a bit field to request beam pairing.

[0154] Referring now to FIG. 10, FIG. 10 shows a diagram illustrating an intra-TTI DL assignment with a guard period to detect the Tx beam for data and switch the Rx beam. While the beams shown in 10 are described in the context of Tx beams used by a transmitter, it will be appreciated that a receiver uses a

corresponding Rx beam in a similar manner. Therefore, Tx and Rx may be used interchangeably in the context of a transmitter or a receiver, respectively.

[0155] In FIG. 10, two TTIs 1001 and 1002 are shown. In TTI 1001, a normal control Tx beam B1 (i.e., wide beam) is associated with a normal data Tx beam B1x, which is a narrow beam. A guard period G is present between the control Tx beam B1 and the normal data Tx beam B1x. In TTI 1002, normal control Tx beams B1 and B2 (i.e., wide beams) are associated with normal data Tx beams B1x and B2y, respectively, where the normal data Tx beams B1x and B2y are narrow beams. A guard period G is present between control Tx beam B2 and the data Tx beam B1x.

[0156] Spatially, narrow beams B2x, B2y, etc., are within the area of wide beam B2. Similarly, a number of narrow beams B1x, B1y, etc., reside within the area of wide beam B1. Thus, narrow beams B2x, B2y, etc., are associated with wide beam B2 and narrow beams B1x, B1y, etc., are associated with wide beam B1.

[0157] The WTRU may need to decode the control channel, and may extract from the DCI, the ID of the Tx beam (and thus information on the BRS) of the data channel. This may require a guard time G to be used between the end of the control region B1 and the start of the associated data Tx beam B1x, to allow the WTRU enough time to correctly steer its receive beam to receive the data channel (i.e., to align its (narrow) receive beam with the mB's transmit beam). Within a TTI, a guard period G may be achieved by creating a gap between the end of the control region and the start of the data region, as illustrated in FIG. 10. The length of the guard period may need to be set such that the WTRU may be able to decode the control channel and switch its receive beam before the start of the data region.

[0158] A guard period G may be present between the control channel and its associated data channel in a certain DCI format in which beam index is provided for the associated data channel. One or more of following parameters may apply.

[0159] A guard period G may be used for a WTRU with a certain receiver beamforming capability. For example, if a WTRU indicated that the WTRU has analog beamforming capability only at the receiver, the guard period G may be configured by the base station via higher layer signaling. Alternatively, a WTRU may indicate a required guard period for the receiver beamforming adaptation.

[0160] A guard period G may include the control channel reception time and receiver beam switching time. Therefore, the portion of control channel reception time may be used, depending on the WTRU receiver beamforming capabilities.

[0161] A guard period G may be present if the DCI in the control channel indicates that the beam index of the associated data channel is changed from the latest beam index. Alternatively, the guard period G may be present if the DCI in the control channel indicates that the beam index of the associated channel is different from the beam index of the control channel. A single bit or state in the DCI may indicate the beam index change confirmation, or guard period indication. Other bits or states may also indicate the beam index change.

[0162] If the length of the guard period G is smaller than the CP length, no explicit guard period may be used. If a system supports two or more CP lengths (e.g., a normal CP length and an extended CP length), the guard period G may be used in the normal CP case, while no guard period is used in the extended CP case. Therefore, the guard period G may be considered as '0' in FIG. 10 if the CP length is larger than beam switching time and the decoding time.

[0163] It should be noted that CP length and guard time can be interchangeably used. For example, CP length may be used in a certain waveform (e.g., OFDM) and guard time may be used in another waveform (e.g., single carrier modulation) but is not limited to a specific waveform. The CP may be used between modulation symbols and the guard period may be used between the control channel and the associated data channel.

[0164] Referring now to FIG. 11, FIG. 11 shows a diagram illustrating a cross-TTI DL assignment with narrow beam indication. Instead of creating guard

periods within a TTI, cross-TTI DL assignments may be used where a control Tx beam in one TTI is associated with a data Tx beam in a subsequent TTI. The subsequent TTI may immediately follow the corresponding TTI, or may follow by one or more TTIs. Suffixes "x", "y" and "z" are further used to identify different narrow data Tx beams associated with different wide control Tx beams. For example, B1x/B1y/B1z denote narrow beams associated to wide beam B1, B2x/B2y denote narrow beams associated to wide beam B2, and so on. In one or more instances, narrow data Tx beams (e.g., B1x and B2y) may be sequentially transmitted in the same TTI (e.g., TTI1). In other instances, narrow data Tx beams (e.g., B3x and B3y) may be transmitted in parallel in the same TTI (e.g., TTI3)

[0165] For the cross-TTI assignments, the control channel signaled during TTI "n" may point to DL data assignments for TTI "n+k". In this case, both the offset "k" and the narrow beam for data transmission may need to be signaled in the DCI in addition to the default information fields that may need to be carried in the DCI.

[0166] The above examples illustrate schemes using a single transport block (TB) per TTI. In another example, a transmission scheme may use two or more transport blocks (TBs) within a TTI.

[0167] Referring now to FIG. 12, FIG. 12 shows a diagram for a dual TB transmission scheme. Two or more transport blocks may be transmitted with a same beam as the control channel, or may be transmitted with different beams. For example, FIG. 12 illustrates two transport blocks 1201 and 1202 transmitted (multiplexed) in a TDM fashion within a single TTI (e.g., TTI1). The transmission of the individual transport blocks may use the same beam as the control channel (e.g., transport block 1201 which uses a wide beam), or may use a different beam (e.g., transport block 1202 which uses a narrow beam). In the latter case, the narrow beam ID may need to be signaled in the control region of the TTI.

[0168] In particular, as shown in FIG. 12, a first TB (TB1) may use the same wide beam or the same beam ID as the control channel, and a second TB

(TB2) may use a narrow beam or a beam ID that is different from the beam ID used by the control channel. The beam ID for TB2 may be signal in a DCI transmitted in control data B1 that is associated with TB2. In addition, the dual TB transmission scheme shown in FIG. 12 may be used to carry out a fallback transmission, to be described in more detail below. As a fallback mechanism, data carried by TB1 may be a subset of the data carried by TB2, and TB1 may use a lower modulation and coding scheme (MCS) value than TB2.

[0169] In an example which the two transport blocks may be transmitted in a TDM fashion, the control channel and the DL data assignment may be in the same TTI. For example, transport block 1201 may be associated with control Tx beam 1203 and transport block 1202 may be associated with control Tx beam 1204. The first transport block may be mapped on to a first codeword provided in the control Tx beam 1203 and the second transport block may be mapped on to a second codeword provided in control Tx beam 1204. The codeword may be associated with: a specific beam or beam ID, a BRS, and/or a time/frequency location. As used herein, a codeword represents user data before it is formatted for transmission.

[0170] There may be a one-to-one mapping between the transport block and the codeword. The mapping rule may be fixed. For instance, the first transport block may be mapped onto the first codeword and the second transport block may be mapped onto the second codeword. Alternatively, the mapping rule may be dynamically indicated. For instance, the first transport block may be mapped onto one of the codeword according to the indication. The number of codeword(s) could be equal to or smaller than the number of the transport block(s). If a single codeword is defined, irrespective of the number of transport block, the same beam may be used. Therefore, the transport blocks within a TTI may be mapped on to a single codeword.

[0171] Furthermore, the first codeword (codeword #1) may be transmitted on the same wide beam as the control channel, and the second codeword (codeword #2) may be transmitted on a narrow beam. In this case, mapping of

codeword #2 in the data region of the TTI may be done such that the WTRU has enough time to decode the control channel and switch its receive beam before it may start buffering and receiving the symbols corresponding to codeword #2.

[0172] In another example in which the two transport blocks are transmitted in a TDM fashion, the control channel and the DL data assignment may be in different TTIs. In this case, the network (e.g., mB) may include in the DCI the following information: the relative TTI offset of the DL data assignment and/or the Tx beam index (or beam ID) for both codewords. In this example, codeword #1 and codeword #2 may be mapped anywhere in the data region of the TTI (i.e., flexible mapping).

[0173] In an example, a normal transmission scheme in DL may use an open loop wide beam transmission with channel quality indication (CQI) only reporting for link adaptation purposes. For this scheme, the WTRU may use the BRS associated to the mB DL Tx wide beam, to perform channel estimation, receive the data channel and measure the CQI.

[0174] In another example, a normal Tx scheme may use closed loop narrow beam transmission. The WTRU may report, in addition to the CQI for the active beam, measurements on other detected narrow beams. For this scheme, the WTRU may use the BRS associated to the active narrow beam to perform channel estimation, receive the data channel, and report the CQI. Additionally, the WTRU may use BRS of other beams to perform and report other narrow beam measurements and report the beam ID of its preferred narrow beam.

[0175] One or more fallback transmission schemes are provided herein. The term “fallback transmission scheme” may be interchangeably used with the following: open-loop transmission scheme, coverage enhanced transmission scheme, beam diversity transmission scheme, beam sweeping transmission scheme, and transmit diversity scheme.

[0176] In one or more embodiments, a fallback transmission scheme may be defined as a transmission scheme which may not require a beam pairing process, WTRU reporting assistance for beam pairing, and/or beam ID indication

for the associated data channel. One or more of following parameters may apply for fallback transmission scheme. A certain DCI format may be used for fallback transmission scheme which may not include beam ID for the associated data channel. The control channel and/or data channel may be transmitted with one or more beams. A single wide beam may be used. Two or more wide beams may be used, where the two or more wide beams may be configured for a control channel and/or a data channel transmission. Two or more narrow beams associated with a wide beam which may be used in the normal transmission configured or used.

[0177] The control channel and/or data channel may be transmitted with repetitions. Two or more TTIs may be used for repetitions. A different beam may be used in each TTI. The beam ID in each TTI may be predefined or configured by higher layer signaling. Alternatively, the beam ID in each TTI may be determined as a function of the subframe number and/or SFN. The number of repetition of the fallback transmission scheme may be determined by one or more of following: configuration via higher layer signaling and/or broadcasting channel, a function of number of wide beams and/or number of narrow beams, an indication from the associated DCI, the time/frequency resource used during random access procedure, and/or system parameters.

[0178] In another example, a fallback transmission scheme may be defined as a transmission scheme which may be transmitted in a subset of the TTIs. A subset of TTIs may be defined or configured for the fallback transmission. A subset of TTIs may be defined or configured to monitor control channel associated with a fallback transmission. The subset of TTIs may be configured via higher layer signaling. The subset of TTIs may be determined as a function of the wide beam index associated with the control channel which is used for normal transmission. The subset of TTIs may be determined as a function of one or more of system parameters including physical cell ID, SFN number, and/or system bandwidth.

[0179] There may be a BRS association for normal and fallback transmission schemes. Each of two or more BRSs may be defined with a BRS

index associated with a beam. The BRS index may be defined according to the beam width. In an example, a BRS index associated with wide beam may be defined as W_x, where $x \in \{1,2,\ldots,N\}$, and a BRS index associated with narrow beam may be defined as N_y, where $y \in \{1,2,\ldots,M\}$. N wide beams and M narrow beams are used in the system with a BRS index. A WTRU may determine an associated receiver beam for each BRS index. The wide beams and the narrow beams may be independently defined. Alternatively, a wide beam may be associated with two or more narrow beams.

[0180] In another example, the BRS index may be defined in a hierarchical manner. For example, B_x, where $x \in \{1,2,\ldots,N\}$ may be defined as BRS index associated with a wide beam and each wide beam may be associated with two or more narrow beams B_xy, where $y \in \{1,2,\ldots,M\}$. Each wide beam may have two or more associated narrow beams. The number of narrow beam may be different according to the wide beam index.

[0181] According to the BRS index used, a WTRU may determine a receive beam to receive the signal and perform signal reception procedures. For example, the WTRU may form a receiver beam in analog, digital, or hybrid domain to receive the signal and buffer the signals before it starts demodulation.

[0182] In one or more embodiments, a first BRS index may be used to monitor and/or receive a control channel and a second BRS index may be used to receive an associated data channel. One or more of following parameters may apply.

[0183] The first BRS index may be associated with a wide beam and the second BRS index may be associated with a narrow beam. The first BRS index may be one of the beam indexes of wide beams. The second BRS index may be a narrow beam index associated with the first BRS index. For example, if the first BRS index is B_x, the narrow beam index may be B_xy, where the x is the same for both first BRS index and the second BRS index.

[0184] The first BRS index may be determined during random access procedures and the second BRS index may be determined by a transmitter (e.g., a

mB). For example, the first BRS index may be determined as a function of the PRACH resource used and the second BRS index may be indicated in the associated DCI.

[0185] The first BRS index may be determined during initial access procedures including cell selection/reselection procedures. The first BRS index may be determined as a function of the physical cell ID. The first BRS index may be determined based on the downlink measurement which may be used for cell selection/reselection. The first BRS index may be determined based on the time location of the synchronization signal received.

[0186] In one or more embodiments, a first BRS index may be used to monitor and/or receive a first type of control channel and a second BRS index may be used to monitor and/or receive a second type of control channel. One or more of following parameters may apply. The first BRS index and the second BRS index may be associated with a wide beam. The first BRS index may be associated with a wide beam and the second BRS index may be associated with a narrow beam. The second BRS index may be one of the narrow beams associated with the first BRS index. The second BRS index may be one of the narrow beams which may be independent from the wide beam index.

[0187] The first type of control channel may be a broadcasting/multi-casting channel and the second type of control channel may be a WTRU-specific control channel. For example, the first type of control channel may be defined as a common search space and the second type of the control channel may be defined as a WTRU-specific search space. A WTRU may monitor the first type of control channel in a common search space to receive a multi-casting and broadcasting channels including system information, group power control, paging, and MBMS. A WTRU may monitor the second type of control channel in a WTRU-specific search space to receive unicast traffic.

[0188] In one or more embodiments, the WTRU and the mB may operate using multiple transmission schemes. For example, both wide beams and narrow beams may be used in a first transmission scheme and wide beams may be only

used in a second transmission scheme. One or more of following parameters may apply. The first transmission scheme may be a normal transmission scheme and the second transmission may be a fallback transmission scheme.

[0189] The first transmission scheme may use one beam for a single transmission while the second transmission scheme may use beams available for a single transmission. The single transmission may be a control channel transmission or a data channel transmission. The single transmission may be a single transport block transmission for the data channel. In case of the control channel, the single transmission may be a single DCI transmission. The second transmission scheme may use beams available with repetitions. For example, N repetitions may be used with N beams. Therefore, one BRS index associated with a repetition transmission and all BRS indices are used with N repetitions, where N wide beams may be used in the system.

[0190] The first transmission scheme may use the BRS index indicated from a transmitter while the second transmission scheme may use a predefined BRS index. The predefined BRS index may be determined by one or more of following: a fixed number, a predefined sequence, a subframe number and/or frame number, time/frequency location, a WTRU ID, and/ or system parameters.

[0191] In one or more embodiments, a WTRU may report downlink reference signal received power (e.g., RSRP) for one or more BRS in order to provide physical layer (i.e., layer 1 (L1)) measurement and CSI feedback. For example, a hierarchical BRS structure may be used, wherein N wide beams may be used with M narrow beams for each N wide beams. It should be noted that the terms reference signal received power, downlink pathloss, pathloss, channel quality indicator, wideband channel quality indicator, RSRP and downlink measurement may be used interchangeably.

[0192] One or more of following parameters may apply for the downlink measurement reporting. A downlink measurement may be reported for the currently configured or used wide beam. A downlink measurement may be reported for a subset of N wide beams wherein the subset may be determined

based on currently configured or used wide beam. For example, adjacent wide beams of the currently configured or used wide beam may be determined as the subset. The downlink measurement reporting for a subset of N wide beams may include individual downlink measurement value for each wide beam within the subset. The downlink measurement reporting for a subset of N wide beams may include an index of the wide beam within the subset of N wide beams, which may provide the highest value and its associated downlink measurement value.

[0193] A downlink measurement may be reported for all N wide beams configured by mB. A WTRU may report one downlink measurement for a wide beam at a time. A reporting cycle (e.g., duty cycle) may be determined or configured for each wide beam. Therefore, each wide beam may have a same or a different reporting cycle. A time offset (e.g., TTIs) may be used for downlink measurement reporting for each wide beam.

[0194] In one or more embodiments, a WTRU may send a beam pairing, or beam re-pairing, request to a mB. For example, if a currently configured or used downlink transmit beam is below a predefined threshold, the WTRU may send a request of beam pairing between transmit and receive beams. The beam pairing request information may be transmitted in a higher layer configured uplink control resource. The higher layer configured uplink control resource may be the same as the uplink control resource configured for scheduling request. The beam pairing request information may be interchangeably used by a fallback transmission request.

[0195] The following provides a description of DL/UL transmission modes and modes of operation. In the current 3GPP specifications, the transmission modes may only be applicable to a downlink shared channel (DL-SCH) transmission, and may define the single or multi antenna transmission scheme, the specific antenna mapping, the reference symbols used for demodulation (e.g., CRS or DM-RS), and the associated CSI feedback. For systems operating at frequencies above 6 GHz, there may be a need to expand the concept of transmission mode to address aspects of the propagation channel specific to the

use of directional antennas (i.e., narrow and wide beams), such as: effects of change in the WTRU orientation, blocking effects, delay and angle spread, and so on.

[0196] One or more transmission modes may be used in a system and a transmission mode may use one or more transmission schemes. A WTRU may be configured with a transmission mode in a semi-static manner and the transmission schemes used within a transmission mode may be switched dynamically (e.g., according to a dynamic switching transmission mode). A transmission mode may be configured via higher layer signaling. A transmission mode may be determined as a function of at least one of the number of antenna ports, WTRU capability, and system parameters. A transmission mode may be determined based on the beamforming capability of a WTRU which may include the number of RF chains, number of receive beams, and/or beam switching time.

[0197] For example, a transmission mode may use two transmission schemes where a normal transmission scheme and a fallback transmission scheme may be used. One or more of following parameters may apply. Within a transmission mode, a transmission scheme used in a TTI may be determined by a DCI format received in the control region. A first transmission scheme may be used if a first DCI format (e.g., DCI format-A) is received in the control region and a second transmission scheme may be used if a second DCI format (e.g., DCI format-B) is received in the control region. The first transmission scheme may be a normal transmission scheme and the second transmission scheme may be a fallback transmission scheme.

[0198] The transmission scheme used in the TTI may be determined by a TTI type associated with a transmission. Each TTI may be associated with a transmission among the transmission schemes associated with the transmission mode. Therefore, the transmission scheme may be determined as a function of the subframe number and/or frame number.

[0199] The transmission scheme used in the TTI may be determined by a search space of the control channel. The control channel monitored by WTRU

may be split into multiple subsets and each subset may be associated with a certain transmission scheme.

[0200] The transmission scheme used in the TTI may be determined by an indication in the DCI.

[0201] A WTRU may monitor a control channel according to a first transmission scheme in all TTIs, while the WTRU may monitor a control channel according to a second transmission scheme in a subset of TTIs. The first transmission scheme may be a normal transmission scheme and the second transmission scheme may be a fallback transmission scheme. A WTRU may monitor the control channel for the second transmission scheme if one or more of the following applies: the WTRU is not scheduled for a certain number of consecutive TTIs, the WTRU sends a certain number of consecutive negative ACK corresponding to downlink transmissions, or a downlink measurement is below a predefined threshold.

[0202] A WTRU receiver may use a narrow beam in the first transmission scheme and the WTRU may use a wide beam in the second transmission.

[0203] A WTRU receiver may use a beam ID indicated in the associated control channel to receive the corresponding data channel for the first transmission scheme, and the WTRU may use a predefined beam to receive the corresponding data channel for the second transmission scheme. The predefined receiver beam for the second transmission scheme may be the same receiver beam used for the associated control channel. Alternatively, a sequence of beams may be predefined.

[0204] The following embodiments may include switching (in a semi-static or dynamic fashion) between fallback and normal transmission schemes and may address the following aspects: DCI and UE monitoring behavior, and WTRU behavior for switching between fallback and normal transmission schemes.

[0205] In one of more embodiments, it may be assumed that the WTRU may be connected to the mB via a narrow beam pair for the DL and UL data, and that the mB may use a wide beam for the DL control channel transmission. Thus,

an operation with data fallback to a wide beam is described such that, as the orientation of the WTRU may change, the paired narrow beams used for data transmission may become misaligned, and the data link may experience a sudden and significant drop in signal-to-noise ratio (SNR). If the change in the WTRU orientation does not exceed a certain value, the DL control channel transmissions using wide beams may still be received by the WTRU. This scenario may trigger the mB to dynamically switch the WTRU to a data fallback scheme that uses the same wide beam as for the DL control channel. The data fallback scheme may allow the WTRU to maintain connection using the current transmission mode, while the mB may perform a RRC reconfiguration of the transmission mode until the mB may perform a beam switch, or until the operating SNR using the current transmission mode may improve.

[0206] The following embodiments may address triggers that initiate the mB to use the data fallback, how the DL data fallback scheme is signaled to the WTRU, and how the WTRU data fallback scheme is signaled to the WTRU.

[0207] In one or more embodiments, signaling the DL data fallback to wide beam is described such that the mB may use the same wide beam as used for the control channel for the transmission of the DL fallback data. One or more of following parameters may apply. The WTRU may need to switch its receive beam for data to the beam used to receive the control channel. If control and fallback data are scheduled in the same TTI, a guard time may be needed between the control and the data regions of the TTI, as shown in FIG. 10. The fallback data may be scheduled for a subsequent TTI. The offset of the TTI carrying fallback data may be signaled in the DCI, may be pre-defined, or may be semi-statically configured.

[0208] A different DCI format may be used for fallback and normal transmission. For example, DCI-A may be used for normal transmission and DCI-B may be used for fallback transmissions. In the embodiment described above, the use of fallback DCI (DCI-B) may implicitly indicate the fallback data is

transmitted on the same wide beam as the control. In this case, the fallback DCI may not include the BRS and beam ID.

[0209] In another embodiment, the fallback DCI may explicitly indicate the data fallback beam. The fallback DCI may include at least one of the following pieces of information: BRS, beam ID, and the offset (in TTIs) of the DL data assignment. The fallback DCI may also include the preferred WTRU transmit beam for UL data fallback.

[0210] In another embodiment, the data fallback beam may be determined implicitly during the reception of the associated control channel. For example, a WTRU may perform a blind decoding of the associated control channel with one or more BRS candidates. The WTRU may determine one BRS for the associated control channel decoding. Based on the determined BRS for the associated control channel, the WTRU may determine the data fallback beam. In another example, a WTRU may perform a blind decoding of the associated control channel with one or more control channel candidates. The WTRU may determine the control fallback beam as a function of the control channel candidate. Based on the determined control fallback beam, the WTRU may determine the data fallback beam.

[0211] A WTRU may monitor for both a first DCI format (e.g. DCI-A) and a second DCI format (e.g., DCI-B) in each TTI. Alternatively, the WTRU may monitor for DCI-B only in configured TTIs. The use of DCI-A versus DCI-B may implicitly indicate a different timing rule for the associated data channel reception. In one example, the data channel associated to DCI-A may be transmitted in TTI n+k1 for a DCI-A signaled in TTI n, while the fallback data channel associated to DCI-B may be transmitted in TTI n+k2 for a DCI-B signaled in TTI n. The offset values k1 and k2 may be either explicitly included in the DCI, or the offset of the fallback data, k2, may be implicitly derived from the fallback DCI-B type.

[0212] Upon the detection of the fallback DCI-B on the control wide beam in TTI #n, the WTRU may configure its receive beam for DL data in TTI #n+k2,

where k2 may be explicitly signaled in DCI-B or implicitly derived from the fallback DCI-B type. This may be done using the appropriate BRS, which may be either the same BRS as used for the wide beam control, or determined based on the beam ID that may be signaled in DCI-B.

[0213] Additionally, the WTRU may transmit the UL Acknowledgment—Negative Acknowledgment (A/N) feedback using an UL beam that has the same orientation as the DL beam used for the data fallback reception. The timing for the transmission of the UL A/N feedback may be determined implicitly based on the TTI index (n+k2) of the fallback data transmission. For example, the UL A/N corresponding to the DL fallback data on TTI #n+k2 may be transmitted in TTI #n+k2+m. During TTI #n+k2+m, the mB may monitor the WTRU UL A/N feedback using an UL Rx beam with the same orientation as the DL Tx beam used for DL data fallback transmission during TTI #n+k2.

[0214] In an embodiment, a mB may indicate a fallback for UL data transmission. The fallback for UL data transmission may have at least one of the following parameters. First, a predefined wide beam may be used for uplink transmission. The predefined wide beam may be based on the beam used for UL control. The predefined wide beam may be a beam index. Second, a wider beam, which may be associated with the most recent narrow beam, may be used. For example, a wider beam may consist of one or more narrow beams that may be used for normal UL data transmission, and if a fallback UL transmission is triggered or indicated, the wider beam may be used for the UL fallback data transmission. Third, repetitions of the UL data transmission may be used. Fourth, the UL data transmission may be within a narrower bandwidth. Fifth, a higher transmission power may be used.

[0215] In an embodiment, the indication of a fallback UL data transmission may be transmitted in a DCI. For example, a reserved bit in a DCI, which may be used for uplink grant, may be used to indicate a fallback UL data transmission. In another example, a fallback DCI may be used and a WTRU may monitor for

the fallback DCI as well as for a normal DCI for normal UL data transmission (e.g., normal DCI). One or more of the following parameters may apply.

[0216] The fallback DCI may be monitored for in a subset of resources in which a WTRU may monitor for normal DCI. For example, if a WTRU monitors for normal DCI in every TTI, the WTRU may monitor for the fallback DCI in a subset of TTIs. A WTRU may monitor for both normal DCI and fallback DCI in a TTI, which may be a subset of TTIs determined for the fallback DCI.

[0217] The fallback DCI and the normal DCI may be monitored in a disjoint set of TTIs. For example, a first set of TTIs may be used for normal DCI and a second set of TTIs may be used for fallback DCI, and there may be no overlap between the first set and the second set. The first set of TTIs may be larger than the second set of TTIs. A transmission scheme for the associated UL data transmission may be different for the first set of TTIs and the second set of TTIs.

[0218] A fallback DCI may be received over multiple TTIs while a normal DCI may be received within a single TTI. For example, the fallback DCI may be transmitted with repetitions with multiple (e.g., consecutive) TTIs, while the normal DCI may be transmitted within a TTI.

[0219] When the fallback DCI is transmitted with repetitions, at least one of following parameters may apply. A different transmit beam (e.g., beam ID) may be used for each repetition. For example, if the number of repetitions (i.e., number of TTIs) is N, the transmit beam may change in each repetition. Therefore, N transmit beams may be used for a single fallback DCI transmission. If a total number of transmit beams at a transmitter is M and M is smaller than N, the M transmit beams may be cyclically used with N repetitions. Therefore, M transmit beams may be used for a single fallback DCI transmission with N repetitions. If a different transmit beam (e.g., beam ID) may be used for each repetition, a corresponding receiver beam may be used at a receiver.

[0220] The embodiments described herein may be used for the DCI that is used for normal and fallback downlink data transmissions, although an uplink

transmission beam may be replaced by a downlink receiver beam and still be consistent with the embodiments.

[0221] In one or more embodiments, the dual TB transmission scheme described above (see e.g., FIG. 12) may be used as a fallback transmission while operating in the dynamic switching transmission mode. Thus, an operation with dual TB based fallback Tx scheme is provided. As used herein, transport block and codeword may be used interchangeably.

[0222] When the mB detects that a particular WTRU needs data fallback, it may partition the transmission of the next transport block (MAC PDU) into two physical layer code words, which may be transmitted on a single spatial layer, in a TDM fashion within the TTI. The first codeword may use the same wide beam as the control channel, while the second codeword may use a narrow beam, with the beam ID or the beam index signaled by the mB in the DCI (see e.g., FIG. 12).

[0223] In an embodiment, the first codeword may use a robust coding and modulation scheme, and the data carried in the first codeword may be a subset of the data in the second codeword (current MAC PDU being transmitted). The WTRU may use the data that is correctly decoded in the first codeword to decode the second codeword.

[0224] Referring now to FIG. 13, FIG. 13 shows a diagram illustrating using a dual TB transmission scheme for data fallback. In an embodiment according to FIG. 13, the size of a MAC PDU 1301 to be transmitted may exceed a max Turbo coder block size and code block segmentation with M code blocks 1302 may be used. In this scenario, in a first transmission, the data transmitted by the first codeword may be a full code block of the MAC PDU carried in the second codeword, as illustrated in FIG. 13. The next (e.g., second) transmission of fallback data using this scheme may transmit, in the first codeword, the next code block of the current MAC PDU, and may re-transmit the full MAC PDU in the second codeword. This transmission scheme may continue (e.g., for M transmissions) until the WTRU correctly decodes the MAC PDU and the mB

receives an ACK for the current MAC PDU transmission. The A/N signaling for this scheme will be described in more detail below. Thus, a wide data Tx beam B1 may be used for transmitting TB1 (i.e., first codeword) of a transmission and a narrow data Tx beam B1x or B1y may be used for transmitting TB2 (i.e., second codeword).

[0225] Referring now to FIG. 14, FIG. 14 shows a diagram illustrating another example of using the dual TB transmission scheme for data fallback. In an embodiment according to FIG. 14, if a size of the MAC PDU does not exceed the max Turbo coder block size, the MAC PDU 1401 may be partitioned in M sub-blocks 1402. The first codeword may be used for sequential transmission of independently coded sub-blocks and the second codeword may be used for the transmission (and re-transmission) of the entire MAC PDU, as shown in FIG. 14. For example, for the first transmission of the fallback data, codeword #1 may transmit sub-block #1 of the MAC PDU, and codeword #2 may transmit the entire MAC PDU. For the first re-transmission (e.g., second transmission) of the fallback data, codeword #1 may carry sub-block #2, and codeword #2 may carry the full MAC PDU. The process may continue for a next transmission (e.g., third transmission) until the WTRU ACKs codeword #2. Thus, a wide data Tx beam B1 may be used for transmitting TB1 (i.e., first codeword) of a transmission and a narrow data Tx beam B1x or B1y may be used for transmitting TB2 (i.e., second codeword).

[0226] DL assignment for the dual TB transmission may be provided such that the dual TB transmission may be used as a normal transmission scheme, or as a fallback scheme. The DCI for the dual TB transmission scheme may include the default information: resource assignment information for each codeword (e.g., resource block allocation), HARQ process number, transport block information (modulation and coding scheme (MCS), redundancy version (RV), new data indicator (NDI), etc.), antenna configuration (as needed), DAI, power control indicator, and other flags as needed. Additionally, the DCI may include beam ID or beam index for each TB. In one or more embodiments, the beam ID or beam

index of the first codeword may implicitly be set to the beam ID or beam index used for the control channel transmission, and thus it may not be included in the DCI.

[0227] As the segmentation of the MAC PDU may be different for the fallback scheme as compared to the normal scheme, the segmentation configuration may be signaled to the WTRU. The type of segmentation may be indicated in the DCI, or may be included in the MAC header. For the case where the type of segmentation is included in the DCI, the DCI format for the dual TB scheme used for fallback may be different from the DCI format for the dual TB scheme used for normal transmission.

[0228] In one example, for the data fallback transmission, the DCI may include the following: a field indicating that a single MAC PDU is transmitted using the 2 CW scheme, a field indicating the number M of sub-blocks (or code blocks) the MAC PDU is partitioned in for mapping to codeword #1 (see e.g., FIG. 13 and FIG. 14), and the index (in the range 1 to M) of the sub-block (or code block) transmitted in the current TTI. The maximum value of M may be pre-defined. The choice for the maximum value of M may be a trade-off between the maximum transport block size to be transmitted with the fallback scheme, and the maximum number of TTIs the MAC PDU may be transmitted due to sub-block or code-block partitioning for transmission on codeword #1.

[0229] The dual TB transmission scheme may be used in all TTIs, or may be used in configured TTIs. When the scheme is used in all TTIs, the WTRU may need to monitor the normal DCI as well as the fallback DCI in all TTIs. When the scheme is used in configured TTIs, the WTRU may monitor the normal DCI and the fallback DCI during the configured TTIs, and may monitor the normal DCI only for the rest of the TTIs.

[0230] In one or more embodiments, HARQ retransmissions may be used when using the dual TB scheme. For example, when the dual TB scheme is used for fallback data, the mB may transmit in the first codeword, consecutive code blocks (or sub-blocks) of the original MAC PDU (as shown in FIG. 13 and FIG.

14). The WTRU may only transmit UL A/N signals for the second codeword. The mB may sequentially transmit code block (or sub-block) index 1, 2, ...M of the current MAC PDU on codeword #1 and the full MAC PDU on codeword #2. This may be done until the WTRU correctly decodes the MAC PDU on codeword #2. Due to HARQ processing latencies, and depending on how the DL fallback data transmissions are scheduled, it may happen that the mB transmits code block (or sub-block) k+1 after the WTRU has ACK-ed the MAC PDU after receiving code block (or sub-block) k. In this case, the WTRU may discard all the subsequent received buffers for the current MAC PDU.

[0231] In another embodiment, when the dual TB scheme is used for normal data transmission, the WTRU may transmit UL A/N signals for each codeword. In this case, if the WTRU correctly decodes codeword #1, but not codeword #2, the WTRU may send an ACK for codeword #1 and a NACK for codeword #2. When the mB receives an ACK for codeword #1 and a NACK for codeword #2, for the next transmission to the WTRU, the mB may transmit the next code block (or sub-block) of the sequence in codeword #1, and re-transmit the entire MAC PDU in codeword #2.

[0232] A control channel fallback operation is described such that fallback TTIs may be pre-defined TTIs within sub-frames, which may be used by the mB to transmit the control channel on multiple wide beams (i.e., perform wide beam sweeping) to WTRUs that may need control fallback. For example, for cases where the WTRU may change its orientation, or when blockage of an active beam pair may occur, the mB may determine the need to use a fallback transmission scheme for the control channel and the data channel of a specific WTRU. In this case, during the fallback TTIs, the mB may repeat the transmission of the control channel on several spatial beams, to enable the WTRU to correctly receive the control channel in one or more beams. The one or more beams may be different from the original active beam of the active beam pair. The mB may use a fallback DCI (e.g., DCI-B) to transmit the fallback control channel during the fallback TTIs.

[0233] To make efficient use of the spectrum resources, the fallback TTIs may be used for regular transmissions when fallback schemes are not used. Thus, the mB may use fallback schemes only if the mB determines it needs to. In this case, the mB may use normal DCI (e.g., DCI-A) for the control channel transmissions. During fallback TTIs, the WTRU may monitor for both the normal DCI (e.g., DCI-A) and the fallback DCI (e.g., DCI-B).

[0234] In one or more embodiments, when the mB determines the need for control fallback for a WTRU, it may use the same reference signal (BRS) for all control beams that it re-transmits to the WTRU. In this case, the WTRU may need knowledge of the number of repetitions of the control channel, as well as of the time and frequency resources that may be assigned to the fallback TTI. Accordingly, the WTRU may monitor the fallback TTIs using the same reference signals (BRS) as used for the normal transmission scheme.

[0235] In another embodiment, the mB may use different BRSs for each beam, which may enable the WTRU to perform beam measurements. In this case, a mapping of the mB Tx beam ID (or beam index, or BRS) to time-frequency resources within the fallback TTIs may need to be known at the WTRU. This mapping may be either cell-specific (in which case, it may be signaled on broadcast), or WTRU specific, which may be configured via RRC signaling.

[0236] Mapping of Tx beam for fallback DCI to resources (TTI/OFDM symbol) is provided according to one or more embodiments. As previously indicated, the first element that enables the control channel fallback operation may be the provisioning of fallback TTIs. The fallback TTIs may be either cell specific or WTRU specific.

[0237] In addition to provisioning the fallback TTIs, the WTRU may need to be able to find and decode the fallback control channel within the fallback TTIs. Therefore, a mapping between the mB transmit beam and the resources used for the fallback control channel may need to be defined. The mapping may be cell specific or WTRU specific and may be signaled to the WTRU via broadcast signals or RRC signaling. The signaling may include information on the number

of Tx wide beams supported by the mB, the number of fallback TTIs per sub-frame, the length of the control region in the fallback TTIs.

[0238] In one or more mapping embodiments, the number of mB Tx wide beams is denoted by Nwb, the size (in OFDM symbols) of the control region within a TTI is denoted by Lc, and the number of fallback TTIs per sub-frame is denoted by Nf. The mapping may be static, and pre-defined, as follows.

[0239] The sub-frame pattern periodicity, T, may be determined as the ratio between the number of mB wide beams (Nwb) and the number of OFDM symbols per sub-frame that may be used for fallback control signaling ($L_c N_f$).

[0240] The index of the fallback TTI (t_f) within a sub-frame may be fixed (pre-defined), or it may be WTRU specific. If the index of the fallback TTI is WTRU specific, in one example, the index may be set as: $t_f = mod\left(\frac{UE_{ID}}{N_f}\right)$. If more than one fallback TTIs per sub-frame are assigned to a WTRU, the index of the first fallback TTI may be calculated as indicated above. The indices of the subsequent fallback TTIs in the sub-frame may be at a fixed offset (pre-defined or signaled) with respect to the first fallback TTI.

[0241] The mapping between the mB Tx wide beam b, $(0 \le b \le N_{wb} - 1)$, the fallback TTI index $n, (0 \le n \le N_f - 1)$ within sub-frame k, $(0 \le k \le T - 1)$, and the OFDM symbol index (l), may be expressed as: $b = k \cdot N_f \cdot L_c + n \cdot L_c + l$.

[0242] In this example, the mB would transmit the fallback DCI on wide beam index b in sub-frame k, fallback TTI index n within sub-frame k, and OFDM index l within the fallback TTI. FIG. 15 shows a diagram of a mapping of Tx beams for fallback DCI to resources for a single RF chain mB. According to this mapping, Nwb = 6, Nf=1 and Lc = 3 and a WTRU and mB behavior during fallback TTI is provided according to such mapping.

[0243] In particular, FIG. 15 shows a diagram illustrating an example of fallback TTI and linkage between fallback DCI and fallback data, where the mB has one RF chain. In particular, a control channel fallback transmission scheme using fallback TTIs is shown such that a DL control channel in a fallback TTI

may be repeated for one or more beam identities in a TDM manner. A WTRU may monitor and/or attempt to decode one or more of the control channels. Furthermore, the WTRU may use one Rx beam or sweep its Rx beam over a set of predefined or configured beam indices for monitoring/decoding the control channels.

[0244] During the TTIs that the mB configures as fallback, the mB may sweep the wide beam control channel using fallback DCI (DCI-B) for the WTRUs that may need control fallback. During the TTIs configured for fallback, the WTRU may monitor for both the regular DCI (DCI-A) and the fallback DCI (DCI-B). During the TTIs not configured for fallback (i.e., non-fallback TTIs), the WTRU may monitor for the regular DCI (DCI-A). The WTRU may not monitor for the fallback DCI (DCI-B) during the non-fallback TTIs.

[0245] The fallback DCI (DCI-B) may point to the DL resource assignment (time, frequency and beam) for fallback data. The mB may schedule fallback data repeated on multiple wide beams (e.g., B1, B2, B3 in FIG. 15), using smaller TBs (i.e., a smaller TB size).

[0246] In one example, the association between the fallback control (DCI-B) and the fallback data is shown in FIG. 15. The fallback data may be assigned on the same wide beam as the wide beam used for signaling the fallback control (DCI-B). In this case, in addition to the regular information carried in the DCI, DCI-B may also signal the offset (in TTIs) of the TTI that carries the fallback data, with respect to the current TTI (the offset may also be set to zero). Alternatively, the DCI-B may signal the beam ID or the beam index, and correspondingly the BRS of the beam that carries the fallback data.

[0247] Referring now to FIG. 16, FIG. 16 shows a diagram illustrating an example of fallback TTI and linkage between fallback DCI and fallback data, where the mB supports multiple RF chains. Since the mB may support multiple Tx RF chains, the mB may simultaneously transmit multiple beams during either the control region of the TTI, or the data region, or both. For example, in FIG. 16, the mB may simultaneously transmit control channels on beams B1 and

B3 during the first time resource of the fallback TTI, followed by control channel on beams B2 and B3 during the second time resource of the fallback TTI, and so on. The time-frequency resources may be used across different beams in a SDM fashion. For this example, the mB may insert beam-specific reference signals (BRS) in the appropriate time-frequency resources to enable correct reception by the WTRU.

[0248] Uplink A/N feedback may be signaled by a WTRU that received fallback DCI-B using an UL Tx wide beam that matches the DL Rx beam that the fallback DCI-B was received on (as an example, use the same steering vector).

[0249] The WTRU may transmit UL A/N feedback for the fallback data that corresponds to the fallback DCI-Bs that the WTRU decoded. For example, if in FIG. 15, the UE successfully decoded DCI-B transmitted on beams B2 and B3 in the fallback TTI, but it did not decode DCI-B transmitted on beam B1, it may transmit UL A/N corresponding to the fallback data on Tx beam B2 in TTI4 and UL A/N corresponding to the fallback data on Tx beam B3 in TTI5.

[0250] The timing of the UL A/N feedback may be derived by the WTRU according to the duplexing mode that the system operates on. For example, if the system operates in a TDD mode (including dynamic or enhanced TDD operation), the UL A/N feedback for data received on Tx beam B2 in TTI4 may be transmitted in the UL transmission opportunity that meets the HARQ timing requirements. The mB may use the timing of the ACK transmitted by the WTRU, to determine the DL Tx beam ID of the successful reception of fallback control and data. Corresponding to that TTI, and in order to monitor for the UL A/N transmission from the WTRU, the mB may configure the UL Rx beam to match DL Tx beam B2.

[0251] The mB may continue transmitting fallback control (DCI-B) during the configured fallback TTIs, until either it receives a positive ACK for the current transport block, or a fallback timer expires.

[0252] If the WTRU correctly decodes a fallback DCI-B and its associated fallback data on a beam that is different from the current active beam, the mB

may issue a measurement request for that different beam, or the WTRU may send a measurement report of the (preferred) different beam. If a measurement (e.g., signal quality or strength) in the measurement report is above a threshold, the mB may issue a beam switch command to the WTRU, while maintaining the same transmission mode. In another solution, if the WTRU correctly decodes the fallback data on only one of the fallback beams used for re-transmission, the mB may directly issue a beam switch command to the WTRU for the ACK'ed beam, and maintain the same transmission mode.

[0253] Fallback DCI using wide beam sweeping in the PDSCH region may be provided in one or more embodiments. For example, FIG. 17 shows a diagram of fallback DCI mapped to the data region, and linkage to fallback data, where the mB supports one or more RF chains. Accordingly, the fallback TTIs may be still be defined and assigned as described above, but within the fallback TTIs, the fallback DCI (DCI-B) may be mapped to the data region. This approach may be used for scenarios that require control channel congestion mitigation. To enable the WTRU to decode the fallback DCI (DCI-B), the mapping between the transmitted beam and the specific time-frequency resources may need to be known by the WTRU. This mapping may be cell-specific or WTRU specific, and may be signaled to the WTRU via broadcast signaling (MIB or SIB) or via RRC signaling.

[0254] In the example illustrated in FIG. 17, the end of the data region (and the start of the region that may be used for the fallback control channel) may be indicated explicitly via signaling, implicitly to the WTRU, or may be pre-defined. For single Tx RF chain mBs, the mB may sweep the fallback DCI (DCI-B) on multiple beams in a TDM fashion, according to the beam to resource mapping. In this case, the mB may apply beam-specific reference signals (BRS) to the time-frequency resources used for each beam. In the fallback TTI (TTI2) of FIG. 17, fallback DCI-B may be transmitted on Beam B2 during the data region of the TTI. BRS specific to beam B2 may need to be inserted in the time-frequency resources used for the DCI-B transmission with beam B2.

Furthermore, BRS specific to beam B3 may need to be inserted in the time-frequency resources used for the DCI-B transmission with beam B3.

[0255] The mB may transmit fallback DCI in that data region if it determines the need to do so. If no WTRUs need fallback transmissions, the mB may reuse the time-frequency resources to schedule regular data. The WTRUs that may monitor for the fallback DCI during the fallback TTI may still attempt to blind decode the fallback control channel, but may not successfully detect the fallback control channel.

[0256] Referring now to FIG. 18, FIG. 18 shows a diagram illustrating fallback DCI mapped to the data region using narrow beam transmission. Accordingly, the fallback DCI may be transmitted in a narrow band within the assigned time-frequency resources in the data region of the TTI. This may allow the mB to use the rest of the frequency resource(s) for data transmission to the WTRUs operating in normal transmission mode. Mapping between the fallback TTI & time resource within a TTI and the mB DL beam for fallback DCI transmission may be done in a similar fashion as described above.

[0257] FIG. 19 shows a flow diagram utilizing a dual TB transmission scheme, for example, as shown in FIG. 12, according to one or more embodiments. While FIG. 12 may serve as an example of a dual TB transmission scheme, process 1900 shown in FIG. 19 can be applied to any dual TB transmission scheme.

[0258] The process 1900, implemented by a WTRU while operating in the high frequency bands (e.g., above 6 GHz), includes receiving multiple signals in a time transmission interval (TTI) (operations 1905, 1910 and 1920). In particular, the receiving of multiple signals includes receiving at least one control signal (operation 1905) using a first beam associated with a first beam identifier (ID), receiving a first data signal (operation 1910) using the first beam associated with the first beam ID, and receiving a second data signal (operation 1920), subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID. At least one of the control signal(s)

indicates the second beam ID. The process 1900 further includes switching a receive beam of the WTRU from the first beam to the second beam based on the second beam ID to receive the second data signal (operation 1915).

[0259] According to another embodiment, a method implemented by a WTRU includes receiving, in a time transmission interval (TTI), at least one control signal, a first transport block and a second transport block. The at least one control signal and the first transport block are received using a first beam, and the second transport block is received using a second beam that has a beam width that is more narrow than a beam width of the first beam. In addition, the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block. The method further includes switching a receive beam of the WTRU from the first beam to the second beam, to receive the second transport block, based on beam information associated with the second beam received in one of the at least one control signal.

[0260] FIG. 20 shows a flow diagram utilizing a dual TB transmission scheme, for example, as shown in FIG. 12, according to one or more embodiments. While FIG. 12 may serve as an example of a dual TB transmission scheme, the process shown in FIG. 20 can be applied to any dual TB transmission scheme.

[0261] The process 2000, implemented by wireless communication device (e.g., a base station, eNB, mB, or the like) while operating in the high frequency bands (e.g., above 6 GHz), includes transmitting multiple signals in a time transmission interval (TTI) (operations 2005, 2010 and 2020). In particular, the transmitting of multiple signals includes transmitting at least one control signal (operation 2005) using a first beam associated with a first beam identifier (ID), transmitting a first data signal (operation 20910) using the first beam associated with the first beam ID, and transmitting a second data signal (operation 2020), subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID. At least one of the control signal(s)

indicates the second beam ID. The process 2000 further includes switching a transmit beam of the wireless communication device from the first beam to the second beam based on the second beam ID to transmit the second data signal (operation 2015).

[0262] According to another embodiment, a method implemented by a wireless communication device includes transmitting, in a time transmission interval (TTI), at least one control signal, a first transport block and a second transport block. The at least one control signal and the first transport block are transmitted using a first beam, and the second transport block is transmitted using a second beam that has a beam width that is more narrow than a beam width of the first beam. In addition, the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is transmitted subsequent to the first transport block. The method further includes switching a transmit beam of the wireless communication from the first beam to the second beam, to transmit the second transport block, based on beam information associated with the second beam transmitted in one of the at least one control signal.

[0263] Although features and elements are described above in particular combinations, one of ordinary skill in the art will appreciate that each feature or element can be used alone or in any combination with the other features and elements. In addition, the methods described herein may be implemented in a computer program, software, or firmware incorporated in a computer-readable medium for execution by a computer or processor. Examples of computer-readable media include electronic signals (transmitted over wired or wireless connections) and computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as internal hard disks and removable disks, magneto-optical media, and optical media such as CD-ROM disks, and digital versatile disks (DVDs). A processor in association with software

may be used to implement a radio frequency transceiver for use in a WTRU, UE, terminal, base station, RNC, or any host computer.

* * *

CLAIMS

What is claimed is:

1. A wireless transmit/receive unit (WTRU) configured to perform wireless communications in higher frequency bands using a fallback scheme, comprising:

a receiver configured to receive, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID, wherein one of the at least one control signal indicates the second beam ID; and

a processor configured to switch a receive beam of the receiver from the first beam to the second beam based on the second beam ID to receive the second data signal.

2. The WTRU of claim 1, wherein the first data signal is carried in a first transport block in the TTI and the second data signal is carried in a second transport block in the TTI.

3. The WTRU of claim 2, wherein the first transport block uses a lower modulation and coding scheme value than the second transport block.

4. The WTRU of claim 2, wherein the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block.

5. The WTRU of claim 4, wherein the receiver is configured to receive the at least one control signal in a control region of the TTI that precedes the first and the second transport blocks.

6. The WTRU of claim 1, wherein the one of the at least one control signal includes downlink control information (DCI) that indicates the second beam ID.

7. The WTRU of claim 1, wherein the second beam is a subset of the first beam such that a beam width of the second beam is more narrow than a beam width of the first beam.

8. The WTRU of claim 1, wherein first data received in the first data signal is a subset of second data received in the second data signal.

9. The WTRU of claim 8, wherein the processor is configured to decode the second data using the received first data.

10. The WTRU of claim 1, wherein the at least one control signal includes a first control signal associated with the first data signal and a second control signal associated with the second data signal, wherein first control signal includes control information that indicates the first beam ID and the second control signal includes control information that indicates the second beam ID.

11. A method implemented by a wireless transmit/receive unit (WTRU) configured to perform wireless communications in higher frequency bands using a fallback scheme, the method comprising:

receiving, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second

beam associated with a second beam ID different from the first beam ID, wherein one of the at least one control signal indicates the second beam ID; and

switching a receive beam of the WTRU from the first beam to the second beam based on the second beam ID to receive the second data signal.

12. The method of claim 11, wherein the first data signal is carried in a first transport block in the TTI and the second data signal is carried in a second transport block in the TTI.

13. The method of claim 12, wherein the first transport block uses a lower modulation and coding scheme value than the second transport block.

14. The method of claim 12, wherein the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block.

15. The method of claim 14, further comprising:

receiving the at least one control signal in a control region of the TTI that precedes the first and the second transport blocks.

16. The method of claim 11, wherein the one of the at least one control signal includes downlink control information (DCI) that indicates the second beam ID.

17. The method of claim 11, wherein the second beam is a subset of the first beam such that a beam width of the second beam is more narrow than a beam width of the first beam.

18. The method of claim 11, wherein first data received in the first data signal is a subset of second data received in the second data signal.

19. The method of claim 18, further comprising:
decoding the second data using the received first data.

20. The method of claim 11, wherein the at least one control signal includes a first control signal associated with the first data signal and a second control signal associated with the second data signal, wherein first control signal includes control information that indicates the first beam ID and the second control signal includes control information that indicates the second beam ID.

21. A wireless transmit/receive unit (WTRU) configured to perform wireless communications in higher frequency bands using a fallback scheme, comprising:

a receiver configured to receive, in a time transmission interval (TTI), at least one control signal, a first transport block and a second transport block, wherein the at least one control signal and the first transport block are received using a first beam, and the second transport block is received using a second beam that has a beam width that is more narrow than a beam width of the first beam, and wherein the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block; and

a processor configured to switch a receive beam of the WTRU from the first beam to the second beam, to receive the second transport block, based on beam information associated with the second beam received in one of the at least one control signal.

AMENDED CLAIMS
received by the International Bureau on 15 March 2017 (15.03.2017)

CLAIMS

What is claimed is:

1. A wireless transmit/receive unit (WTRU) configured to perform wireless communications, comprising:

a receiver configured to receive, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID, wherein one of the at least one control signal indicates the second beam ID; and

a processor configured to switch a receive beam of the receiver from the first beam to the second beam based on the second beam ID to receive the second data signal.

2. The WTRU of claim 1, wherein the first data signal is carried in a first transport block in the TTI and the second data signal is carried in a second transport block in the TTI.

3. The WTRU of claim 2, wherein the first transport block uses a lower modulation and coding scheme value than the second transport block.

4. The WTRU of claim 2, wherein the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block.

5. The WTRU of claim 4, wherein the receiver is configured to receive the at least one control signal in a control region of the TTI that precedes the first and the second transport blocks.

6. The WTRU of claim 1, wherein the one of the at least one control signal includes downlink control information (DCI) that indicates the second beam ID.

7. The WTRU of claim 1, wherein the second beam is a subset of the first beam such that a beam width of the second beam is more narrow than a beam width of the first beam.

8. The WTRU of claim 1, wherein first data received in the first data signal is a subset of second data received in the second data signal.

9. The WTRU of claim 8, wherein the processor is configured to decode the second data using the received first data.

10. The WTRU of claim 1, wherein the at least one control signal includes a first control signal associated with the first data signal and a second control signal associated with the second data signal, wherein first control signal includes control information that indicates the first beam ID and the second control signal includes control information that indicates the second beam ID.

11. A method implemented by a wireless transmit/receive unit (WTRU) configured to perform wireless, the method comprising:

receiving, in a time transmission interval (TTI), at least one control signal and a first data signal using a first beam associated with a first beam identifier (ID) and a second data signal, subsequent to the first data signal, using a second beam associated with a second beam ID different from the first beam ID, wherein one of the at least one control signal indicates the second beam ID; and

switching a receive beam of the WTRU from the first beam to the second beam based on the second beam ID to receive the second data signal.

12. The method of claim 11, wherein the first data signal is carried in a first transport block in the TTI and the second data signal is carried in a second transport block in the TTI.

13. The method of claim 12, wherein the first transport block uses a lower modulation and coding scheme value than the second transport block.

14. The method of claim 12, wherein the first transport block and the second transport block are multiplexed using time division multiplexing such that the second transport block is received subsequent to the first transport block.

15. The method of claim 14, further comprising:

receiving the at least one control signal in a control region of the TTI that precedes the first and the second transport blocks.

16. The method of claim 11, wherein the one of the at least one control signal includes downlink control information (DCI) that indicates the second beam ID.

17. The method of claim 11, wherein the second beam is a subset of the first beam such that a beam width of the second beam is more narrow than a beam width of the first beam.

18. The method of claim 11, wherein first data received in the first data signal is a subset of second data received in the second data signal.

19. The method of claim 18, further comprising:

decoding the second data using the received first data.

20. The method of claim 11, wherein the at least one control signal includes a first control signal associated with the first data signal and a second

control signal associated with the second data signal, wherein first control signal includes control information that indicates the first beam ID and the second control signal includes control information that indicates the second beam ID.

(54) Title: METHOD AND APPARATUS FOR REFERENCE SIGNAL TRANSMITTING AND RECEIVING IN ACTIVE ANTENNA SYSTEMS

(57) Abstract: Embodiments of the present disclosure provide reference signal transmitting and receiving methods and devices in an active antenna system. Port virtualization to a transmit antennas may be implemented for multiple cell-specific reference signal (CRS) antenna ports and applying different vertical beamforming vectors to implement port virtualization for the different CRS antenna ports. The User Equipment (UE) reports the maximum RSRP/RSRQ value measured based on multiple CRS ports, or the UE simultaneously reports multiple RSRP/RSRQ values and the information of the multiple CRS antenna ports. Therefore, the coverage problem of the CRS signal and Physical Broadcast Channel (PBCH)/Physical Downlink Control Channel (PDCCH)/Physical Downlink Shared Channel (PDSCH) demodulated based on CRS and the problem of measurement for Radio Resource Management (RRM) in the active antenna system may be avoided. Specifically, the following problems may be solved. 1) Coverage differences between CRS and PBCH/PDCCH/PDSCH demodulated based on CRS transmission and Enhanced PDCCH (E-PDCCH)/PDSCH signal transmission, which is measured based on the CSI-RS or demodulated based on the DMRS may be reduced or avoided. 2) The cell association problem due to the different vertical beamforming technologies adopted by the CSI-RS or DMRS and by the CRS may be avoided. 3) Deep spatial fading state may be avoided for CRS reception and PBCH/PDCCH/PDSCH demodulated based on the CRS.

Description

Title of Invention: METHOD AND APPARATUS FOR REFERENCE SIGNAL TRANSMITTING AND RECEIVING IN ACTIVE ANTENNA SYSTEMS

Technical Field

[1] The present disclosure relates to a field of mobile communication systems, and more particularly to a method and apparatus for reference signal transmitting and receiving in active antenna systems.

Background Art

[2] In mobile communication systems, the wireless fading channels are time-varying. In order to effectively detect signals, channel information is needed to implement relevant detection. In order to obtain the channel information, the base station transmits the signals or sequences, which are known to the UE, via wireless channels. And the UE obtains the channel information via detecting the known signals or sequences. The known signals or sequences are called pilot signals or reference signals.

[3] A Long Term Evolution/ Long Term Evolution-Advanced (LTE/LTE-A) system is a typical correlation detection system. There are seven kinds of pilot signals or reference signals according to the purposes as described below.

[4] A Cell-specific Reference Signal (CRS) is used for data demodulation of PBCH, PDCCH, and some of PDSCHs, measurement of Channel State Information (CSI) of downlink shared channel (PDSCH) of transmission modes 1 to 8.

[5] A Multimedia Broadcast Multicast Service Single Frequency Network Reference Signal (MBSFN- RS) is used for data demodulation of a Multicast Channel (MCH).

[6] A downlink User Equipment-specific Reference Signal (DMRS) is used for data demodulation of PDSCH of transmission modes 7 to 10.

[7] A Channel State Information Reference Signal (CSI-RS) is used for measurement of the CSI for PDSCH of transmission modes 9 to 10.

[8] A Positioning Reference Signal (PRS) is used for performing positioning function.

[9] An uplink Demodulation Reference Signal (DMRS) is used for data demodulation of physical uplink shared channel (PUSCH) and physical uplink control channel (PUCCH).

[10] An uplink Sounding Reference Signal (SRS) is used for measurement of uplink CSI and obtaining downlink channel information via channel reciprocity for TDD systems.

[11] Besides CSI measurement, data demodulation and synchronization assistance, the CRS is further used for measurement of Reference Signal Receive Power (RSRP/RSRQ) to implement path loss estimation, cell association, etc.

[12] Reference signal received power (RSRP/RSRQ), is defined as the linear average over the power contributions (in [W]) of the resource elements that carry cell-specific reference signals within the considered measurement frequency bandwidth.

[13] For RSRP/RSRQ determination the cell-specific reference signals R0 according to TS 36.211 shall be used. If the UE can reliably detect that R1 is available it may use R1 in addition to R0 to determine RSRP/RSRQ, where R0 and R1 are reference signal of CRS port 0 and port 1, respectively.

[14] Reference Signal Received Quality (RSRQ) is defined as the ratio K×RSRP/RSRQ / (E-UTRA carrier RSSI), where K is the number of RB's of the E-UTRA carrier RSSI measurement bandwidth. The measurements in the numerator and denominator shall be made over the same set of resource blocks.

[15] E-UTRA Carrier Received Signal Strength Indicator (RSSI), comprises the linear average of the total received power (in [W]) observed only in OFDM symbols containing reference symbols for antenna port 0, in the measurement bandwidth, over K number of resource blocks by the UE from all sources, including co-channel serving and non-serving cells, adjacent channel interference, thermal noise etc. If higher-layer signalling indicates certain subframes for performing RSRQ measurements, then RSSI is measured over all OFDM symbols in the indicated subframes.

[16] An antenna port is defined such that the channel over which a symbol on the antenna port is conveyed can be inferred from the channel over which another symbol on the same antenna port is conveyed. There is not necessarily a one-to-one relationship between the antenna port and physical antenna. The signal of each antenna port may be transmitted by combining signals over one antenna or multiple antennas. This process is called port virtualization.

[17] With development of antenna technologies, particularly active antenna array technologies, physical antenna elements are not only distributed in a horizontal dimension, but also distributed in both the vertical dimension and the horizontal dimension to form a 2-Dimension (2-D) antenna array. As shown in Fig. 1 and Fig. 2, Fig. 1 is a schematic diagram illustrating structure of an active antenna cross-polarized 2-D antenna array in accordance with an embodiment of the prior art. Fig. 2 is a schematic diagram illustrating structure of a co-polarized 2-D antenna array in accordance with an embodiment of the prior art. N is the number of antennas in a horizontal co-polarized direction and M is the number of antennas in the vertical dimension.

[18] Using the 2-D antenna array, thevertical beamforming and/or dynamic vertical sectorization is possible. Narrow beams, which directly point to the UE or avoid interfere to the UE using the same time frequency resource, are generated in the vertical dimension via multiplexing different weighting factor to each antenna. Therefore, the received signal power may be improved or the interference to the other UEs using the

same time frequency resources may be avoided.

[19] At present, although the LTE/LTE-A system supports that different reference signals may adopt different port virtualization methods, in the LTE/LTE-A specification, only passive antenna array is only taken into consideration in standardization process, the characteristics of the active antenna array are not taken into consideration.

[20] For the convenience of description, the wireless communication system with the active antenna array is called an active antenna system hereinafter. In order to obtain a vertical beamforming gain, a UE-specific vertical beamforming technology may be adopted for PDSCH. In order to ensure that UE in anywhere of a cell can receive the CRS, a cell-specific vertical beamforming vector may be adopted in the vertical dimension. In this way, the transmission of the CRS and transmission of data, which is measured based on the CSI-RS or demodulated based on the DMRSDMRS, may have different beamforming gains in the vertical dimension, resulting in different received signal strength. Fig. 3 is a diagram illustrating that the CRS and the PDSCH, which is measured based on the CSI-RS or demodulated based on the DMRS, adopt different vertical beamforming in accordance with an embodiment in the prior art.

[21] In LTE/LTE-A systems, cell association is implemented based on a Reference Signal Receiving Power RSRP/RSRQ value reported measured based on CRS port 0. Since the CRS and PDSCH, which is measured based on the CSI-RS or demodulated based on the DMRS, are transmitted with different vertical beamforming technologies, the cell association may be not suitable for PDSCH, which is measured based on the CSI-RS or demodulated based on the DMRS.

[22] Fig. 4 is a diagram illustrating the transmission of the CRS in accordance with an embodiment in the prior art. As shown in Fig. 4, the CRS is virtualized with a fixed vertical beamforming vector. Generally, in order to control interference to the adjacent cells, a down-tilt angle may be to be formed. For instance, in the typical Urban Marco (UMa) scenario, the base station (BS) antenna height is 25m, and the inter-site distance is 500m. The UEs are distributed outdoor or in low buildings with height of 18~24m. The 90 degree represents the horizontal direction, the 0 degree represents vertically pointing to the sky, and the 180 degree presents vertically pointing to the ground. Then, electronic down-tilt of CRS is 102 degree. In that case, the CRS vertical antenna array gain received by the UE is much small if the UE antenna height is larger than or equal to the BS antenna height. The signal strength of the CRS received by the UE is relatively weak no matter of accessing which cell. The CRS receiving for these UEs are in deep spatial fading.

[23] On the other hand, the RSRP/RSRQ value measured based on the CRS port 0 is used to estimate the path loss value for the uplink power control. Inappropriate RSRP/RSRQ report may affect performance of the uplink control in the active antenna

systems. In LTE/LTE-A standardization with passive antennas, it is assumed that the uplink path loss and downlink path loss is approximately symmetrical. This is because in the passive antenna system, the uplink channel and downlink channel may experience the same large-scale fading and similar antenna array gain. However, in the active antenna systems adopting the vertical beamforming, if the CRS adopts the fixed vertical beamforming, while the Maximal Ratio Combining (MRC) detection is used in the uplink receiving, the antenna gains for the uplink and downlink are asymmetric. Therefore, the downlink path loss estimated with the RSRP/RSRQ value is significantly different from the actual uplink path loss and the uplink power control performance may be further affected.

Disclosure of Invention

Technical Problem

[24] In view of the above, embodiments of the present disclosure provide reference signal transmitting and receiving methods in the active antenna systems. With these methods, the coverage problem of CRS signal and physical broadcast channel (PBCH)/physical downlink control channel (PDCCH)/physical downlink shared channel (PDSCH) demodulated based on CRS and the problem of measurement for radio resource management (RRM) in the active antenna systems may be avoided.

[25] Embodiments of the present disclosure further provide reference signal transmitting and receiving devices in the active antenna system. With these devices, the coverage problem of CRS signal and physical broadcast channel (PBCH)/physical downlink control channel (PDCCH)/physical downlink shared channel (PDSCH) demodulated based on CRS and the problem of measurement for radio resource management (RRM) in the active antenna systems may be avoided.

Solution to Problem

[26] According to the above objectives, the present disclosure is implemented as follows.

[27] A reference signal transmitting method in an active antenna system includes:

[28] setting number of Cell-specific Reference Signal (CRS) ports and transmitting a notification of number of the CRS ports, wherein the number of the CRS ports is larger than 1;

[29] precoding a reference signal with a different precoding vector for each of the CRS ports, wherein number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports; and

[30] transmitting the precoded reference signal for the each of the CRS ports over a corresponding frequency-time resource.

[31] A reference signal receiving method in an active antenna system includes:

[32] receiving a notification of number of Cell-specific Reference Signal (CRS) ports,

wherein the number of the CRS ports is larger than 1; and

[33] receiving a reference signal over a time-frequency resource.

[34] A reference signal transmitting device in an active antenna system includes:

[35] a notification module, to set number of Cell-specific Reference Signal (CRS) ports and transmit a notification of number of the CRS ports, wherein the number of the CRS ports is larger than 1;

[36] a precoding module, to precode a reference signal with a different precoding vector for each of the CRS ports, wherein number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports; and

[37] a transmitting module, to transmit the precoded reference signal for the each of the CRS ports over a corresponding frequency-time resource.

[38] A reference signal receiving device in an active antenna system includes:

[39] a signaling receiving module, to receive a notification of number of Cell-specific Reference Signal (CRS) ports, wherein the number of the CRS ports is larger than 1; and

[40] a signal receiving module, to receive a reference signal over a time-frequency resource.

[41] It can be seen from the above technical scheme that embodiments of the present disclosure implement port virtualization to transmit antennas via using multiple CRS antenna ports and applying different vertical beamforming vectors to the different CRS antenna ports. When the UE reports the RSRP/RSRQ value, the UE simultaneously reports the information of the CRS antenna ports. Therefore, the problems of unsatisfactory CRS signal coverage and RSRP/RSRQ report in the active antenna system may be solved. Specifically, following problems may be solved. 1) Differences between transmission signal coverage of the CRS and transmission signal coverage of data, which is measured based on the CSI-RS or demodulated based on the DMRS may be reduced or avoided. 2) The problem that differences between the vertical beamforming technologies adopted by the CSI-RS or DMRS and that adopted by the CRS make it inappropriate for the UE to access a cell may be avoided. 3) It may be avoided that when the UE with a specific-height antenna receives the data signal and/or control signal, which are demodulated based on the CRS, the vertical antenna array gain is in a deep spatial fading state.

[61] Fig. 20 is a flow chart illustrating a third method for determining the specific UE-specific information/configuration in accordance with a fourth embodiment of the present disclosure.

Mode for the Invention

[62] To make the objective and technical solution of the merits of the present disclosure more apparent, the present disclosure may be described in detail with reference to accompanying Fig.s.

[63] In the active antenna system, following problems are caused when the reference signal is transmitted or received. 1) Coverage differences between CRS and PBCH/PDCCH/PDSCH demodulated based on CRS transmission and Enhanced PDCCH (E-PDCCH)/PDSCH signal transmission, which is measured based on the CSI-RS or demodulated based on the DMRS may be occurred. 2) Cell association using RSRP/RSRQ measured from CRS may not guarantee the best performance in PDSCH/EPDCCH reception due to different beamforming gains between CRS and PDSCH/EPDCCH/DMRS for port virtualization. 3) A fixed vertical weighted vector is used by CRS while the UE is distributed in a large range of height, which leads to deep spatial fading for some UEs of CRS/PBCH/PDCCH/PDSCH demodulated based on the CRS. Therefore, in order to avoid the above problems, an embodiment of the present disclosure using multiple CRS ports. Port virtualization to transmit antennas may be implemented for multiple Cell-specific Reference Signal (CRS) antenna ports and applying different vertical beamforming vectors to implement port virtualization for the different CRS antenna ports. When the User Equipment (UE) reports the maximum RSRP/RSRQ values measured based on multiple CRS ports, or the UE simultaneously reports multiple RSRP/RSRQ values and the information of the multiple CRS antenna ports.

[64] Further, on the premise that a same channel measurement effect is obtained, the method and device provided by embodiments may reduce the resource of CSI-RS, which are used by the UE to perform CSI measurement, and may reduce the path loss estimation error RSRP/RSRQ for uplink power control.

[65] Fig. 5 is a flow chart illustrating a reference signal transmitting method in an active antenna system in accordance with an embodiment of the present disclosure. The blocks are as follows.

[66] AT block 501, number of CRS ports is set and a notification of the number of the CRS ports is transmitted. The number of the CRS ports is larger than one.

[67] At block 502, a reference signal for each CRS port is precoded with a different precoding vector. Number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports.

[68] At block 503, the precoded reference signal for the each CRS port is transmitted over a time-frequency resource.

[69] After block 503, the method further includes:

[70] receiving RSRP/RSRQ information and/or CRS port information. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[71] After block 502 and before block 503, the method further includes:

[72] respectively precoding a data signal and/or control signal corresponding to the each CRS port based on the precoding vector adopted by the each CRS port.

[73] When block 503 is performed, the precoded data signal and/or control signal is transmitted over the time-frequency resource.

[74] Fig. 6 is a flow chart illustrating a reference signal receiving method in an active antenna system in accordance with an embodiment of the present disclosure. The blocks are as follows.

[75] At block 601, a notification of number of CRS ports is received. The number of the CRS ports is larger than 1.

[76] At block 602, a precoded reference signal is received over a time-frequency resource.

[77] This method further includes: obtaining RSRP/RSRQ information and/or CRS port information by measurement based on the CRS ports. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than 1 or equal to 1.

[78] The method further includes: receiving a precoded data signal and/or control signal over the time-frequency resource.

[79] Fig. 7 is a schematic diagram illustrating structure of a reference signal transmitting device in an active antenna system in accordance with an embodiment of the present disclosure. As shown in Fig. 7, the reference signal transmitting device includes: a notification module, a precoding module and a transmitting module.

[80] The notification module is to set number of CRS ports and transmit a notification of the number of the CRS ports. The number of the CRS ports is larger than 1.

[81] The precoding module is to precode a reference signal with a different precoding vector for each CRS port. Number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports.

[82] The transmitting module is to transmit the precoded reference signal for the each CRS port over a time-frequency resource.

[83] The reference signal transmitting device further includes a RSRP/RSRQ receiving module. The RSRP/RSRQ receiving module is to receive RSRP/RSRQ information and/or CRS port information. Number of RSRP/RSRQ values in the RSRP/RSRQ in-

formation is larger than or equal to 1.

[84] In this reference signal transmitting device, the precoding module is further to respectively precode a data signal and/or control signal corresponding to each CRS port based on the precoding vector adopted by the each CRS port.

[85] The transmitting module is further to transmit the precoded data signal and/or control over the time-frequency resource.

[86] In this reference signal transmitting device, the RSRP/RSRQ receiving module is further to determine specific UE-specific information/configuration according to the RSRP/RSRQ information and/or CRS port information.

[87] Fig. 8 is a schematic diagram illustrating structure of a reference signal receiving device in an active antenna system in accordance with an embodiment of the present disclosure. As shown in Fig. 8, the reference signal receiving device includes: a signaling receiving module and a signal receiving module.

[88] The signaling receiving module is to receive a notification of number of CRS ports. The number of the CRS port is larger than 1.

[89] The signal receiving module is to receive a precoded reference signal over a time-frequency resource.

[90] The reference signal receiving device further includes: a measurement report module. The measurement report module is to obtain RSRP/RSRQ information and/or CRS port information by measurement based on the CRS ports and transmit the RSRP/RSRQ information and/or CRS port information. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[91] In the reference signal receiving device, the signal receiving module is further to receive a precoded data signal and/or control signal over the time-frequency resource.

[92] The present disclosure is described hereinafter in detail with reference to several specific embodiments.

[93] Embodiment one

[94] Fig. 9 is a flow chart illustrating a reference signal transmitting method in an active antenna system in accordance with a first embodiment of the present disclosure. Blocks are as follows.

[95] At block 901, the number of CRS ports is set and a notification of the number of the CRS ports is transmitted. The number of the CRS ports is larger than one.

[96] At this block, the notification of the number of the CRS ports may be performed in an implicit way. Specifically, the notification of the number of the CRS ports is implicitly performed by different Physical Broadcast Channel (PBCH) Cyclic Redundancy Check (CRC) scrambling codes. After the CRC attachment of PBCH, the CRC bits are scrambled according to the eNodeB transmit antenna configuration with the sequence as indicated in Table 1, Thus, the CRS port index can be determined

based on CRC mask at the UE side.

[97] Table 1

[Table 1]

Number of transmit antenna ports at eNodeB	PBCH CRC mask<$x_{ant,0}$, $x_{ant,1}$, ..., $x_{ant,15}$>
1	<0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0>
2	<1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1>
4	<0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1>

[98] In the active antenna systems, the number of the CRS ports is a positive integer, which is larger than 1. The base station may determine the number of CRS ports considering CRS overheads and the UE distribution of , d and transmit the notification of the number of the CRS ports. For instance, in typical UMa scenarios, the BS antenna height of a base station antenna is 25m. The inter-site distance is 500m. The UEs are distributed outdoor or distributed in low buildings with height of 18-24m. All vertical leaving angles of the UE are larger than 90 degree (The 90 degree represents a horizontal direction. The 0 degree represents vertically pointing to the sky. The 180 degree presents vertically pointing to the ground). Considering the CRS overhead and UE distribution, the number of the CRS ports may be set as 2.

[99] At block 902, a reference signal for each CRS port is precoded with a different precoding vector. Number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports.

[100] At this block, the CRS port adopts a different precoding vector to implement port virtualization to transmit antennas. Fig. 10 is a schematic diagram illustrating a CRS transmitting process in the physical layer in accordance with a first embodiment of the present disclosure. The port virtualization to transmit antennas refers to precoding the reference signal for the CRS port with a precoding vector. The number of elements in the precoding vector is equal to the number of transmit antennas, which transmitting the same CRS.

[101] Take the typical UMa for example, assuming a physical antenna configuration is cross-polarized 2-D antenna array, M=10 and N=1. Both the two polarization directions include M antenna groups distributed in the vertical dimension, i.e. antenna group 0 and antenna group 1. Suppose the distance between two transmit antennas is half-wavelength. The virtualization from signals of CRS port 0 to the antenna group 0 is implemented via the precoding vector $W_0 = \left[w_0^{(0)} w_1^{(0)} \cdots w_{M-1}^{(0)} \right]^T$. The virtualization from signals of CRS port 1 to the antenna group 1 is implemented via the

$W_1 = [\, w_0^{(1)} w_1^{(1)} \cdots w_{M-1}^{(1)} \,]^T$, $w_m^{(p)} = \frac{1}{\sqrt{M}} \exp(-j \frac{2\Pi}{\lambda} m \cdot d_v \cdot \cos\theta_p)$, dv denotes the distance between the vertical antennas, p denotes the index of CRS port, m denotes the m-th element of the precoding vectors, θ_p denotes the down-tilt angle corresponding to the p-th port. For instance, the electronic down-tilt angle corresponding to the port 0 is 102 degree, and the electronic down-tilt angle corresponding to port 1 is 95 degree.

[102] At block 903, the precoded reference signal for each CRS port is transmitted over the time-frequency resource.

[103] At this block, Fig. 11 is a diagram illustrating a CRS time-frequency resource pattern in accordance with a first embodiment of the present disclosure.

[104] At block 904, RSRP/RSRQ information and/or CRS port information is received. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[105] At this block, the RSRP/RSRQ information and/or CRS port information may be an RSRP/RSRQ value measured by a CRS port with the maximum receiving power and the corresponding CRS port index. As shown in table 2, the reporting range of RSRP/RSRQ is defined from -140 dBm to -44 dBm with 1 dB resolution. The mapping of measured quantity and CRS port index may be mapped in Table 2. 4 RSRP/RSRQ states indicating the number of the CRS antenna ports may be reported RSRP/RSRQ simultaneously with RSRP/RSRQ value.

[106] Table 2

[Table 2]

Reported value	Measured quantity value	Unit
RSRP/RSRQ _00	RSRP/RSRQ -140	dBm
RSRP/RSRQ _01	-140 $\leq$ RSRP/RSRQ < -139	dBm
RSRP/RSRQ _02	-139 $\leq$ RSRP/RSRQ < -138	dBm
...	...	...
RSRP/RSRQ _95	-46 $\leq$ RSRP/RSRQ < -45	dBm
RSRP/RSRQ _96	-45 $\leq$ RSRP/RSRQ < -44	dBm
RSRP/RSRQ _97	-44 $\leq$ RSRP/RSRQ	dBm
RSRP/RSRQ _98	Port 0	
RSRP/RSRQ _99	Port 1	
RSRP/RSRQ _100	Port 2	
RSRP/RSRQ _101	Port 3	

[107] As shown in table 3, the RSRP/RSRQ information and/or CRS port information may further be the RSRP/RSRQ value measured by the port.

[108] Table 3

[Table 3]

Reported value	Measured quantity value	Unit
RSRP/RSRQ _00	Port 0 RSRP/RSRQ < -140	dBm
RSRP/RSRQ _01	Port 0 -140 $\leq$ RSRP/RSRQ < -139	dBm
RSRP/RSRQ _02	Port 0 -139 $\leq$ RSRP/RSRQ < -138	dBm
...	...	...
RSRP/RSRQ _95	Port 0 -46 $\leq$ RSRP/RSRQ < -45	dBm
RSRP/RSRQ _96	Port 0 -45 $\leq$ RSRP/RSRQ < -44	dBm
RSRP/RSRQ _97	Port 0 -44 $\leq$ RSRP/RSRQ	dBm
RSRP/RSRQ _98	Port 1 RSRP/RSRQ < -140	dBm
RSRP/RSRQ _99	Port 1 -140 $\leq$ RSRP/RSRQ < -139	dBm
RSRP/RSRQ _100	Port 1 -139 $\leq$ RSRP/RSRQ < -138	dBm
...	...	...
RSRP/RSRQ _183	Port 1 -46 $\leq$ RSRP/RSRQ < -45	dBm
RSRP/RSRQ _184	Port 1 -45 $\leq$ RSRP/RSRQ < -44	dBm
RSRP/RSRQ _185	Port 1 -44 $\leq$ RSRP/RSRQ	dBm
...	...	...

[109] The RSRP/RSRQ information and/or CRS port information may further be the RSRP/RSRQ value measured by the CRS port 0 or a relative RSRP/RSRQ value of another port to that of the CRS port 0.

[110] The RSRP/RSRQ information and/or CRS port information may further be the RSRP/RSRQ values measured by K CRS ports. K is larger than 1 and less than total number of the CRS antenna ports. Corresponding antenna port index is also reported.

[111] With the above processing, since different CRS ports adopt different vertical beamforming, UE which is not covered by the beam of the CRS port 0, may be covered by the beam of another CRS port. Therefore, it may be reduced or avoided that when the terminal with the specific-height antenna receives the CRS, the vertical antenna gain remains at the deep spatial fading state for a long time of given UE.

[112] In this embodiment, the received RSRP/RSRQ information and/or CRS port information provides not only the information of the RSRP/RSRQ value measured based on the CRS port with the maximum receiving power, but also the port information corresponding to the RSRP/RSRQ value measured based on the CRS port with the maximum receiving power. The BS may implement subsequent optimization for PBCH/PDCCH/PDSCH transmission, cell association, uplink power control, etc. with the above information.

[113] Embodiment two

[114] Fig. 12 is a flow chart illustrating a reference signal transmitting method in an active antenna system in accordance with a second embodiment of the present disclosure. Specific blocks are as follows.

[115] At block 1201, number of CRS ports is set and a notification of the number of the CRS ports is transmitted. The number of the CRS ports is larger than one.

[116] At block 1202, a reference signal for each CRS port is precoded with a different precoding vector. Number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports.

[117] At block 1203, a data signal and/or control signal corresponding to the each CRS port is respectively precoded based on the precoding vector adopted by the each CRS port. Number of elements in the precoding vector is equal to number of transmit antennas, which transmit the data signal and/or control signal.

[118] At this block, port virtualization to transmit antenna processing is performed for PBCH/PDCCH/PDSCH, which is demodulated based on the CRS, using the precoding vectors corresponding to the CRS ports. The physical layer processing process of PBCH/PDCCH/PDSCH, which is demodulated based on the CRS, is shown in Fig. 13. Fig. 13 is a diagram illustrating a physical layer processing of PBCH/PDCCH/PDSCH, which is demodulated based on CRS, in accordance with the second embodiment of the present disclosure. For instance, the CRS of port 0 adopts the precoding vector W0 to implement the port virtualization to transmit antennas. The PBCH/PDCCH/PDSCH over port 0 also implements the port virtualization to transmit antennas with the same precoding vector. Other ports adopt similar processing.

[119] At block 1204, the precoded reference signal for the each CRS port and the precoded data signal and/or control signal for the each CRS port are transmitted over the time-frequency resource.

[120] At block 1205, the RSRP/RSRQ information and/or CRS port information is received. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[121] With the method shown in Fig. 12, since the reference signal and PBCH/PDCCH/PDSCH, which is demodulated based on the CRS of each CRS port adopt

different vertical beamforming, UE, which is not covered by the beam of the CRS port 0, may be covered by the beam of another CRS ports. Therefore, it may be reduced or avoided that the deep spatial fading problem may be reduced or avoided. Thus, the coverage of PBCH/PDCCH/PDSCH, which is demodulated based on the CRS, is improved.

[122] Embodiment three

[123] Fig. 14 is a flow chart illustrating a reference signal receiving method in an active antenna system in accordance with a third embodiment of the present disclosure. Specific blocks are as follows.

[124] At block 1401, a notification of number of CRS ports is received. The number of the CRS port is larger than 1.

[125] At this block, the number of antenna ports may be determined according to PBCH scrambling mask via decoding the signals of the PBCH over the CRS port 0.

[126] At block 1402, a precoded reference signal is received over a time-frequency resource.

[127] As exclusively used at this block, the precoded reference signal may be received according to the CRS time-frequency resource pattern shown in Fig. 15. Fig. 15 is a diagram illustrating a CRS time-frequency resource pattern in accordance with a third embodiment of the present disclosure.

[128] At block 1403, RSRP/RSRQ information and/or CRS port information is obtained by measurement based on the CRS ports. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[129] At this block, the RSRP/RSRQ value measured based on the CRS port with maximum receiving power and the corresponding CRS antenna port index may be reported. For instance, as shown in table 2, four states indicating the CRS antenna port index are reported during the report of the RSRP/RSRQ value. Alternatively, as shown in table 3, the RSRP/RSRQ value of the each port is reported at the same time. Alternatively, the RSRP/RSRQ value of the CRS port 0 and a relative RSRP/RSRQ value of another port to that of the CRS port 0 are reported. Alternatively, the RSRP/RSRQ values of N CRS ports and corresponding antenna port number information are reported. N is larger than 1 and less than total number of the CRS antenna ports.

[130] With the above processing, the base station may obtain more RSRP/RSRQ information of the CRS port, which is convenient for the network side to make further processing to obtain the corresponding gain.

[131] Embodiment four

[132] Fig. 16 is a flow chart illustrating a reference signal transmitting method in an active antenna system in accordance with a fourth embodiment of the present disclosure. Specific blocks are as follows.

[133] At block 1601, number of CRS ports is set and a notification of the number of the CRS ports is transmitted. The number of the CRS ports is larger than one.

[134] At this block, in typical UMa scenarios, the BS antenna height is 10m. The inter-site distance is 200m. The UEs are distributed outdoor or distributed in low buildings with the height of 18-24m. Taking account of that vertical leaving angles of the UEs are in a large range and taking account of factors, such CRS overhead influence, the number of the CRS ports is set as 4.

[135] At block 1602, each CRS port adopts a different precoding vector to implement port virtualization to transmit antennas.

[136] At this block, four different precoding vectors are adopted to implement the port virtualization to transmit antennas of four CRS ports. The virtualization of the CRS port 0 to the antenna group 0 is implemented via the precoding vector $W_0 = [w_0^{(0)} w_1^{(0)} \dots w_{M-1}^{(0)}]^T$. The virtualization of the CRS port 1 to the antenna group 1 is implemented via the precoding vector $W_1 = [w_0^{(1)} w_1^{(1)} \dots w_{M-1}^{(1)}]^T$.

$w_m^{(p)} = \frac{1}{\sqrt{M}} \exp(-j\frac{2\Pi}{\lambda} m \cdot d_v \cdot \cos\theta_p)$, dv denotes the distance between the vertical antennas, p denotes the index of the CRS port, m denotes the m-th element of the precoding vectors, θ_p denotes a down-tilt angle corresponding to the p-th port. The down-tilt angle corresponding to the port 0 is 102 degree, the downward inclination angle corresponding to the port 1 is 95 degree, the down-tilt angle corresponding to the port 2 is 85 degree, the down-tilt angle corresponding to the port 3 is 75 degree.

[137] At block 1603, the precoded reference signal of each CRS port is transmitted over the time-frequency resource.

[138] At block 1604, the RSRP/RSRQ information and/or CRS port information is received. Number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[139] At this block, the RSRP/RSRQ information may be the RSRP/RSRQ value measured by the CRS port with the maximum receiving power. The corresponding port information is the CRS port index corresponding to the RSRP/RSRQ value of measured by the CRS port with the maximum receiving power. The RSRP/RSRQ information may include the RSRP/RSRQ value of the each CRS port. The RSRP/RSRQ information may include the RSRP/RSRQ values of partial CRS ports and the number index information of the partial CRS ports.

[140] At block 1605, after the RSRP/RSRQ information and/or CRS port information is received, specific UE-specific information/configuration is determined.

[141] At this block, the specific UE-specific information/configuration includes: one or

combination of information of cell association, a path loss value for uplink power control and/or UE-specific CSI-RS resource configuration.

[142] Specifically speaking, Fig. 17 is a flow chart illustrating a first method for determining UE-specific information/configuration in accordance with a fourth embodiment of the present disclosure. Following blocks are included.

[143] At block 1701, RSRP/RSRQ information and/or CRS port information is received.

[144] At block 1702, a cell association is determined based on the RSRP/RSRQ information.

[145] At this block, each CRS port adopts a different vertical beam. The RSRP/RSRQ information includes the vertical beamforming gain of the best direction. Therefore, the difference between the RSRP/RSRQ and the beamforming gain of the CSI-RS and DMRS after the UE-specific vertical beamforming adopted is relatively reduced. Therefore, the selected cell is more suitable for the PDSCH/E-PDCCH transmission of the UE.

[146] Fig. 18 is a flow chart illustrating a second method for determining the specific UE-specific information/configuration in accordance with a fourth embodiment of the present disclosure. Following blocks are included.

[147] At block 1801, RSRP/RSRQ information and/or CRS port information is received.

[148] At block 1802, a UE-specific CSI-RS resource configuration is determined based on the RSRP/RSRQ information.

[149] At this block, the UE-specific CSI-RS resource configuration is determined based on the correlation of beamforming vectors used for the CSI-RS resources port virtualization and the CRS ports virtualization, RSRP/RSRQ information and CRS port information. The CSI-RS resources in the active antenna system are grouped according to the correlation of the vertical beamforming vectors used for CSI-RS port virtualization and CRS port virtualization. After the RSRP/RSRQ information and/or CRS port information is received, the CSI-RS resources in the CSI-RS resource group corresponding to the CRS port with RSRP/RSRQ value measured with the maximum receiving power, may be determined as the UE-specific CSI-RS resource configuration. Alternatively, CSI-RS resources in CSI-RS resource groups corresponding to the two CRS ports with the RSRP/RSRQ values with the maximum receiving power and second maximum receiving power may be determined as the UE-specific CSI-RS resource configurations.

[150] A specific example is given hereinafter for illustration, suppose two CRS ports adopt two different vertical beams. In the transmission mode using the CSI-RS measurement and DMRS demodulation, such as transmission mode 10 of LTE/LTE-A, the UE-specific vertical beamforming may be implemented via configuring multiple CSI-RS resources and multiple CSI processes for the UE. Fig. 19 is a diagram illustrating de-

termination of UE-specific CSI-RS resource configuration with RSRP/RSRQ reporting in accordance with a fourth embodiment of the present disclosure. As shown in Fig. 19, 9 CSI-RS resources are conFig.d in the active antenna systems. Each CSI-RS resource adopts different vertical beams to perform the beamforming. The 9 CSI-RS resources are divided into three groups. Each group includes 3 CSI-RS resources and the 3 CSI-RS resources adopt adjacent vertical beams to implement port virtualization to transmit antennas. The coverage of the first group of CSI-RS vertical beams in the vertical dimension is close to that of the CRS beam 0. The coverage of the third group of CSI-RS vertical beams in the vertical dimension is close to that of the CRS beam 1. And the coverage of the second group of CSI-RS vertical beams in the vertical dimension is between that of two CRS beams.

[151] If the RSRP/RSRQ CRS port with largest RSRP/RSRQ value is CRS port 0, the first group of CSI-RS resources is allocated to the UE. If the reported port with the largest RSRP/RSRQ value is port 01, the third group of CSI-RS resources is allocated to the UE. If the reported two ports, the RSRP/RSRQ values of which are close to each other, the second group of CSI-RS resources are allocated to the UE.

[152] The UE performs feedback of three CSI processes based three conFig.d CSI-RS resources in one group, such as CSI-RS resource 2-1, CSI-RS resource 2-2 and CSI-RS resource 2-3 in the second group. The base station selects the best vertical beamforming direction based on CSI feedback. For instance, the vertical beamforming direction corresponding to the CSI-RS resource 2-3 is taken as the beamforming direction used by the UE in the data transmission.

[153] In the above second embodiment, apparently, if the CRS port information is not reported, the UE needs to measure 9 different CSI-RS configurations to select the best beam from the nine vertical beams and simultaneously complete nine CSI report processes. Using the RSRP/RSRQ and CRS port information report, the best beam may be selected from the nine vertical beams via measuring only three CSI-RS configurations and completing three CSI report processes.

[154] Fig. 20 is a flow chart illustrating a method for determining the specific UE-specific information/configuration in accordance with a fourth embodiment of the present disclosure. Following blocks are included.

[155] At block 2001, RSRP/RSRQ information and/or CRS port information is received.

[156] At block 2002, the path loss value for uplink power control of a UE is determined based on the RSRP/RSRQ information.

[157] At this block, each CRS port adopts a different vertical beam. The RSRP/RSRQ information is measured based on the vertical beamforming in the best direction. Therefore, the difference between the RSRP/RSRQ value and an uplink antenna array gain of receiver is relatively reduced. Therefore, the difference between the path loss

estimation based on the RSRP/RSRQ and the uplink actual path loss is reduced and thus the uplink power control performance is improved.

[158] It can be seen from the methods and devices provided by embodiments of the present disclosure, coverage differences between CRS and PBCH/PDCCH/PDSCH demodulated based on CRS transmission and Enhanced PDCCH (E-PDCCH)/PDSCH signal transmission, which is measured based on the CSI-RS or demodulated based on the DMRS may be reduced or avoided. The cell association problem due to the different vertical beamforming technologies adopted by the CSI-RS or DMRS and by the CRS may be avoided. Deep spatial fading state may be avoided for CRS reception and PBCH/PDCCH/PDSCH demodulated based CRS. On the premise that a same channel measurement effect is obtained, embodiments of the present disclosure may reduce the number of CSI-RS configurations, which are used by the UE to perform channel estimation. Embodiments of the present disclosure may reduce the differences between the path loss of RSRP/RSRQ value estimation and the uplink actual path loss and may improve the uplink power control performance.

[159] The foregoing description only describes preferred embodiments of the present invention and may not be used for limiting the protection scope thereof. Any modification, equivalent substitution, or improvement made without departing from the spirit and principle of the present invention should be covered by the protection scope of the present invention.

Claims

[Claim 1] A reference signal transmitting method in an active antenna system, comprising:
setting number of Cell-specific Reference Signal (CRS) ports and transmitting a notification of number of the CRS ports, wherein the number of the CRS ports is larger than 1;
precoding a reference signal with a different precoding vector for each of the CRS ports, wherein number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports; and
transmitting the precoded reference signal for the each of the CRS ports over a corresponding frequency-time resource.

[Claim 2] The transmitting method according to claim 1, further comprising:
receiving Reference Signal Receive Power (RSRP)/Reference Signal Received Quality (RSRQ) information and/or CRS port information;
wherein number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[Claim 3] The transmitting method according to claim 2, wherein the RSRP/RSRQ information and/or CRS port information comprises:
an RSRP/RSRQ value measured by a CRS port with the maximum receiving power and a corresponding CRS port index; or
RSRP/RSRQ values measured by the CRS ports; or
an RSRP/RSRQ value measured by CRS port 0 and a relative RSRP/RSRQ value of another port to that of the CRS port 0; or
RSRP/RSRQ values measured by N CRS ports and corresponding CRS port indexes, N is larger than 1 and less than total number of the CRS ports.

[Claim 4] The transmitting method according to claim 2, further comprising:
determining specific UE-specific information/configuration according to the RSRP/RSRQ information and/or the CRS port information.

[Claim 5] The transmitting method according to claim 4, wherein the specific UE-specific information/configuration comprises one or any combination of: information of cell association, a path loss value for uplink power control and Channel State Information Reference Signal (CSI-RS) resource configuration.

[Claim 6] The transmitting method according to claim 5, wherein when the specific UE-specific information/configuration is the information of

cell association, determining the specific UE-specific information/ configuration according to the RSRP/RSRQ information and/or the CRS port information comprises:
determining the cell association according to an RSRP/RSRQ value measured by the CRS port with maximum receiving power.

[Claim 7] The transmitting method according to claim 5, when the specific UE-specific information/configuration is the path loss value for uplink power control, determining the specific UE-specific information/configuration according to the RSRP/RSRQ information and/or the CRS port information comprises:
determining the path loss value for uplink power control based on an RSRP/RSRQ value measured by the CRS port with the maximum receiving power.

[Claim 8] The transmitting method according to claim 5, when the specific UE-specific information/configuration is the CSI-RS resource configuration, determining the specific UE-specific information/configuration according to the RSRP/RSRQ information and/or CRS port information comprises:
determining the UE-specific CSI-RS resource configuration based on correlation of beamforming vectors used for CSI-RS port virtualization and CRS port virtualization.

[Claim 9] The transmitting method according to claim 8, wherein determining the UE-specific CSI-RS resource configuration comprises:
grouping CSI-RS resources in an active antenna system according to the correlation of beamforming vectors used for the CSI-RS port virtualization and the CRS port virtualization;
after receiving the reported RSRP/RSRQ information and/or the CRS port information, determining CSI-RS resources in a CSI-RS resource group corresponding to a CRS port with an RSRP/RSRQ value measured by the CRS port with the maximum receiving power, as the UE-specific CSI-RS resource configuration; or
determining CSI-RS resources in CSI-RS resource groups corresponding to two CRS ports with RSRP/RSRQ values measured with the maximum receiving power and second maximum receiving power, as the UE-specific CSI-RS resource configurations.

[Claim 10] The transmitting method according to claim 1, wherein before transmitting the precoded reference signal for the each of the CRS ports over the corresponding frequency-time resource, the method further

comprises:
respectively precoding a data signal and/or control signal corresponding to the each of the CRS ports based on the precoding vector adopted by the each of the CRS ports;
when transmitting the precoded reference signal for the each of the CRS ports over corresponding frequency-time resource, the method further comprises:
transmitting the precoded data signal and/or control signal for the each of the CRS ports over the corresponding frequency-time resource.

[Claim 11] A reference signal receiving method in an active antenna system, comprising:
receiving a notification of number of Cell-specific Reference Signal (CRS) ports, wherein the number of the CRS ports is larger than 1; and
receiving a reference signal over a time-frequency resource.

[Claim 12] The receiving method according to claim 11, further comprising:
obtaining Reference Signal Receive Power (RSRP)/Reference Signal Received Quality (RSRQ) information and/ or CRS port information by measurement based on the CRS ports; wherein number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[Claim 13] The receiving method according to claim 11, wherein the RSRP/RSRQ information and/or CRS port information comprises:
an RSRP/RSRQ value measured by a CRS port with the maximum receiving power and a corresponding CRS port index; or
RSRP/RSRQ values measured by the CRS ports; or
an RSRP/RSRQ value measured by CRS port 0 and a relative RSRP/RSRQ value of another port to that of the CRS port 0; or
RSRP/RSRQ values measured by N CRS ports and corresponding CRS port indexes, N is larger than 1 and less than total number of the CRS ports.

[Claim 14] The receiving method according to claim 11, further comprising:
receiving a precoded data signal and/or control signal, which are demodulated based on the CRS ports.

[Claim 15] A reference signal transmitting device in an active antenna system, comprising:
a notification module, to set number of Cell-specific Reference Signal (CRS) ports and transmit a notification of number of the CRS ports, wherein the number of the CRS ports is larger than 1;
a precoding module, to precode a reference signal with a different

precoding vector for each of the CRS ports, wherein number of elements in the precoding vector is equal to number of transmit antennas, which correspond to the CRS ports; and

a transmitting module, to transmit the precoded reference signal for the each of the CRS ports over a corresponding frequency-time resource.

[Claim 16] The transmitting device according to claim 15, further comprising:

a Reference Signal Receive Power (RSRP)/Reference Signal Received Quality (RSRQ) receiving module, to receive Reference Signal Receive Power (RSRP)/Reference Signal Received Quality (RSRQ) information and/or CRS port information; wherein number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[Claim 17] The transmitting device according to claim 16, wherein the RSRP/ RSRQ receiving module is further to determine specific UE-specific information/configuration according to the RSRP/RSRQ information and/or CRS port information.

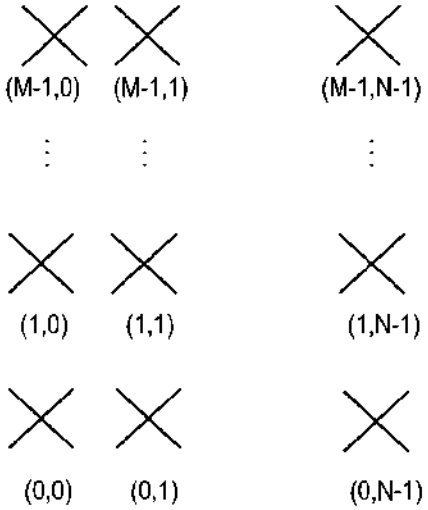
[Claim 18] The transmitting device according to claim 15, wherein

the precoding module is further to respectively precode a data signal and/or control signal corresponding to the each of the CRS ports based on the precoding vector adopted by the each of the CRS ports; and

the transmitting module is further to transmit the precoded data signal and/or control over the time-frequency resource.

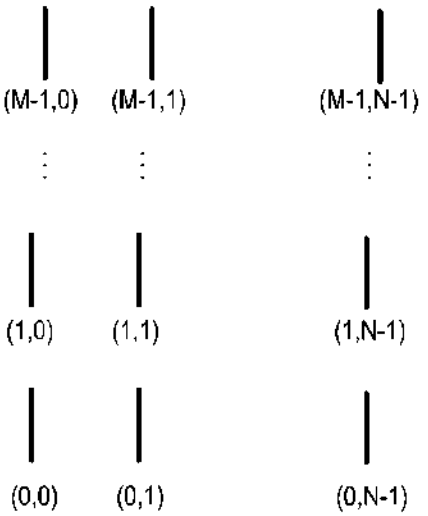
[Claim 19] A reference signal receiving device in an active antenna system, comprising:

a signaling receiving module, to receive a notification of number of Cell-specific Reference Signal (CRS) ports, wherein the number of the CRS ports is larger than 1; and



a signal receiving module, to receive a reference signal over a time-frequency resource.

[Claim 20] The receiving device according to claim 19, further comprising:



a measurement report module, to obtain Reference Signal Receive Power (RSRP)/ Reference Signal Received Quality (RSRQ) information and/or CRS port information by measurement based on the CRS ports; wherein number of RSRP/RSRQ values in the RSRP/RSRQ information is larger than or equal to 1.

[Claim 21] The receiving device according to claim 19, wherein the signaling receiving module is further to receive a data signal and/or control signal over the time-frequency resource.

(54) Title: SUPPORTING RANDOM ACCESS AND PAGING PROCEDURES FOR REDUCED CAPABILITY WTRUS IN AN LTE SYSTEM

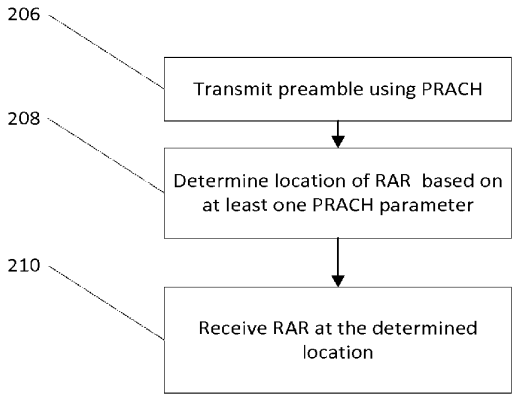

FIG. 2

(57) Abstract: A wireless transmit/receive unit (WTRU) may transmit a preamble using a physical random access channel (PRACH) and determine a location of a random access response (RAR) based on a parameter of the PRACH. The location may include a subframe and/or a frequency resource on which the RAR is transmitted. The RAR may be received at the location. A device may receive a preamble using a PRACH associated with a coverage enhancement (CE) level and/or a CE mode of a WTRU. The device may determine a location of an RAR based on a parameter of the PRACH. The location may include a subframe and/or a frequency resource on which the RAR is to be transmitted. The device may determine a number of repetitions of the RAR to transmit based on the CE level or CE mode. The RAR may be transmitted at the location with the determined number of repetitions.

WO 2016/025899 A1

SUPPORTING RANDOM ACCESS AND PAGING PROCEDURES FOR REDUCED CAPABILITY WTRUS IN AN LTE SYSTEM

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of United States Provisional Patent Application 62/038,194, filed August 15, 2014; United States Provisional Patent Application 62/075,555, filed November 5, 2014; United States Provisional Patent Application 62/149,053, filed April 17, 2015; United States Provisional Patent Application 62/161,212, filed May 13, 2015; and United States Provisional Patent Application 62/204,341, filed August 12, 2015.

BACKGROUND

[0002] A coverage enhanced wireless transmit/receive unit (WTRU) may be a WTRU that may need or may use coverage enhancement or a WTRU that may support or use a coverage enhancement (CE) mode. A coverage limited WTRU may refer to a coverage enhanced WTRU, and *vice versa*.

[0003] A reduced bandwidth (BW) WTRU may be a WTRU that may support a certain limited bandwidth (*e.g.*, RF bandwidth) or a certain limited number of resource blocks (RBs) in the downlink (DL) and/or uplink (UL) that may be independent of the bandwidth of the eNB or cell with which the WTRU may communicate. For example, a limited bandwidth WTRU may support a certain number of RBs (*e.g.*, 6 RBs) or bandwidth (*e.g.*, 1.4 MHz) for transmission and/or reception. Such a WTRU may communicate with an eNB or cell for which the bandwidth may be larger (*e.g.*, 20 MHz or 100 RBs). This WTRU may use procedures to operate in a portion of the full bandwidth of the cell. Reduced bandwidth, limited bandwidth, and bandwidth limited may be used interchangeably.

SUMMARY

[0004] PRACH resource allocation and random access procedures may be provided for WTRUs that may be coverage limited and/or bandwidth limited. Some (*e.g.*, all) of the PRACH resources that may be allocated, *e.g.*, by an eNB, for coverage limited WTRUs may be located in

a bandwidth that may be supported by bandwidth limited WTRUs. WTRUs that may be both coverage limited and bandwidth limited may choose from and/or use one or more PRACH resources for PRACH transmission to an eNB. PRACH resources that may be allocated or designated for each of one or more (*e.g.*, all) levels of coverage limitation may include a subset that may be used by WTRUs that may be coverage limited and bandwidth limited.

[0005] PRACH resources may be allocated or designated for WTRUs that may be both coverage limited and bandwidth limited. WTRUs that may be both coverage limited and bandwidth limited may choose from and/or use these allocated or designated PRACH resources for PRACH transmission to an eNB. PRACH resources (which may be differentiated, for example, by one or more of preamble, time, and/or frequency) may be allocated and/or used for different levels of coverage limitation.

[0006] A WTRU may transmit a preamble using a PRACH and may determine a location of a random access response (RAR) based on a parameter of the PRACH, the location comprising at least one of a subframe or a frequency resource on which the RAR is transmitted. The WTRU may receive the RAR at the determined location.

[0007] A device may receive a preamble using a PRACH associated with at least one of a coverage enhancement (CE) level or a CE mode of a WTRU from which the preamble is received. The device may determine a location of an RAR based on a parameter of the PRACH. The location may comprise at least one of a subframe or a frequency resource on which the RAR is to be transmitted. The device may determine a number of repetitions of the RAR to transmit based on the CE level or CE mode. The device may transmit the RAR at the determined location with the determined number of repetitions.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] FIG. 1A is a system diagram of an example communications system in which one or more disclosed embodiments may be implemented.

[0009] FIG. 1B is a system diagram of an example wireless transmit/receive unit (WTRU) that may be used within the communications system illustrated in FIG. 1A.

[0010] FIG. 1C is a system diagram of an example radio access network and an example core network that may be used within the communications system illustrated in FIG. 1A.

[0011] FIG. 1D is a system diagram of another example radio access network and another example core network that may be used within the communications system illustrated in FIG. 1A.

[0012] FIG. 1E is a system diagram of another example radio access network and another example core network that may be used within the communications system illustrated in FIG. 1A.

[0013] FIG. 2 illustrates an example of preamble transmission and RAR reception by a WTRU.

[0014] FIG. 3A illustrates an example of preamble transmission and RAR reception by a WTRU.

[0015] FIG. 3B illustrates an example RA configuration.

[0016] FIG. 4A illustrates an example of preamble transmission and RAR reception by a WTRU.

[0017] FIG. 4B illustrates an example RA configuration.

[0018] FIG. 5 illustrates an example of preamble reception and RAR transmission.

DETAILED DESCRIPTION

[0019] A detailed description of illustrative embodiments will now be described with reference to the various Figures. Although this description provides a detailed example of possible implementations, it should be noted that the details are intended to be exemplary and in no way limit the scope of the application.

[0020] FIG. 1A is a diagram of an example communications system 100 in which one or more disclosed embodiments may be implemented. The communications system 100 may be a multiple access system that provides content, such as voice, data, video, messaging, broadcast, *etc.*, to multiple wireless users. The communications system 100 may enable multiple wireless users to access such content through the sharing of system resources, including wireless bandwidth. For example, the communications system 100 may employ one or more channel access methods, such as code division multiple access (CDMA), time division multiple access (TDMA), frequency division multiple access (FDMA), orthogonal FDMA (OFDMA), single-carrier FDMA (SC-FDMA), and the like.

[0021] As shown in FIG. 1A, the communications system 100 may include wireless transmit/receive units (WTRUs) 102a, 102b, 102c, and/or 102d (which generally or collectively may be referred to as WTRU 102), a radio access network (RAN) 103/104/105, a core network 106/107/109, a public switched telephone network (PSTN) 108, the Internet 110, and other networks 112, though it will be appreciated that the disclosed embodiments contemplate any

number of WTRUs, base stations, networks, and/or network elements. Each of the WTRUs 102a, 102b, 102c, 102d may be any type of device configured to operate and/or communicate in a wireless environment. By way of example, the WTRUs 102a, 102b, 102c, 102d may be configured to transmit and/or receive wireless signals and may include user equipment (UE), a mobile station, a fixed or mobile subscriber unit, a pager, a cellular telephone, a personal digital assistant (PDA), a smartphone, a laptop, a netbook, a personal computer, a wireless sensor, consumer electronics, and the like.

[0022] The communications system 100 may also include a base station 114a and a base station 114b. Each of the base stations 114a, 114b may be any type of device configured to wirelessly interface with at least one of the WTRUs 102a, 102b, 102c, 102d to facilitate access to one or more communication networks, such as the core network 106/107/109, the Internet 110, and/or the networks 112. By way of example, the base stations 114a, 114b may be a base transceiver station (BTS), a Node-B, an eNode B, a Home Node B, a Home eNode B, a site controller, an access point (AP), a wireless router, and the like. While the base stations 114a, 114b are each depicted as a single element, it will be appreciated that the base stations 114a, 114b may include any number of interconnected base stations and/or network elements.

[0023] The base station 114a may be part of the RAN 103/104/105, which may also include other base stations and/or network elements (not shown), such as a base station controller (BSC), a radio network controller (RNC), relay nodes, *etc.* The base station 114a and/or the base station 114b may be configured to transmit and/or receive wireless signals within a particular geographic region, which may be referred to as a cell (not shown). The cell may further be divided into cell sectors. For example, the cell associated with the base station 114a may be divided into three sectors. Thus, in one embodiment, the base station 114a may include three transceivers, *e.g.*, one for each sector of the cell. In another embodiment, the base station 114a may employ multiple-input multiple output (MIMO) technology and, therefore, may utilize multiple transceivers for each sector of the cell.

[0024] The base stations 114a, 114b may communicate with one or more of the WTRUs 102a, 102b, 102c, 102d over an air interface 115/116/117, which may be any suitable wireless communication link (*e.g.*, radio frequency (RF), microwave, infrared (IR), ultraviolet (UV), visible light, *etc.*). The air interface 115/116/117 may be established using any suitable radio access technology (RAT).

[0025] More specifically, as noted above, the communications system 100 may be a multiple access system and may employ one or more channel access schemes, such as CDMA, TDMA,

FDMA, OFDMA, SC-FDMA, and the like. For example, the base station 114a in the RAN 103/104/105 and the WTRUs 102a, 102b, 102c may implement a radio technology such as Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access (UTRA), which may establish the air interface 115/116/117 using wideband CDMA (WCDMA). WCDMA may include communication protocols such as High-Speed Packet Access (HSPA) and/or Evolved HSPA (HSPA+). HSPA may include High-Speed Downlink Packet Access (HSDPA) and/or High-Speed Uplink Packet Access (HSUPA).

[0026] In another embodiment, the base station 114a and the WTRUs 102a, 102b, 102c may implement a radio technology such as Evolved UMTS Terrestrial Radio Access (E-UTRA), which may establish the air interface 115/116/117 using Long Term Evolution (LTE) and/or LTE-Advanced (LTE-A).

[0027] In other embodiments, the base station 114a and the WTRUs 102a, 102b, 102c may implement radio technologies such as IEEE 802.16 (*e.g.*, Worldwide Interoperability for Microwave Access (WiMAX)), CDMA2000, CDMA2000 1X, CDMA2000 EV-DO, Interim Standard 2000 (IS-2000), Interim Standard 95 (IS-95), Interim Standard 856 (IS-856), Global System for Mobile communications (GSM), Enhanced Data rates for GSM Evolution (EDGE), GSM EDGE (GERAN), and the like.

[0028] The base station 114b in FIG. 1A may be a wireless router, Home Node B, Home eNode B, or access point, for example, and may utilize any suitable RAT for facilitating wireless connectivity in a localized area, such as a place of business, a home, a vehicle, a campus, and the like. In one embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.11 to establish a wireless local area network (WLAN). In another embodiment, the base station 114b and the WTRUs 102c, 102d may implement a radio technology such as IEEE 802.15 to establish a wireless personal area network (WPAN). In yet another embodiment, the base station 114b and the WTRUs 102c, 102d may utilize a cellular-based RAT (*e.g.*, WCDMA, CDMA2000, GSM, LTE, LTE-A, *etc.*) to establish a picocell or femtocell. As shown in FIG. 1A, the base station 114b may have a direct connection to the Internet 110. Thus, the base station 114b may not be required to access the Internet 110 via the core network 106/107/109.

[0029] The RAN 103/104/105 may be in communication with the core network 106/107/109, which may be any type of network configured to provide voice, data, applications, and/or voice over internet protocol (VoIP) services to one or more of the WTRUs 102a, 102b, 102c, 102d. For example, the core network 106/107/109 may provide call control, billing services, mobile

location-based services, pre-paid calling, Internet connectivity, video distribution, *etc.*, and/or perform high-level security functions, such as user authentication. Although not shown in FIG. 1A, it will be appreciated that the RAN 103/104/105 and/or the core network 106/107/109 may be in direct or indirect communication with other RANs that employ the same RAT as the RAN 103/104/105 or a different RAT. For example, in addition to being connected to the RAN 103/104/105, which may be utilizing an E-UTRA radio technology, the core network 106/107/109 may also be in communication with another RAN (not shown) employing a GSM radio technology.

[0030] The core network 106/107/109 may also serve as a gateway for the WTRUs 102a, 102b, 102c, 102d to access the PSTN 108, the Internet 110, and/or other networks 112. The PSTN 108 may include circuit-switched telephone networks that provide plain old telephone service (POTS). The Internet 110 may include a global system of interconnected computer networks and devices that use common communication protocols, such as the transmission control protocol (TCP), user datagram protocol (UDP) and the internet protocol (IP) in the TCP/IP internet protocol suite. The networks 112 may include wired or wireless communications networks owned and/or operated by other service providers. For example, the networks 112 may include another core network connected to one or more RANs, which may employ the same RAT as the RAN 103/104/105 or a different RAT.

[0031] Some or all of the WTRUs 102a, 102b, 102c, 102d in the communications system 100 may include multi-mode capabilities, *e.g.*, the WTRUs 102a, 102b, 102c, 102d may include multiple transceivers for communicating with different wireless networks over different wireless links. For example, the WTRU 102c shown in FIG. 1A may be configured to communicate with the base station 114a, which may employ a cellular-based radio technology, and with the base station 114b, which may employ an IEEE 802 radio technology.

[0032] FIG. 1B is a system diagram of an example WTRU 102. As shown in FIG. 1B, the WTRU 102 may include a processor 118, a transceiver 120, a transmit/receive element 122, a speaker/microphone 124, a keypad 126, a display/touchpad 128, non-removable memory 130, removable memory 132, a power source 134, a global positioning system (GPS) chipset 136, and other peripherals 138. It will be appreciated that the WTRU 102 may include any sub-combination of the foregoing elements while remaining consistent with an embodiment. Also, embodiments contemplate that the base stations 114a and 114b, and/or the nodes that base stations 114a and 114b may represent, such as but not limited to transceiver station (BTS), a Node-B, a site controller, an access point (AP), a home node-B, an evolved home node-B

(eNodeB), a home evolved node-B (HeNB or HeNodeB), a home evolved node-B gateway, and proxy nodes, among others, may include some or all of the elements depicted in FIG. 1B and described herein.

[0033] The processor 118 may be a general purpose processor, a special purpose processor, a conventional processor, a digital signal processor (DSP), a plurality of microprocessors, one or more microprocessors in association with a DSP core, a controller, a microcontroller, Application Specific Integrated Circuits (ASICs), Field Programmable Gate Array (FPGAs) circuits, any other type of integrated circuit (IC), a state machine, and the like. The processor 118 may perform signal coding, data processing, power control, input/output processing, and/or any other functionality that enables the WTRU 102 to operate in a wireless environment. The processor 118 may be coupled to the transceiver 120, which may be coupled to the transmit/receive element 122. While FIG. 1B depicts the processor 118 and the transceiver 120 as separate components, it will be appreciated that the processor 118 and the transceiver 120 may be integrated together in an electronic package or chip. A processor, such as the processor 118, may include integrated memory (*e.g.*, WTRU 102 may include a chipset that includes a processor and associated memory). Memory may refer to memory that is integrated with a processor (*e.g.*, processor 118) or memory that is otherwise associated with a device (*e.g.*, WTRU 102). The memory may be non-transitory. The memory may include (*e.g.*, store) instructions that may be executed by the processor (*e.g.*, software and/or firmware instructions). For example, the memory may include instructions that when executed may cause the processor to implement one or more of the implementations described herein.

[0034] The transmit/receive element 122 may be configured to transmit signals to, or receive signals from, a base station (*e.g.*, the base station 114a) over the air interface 115/116/117. For example, in one embodiment, the transmit/receive element 122 may be an antenna configured to transmit and/or receive RF signals. In another embodiment, the transmit/receive element 122 may be an emitter/detector configured to transmit and/or receive IR, UV, or visible light signals, for example. In yet another embodiment, the transmit/receive element 122 may be configured to transmit and receive both RF and light signals. It will be appreciated that the transmit/receive element 122 may be configured to transmit and/or receive any combination of wireless signals.

[0035] In addition, although the transmit/receive element 122 is depicted in FIG. 1B as a single element, the WTRU 102 may include any number of transmit/receive elements 122. More specifically, the WTRU 102 may employ MIMO technology. Thus, in one embodiment, the

WTRU 102 may include two or more transmit/receive elements 122 (*e.g.*, multiple antennas) for transmitting and receiving wireless signals over the air interface 115/116/117.

[0036] The transceiver 120 may be configured to modulate the signals that are to be transmitted by the transmit/receive element 122 and to demodulate the signals that are received by the transmit/receive element 122. As noted above, the WTRU 102 may have multi-mode capabilities. Thus, the transceiver 120 may include multiple transceivers for enabling the WTRU 102 to communicate via multiple RATs, such as UTRA and IEEE 802.11, for example.

[0037] The processor 118 of the WTRU 102 may be coupled to, and may receive user input data from, the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128 (*e.g.*, a liquid crystal display (LCD) display unit or organic light-emitting diode (OLED) display unit). The processor 118 may also output user data to the speaker/microphone 124, the keypad 126, and/or the display/touchpad 128. In addition, the processor 118 may access information from, and store data in, any type of suitable memory, such as the non-removable memory 130, the removable memory 132, and/or memory integrated with the processor 118. The non-removable memory 130 may include random-access memory (RAM), read-only memory (ROM), a hard disk, or any other type of memory storage device. The removable memory 132 may include a subscriber identity module (SIM) card, a memory stick, a secure digital (SD) memory card, and the like. In other embodiments, the processor 118 may access information from, and store data in, memory that is not physically located on the WTRU 102, such as on a server or a home computer (not shown).

[0038] The processor 118 may receive power from the power source 134, and may be configured to distribute and/or control the power to the other components in the WTRU 102. The power source 134 may be any suitable device for powering the WTRU 102. For example, the power source 134 may include one or more dry cell batteries (*e.g.*, nickel-cadmium (NiCd), nickel-zinc (NiZn), nickel metal hydride (NiMH), lithium-ion (Li-ion), *etc.*), solar cells, fuel cells, and the like.

[0039] The processor 118 may also be coupled to the GPS chipset 136, which may be configured to provide location information (*e.g.*, longitude and latitude) regarding the current location of the WTRU 102. In addition to, or in lieu of, the information from the GPS chipset 136, the WTRU 102 may receive location information over the air interface 115/116/117 from a base station (*e.g.*, base stations 114a, 114b) and/or determine its location based on the timing of the signals being received from two or more nearby base stations. It will be appreciated that the

WTRU 102 may acquire location information by way of any suitable location-determination implementation while remaining consistent with an embodiment.

[0040] The processor 118 may further be coupled to other peripherals 138, which may include one or more software and/or hardware modules that provide additional features, functionality and/or wired or wireless connectivity. For example, the peripherals 138 may include an accelerometer, an e-compass, a satellite transceiver, a digital camera (for photographs or video), a universal serial bus (USB) port, a vibration device, a television transceiver, a hands free headset, a Bluetooth® module, a frequency modulated (FM) radio unit, a digital music player, a media player, a video game player module, an Internet browser, and the like.

[0041] FIG. 1C is a system diagram of the RAN 103 and the core network 106 according to an embodiment. As noted above, the RAN 103 may employ a UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 115. The RAN 103 may also be in communication with the core network 106. As shown in FIG. 1C, the RAN 103 may include Node-Bs 140a, 140b, 140c, which may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 115. The Node-Bs 140a, 140b, 140c may each be associated with a particular cell (not shown) within the RAN 103. The RAN 103 may also include RNCs 142a, 142b. It will be appreciated that the RAN 103 may include any number of Node-Bs and RNCs while remaining consistent with an embodiment.

[0042] As shown in FIG. 1C, the Node-Bs 140a, 140b may be in communication with the RNC 142a. Additionally, the Node-B 140c may be in communication with the RNC 142b. The Node-Bs 140a, 140b, 140c may communicate with the respective RNCs 142a, 142b via an Iub interface. The RNCs 142a, 142b may be in communication with one another via an Iur interface. Each of the RNCs 142a, 142b may be configured to control the respective Node-Bs 140a, 140b, 140c to which it is connected. In addition, each of the RNCs 142a, 142b may be configured to carry out or support other functionality, such as outer loop power control, load control, admission control, packet scheduling, handover control, macrodiversity, security functions, data encryption, and the like.

[0043] The core network 106 shown in FIG. 1C may include a media gateway (MGW) 144, a mobile switching center (MSC) 146, a serving GPRS support node (SGSN) 148, and/or a gateway GPRS support node (GGSN) 150. While each of the foregoing elements are depicted as part of the core network 106, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0044] The RNC 142a in the RAN 103 may be connected to the MSC 146 in the core network 106 via an IuCS interface. The MSC 146 may be connected to the MGW 144. The MSC 146 and the MGW 144 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices.

[0045] The RNC 142a in the RAN 103 may also be connected to the SGSN 148 in the core network 106 via an IuPS interface. The SGSN 148 may be connected to the GGSN 150. The SGSN 148 and the GGSN 150 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between and the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0046] As noted above, the core network 106 may also be connected to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0047] FIG. 1D is a system diagram of the RAN 104 and the core network 107 according to an embodiment. As noted above, the RAN 104 may employ an E-UTRA radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 116. The RAN 104 may also be in communication with the core network 107.

[0048] The RAN 104 may include eNode-Bs 160a, 160b, 160c, though it will be appreciated that the RAN 104 may include any number of eNode-Bs while remaining consistent with an embodiment. The eNode-Bs 160a, 160b, 160c may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 116. In one embodiment, the eNode-Bs 160a, 160b, 160c may implement MIMO technology. Thus, the eNode-B 160a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a.

[0049] Each of the eNode-Bs 160a, 160b, 160c may be associated with a particular cell (not shown) and may be configured to handle radio resource management decisions, handover decisions, scheduling of users in the uplink and/or downlink, and the like. As shown in FIG. 1D, the eNode-Bs 160a, 160b, 160c may communicate with one another over an X2 interface.

[0050] The core network 107 shown in FIG. 1D may include a mobility management gateway (MME) 162, a serving gateway 164, and a packet data network (PDN) gateway 166. While each of the foregoing elements are depicted as part of the core network 107, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0051] The MME 162 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via an S1 interface and may serve as a control node. For example, the MME 162 may be responsible for authenticating users of the WTRUs 102a, 102b, 102c, bearer activation/deactivation, selecting a particular serving gateway during an initial attach of the WTRUs 102a, 102b, 102c, and the like. The MME 162 may also provide a control plane function for switching between the RAN 104 and other RANs (not shown) that employ other radio technologies, such as GSM or WCDMA.

[0052] The serving gateway 164 may be connected to each of the eNode-Bs 160a, 160b, 160c in the RAN 104 via the S1 interface. The serving gateway 164 may generally route and forward user data packets to/from the WTRUs 102a, 102b, 102c. The serving gateway 164 may also perform other functions, such as anchoring user planes during inter-eNode B handovers, triggering paging when downlink data is available for the WTRUs 102a, 102b, 102c, managing and storing contexts of the WTRUs 102a, 102b, 102c, and the like.

[0053] The serving gateway 164 may also be connected to the PDN gateway 166, which may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices.

[0054] The core network 107 may facilitate communications with other networks. For example, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. For example, the core network 107 may include, or may communicate with, an IP gateway (*e.g.*, an IP multimedia subsystem (IMS) server) that serves as an interface between the core network 107 and the PSTN 108. In addition, the core network 107 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0055] FIG. 1E is a system diagram of the RAN 105 and the core network 109 according to an embodiment. The RAN 105 may be an access service network (ASN) that employs IEEE 802.16 radio technology to communicate with the WTRUs 102a, 102b, 102c over the air interface 117. As will be further discussed below, the communication links between the different functional entities of the WTRUs 102a, 102b, 102c, the RAN 105, and the core network 109 may be defined as reference points.

[0056] As shown in FIG. 1E, the RAN 105 may include base stations 180a, 180b, 180c, and an ASN gateway 182, though it will be appreciated that the RAN 105 may include any number of base stations and ASN gateways while remaining consistent with an embodiment. The base stations 180a, 180b, 180c may each be associated with a particular cell (not shown) in the RAN 105 and may each include one or more transceivers for communicating with the WTRUs 102a, 102b, 102c over the air interface 117. In one embodiment, the base stations 180a, 180b, 180c may implement MIMO technology. Thus, the base station 180a, for example, may use multiple antennas to transmit wireless signals to, and receive wireless signals from, the WTRU 102a. The base stations 180a, 180b, 180c may also provide mobility management functions, such as handoff triggering, tunnel establishment, radio resource management, traffic classification, quality of service (QoS) policy enforcement, and the like. The ASN gateway 182 may serve as a traffic aggregation point and may be responsible for paging, caching of subscriber profiles, routing to the core network 109, and the like.

[0057] The air interface 117 between the WTRUs 102a, 102b, 102c and the RAN 105 may be defined as an R1 reference point that implements the IEEE 802.16 specification. In addition, each of the WTRUs 102a, 102b, 102c may establish a logical interface (not shown) with the core network 109. The logical interface between the WTRUs 102a, 102b, 102c and the core network 109 may be defined as an R2 reference point, which may be used for authentication, authorization, IP host configuration management, and/or mobility management.

[0058] The communication link between each of the base stations 180a, 180b, 180c may be defined as an R8 reference point that includes protocols for facilitating WTRU handovers and the transfer of data between base stations. The communication link between the base stations 180a, 180b, 180c and the ASN gateway 182 may be defined as an R6 reference point. The R6 reference point may include protocols for facilitating mobility management based on mobility events associated with each of the WTRUs 102a, 102b, 102c.

[0059] As shown in FIG. 1E, the RAN 105 may be connected to the core network 109. The communication link between the RAN 105 and the core network 109 may defined as an R3 reference point that includes protocols for facilitating data transfer and mobility management capabilities, for example. The core network 109 may include a mobile IP home agent (MIP-HA) 184, an authentication, authorization, accounting (AAA) server 186, and a gateway 188. While each of the foregoing elements are depicted as part of the core network 109, it will be appreciated that any one of these elements may be owned and/or operated by an entity other than the core network operator.

[0060] The MIP-HA may be responsible for IP address management, and may enable the WTRUs 102a, 102b, 102c to roam between different ASNs and/or different core networks. The MIP-HA 184 may provide the WTRUs 102a, 102b, 102c with access to packet-switched networks, such as the Internet 110, to facilitate communications between the WTRUs 102a, 102b, 102c and IP-enabled devices. The AAA server 186 may be responsible for user authentication and for supporting user services. The gateway 188 may facilitate interworking with other networks. For example, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to circuit-switched networks, such as the PSTN 108, to facilitate communications between the WTRUs 102a, 102b, 102c and traditional land-line communications devices. In addition, the gateway 188 may provide the WTRUs 102a, 102b, 102c with access to the networks 112, which may include other wired or wireless networks that are owned and/or operated by other service providers.

[0061] Although not shown in FIG. 1E, it will be appreciated that the RAN 105 may be connected to other ASNs and the core network 109 may be connected to other core networks. The communication link between the RAN 105 the other ASNs may be defined as an R4 reference point, which may include protocols for coordinating the mobility of the WTRUs 102a, 102b, 102c between the RAN 105 and the other ASNs. The communication link between the core network 109 and the other core networks may be defined as an R5 reference, which may include protocols for facilitating interworking between home core networks and visited core networks.

[0062] A WTRU that may support the full bandwidth of a cell may be referred to as a full bandwidth WTRU. Bandwidth may include a number of RBs and/or a location in a band, such as the center of the band.

[0063] A WTRU may at least sometimes communicate, behave, or operate in a manner that may be consistent (*e.g.*, at least partially consistent) with that of a full bandwidth (BW) WTRU and may at least sometimes (*e.g.*, at other times) communicate, behave, or operate in a manner that may be consistent (*e.g.*, at least partially consistent) with that of a reduced BW WTRU. For example, a WTRU that may support the full bandwidth of a cell may communicate, behave, or operate in a manner that may be consistent (*e.g.*, at least partially consistent) with that of a reduced BW WTRU at certain times, such as when it may be coverage limited or when it may operate in coverage enhanced (CE) mode. A WTRU may be or may be considered a full BW WTRU and/or a reduced BW WTRU, for example, at least sometimes.

[0064] A WTRU may be or may be considered a reduced BW WTRU while it may (or may need to or may intend to) behave or operate like (*e.g.*, at least partially like) a reduced BW WTRU. A WTRU that may communicate (*e.g.*, with an eNB), behave, or operate in a manner that may be consistent (*e.g.*, at least partially consistent) with that of a reduced BW WTRU may be or may be considered to be a reduced BW WTRU, for example, at least sometimes, such as when the WTRU may communicate, behave, or operate in a manner that may be consistent (*e.g.*, at least partially consistent) with that of a reduced BW WTRU.

[0065] The examples disclosed herein may apply to eNBs and cells. The examples disclosed herein may apply to WTRUs such as coverage limited and reduced bandwidth (BW) WTRUs. The examples disclosed herein as being applicable to reduced BW WTRUs may apply to coverage limited WTRUs. The examples disclosed herein as being applicable to coverage limited WTRUs may apply to reduced BW WTRUs. The examples disclosed herein may apply to WTRUs of other types, with other capabilities, or with reduced capabilities.

[0066] For purposes of description and explanation, PDCCH may be replaced with EPDCCH, and *vice versa*, and may still be consistent with the examples disclosed herein. For purposes of description and explanation, PDCCH (or EPDCCH) may be replaced with a DL control channel or another DL control channel and may still be consistent with the examples disclosed herein. For purposes of description and explanation, component carrier (CC) and serving cell may be used interchangeably. For purposes of description and explanation, WTRU, WTRU MAC entity, and MAC entity may be used interchangeably. For purposes of description and explanation, eNB and cell may be used interchangeably. CE level may be replaced with number of repetitions, and *vice versa*, and may still be consistent with the examples disclosed herein. Repetition number, number of repetitions, and repetition level may be used interchangeably.

[0067] A WTRU or WTRUs may be replaced with at least a WTRU or at least WTRUs, and may still be consistent with the examples disclosed herein. Intended for may be replaced with at least intended for or with intended for at least and may still be consistent with the examples disclosed herein.

[0068] Examples disclosed herein may be disclosed for RAR, PCH, or for a physical downlink shared channel (PDSCH) that may carry RAR or PCH. Such examples are non-limiting. RAR may be replaced by PCH, PCH PDSCH, or PDSCH, and *vice versa*, and may still be consistent with the examples disclosed herein. The channel or other content that may be

carried by the PDSCH may be replaced by another channel or content and may still be consistent with the examples disclosed herein.

[0069] An eNB and/or a WTRU may use a random access procedure for WTRU initial access (for example, to a cell or eNB), reset of UL timing (for example, to reset or align WTRU UL timing with respect to a cell), and/or reset of timing during handover (for example, to reset or align WTRU timing with respect to the handover target cell). The WTRU may transmit a physical random access channel (PRACH) preamble sequence at a power P_{PRACH}, which may be based on configured parameters and/or measurements, and the WTRU may transmit the preamble using a time-frequency resource or resources. The configured parameters, which may be provided or configured by the eNB, may include one or more of initial preamble power (*e.g.*, preambleInitialReceivedTargetPower), a preamble format based offset (*e.g.*, deltaPreamble), a random access response window (*e.g.*, ra-ResponseWindowSize), a power ramping factor (*e.g.*, powerRampingStep), and/or a maximum number of retransmissions (*e.g.*, preambleTransMax). The PRACH resources (which may include preambles or sets of preambles and/or time/frequency resources that may be used for preamble transmission) may be provided or configured by the eNB. The measurements may include pathloss. The time-frequency resource or resources may be chosen by the WTRU from an allowed set or may be chosen by the eNB and signaled to the WTRU. Following WTRU transmission of a preamble, if the eNB may detect the preamble, it may respond with a random access response (RAR). If the WTRU may not or does not receive an RAR for the transmitted preamble (which may, for example, correspond to a certain preamble index and time/frequency resource), within an allotted time (for example, ra-ResponseWindowSize), the WTRU may send another preamble at a later time, at a higher power, (for example, higher than the previous preamble transmission by powerRampingStep) where the transmission power may be limited by a maximum power, for example, a WTRU-configured maximum power which may be for the WTRU as a whole (for example, P_{CMAX}) or for a serving cell of the WTRU (for example, $P_{CMAX,c}$). The WTRU may wait again for receipt of an RAR from the eNB. This sequence of transmitting and waiting may continue until the eNB may respond with an RAR or until the maximum number of random access preamble transmissions (for example, preambleTransMax) may have been reached. The eNB may transmit and the WTRU may receive the RAR in response to a single preamble transmission.

[0070] The term time/frequency or time-frequency may be used to represent time and/or frequency. The term time-frequency may be used to represent a specific time and frequency.

[0071] A random access procedure (*e.g.*, an instance of a random access procedure) may be contention-based or contention-free. A contention-free procedure may be initiated by a request, for example from an eNB, which may, for example, be via physical layer signaling such as a PDCCH order or by higher layer signaling such as an RRC reconfiguration message (*e.g.*, an RRC connection reconfiguration message) that may include mobility control information and may, for example, indicate or correspond to a handover request. For a contention-free procedure that may be initiated by PDCCH order in subframe n, the PRACH preamble may be transmitted in the first subframe (or the first subframe available for PRACH) $n+k_2$, where k_2 may be at least 6. When initiated by RRC command, there may be other delays that may be specified (for example, there may be minimum and/or maximum required or allowed delays). The WTRU may autonomously initiate a contention-based procedure for reasons that may include for example, initial access, restoration of UL synchronization, and/or recovering from radio link failure. For certain events, for example, events other than recovery from radio link failure, it may not be defined or specified as to how long after such an event the WTRU may send the PRACH preamble.

[0072] For a contention-free random access (RA) procedure, a network-signaled PRACH preamble may be used, *e.g.*, by a WTRU. For a contention-based random access procedure, the WTRU may autonomously choose a preamble where the preamble format and/or the time/frequency resource or resources available for preamble transmissions may be based on an indication or index (*e.g.*, prach configIndex) that may be provided or signaled by the eNB.

[0073] In an LTE system, one of the preambles transmitted at the progressively higher transmit powers may be detected by the eNB. An RAR may be sent by the eNB in response to that one detected preamble.

[0074] A WTRU may monitor (*e.g.*, periodically) the PDCCH for DL assignments on the PDCCH masked with a P-RNTI (Paging Radio Network Temporary Identifier (RNTI)) in idle mode and/or in connected mode. When such a DL assignment using the P-RNTI may be detected, the WTRU may demodulate the assigned PDSCH resource blocks (RBs) and may decode the paging channel (PCH) carried on that PDSCH. A PDSCH that may carry PCH may be a PCH PDSCH. Paging, paging message, paging information, and PCH may be used interchangeably.

[0075] In idle mode, the specific paging frame (PF) and subframe within that PF, for example, the paging occasion (PO) that a WTRU may monitor for the paging channel may be determined based on the WTRU ID (*e.g.*, WTRU_ID) and parameters that may be specified by

the network. The parameters may include the paging cycle (PC) length (*e.g.*, in frames), which may be the same as a DRX cycle and another parameter, *e.g.*, nB, which together may facilitate the determination of the number of PF per PC and the number of PO per PF that may be in the cell. The WTRU ID may be the WTRU IMSI or the WTRU IMSI modulo a number such as 1024. For example, the PO may be determined based on WTRU IMSI mod 1024.

[0076] There may be multiple PFs per paging cycle and multiple POs within a PF, for example, more than one subframe per paging cycle may carry PDCCH masked with a P-RNTI. A WTRU may monitor a (*e.g.*, one) PO per paging cycle, and such a PO may be determined based on WTRU ID and/or one or more of the parameters disclosed herein, which may be provided to the WTRU via system information, dedicated signaling information, and the like. POs may include pages for one or more specific WTRUs, or they may include system information change pages that may be directed to each of the WTRUs, some of the WTRUs, or all of the WTRUs. For WTRU-specific pages (*e.g.*, pages that may be specific to one or more WTRUs), a WTRU (*e.g.*, a WTRU in idle mode) may monitor one PO per PC that may be based on a WTRU ID. For pages that may indicate a system information change (*e.g.*, a change that has occurred or an upcoming system information change), a WTRU (*e.g.*, a WTRU in idle or connected mode) may monitor one or more POs in a system information modification period that may or may not be based on the WTRU ID.

[0077] In connected mode, a WTRU may receive pages related to a system information change, for example, and it may not receive WTRU-specific pages such as those that may be used for an incoming call. A WTRU in the connected mode may not monitor a specific PO (*e.g.*, a PO that may be based on its WTRU ID). For frequency division duplexing (FDD), the PO subframes may include certain subframes, such as subframes 0, 4, 5, and 9. For time division duplexing (TDD), the PO subframes may include certain subframes, such as subframes 0, 1, 5, and 6.

[0078] A number of repetitions, such as of a preamble, a control channel, a PDSCH (*e.g.*, an RAR PDSCH), a PUSCH, and/or a PUCCH may include the first transmission (or reception). A number of repetitions (*e.g.*, other repetitions) may exclude the first transmission (or reception). Inclusion may be substituted for exclusion and *vice versa* and still be consistent with the examples disclosed herein. Downlink control channel, downlink control channel for MTC WTRU, (E)PDCCH (*e.g.*, EPDCCH and/or PDCCH), PDCCH, and/or M-PDCCH may be used interchangeably. System information, system information for MTC WTRU, MTC-SIB, M-SIB, and/or SIB may be used interchangeably.

[0079] A random access (RA) procedure may be provided and/or used. An eNB or cell may support WTRUs with capabilities or limitations, such as coverage limited WTRUs and/or WTRUs with reduced capabilities, such as reduced bandwidth WTRUs. A WTRU may be coverage limited and/or reduced bandwidth. Reduced capabilities may or may also include reduced complexity, such as inclusion or use of (*e.g.*, only of) a single receive antenna and/or receiver chain and/or support for a reduced transport block size.

[0080] PRACH resources may be partitioned such that resources (*e.g.*, certain resources) which may be or include preambles and/or resources in time and/or frequency may be used by WTRUs such as coverage limited WTRUs and the use of the resources (*e.g.*, certain resources) may indicate to an eNB that the WTRU using the resources may be coverage limited and/or the coverage limitation of the WTRU using the resources may be of a certain level.

[0081] An eNB, for example, one that may support a bandwidth (BW) larger than that of a reduced bandwidth WTRU and/or that may support reduced bandwidth WTRUs, may allocate PRACH resources that may be used by at least certain WTRUs, such as reduced bandwidth WTRUs. The allocated resources may be located in a bandwidth (*e.g.*, number of RBs and/or band location such as a band center) in which a reduced bandwidth WTRU may or may be able to transmit. These resources may be the same as, separate from, or a subset of those which may be allocated for legacy or other WTRUs. The allocated resources may include preambles that may or may only be used by reduced bandwidth WTRUs.

[0082] PRACH resource allocation (*e.g.*, for resources that may be used by at least certain WTRUs) may include the designation of one or more of preambles (*e.g.*, certain preambles), times (*e.g.*, subframes or certain subframes), and/or frequencies (*e.g.*, RBs or certain RBs). PRACH resources (*e.g.*, for use by at least certain WTRUs) may be differentiated (*e.g.*, from resources that may not be used by the certain WTRUs) by at least one or more of preamble, time (*e.g.*, subframe allocation), and/or frequency (*e.g.*, RB allocation). Allocation and/or designation may be via signaling (*e.g.*, by the eNB), such as dedicated or broadcast signaling and/or system information.

[0083] PRACH resource allocation and random access procedures may be provided for WTRUs that may be coverage limited and/or bandwidth limited. Some (*e.g.*, all) of the PRACH resources that may be allocated, *e.g.*, by an eNB, for coverage limited WTRUs may be or may always be located in a bandwidth that may be supported by bandwidth limited WTRUs. WTRUs that may be coverage limited and/or bandwidth limited may choose from and/or use one or more PRACH resources (*e.g.*, from among the PRACH resources that may be allocated for coverage

limited WTRUs and/or may be located in a bandwidth that may be supported by bandwidth limited WTRUs) for PRACH transmission to an eNB. PRACH resources that may be allocated or designated for each of one or more (*e.g.*, all) levels of coverage limitation may include a subset (which may include the full set) that may be used by WTRUs that may be coverage limited and bandwidth limited.

[0084] An eNB may consider a coverage limited WTRU (*e.g.*, a WTRU that the eNB may determine to be coverage limited) as a bandwidth limited WTRU as well, for example, until informed or determined otherwise. The eNB may determine the WTRU to be coverage limited based on the PRACH resource the WTRU may have used (*e.g.*, transmitted) or the eNB may have received from the WTRU. The eNB may communicate with the WTRU accordingly.

[0085] An eNB that may receive a PRACH from a PRACH resource that may be designated or allocated for coverage limited WTRUs and that may be used by bandwidth limited WTRUs (*e.g.*, by designation or by location in the supportable bandwidth of the WTRU) may consider the WTRU that may have transmitted the PRACH as a bandwidth limited WTRU, for example, until informed or determined otherwise. The eNB may communicate with the WTRU accordingly.

[0086] PRACH resources may be specifically allocated or designated for WTRUs that may be both coverage limited and bandwidth limited. WTRUs that may be both coverage limited and bandwidth limited may choose from and/or use these allocated or designated PRACH resources for PRACH transmission to an eNB. Separate PRACH resources (which may be differentiated, for example, by one or more of preamble, time, and/or frequency) may be allocated and/or used for different levels of coverage limitation. For example, one level of coverage limitation, *e.g.*, the worst case level, may be used by WTRUs that may be both coverage limited and bandwidth limited.

[0087] An eNB that may receive a PRACH from a PRACH resource that may be designated or allocated for WTRUs that may be both coverage limited and bandwidth limited may consider the WTRU that may have transmitted the PRACH as both a coverage limited and bandwidth limited WTRU. Based on the PRACH resource, the eNB may also know the coverage limitation level. The eNB may communicate with the WTRU accordingly.

[0088] A random access response (RAR) may be provided and/or used. During a random access procedure with a WTRU, an eNB may not know if the WTRU is a reduced bandwidth WTRU, for example, until it may receive an indication or message from the WTRU, and may, for example, not know whether to respond to the WTRU in a reduced bandwidth.

[0089] An eNB may consider a WTRU that may have transmitted (or from which the eNB may have received) a PRACH in a certain bandwidth (*e.g.*, a certain number of RBs and/or a certain location such as a center set of RBs, such as the center 6 RBs) to be a reduced bandwidth WTRU, for example, until it receives an indication that the WTRU is not a reduced bandwidth WTRU. The indication may be provided by the WTRU in a message (*e.g.*, RRC message such as a RRC connection request or WTRU capabilities message, which may be from the WTRU).

[0090] When responding to PRACH from a WTRU such as one that may be or may be considered by an eNB to be a reduced bandwidth WTRU, the eNB may provide the random access response (RAR) in a way in which the WTRU may be able to receive it.

[0091] An eNB may, for example, until it knows or determines a WTRU is not a reduced bandwidth WTRU, limit transmissions intended for the WTRU to a maximum of a certain number R RBs (*e.g.*, 6) and/or location, such as a set (*e.g.*, a certain set) of R RBs (*e.g.*, the center R RBs). The eNB may or may also limit an UL grant (*e.g.*, the UL grant for msg3 of the RA procedure) size to a certain maximum number Y RBs (*e.g.*, 6 RBs) and/or location such as a set (*e.g.*, a certain set) of Y RBs (*e.g.*, the center Y RBs). R may be equal to Y. The RB location(s) may be provided (*e.g.*, by the eNB, in signaling such as broadcast signaling (*e.g.*, in system information). This may apply (*e.g.*, may only apply) for WTRUs that may or may be determined to be coverage limited (*e.g.*, based on the PRACH resource used by the WTRU).

[0092] An eNB that may receive a PRACH from a PRACH resource that may be allocated or designated for or used by at least certain, *e.g.*, bandwidth limited and/or coverage limited, WTRUs may do one or more of the following: provide RAR in a manner in which a WTRU, such as a bandwidth limited WTRU and/or a coverage limited WTRU, may receive the RAR, provide an UL grant for resources (*e.g.*, for message 3 of the RA procedure) in the bandwidth in which a bandwidth limited WTRU may transmit, and/or provide or continue to provide DL grants and/or UL grants for a limited bandwidth WTRU until, for example, it may receive an indication (explicit or otherwise) that the WTRU may not be a limited bandwidth WTRU. The indication may be included in an RRC message such as an RRC connection request message or a WTRU capabilities message, which may be from the WTRU.

[0093] Providing RAR in a manner in which a WTRU, such as a bandwidth limited WTRU and/or a coverage limited WTRU, may receive the RAR may include using EPDCCH (or both EPDCCH and PDCCH) to send the control information (*e.g.*, DCI format) that may indicate the location and/or parameters for the PDSCH that may carry the RAR. Providing RAR in a manner in which a WTRU, such as a bandwidth limited WTRU and/or a coverage limited WTRU, may

receive the RAR may include transmitting the PDSCH that may carry RAR in the bandwidth (*e.g.*, number of RBs and/or band location such as the center of the band) in which a limited bandwidth WTRU may receive it. Providing RAR in a manner in which a WTRU, such as a bandwidth limited WTRU and/or a coverage limited WTRU, may receive the RAR may include transmitting the RAR PDSCH in a fixed, known, or determined location and/or with one or more fixed, known, or determined parameters (*e.g.*, transmission parameters such as MCS) such that a DCI format may not be required or used (*e.g.*, for the RAR) by or for a WTRU, which may be a bandwidth limited WTRU or a coverage limited WTRU. The fixed, known, or determined location and/or parameters may be provided by the eNB in signaling, such as broadcast system information and/or may be a function of the PRACH or PRACH transmission to which the RAR may respond or may include a response.

[0094] A known location, parameter, or value may be determined by the WTRU and/or eNB. Known and determined may be used interchangeably.

[0095] Providing DL grants and/or UL grants for a limited bandwidth WTRU may include one or more of using EPDCCH (or both EPDCCH and PDCCH) to send the control information (*e.g.*, DCI format) associated with the grant, transmitting the granted PDSCH in the bandwidth (*e.g.*, number of RBs and/or band location such as the center of the band) in which a limited bandwidth WTRU may receive it, and/or granting UL resources in the bandwidth (*e.g.*, number of RBs and/or band location such as the center of the band) in which a limited bandwidth WTRU may transmit.

[0096] The location and/or transmission parameters of an RAR that may be intended for a WTRU (or at least a WTRU) that may be bandwidth limited and/or coverage limited may be a function of one or more parameters of the PRACH (*e.g.*, the PRACH resource) for which the RAR may provide or include a response. A location (*e.g.*, of an RAR) may be or may include time (*e.g.*, subframe) and/or frequency (*e.g.*, one or more RBs). A PRACH or PRACH resource parameter may be or may include time (*e.g.*, subframe or subframe set), frequency (*e.g.*, one or more RBs), and/or preamble.

[0097] An RAR may be or may represent a certain instance or repetition of an RAR. Repetitions of an RAR that may be combined by a WTRU, such as a WTRU that may be coverage limited, may be in the same or different locations (*e.g.*, subframes may be different and RBs may be the same or different) and/or may use the same or different parameters.

[0098] A WTRU, such as a bandwidth limited and/or coverage limited WTRU, may transmit a PRACH, *e.g.*, to an eNB. The WTRU and/or the eNB may determine the location of an RAR

that may be intended for the WTRU (or at least the WTRU), for example, in response to the PRACH transmission of the WTRU, based on one or more parameters of the PRACH (*e.g.*, the PRACH resource). For example, the RB or RBs in which a WTRU may transmit a PRACH may determine (or may be used by the WTRU and/or eNB to determine) the RB or RBs for the RAR that may correspond to the PRACH. The eNB may transmit and/or the WTRU may receive or attempt to receive the RAR in the determined location. Determination by the WTRU may be based on at least configuration, *e.g.*, of the relationship or correspondence between RAR location and/or parameters and PRACH parameters and/or PRACH resources, which may be provided by the eNB via signaling, such as broadcast signaling or in system information, which may be broadcast.

[0099] A location (*e.g.*, which may be fixed or known) and/or one or more transmission parameters (*e.g.*, which may be fixed or known) of an RAR that may be intended for a WTRU (or at least a WTRU), such as a WTRU that may be bandwidth limited and/or coverage limited, may be a function of a capability (or reduced capability) of the WTRU. For example, RAR location and/or one or more RAR transmission parameters may be a function of at least one of CE mode, CE level, and/or bandwidth limitation. The capability (or reduced capability) of the WTRU, such as the CE mode and/or CE level, and/or bandwidth limitation of the WTRU, may determine (or may be used by the WTRU and/or eNB to determine) the location (*e.g.*, subframes and/or RBs) and/or one or more transmission parameters (*e.g.*, MCS) for the RAR that may correspond to the PRACH. The eNB may transmit and/or the WTRU may receive or attempt to receive the RAR in the determined location. Determination by the WTRU may be based on at least configuration (*e.g.*, of RAR location and/or parameters) for one or more capabilities (or reduced capabilities, such as CE mode or level) that may be provided by the eNB via signaling such as broadcast signaling.

[0100] FIG. 2 illustrates an example of preamble transmission and RAR reception by a WTRU. The WTRU may transmit a preamble on or using a PRACH at 206. The WTRU may determine the location of the RAR based on at least one parameter of the PRACH at 208. The location of the RAR may comprise at least one of a subframe or a frequency resource on which the RAR may be or will be transmitted. A PRACH parameter may comprise at least one of a subframe, a frequency resource, *e.g.*, on which the preamble is transmitted, or the preamble. The WTRU may receive or may attempt to receive the RAR at the determined location at 210. The WTRU may transmit the preamble with repetitions, for example, when the WTRU is in CE mode, using CE, and/or using a CE level. The WTRU may receive and combine repetitions of an RAR to successfully receive and/or decode the RAR, for example, when the WTRU is in CE

mode, using CE, and/or using a CE level. The location of the RAR repetitions may be determined based on the at least one parameter of the PRACH and/or one or more other PRACH parameters. The association or correspondence between the one or more PRACH parameters and the RAR location (or locations, for example for repetitions) may be provided to and/or received by the WTRU via a configuration, *e.g.*, a random access (RA) configuration. The configuration may be provided and/or received in system information, which may be broadcast.

[0101] FIG. 3A illustrates another example of preamble transmission and RAR reception by a WTRU. The WTRU receives an RA configuration at 302. The WTRU determines one or more PRACH parameters based on the RA configuration at 304. The WTRU transmits a preamble on or using a PRACH at 306. The WTRU determines the location of the RAR based on at least one parameter of the PRACH at 308. The location of the RAR may comprise at least one of a subframe or a frequency resource on which the RAR may be or will be transmitted. A PRACH parameter may comprise at least one of a subframe, a frequency resource, *e.g.*, on which the preamble is transmitted, or the preamble. The WTRU may receive or may attempt to receive the RAR at the determined location at 310. The WTRU may transmit the preamble with repetitions, for example, when the WTRU is in CE mode, using CE, and/or using a CE level. The WTRU may receive and combine repetitions of an RAR to successfully receive and/or decode the RAR, for example, when the WTRU is in CE mode, using CE, and/or using a CE level. The location of the RAR repetitions may be determined based on the at least one parameter of the PRACH and/or one or more other PRACH parameters. The RA configuration may provide the WTRU with the association or correspondence between the one or more PRACH parameters and the RAR location (or locations, for example, for repetitions).

[0102] FIG. 3B illustrates an example RA configuration that includes one or more PRACH parameters 314 and one or more RAR locations 316. The RA configuration may provide the association or correspondence between one or more PRACH parameters and an RAR location or locations, for example for repetitions. The PRACH parameters and/or RAR locations may be associated with CE levels.

[0103] FIG. 4A illustrates an example of preamble transmission and RAR reception by a WTRU. The WTRU may receive an RA configuration at 402. The WTRU may determine PRACH parameters based on the RA configuration and/or CE level at 404. For example, the RA configuration may include one or more PRACH parameters or sets of PRACH parameters that may be associated with one or more CE levels. PRACH parameters may include one or more preambles and/or one or more PRACH time and/or frequency resources. The WTRU may

determine a preamble, *e.g.*, select a preamble from a set of one or more preambles. The WTRU may determine a subframe or set of subframes (*e.g.*, for repetition) from the one or more time resources. The WTRU may determine a frequency resource such as one or more (*e.g.*, a set of) PRBs from the one or more frequency resources. The CE level may be determined by the WTRU, for example, based on a measurement. The CE level may be determined by the WTRU according to a starting CE level and a number of prior failed random access attempts. For a WTRU that may be using a reduced BW but may not be in or using a CE mode, CE level may not be included in the determination of PRACH parameters at 404.

[0104] The WTRU may transmit a preamble based on the PRACH parameters at 406. For example, the WTRU may transmit the determined preamble on or using the determined PRACH. The WTRU may transmit the determined preamble in the determined subframe or set of subframes in the determined frequency resource (or frequency resources, *e.g.*, if frequency hopping is used for one or more repetitions).

[0105] The WTRU may determine the RAR location based on at least one PRACH parameter and/or CE level at 408. The RAR location may comprise at least one of a subframe and/or a frequency resource on which the RAR may be transmitted. For RAR with repetition, the location may comprise multiple (*e.g.*, a set of) subframes. For RAR with repetition, the location may comprise multiple (*e.g.*, a set of) frequency locations, *e.g.*, if frequency hopping is used.

[0106] The WTRU may determine the number of repetitions with which the RAR will be transmitted based on at least one PRACH parameter and/or CE level at 410. For some WTRUs, *e.g.*, a WTRU that may be using a reduced BW but may not be in or using a CE mode, this determination may not be made.

[0107] The WTRU may receive or may attempt to receive an RAR at the determined location and, optionally, with up to the determined number of repetitions at 412. The WTRU may receive a repetition of an RAR at one or more determined locations and may combine the repetitions to successfully receive and decode the RAR. The WTRU may receive and combine up to the determined number of repetitions at 412.

[0108] If the WTRU successfully receives an RAR within an RA response window, the WTRU may transmit a success message on resources which may be allocated or granted by the RAR. The success message may be a random access msg3 or another message. If the WTRU does not successfully receive an RAR within an RA response window, the WTRU may stop or may try again depending on the random access procedure and the number of attempts already made, *e.g.*, at one or more CE levels.

[0109] FIG. 4B illustrates another example RA configuration that includes one or more PRACH parameters 414 and one or more RAR locations 416. The RA configuration may provide the WTRU with the association or correspondence between one or more PRACH parameters and an RAR location or locations, for example for repetitions. The PRACH parameters and/or RAR locations may be associated with CE levels.

[0110] FIG. 5 illustrates an example of preamble reception and RAR transmission, for example by an eNB or cell. A preamble may be received on or using a PRACH associated with a CE level at 506. The location of the RAR and/or the number RAR repetitions may be determined based on at least one parameter of the PRACH at 508. The location of the RAR may comprise at least one of a subframe or a frequency resource on which the RAR may be or will be transmitted. A PRACH parameter may comprise at least one of a subframe, a frequency resource, *e.g.*, on which the preamble is transmitted or received, or the preamble. The RAR may be transmitted at the determined location and/or with the determined repetitions at 510.

[0111] RAR location may be used to represent the location of a PDSCH that may carry a (or at least one) RAR. RAR location may be used to represent the location of a control channel or control information, *e.g.*, one or more of a PDCCH, EPDCCH, M-PDCCH, a DCI, or a DCI format, that may include or carry a (or at least one) RAR or may indicate or be associated with a PDSCH that may carry a (or at least one) RAR.

[0112] RAR may be used to represent a PDSCH that may carry an RAR (or at least one RAR). RAR may be used to represent a control channel or control information, *e.g.*, one or more of a PDCCH, EPDCCH, M-PDCCH, a DCI, or a DCI format, that may include or carry a (or at least one) RAR or may indicate or be associated with a PDSCH that may carry a (or at least one) RAR.

[0113] At least one RAR transport block size (TBS) may be configured or fixed and may correspond to a number (*e.g.*, a certain number) of RA responses (*e.g.*, to a number or certain number of preambles). Padding may be used, for example, when the number of responses (*e.g.*, actual responses) may be less than the number (*e.g.*, the certain number) of RA responses or preambles to which the RAR TBS that may be configured or fixed may apply. TBS configuration may be by signaling, such as broadcast signaling, which may be from the eNB. There may be a separate RAR TBS value (*e.g.*, fixed or configured) for one or more CE levels. There may be at least one RAR TBS value for RAR that may be intended for (*e.g.*, at least for) a coverage limited and/or bandwidth limited WTRU. A WTRU, such as a WTRU that may be coverage limited and/or bandwidth limited, may receive or may expect to receive an RAR with a fixed or

configured TBS. An eNB may transmit an RAR that may be intended for (*e.g.*, at least for) a WTRU that may be coverage limited and/or bandwidth limited with a fixed or configured TBS.

[0114] There may be N CE levels and/or there may be PRACH resources (*e.g.*, separate PRACH resources) for one or more (*e.g.*, each) of the N CE levels. A WTRU that may transmit PRACH using the resources that may correspond to a certain CE level may receive or may expect to receive an RAR in time and/or frequency resources (*e.g.*, subframes and/or RBs) that may correspond to the CE level of the WTRU and/or the PRACH resources used by the WTRU. An eNB may transmit an RAR in time and/or frequency resources (*e.g.*, subframes and/or RBs) that may correspond to the resources in which the eNB may have received the PRACH that may correspond to a certain CE level. RAR for different CE levels may be in different frequency resources that may be in the same or different subframes.

[0115] A set of RAR transport block (TB) sizes (*e.g.*, possible or candidate TB sizes) may be fixed or configured (*e.g.*, by the eNB) and/or determined (*e.g.*, by the WTRU). A WTRU may try one or more of the TB sizes in the set to try to successfully receive the RAR, for example, when monitoring for and/or attempting to receive RAR.

[0116] A set of RAR candidates may be fixed or configured (*e.g.*, by the eNB) and/or determined (*e.g.*, by the WTRU). The RAR candidates may differ in one or more characteristics, which may include time (*e.g.*, subframe), frequency (*e.g.*, RBs), TBS, and/or one or more transmission parameters, such as MCS. A WTRU may try one or more of the RAR candidates to try to successfully receive the RAR, for example, when monitoring for and/or attempting to receive RAR.

[0117] An eNB, for example, one that may be unsure if a WTRU from which it may have received a PRACH transmission may be a limited bandwidth WTRU, may transmit RAR in a way in which a limited bandwidth WTRU may receive it and in a way in which a full bandwidth WTRU may receive it.

[0118] The eNB may transmit a PDSCH (which may be repeated in the case of coverage enhancement) that may carry a RAR that may be intended for (*e.g.*, at least) the WTRU. The eNB may transmit the DCI format for the PDSCH that may carry RAR in both PDCCH and EPDCCH. The PDCCH may indicate the location and/or parameters of the PDSCH to be the same as the location and/or parameters indicated by the EPDCCH. The PDSCH may be located in a bandwidth that may be received by a limited bandwidth WTRU. If a DCI format may not be needed for the RAR PDSCH (*e.g.*, for a coverage limited and/or limited bandwidth WTRU), then the EPDCCH may not be transmitted. The PDCCH may indicate the location and/or parameters

of the PDSCH to be the same as the configured or otherwise known or determined location and/or parameters. The PDSCH may provide a grant for UL resources in a bandwidth that a limited bandwidth WTRU may support.

[0119] The eNB may transmit two PDSCH (one or more of which may be repeated in the case of coverage enhancement), *e.g.*, in the same subframe. A PDSCH (*e.g.*, each of the two and/or the repetitions of the two) may carry a RAR that may be intended for (*e.g.*, at least for) the WTRU.

[0120] The eNB may transmit a DCI format for a first PDSCH in a PDCCH. The eNB may transmit a DCI format for a second PDSCH in an EPDCCH. The transmissions may be in the same subframe. The location of the first PDSCH may not be limited to a bandwidth that may be supported by a limited bandwidth WTRU. The location of the second PDSCH may be in (or limited to) a bandwidth that may be supported by a limited bandwidth WTRU. The eNB may not transmit a DCI format for the second PDSCH. The location and/or parameters for the second PDSCH may be configured (*e.g.*, by signaling from the eNB such as broadcast signaling and/or system information) and/or known or determined. One or more (*e.g.*, each) PDSCH may carry an RAR that may be intended for (*e.g.*, at least for) the WTRU from which it may have received the PRACH transmission.

[0121] The eNB may provide two UL grants (*e.g.*, each for a PUSCH transmission) that may be for WTRU transmission of a PUSCH which may carry RA procedure message 3. The two UL grants may be for resources in the same subframe. At least one UL grant may be for resources that a limited bandwidth WTRU may support (*e.g.*, be able to transmit in). The first and/or second (*e.g.*, at least the second) PDSCH may include an UL grant for resources which a limited bandwidth WTRU may support.

[0122] A full bandwidth WTRU (*e.g.*, that may have transmitted the PRACH that may have resulted in the eNB sending the RAR) may receive and/or decode the DCI format in the PDCCH and may receive the first PDSCH (*e.g.*, based on a DL grant in the PDCCH). The full bandwidth WTRU may transmit a PUSCH that may carry message 3 in UL resources granted by the first PDSCH. A limited bandwidth WTRU (*e.g.*, that may have transmitted the PRACH that may have resulted in the eNB sending the RAR) may receive and/or decode the DCI format in the EPDCCH and/or may receive the second PDSCH (*e.g.*, based on a DL grant in the EPDCCH or based on a known or determined location and/or known or determined parameters). The limited bandwidth WTRU may transmit message 3 in a PUSCH in UL resources granted by the second PDSCH.

[0123] The eNB may determine whether the WTRU may be a limited bandwidth WTRU based on the PUSCH in which the WTRU may transmit and/or the eNB may receive message 3 (*e.g.*, from the WTRU that may have been granted the UL resources).

[0124] One or more of a PRACH, PDCCH, EPDCCH, PDSCH, and/or PUSCH may be repeated, *e.g.*, in multiple subframes, for example, when coverage enhancement techniques may be used. Transmitting and/or receiving one of these channels may be replaced by transmitting or receiving one or more repetitions of the channel (*e.g.*, where the first instance of the channel may be considered a repetition of the channel) and still be consistent with this disclosure. For a WTRU or eNB to successfully receive a channel, one or more of the repetitions, which may include a first instance and one or more subsequent repetitions, may be combined.

[0125] An RAR may include an indication of a subframe (*e.g.*, a starting or ending subframe) and/or frequency (*e.g.*, RB or starting RB) of the PRACH transmission to which the RAR may correspond.

[0126] A WTRU may inform an eNB whether or not it is a limited bandwidth WTRU via a message, which may be, for example, an RRC message, such as an RRC connection request message or a WTRU capabilities message.

[0127] Non-receipt of an indication that a WTRU is a limited bandwidth WTRU in a message that may include such an indication (such as a RRC connection request or capabilities message) may be considered the same as receipt of an indication that the WTRU is not a reduced bandwidth WTRU. For example, if the eNB receives a message that may include a reduced bandwidth indication from a WTRU and a limited bandwidth indication is not included, the eNB may consider the WTRU to be a full bandwidth WTRU (*e.g.*, not a limited bandwidth WTRU).

[0128] The eNB may determine the bandwidth capability (*e.g.*, limited or non-limited) of a WTRU based on whether or not the eNB receives a limited bandwidth indication.

[0129] A RA response and/or RA-RNTI may be provided and/or used. After a WTRU may transmit a RA preamble, *e.g.*, regardless of a possible occurrence of a measurement gap, the WTRU may monitor a PDCCH, *e.g.*, of a serving cell such as the PCell, for random access response(s) (RARs) that may be identified by an RA-RNTI and that may arrive in an RA response window. The RA response window may start at a certain subframe, such as the subframe that may include the end of the preamble transmission plus a number of additional subframes, *e.g.*, three additional subframes. The RA response window may have a length in subframes, such as ra-ResponseWindowSize subframes, which may be configured or provided (*e.g.*, by the eNB) via signaling such as broadcast (*e.g.*, system information) signaling.

[0130] The RA-RNTI associated with the PRACH in which a preamble may be transmitted, may be computed, for example, as:

$$RA\text{-}RNTI = 1 + t_id + 10 * f_id$$

where t_id may be the index of the first subframe of the PRACH (*e.g.*, $0 \leq t_id < 10$), and/or f_id may be the index of the PRACH within that subframe, *e.g.*, in ascending order of frequency domain (*e.g.*, $0 \leq f_id < 6$). The WTRU may stop monitoring for RARs after successful reception of a RAR that may include a RA preamble identifier that may match the transmitted RA preamble.

[0131] For a coverage limited WTRU, preambles and/or RAR may be repeated. RA-RNTI for coverage limited WTRUs may collide with those for non-coverage limited WTRUs, and the RA response window definition may be insufficient for coverage limited WTRUs.

[0132] An eNB may transmit RAR in a coverage enhanced manner, for example when transmitting RAR to a UE which may be coverage limited. A WTRU, such as a coverage limited WTRU, may receive RAR in a coverage enhanced manner. Transmission and/or reception in a coverage enhanced manner may include at least one or more of the following, and/or a WTRU and/or eNB may perform transmission and/or reception in a coverage enhanced manner in accordance with at least one or more of the following.

[0133] Transmission and/or reception in a coverage enhanced manner may include transmission of repetitions of RAR, which may include repetitions of a PDSCH that may carry RAR and/or repetitions of the associated PDCCH and/or EPDCCH.

[0134] Transmission and/or reception in a coverage enhanced manner may include reception and/or combining of repetitions of RAR, which may include reception and/or combining repetitions of a PDSCH that may carry RAR and/or reception and/or combining repetitions of the associated PDCCH and/or EPDCCH.

[0135] Transmission and/or reception in a coverage enhanced manner may include use of a modified and/or extended RA response window (*e.g.*, with respect to the RA response window that may be used by or for a non-coverage limited WTRU or WTRUs that may not be in coverage enhanced (CE) mode).

[0136] Transmission and/or reception in a coverage enhanced manner may include transmission of an RNTI for the RAR PDCCH or EPDCCH, *e.g.*, CE-RA-RNTI, which may be specific to coverage limited WTRUs, for example, of a certain coverage enhancement level.

[0137] Transmission and/or reception in a coverage enhanced manner may include monitoring and/or reception of an RNTI for the RAR PDCCH or EPDCCH, *e.g.*, CE-RA-RNTI,

which may be specific to coverage limited WTRUs, for example, of a certain coverage enhancement level.

[0138] RA-RNTI or a new RNTI may be used for PDCCH and/or EPDCCH associated with PDSCH that may carry RAR, for example, for RAR intended for (*e.g.*, at least for) a WTRU that may be coverage limited and/or bandwidth limited.

[0139] PDCCH and/or EPDCCH associated with PDSCH that may carry RAR may be located in a common search space (*e.g.*, PDCCH common search space and/or EPDCCH common search space), for example, for RAR intended for (*e.g.*, at least for) a WTRU that may be coverage limited and/or bandwidth limited.

[0140] The eNB may transmit RAR in a coverage enhanced manner, for example, when responding to receipt of a PRACH preamble that may have been transmitted by a coverage limited WTRU and/or that may be considered or determined by the eNB to have been transmitted by a coverage limited WTRU.

[0141] The RA response window may start at a subframe, such as the subframe that may be or include the end of the preamble transmission (which may be the subframe of the last repetition of the preamble) plus a number of subframes (*e.g.*, three subframes). The start and/or length of the RA response window may be a function of at least one or more of the number of repetitions (or CE level) of the preamble (or PRACH transmission); the number of repetitions or expected repetitions of the RAR; the number of repetitions of the PDCCH and/or EPDCCH that may carry the control information for the RAR and/or that may use RA-RNTI (or CE-RA-RANTI); the gap (*e.g.*, in subframes) that may be between the last RA-RNTI (or CE-RA-RANTI) PDCCH (or EPDCCH) for the RAR and the first RAR; the ra-ResponseWindowSize; a value, *e.g.*, ce-ra-ResponseWindowSize, which may be a fixed value or a configured value (*e.g.*, by eNB signaling such as broadcast and/or system information signaling); a window offset value, which may be a fixed value or a configured value (*e.g.*, by eNB signaling such as broadcast and/or system information signaling); and/or the subframe allocation for the repetitions of the RAR.

[0142] The repetitions and/or expected repetitions of the preamble and/or associated PDCCH (or EPDCCH) and/or RAR may be based on the CE mode and/or level of the WTRU which may be indicated by the WTRU and/or understood by the eNB from the PRACH resource used by the WTRU for the random access. The gap may be a fixed value or a configured value (*e.g.*, by eNB signaling such as broadcast and/or system information signaling).

[0143] For example, if the WTRU may transmit the preamble Nrep times, the length of the window may be Nrep (or a multiple or Nrep such as 2) plus a fixed or configured (*e.g.*, by eNB signaling such as broadcast and/or system information signaling) value such as ra-

ResponseWindowSize or a value, *e.g.*, ce-ra-ResponseWindowSize, subframes. An offset may be added. For example, a CE response window size may be 2 x Nrep + ra-ResponseWindowSize + window offset.

[0144] If the number of times that the RAR may be (or may be expected to be) transmitted is Mrep, the length of the window may be Mrep (or a multiple of Mrep such as 2) plus a fixed or configured value such as ra-ResponseWindowSize or a value, *e.g.*, ce-ra-ResponseWindowSize, subframes. An offset may be added. For example, a CE response window size may be 2 x Mrep + ra-ResponseWindowSize + window offset. The window offset may be a gap of time in subframes between the last of the repetitions of the control channel that may indicate the grant for the RAR PDSCH and the first repetition (*e.g.*, first transmission) of the RAR PDSCH. If the number of repetitions of the control channel may be Crep and the number of repetitions of the RAR may be Rrep, the response window size may be a function of both and may be a function of the size of the gap between them, if any. For example, a CE response window size may be Crep + Rrep + ra-ResponseWindowSize + window offset. ra-ResponseWindowSize may be replaced by ce-ra-ResponseWindowSize or another parameter or value. The window offset may be 0 or a positive integer.

[0145] A subframe allocation for the repetitions of the RAR may be provided or configured by the eNB, for example, by signaling such as broadcast signaling. The subframe allocation may indicate in which subframes an RAR or a certain RAR may be transmitted and/or expected. For example, an RAR that may correspond to a certain CE mode, CE level, BW limitation, or PRACH resource may be transmitted or may only be transmitted in certain subframes. The subframes (*e.g.*, the certain subframes) may be indicated by at least one or more of a periodicity, an indication of the SFNs to which the periodicity may correspond (*e.g.*, x may be designated and periodicity may correspond to SFN mod x=0), and/or an offset (*e.g.*, from the start of the period). The response window start and/or length may be a function of the subframe allocation. For example, if the subframe allocation may have a periodicity of 4 subframes, the response window may be on the order of 4 times longer than if it may have a periodicity of 1 subframe.

[0146] The response window size, for example for TDD, may be a function of the number of DL (or non-UL) subframes in each frame, which may be based on the TDD UL/DL configuration that may be broadcast in a system information block (SIB, *e.g.*, SIB1) of the cell. When counting or considering subframes for RAR, for example for TDD, subframes may (or may only) refer to subframes in which RAR may be transmitted (*e.g.*, DL and/or non-UL subframes).

[0147] If some subframes may not include RAR (*e.g.*, UL subframes, some special subframes, and/or subframes that may include PBCH), then when counting or considering subframes for the RAR window, those subframes may be excluded from the count or consideration and the window may be longer in time than the count. For example, if the RAR response window may be 100 subframes, and 2 out of each 10 subframes in a frame may be excluded, the response window may use a span of 100/0.8 = 125 actual subframes for 100 counted subframes.

[0148] The length of the window may be or may be based on a new configured (*e.g.*, by eNB signaling such as broadcast and/or system information signaling) value, *e.g.*, ce-ra-ResponseWindowSize subframes, which may be a function of the CE level and which may take into account the repetitions of the RAR for the CE level.

[0149] The WTRU may monitor a control channel (*e.g.*, PDCCH and/or EPDCCH) for RA-RNTI and/or CE-RA-RNTI, for example, following transmission of the preamble repetitions that may be for the (*e.g.*, the current) coverage enhancement level of the WTRU. The WTRU may receive PDSCH carrying RAR. The WTRU may perform the monitoring in the response window. The WTRU may combine Crep repetitions (*e.g.*, a moving window of Crep repetitions) of the control channel until it may successfully receive the control channel. The WTRU may combine Rrep or up to Rrep (*e.g.*, a moving window of Rrep or up to Rrep repetitions of the RAR), for example, until it may successfully receive the RAR. A WTRU may or may only monitor a control channel for RA-RNTI and/or CE-RA-RNTI in subframes that may correspond to a subframe allocation that may correspond to a characteristic of the WTRU and/or the PRACH resource that the WTRU may have used for transmission. A WTRU characteristic may include one or more of CE mode, CE level, and/or bandwidth limitation.

[0150] The WTRU may monitor for (*e.g.*, receive or attempt to receive) PDSCH that may carry RAR in a fixed, known, and/or determined location, for example, following transmission of the preamble repetitions that may be for the current coverage enhancement level of the WTRU. The WTRU may perform the monitoring in the response window. The WTRU may combine Rrep or up to Rrep repetitions (*e.g.*, a moving window of Rrep or up to Rrep repetitions of the RAR), for example, until the WTRU may successfully receive an RAR that may include indication of the preamble that the WTRU may have transmitted.

[0151] A WTRU may or may only monitor the PDSCH that may carry RAR in subframes that may correspond to a subframe allocation that may correspond to a characteristic of the WTRU and/or the PRACH resource that the WTRU may have used for transmission.

[0152] A WTRU that may be both coverage limited and bandwidth limited may act at least in accordance with one or more examples disclosed herein for a coverage limited WTRU. For example, a WTRU, such as one that may be both coverage limited and bandwidth limited, may monitor a control channel for CE-RA-RNTI, transmit repeated preambles, combine repetitions of a control channel and/or PDSCH, transmit repeated PUSCH and/or PUCCH, and/or the like.

[0153] The RA-RNTI that may be used for RAR, *e.g.*, CE-RA-RNTI, which may be intended for (*e.g.*, at least for) a coverage limited WTRU, may be determined the same as for legacy WTRUs or may be different or offset from that calculation.

[0154] CE-RA-RNTI may be the same as or different from RA-RNTI. There may be a different CE-RA-RNTI or set of CE-RA-RNTIs for one or more CE levels (*e.g.*, each CE level) that may be supported by an eNB. A CE-RA-RNTI that may be intended (*e.g.*, at least intended) for or monitored for or expected by a certain WTRU may be a function of, for example, one or more of a CE mode (*e.g.*, the CE mode of the WTRU); a CE level (*e.g.*, the CE level of the WTRU); the first or last subframe (*e.g.*, the index of that subframe within a frame) of the preamble transmission (*e.g.*, of the WTRU); the SFN of the frame of the first or last subframe of the preamble transmission (*e.g.*, of the WTRU); the number of repetitions of the preamble (*e.g.*, by the WTRU or that may correspond to the CE mode or CE level of the WTRU); the frequency resource or the index of the frequency resource (*e.g.*, of the set of frequency resources that may be used by certain WTRUs, such as coverage limited WTRUs) of the PRACH or preamble transmission (*e.g.*, of the WTRU); and/or the set of RA-RNTIs.

[0155] For example, the first CE-RA-RNTI may be the first RNTI available after the last RA-RNTI. The first CE-RA-RNTI, *e.g.*, CE-RA-RNTI1, may be (11+10*f_id_max), where f_id_max may be the highest index PRACH in a subframe, *e.g.*, for legacy WTRUs. For example, for FDD, there may be one (*e.g.*, one legacy) PRACH in a subframe, so f_id_max may be 0. For TDD there may be up to six (*e.g.*, six legacy) PRACH configured by the eNB (*e.g.*, with indices 0-5), so f_id_max may be the number of PRACH configured minus 1.

[0156] A CE-RA-RNTI may be a function of the first CE-RA-RNTI, CE-RA-RNTI1, and the first subframe of the preamble transmission or the first PRACH transmission, *e.g.*, t_id where t_id may be an integer from 0 through 9. For example, CE-RA-RNTI may be CE-RA-RNTI1 + t_id.

[0157] CE-RA-RNTI may be CElevel x CE-RA-RNTI1 + t_id, where CElevel may be a value that may correspond to the coverage enhancement level (*e.g.*, a value of 0, 1, or 2 if there may be three coverage enhancement levels) of the WTRU for which the RAR may be intended. No coverage enhancement may or may not be considered a coverage enhancement level.

[0158] CE-RA-RNTI may be CElevel x (1 + t_id+10*f_id).

[0159] A DCI format may not be used for RAR. The PDSCH that may carry the RAR may indicate to the WTRU (*e.g.*, in the contents and/or one or more headers of the PDSCH) whether or not the RAR may include a response that may be intended (*e.g.*, at least intended) for the WTRU, for example, without the need for the WTRU to look for the preamble that it transmitted in the RAR.

[0160] The CRC of the PDSCH that may carry RAR may be scrambled with an RA-RNTI or CE-RA-RNTI or other indication that may correspond to the PRACH that may have been transmitted by a WTRU. The WTRU may discard PDSCH that may carry RAR if the RA-RNTI or CE-RA-RNTI or other indication with which its CRC may be scrambled may not match the one that may correspond to the PRACH transmission of the WTRU. The indication may be a function of one or more of the items described herein of which a CE-RA-RNTI may be a function.

[0161] An RAR may include an indication, such as an RA-RNTI or CE-RA-RNTI, that may assist the WTRU in determining if the RAR may include a response that may be intended for (*e.g.*, at least intended for) it. For example, the indication may be included in a fixed location in the RAR, such as in the MAC header or at the beginning of the RAR. The indication may be a function of one or more of the items described herein of which a CE-RA-RNTI may be a function.

[0162] The WTRU may use the indication to determine if an RAR may be intended (*e.g.*, at least intended) for it. If the WTRU may determine that the RAR may be intended (*e.g.*, at least intended) for it, the WTRU may look for an indication of the preamble that it may have transmitted in the RAR to find the response that may be intended for (*e.g.*, at least intended for) it. If the WTRU may determine that the RAR may not be intended for (*e.g.*, at least intended for) it, the WTRU may discard the RAR and/or may continue to look for an RAR that may include a response that may be intended for (*e.g.*, at least intended for) it.

[0163] A WTRU may monitor for PDSCH that may carry RAR that may be intended for (*e.g.*, at least intended for) the WTRU in a location and/or with one or more parameters that may be known or determined by the WTRU, for example, in accordance with one or more examples disclosed herein. If the WTRU may successfully receive and/or decode the PDSCH, the WTRU may determine whether (or that) the PDSCH may include an RAR and/or whether (or that) the PDSCH may include an RAR that may be intended for (*e.g.*, at least intended for) the WTRU and/or that may include a response (*e.g.*, at least a response) for the WTRU. The WTRU may make the determination based on at least one or more of: whether the RAR may include the

preamble or an indication of the preamble that the WTRU may have transmitted; whether the RAR may include a certain RA-RNTI or CE-RNTI or other indication that may indicate that the RAR may be intended for (or at least intended for) the WTRU. The WTRU may determine that the RAR may be intended for (or at least intended for) the WTRU if the RAR may include the preamble or an indication of the preamble that the WTRU may have transmitted, and/or if the RAR may include a certain RA-RNTI or CE-RNTI or other indication that may indicate that the RAR may be intended for (or at least intended for) the WTRU.

[0164] PRACH subframes may be provided and/or used. For coverage limited WTRUs, the WTRU may repeat the transmission of a preamble a number of times, such as 50 or 100. Given a set of PRACH resources in a (*e.g.*, each) subframe and the large number of repetitions, some rules for preamble selection may result in more collisions with, for example, preamble transmissions of other WTRUs, such as coverage limited or non-coverage limited WTRUs.

[0165] PRACH resources may be defined, for example, in a set of frames such as every frame or every other frame. Certain subframes in those frames may be designated as subframes for PRACH resources. A WTRU may transmit a PRACH preamble and/or may choose a PRACH preamble for transmission in a PRACH subframe.

[0166] A WTRU (*e.g.*, a coverage limited WTRU) may choose a preamble and a PRACH frequency resource, *e.g.*, from a set or pool of such preambles and frequency resources, in one subframe and may repeat that transmission in multiple subframes. If another WTRU may choose a preamble and PRACH frequency resource (*e.g.*, from the same set or pool) in one or more of the subframes in which the first WTRU may transmit its chosen preamble and frequency resource, the opportunities for collision may be increased by the number of repetitions.

[0167] The frames and/or subframes in which PRACH preamble transmission may start (*e.g.*, in which a WTRU may begin PRACH preamble transmission or send a first PRACH preamble transmission before repetitions) may be a reduced set (*e.g.*, a subset) of frames and/or subframes from the full set of frames and/or subframes in which PRACH preambles may be transmitted.

[0168] One or more frames and/or subframes may be designated, allocated, configured (*e.g.*, by an eNB such as by signaling, which may be dedicated or broadcast and/or system information signaling), and/or used as PRACH starting frames and/or subframes.

[0169] One or more PRACH starting frames and/or subframes may be defined, specified, configured (*e.g.*, by an eNB, such as by signaling, such as broadcast signaling and/or system information).

[0170] A starting frame and/or subframe may be a function of a system frame number (SFN).

[0171] A starting frame and/or subframe may be a function of at least one of a PRACH configuration index that may determine or identify one or more of the SFNs (*e.g.*, even or any) in which there may be PRACH resources (*e.g.*, PRACH SFNs), the subframes in each of the PRACH SFNs in which there may be PRACH resources, and/or the preamble format that may be used for transmission.

[0172] A starting frame and/or subframe may be a function of a CE level. A starting frame and/or subframe may be a function of the number of repetitions of the preamble, which may be a function of the CE level. A starting frame and/or subframe may be a function of a configured value (*e.g.*, signaled from the eNB), such as an offset, *e.g.*, a frame offset or subframe offset.

[0173] A starting frame and/or subframe may be a function of a FDD or TDD mode of operation and/or a TDD UL/DL configuration.

[0174] A PRACH starting frame may be a frame (*e.g.*, the first frame) in which a WTRU, such as a coverage limited WTRU, may transmit a certain PRACH preamble (or the first part of a certain PRACH preamble). The certain preamble may be the first preamble of a set of repeated preambles that the WTRU may transmit.

[0175] A PRACH starting subframe may be a subframe (*e.g.*, the first subframe) in which a WTRU such as a coverage limited WTRU, may transmit a PRACH preamble (or the first part of a PRACH preamble). The preamble may be the first preamble of a set of repeated preambles that the WTRU may transmit. A PRACH starting subframe may be in a PRACH starting frame. A PRACH starting subframe may be (or may be identified by) an offset (*e.g.*, in subframes) from the start (*e.g.*, subframe 0) of a PRACH starting frame.

[0176] For example, if a WTRU may (or may only) transmit a preamble beginning in subframe X1 and repeat that preamble in (or beginning in) subframes X2, X3, X4, … Xn, then X1 may be the PRACH starting subframe.

[0177] A WTRU, such as a coverage limited WTRU, may or may only transmit a preamble beginning in a starting PRACH subframe. The WTRU may repeat the preamble N times in (or beginning in) each of a certain N subframes which may be one or more of the next N subframes; the next N subframes that may be available or usable for PRACH transmission (*e.g.*, by the WTRU); the next N PRACH subframes; a designated, allocated, or configured set of N (*e.g.*, next N) subframes or PRACH subframes that may be based on the PRACH starting frame and/or subframe; and/or the same subframe as the starting subframe in one or more (*e.g.*, each) of the next N frames that may include PRACH resources.

[0178] PRACH subframes for CE mode may be the same or different from PRACH subframes for non CE mode use.

[0179] A WTRU that may transmit a preamble beginning in a certain starting PRACH frame and/or subframe, may repeat the preamble N times in (or beginning in) each of a certain N subframes, which may be the next N subframes or PRACH subframes that may be allocated, designated, or configured for the repetitions of a preamble that may have first been transmitted in the certain PRACH starting frame and/or subframe.

[0180] A WTRU, such as a coverage limited WTRU, may or may only select a PRACH resource from available PRACH resources (*e.g.*, preamble and/or frequency) in or for transmission in a PRACH starting frame and/or subframe. A frequency resource may be comprised of one or more RBs or PRBs. The WTRU may use the same resource (*e.g.*, preamble and/or frequency) for one or more (*e.g.*, each) of its (*e.g.*, subsequent N) repetitions of the preamble transmission. A WTRU may not (or may not be able or allowed) to choose a (*e.g.*, a new or another) PRACH resource in a subframe that may not be (or may not be considered to be) a PRACH starting frame and/or subframe. PRACH repetitions (*e.g.*, one or more repetitions) may have or may use different resources (*e.g.*, RBs or PRBs), for example, for frequency diversity. The resources that may be used for the repetitions may be identified (*e.g.*, explicitly), for example, by signaling or may be based on a pattern, such as a frequency hopping pattern.

[0181] A repetition rate of PRACH starting frames, *e,g.*, PFrep may be defined, allocated, or configured (*e.g.*, by an eNB such as by signaling such as dedicated or broadcast signaling and/or system information). A PFrep may be defined, allocated, or configured for CE mode and/or for one or more (*e.g.*, each) CE level, *e.g.*, PFrep(CE level). The PFrep(CE level) values may be the same or different. A PFrep(CE level) value may be a function of the CE level and/or the number repetitions (*e.g.*, preamble repetitions) that may be associated with the CE level.

[0182] PRACH starting frames, may satisfy the equation SFN mod (PFrep) = 0 or SFN mod (PFrep) = frame offset. PRACH starting frames for a CE level may satisfy the equation: SFN mod [PFrep (CE level)] = 0 or SFN mod [PFrep (CE level)] = frame offset.

[0183] PFrep may be a function of the number of repetitions of the PRACH that may be transmitted, for example, for a CE level. PFrep may be the next highest power of 2 from the number of repetitions of the PRACH that may be transmitted, for example for a CE level. For example, for a CE level that may use 50 repetitions, PFrep may be 64. PRrep may be a function of the number of PRACH resources (or available PRACH resources) in a subframe and/or which frames (*e.g.*, any or even) may include PRACH resources. If the number of repetitions may be a power of 2, PFrep may be the number of repetitions of the PRACH which may be transmitted.

[0184] Given a starting frame, starting subframes may be subframes (*e.g.*, certain subframes) within the starting frame and/or subframes (*e.g.*, certain subframes) offset from the start (*e.g.*,

subframe 0) of the starting frame. There may be multiple starting subframes associated with a starting frame. If there may be more than one starting subframe in or associated with a starting frame, a WTRU may choose one that may be designated or configured by the eNB (*e.g.*, for contention free RA) or may choose one randomly. If there may be multiple starting subframes to choose from in or associated with a starting frame, the PRACH resources in the multiple starting subframes may differ in some way such as by preamble(s) and/or frequency resources.

[0185] In an example, starting subframes may repeat every 64 frames and may be offset by 4 frames, *e.g.*, they may satisfy SFN mode 64 = 4. Available PRACH subframes in each frame may be subframes 1 and 3 (*e.g.*, according to a PRACH configuration). In frames that may satisfy SFN mode 64 = 4, a WTRU may select subframe 1 or 3 as a starting subframe, *e.g.*, randomly.

[0186] For a CE level with R repetitions (*e.g.*, preamble repetitions), PRACH starting subframes may be at least R subframes apart.

[0187] PRACH frames may be frames that may include PRACH resources. In an example, the number of repetitions (*e.g.*, preamble repetitions), for example for a CE level, may be R, PRACH frames may occur every F frames, and P subframes may be available per PRACH frame that may include PRACH. PRACH starting subframes, *e.g.*, for a CE level, may be based on or a function of at least one of R, F, and P. PRACH starting subframes may be at least CEIL [(R x F)/P] subframes apart. For example, for R = 100, P = 3, and F = 2, PRACH starting subframes may be at least CEIL [(R x F)/P] = CEIL [(100 x 2)/3] = 67 subframes apart. PRACH starting subframes may be apart by a function of CEIL [(R x F)/P]. For example, PRACH starting subframes may be apart by the next multiple of 10 subframes (*e.g.*, apart by the closest multiple of 10 greater than or equal to CEIL [(R x F)/P]) (*e.g.*, 70 subframes apart for R=100, P=3, and F=2). In another example, PRACH subframes may be apart by the next power of 2 subframes (e.g., apart by the closest power of 2 greater than or equal to CEIL [(R x F)/P]) (*e.g.*, 128 subframes apart for R=100, P=3, and F=2). In another example, PRACH subframes may be apart by the next multiple of a certain number of frames (e.g., apart by the closest multiple of the certain number greater than or equal to CEIL [(R x F)/P]). For example, the certain number of frames may be 4 frames or 40 ms and for R=100, P=3, and F=2, CEIL [(R x F)/P] = 67 and the PRACH subframes may be the next multiple of 40ms greater than 67 apart (*e.g.*, 80 ms apart).

[0188] A PRACH configuration index may indicate which frames and/or subframes may and/or may not include PRACH resources. One or more PRACH configuration indices may be provided for CE mode, *e.g.*, one may be provided for each CE level or one may be used for all

CE levels. The legacy PRACH configuration index may be used for CE mode or may be the default if a CE specific value may not be provided.

[0189] Certain preambles or sets of preambles may (*e.g.*, may only) be configured and/or used, *e.g.*, for PRACH transmission, in certain subframes or sets of subframes. Certain frequency resources or sets of frequency resources may (*e.g.*, may only) be configured and/or used, *e.g.*, for PRACH transmission, in certain subframes or sets of subframes. Allocations and/or usage such as these may enable or facilitate multiple starting subframes in the same frame.

[0190] RAR may be provided in reduced bandwidth, *e.g.*, for at least bandwidth limited WTRUs. For RAR that may be intended (or at least intended) for bandwidth limited WTRUs, if the PDSCH that may carry the RAR may be located in RBs, such as the center 6 RBs of the band, special handling may be used in some subframes, *e.g.*, subframes that may carry synchronization channels (*e.g.*, PSS and/or SSS) and/or a physical broadcast channel (PBCH).

[0191] In subframes that may carry PSS and/or SSS, transmission (*e.g.*, by the eNB) of a channel (*e.g.*, EPDCCH and/or PDSCH, for example, a PDSCH that may carry an RAR) that may be located in RBs that may include PSS and/or SSS, may not use the resource elements (REs) that may include the PSS and/or SSS signals. Not using certain REs may involve omitting transmitting in those REs. Not using certain REs may involve rate matching around those REs.

[0192] If the transmission of a channel (*e.g.*, a PDSCH that may carry RAR) may rate match around certain REs, such as REs that may include PSS and/or SSS, a WTRU that may receive or attempt to receive that channel may account for the rate matching in its reception and/or decoding of the channel.

[0193] Subframes that may carry PBCH may not be used for transmission and/or reception of PDSCH that may carry RAR for certain WTRUs, such as limited bandwidth WTRUs and/or coverage limited WTRUs. An eNB may not transmit RAR (and/or a repeated RAR) intended for a WTRU (*e.g.*, for a certain WTRU such as one that may be a limited bandwidth WTRU and/or a coverage limited WTRU) in a subframe that may carry PBCH. A WTRU (*e.g.*, one that may be bandwidth limited and/or coverage limited) may not monitor a subframe that may carry PBCH for EPDCCH. The RAR window size may exclude PBCH subframes from counting or consideration. A PBCH subframe may be a subframe that may not be used for RAR for at least some WTRUs, such as WTRUs that may be bandwidth limited and/or coverage limited.

[0194] An RAR message size may be reduced and/or limited in size (*e.g.*, compact RAR), for example, for RAR that may be intended for certain WTRUs such as bandwidth limited WTRUs and/or coverage limited WTRUs.

[0195] The size may be reduced by reducing or eliminating elements in the RAR that may relate to the UL grant for message 3 of the RA procedure.

[0196] A limited bandwidth WTRU and/or a coverage limited WTRU may or may only be able to transmit in (or within) a bandwidth that may include a certain RF bandwidth and/or a certain number of RBs. RA message 3, which may be in response to an RAR and/or which may include an RRC connection request message, may be or may need to be allocated resources and/or transmitted in (or within) that bandwidth (BW).

[0197] Since, for example, the possible locations for the transmission of message 3 may be limited (*e.g.*, to 6 RBs), one or more UL grant parameters may be reduced (*e.g.*, to fewer bits) or may be eliminated.

[0198] In an example, one or more UL resources may be predefined and/or configured. One or more of these UL resources may be dynamically selected (*e.g.*, by an index), *e.g.*, by the RAR, for use for UL transmission (*e.g.*, for message 3). This may enable reduction in the size of the UL grant. The WTRU may use this selected resource for UL transmission, *e.g.*, of message 3.

[0199] A WTRU may set its UL power, for example, after a random access (RA) procedure. WTRU transmit power for an UL channel, *e.g.*, a PUSCH, may include an open loop component and/or a closed loop component. The WTRU transmit power for the UL channel may be limited (*e.g.*, by the WTRU) to the WTRU maximum power, *e.g.*, the WTRU configured maximum output power. The open loop component may be at least a function of one or more of: the transmission bandwidth or number of resource blocks to be transmitted, pathloss, and/or one or more configured values. The closed loop component may be a function of transmit power control commands that may be received by the WTRU, *e.g.*, from an eNB. WTRU transmit power for an UL channel, *e.g.*, a PUSCH, may be or may also be a function of the power ramping performed by the WTRU during a random access (RA) procedure, such as an initial RA procedure (e.g., for RRC connection establishment) and/or a contention based RA procedure.

[0200] An example setting for WTRU transmit power for a UL channel, such as a PUSCH transmission, may be as follows for subframe i and serving cell c:

$$P_{PUSCH,c}(i) = min\begin{cases} P_{CMAX,c}(i), \\ 10\log_{10}\left(M_{PUSCH,c}(i)\right) + P_{O_PUSCH,c}(j) + \alpha_c(j)\cdot PL_c + \Delta_{TF,c}(i) + f_c(i) \end{cases}$$

and the value may be in dBm.

[0201] $P_{CMAX,c}$ may be the WTRU configured maximum output power. $M_{PUSCH,c}$ may be the number of resource blocks granted or allowed for the transmission. $P_{O_PUSCH,c}$ may be a configured value or a sum of configured values. α may be a configured value. PL may be the pathloss. $\Delta_{TF,c}$ may be an adjustment factor that may relate to the use of MIMO or the use of one

or more antennas. f_c may be a correction value, *e.g.*, a sum of a starting correction value, $f_c(0)$ and one or more other correction values that may correspond to transmit power control (TPC) commands that the WTRU may receive or may have received, *e.g.*, from an eNB. The starting correction value may be a function of an RA procedure power ramping. Inclusion of the effects of power ramping in the correction value that accumulates TPC commands may be by way of illustration and not limitation. The impact of RA power ramping on the power setting may be separate from the TPC commands. Adjustment for TPC commands may be omitted from the power setting.

[0202] If a WTRU does not perform power ramping during the RA procedure, *e.g.*, if the WTRU may transmit at maximum power or may always transmit at maximum power, *e.g.*, $P_{CMAX,c}$ for the PRACH power, the value to use for $f_c(0)$ and/or the initial power for an UL channel, such as PUSCH, may be undefined. An UL transmission may be or may include one or more of a PUSCH, PUCCH, and SRS. PUSCH may be a non-limiting example of an UL channel or transmission. Another UL channel or transmission, such as PUCCH or SRS, may be used consistently with the subject matter disclosed herein.

[0203] A random access response (RAR) may include one or more parameters that the WTRU may use to determine the value of $f_c(0)$ and/or its UL power setting for one or more channels, *e.g.*, for PUSCH. A UL transmission, *e.g.*, the first UL transmission, that a WTRU may make, *e.g.*, on a PUSCH, following PRACH preamble transmission may be message 3 of the RA procedure, which may be or may include an RRC connection (*e.g.*, RRC connection establishment) request. An RAR, *e.g.*, the RAR in which the WTRU may receive the grant for resources for message 3, may include an indication of an initial power to use for the PUSCH transmission. The RAR may include one or more parameters from which the initial power to use for the PUSCH transmission may be determined. The RAR may include the starting correction value $f_c(0)$ for the PUSCH transmission. The RAR may include a coverage enhancement (CE) level for PUSCH and/or one or more other subsequent UL and/or DL transmissions for the WTRU. The RAR may include a number of repetitions or a value or index that corresponds to a number of repetitions to use for PUSCH and/or one or more other subsequent UL and/or DL transmissions for the WTRU. The RAR may include a power offset or delta, *e.g.*, to subtract from the maximum power to determine the PUSCH power.

[0204] A WTRU may determine its UL power and/or UL repetitions, *e.g.*, PUSCH power and/or PUSCH repetitions, according to one or more of the parameters or values included in the RAR and may transmit according to the determined power and/or repetitions.

[0205] For example, the WTRU may determine its initial and/or subsequent PUSCH power based on a starting correction value $f_c(0)$ or a power offset that may be included in the RAR and may transmit PUSCH using the determined power.

[0206] The WTRU may determine UL power, for example, according to:

$$P_{PUSCH,c(i)} = min\left[P_{CMAX,c}(i), openlooppower(i) + f_c(i)\right]$$

[0207] The WTRU may use a value of $f_c(0)$ that it may have received in the RAR. The open loop power may be a function of the CE level, which may correspond to the CE level of the RA procedure for which the WTRU successfully received an RAR or the CE level that the WTRU received in the RAR. The open loop power may be a function of the number of PRACH repetitions for which the WTRU successfully received an RAR or the number of repetitions that the WTRU received in the RAR. A closed loop component may not be present, *e.g.*, $f_c(i)$ may be 0 or nonexistent for $i > 0$ or $i >= 0$. The closed loop component, if present, may be a function of the CE level or repetitions that may be updated, *e.g.*, dynamically.

[0208] The WTRU may transmit or may always transmit PUSCH at maximum power, *e.g.*, $P_{CMAX,c}$ or $P_{CMAX,c(i)}$. The WTRU may use a number of repetitions or a CE level that may be provided in the RAR for transmission of a channel such as PUSCH, for example, to account or compensate for the use of maximum power when the repetitions are combined at the receiver. For example, the open loop and/or closed loop part of the power control calculation may be a function of the CE level or the number of repetitions for the transmission of the UL channel, which may be included or indicated in the RAR.

[0209] The WTRU may set its PUSCH power (*e.g.*, initial PUSCH power) according to an initial value included in the RAR. The WTRU may reduce its power from maximum by at least a delta or offset provided in the RAR. The WTRU may determine UL power according to, for example:

$$P_{PUSCH,c}(i) = \min[P_{CMAX,c}(i), PUSCH_{initial} + closedlooppower(i)]$$

or

$$P_{PUSCH,c}(i) = \min[P_{CMAX,c}(i), P_{CMAX,c}(i) - \Delta + closedlooppower(i)]$$

[0210] There may be no closed loop component, *e.g.*, closedlooppower(i) may be 0. The initial closed loop value may be zero or the delta may be included in the closed loop value. The closed loop component may be a function of TPC commands, *e.g.*, accumulated TPC commands. The closed loop component may be a function of CE level or repetitions that may be the CE level or repetitions used for the RA procedure (*e.g.*, the successful RA procedure) and/or the CE level

or repetitions included in the RAR. The closed loop component and/or the CE level or repetitions that may impact the closed loop component may be updated, *e.g.*, dynamically.

[0211] One or more values not indicated as a function of subframe or TTI, *e.g.*, i, may be a function of subframe or TTI and may be consistent with the subject matter disclosed herein. For example, $P_{CMAX,c}$ and $P_{CMAX,c}(i)$ may be used interchangeably.

[0212] One or more values indicated as a function of subframe or TTI, *e.g.*, i, may not be a function of subframe or TTI and may be consistent with the subject matter disclosed herein.

[0213] The initial PUSCH power setting may be $P_{CMAX,c}$. The WTRU may determine the initial closed loop value or adjustment value, *e.g.*, $f_c(0)$, to be the value that may make the PUSCH value equal to $P_{CMAX,c}$.

[0214] For example, $P_{PUSCH,c}(i)$ may be determined by:

$$P_{PUSCH,c}(i) = openlooppower(i) + f_C(i)$$

or

$$P_{PUSCH,c}(i) = \min[P_{CMAX,c}(i), openlooppower(i) + f_c(i)]$$

[0215] The WTRU may determine (*e.g.*, may first determine) the initial PUSCH power based on no power ramp-up, *e.g.*, $P_{PUSCH\text{-}noramp}$. $P_{PUSCH\text{-}noramp}$ may be the value of openlooppower(0). The value of openlooppower(0) may be or may be set to $P_{PUSCH\text{-}noramp}$.. The WTRU may determine $f_c(0)$ according to the following: $f_c(0) = \max(0, P_{CMAX,c} - P_{PUSCH-noramp})$.

[0216] With this starting value of f_c, the starting value of the PUSCH power may be $P_{CMAX,c}$. The value of f_c may be adjusted by TPC commands and/or adjustments to CE level or repetitions. The value of $f_c(0)$ may be adjusted or may also be adjusted by a parameter provided in the RAR, such as a TPC command indicated in the RAR, *e.g.*, delta_msg2. $P_{PUSCH\text{-}noramp}$ may include the effects of a TPC command indicated in the RAR.

[0217] $f_c(0)$ may be determined according to the following:

$$f_c(0) = delta\ P_{rampup,c} + delta_msg2, c$$

where delta_msg2,c may be a TPC command indicated in the RAR.

[0218] The value of delta $P_{rampup,c}$ may be determined according to:

$$\begin{aligned} delta\ P_{rampup,c} \\ &= \max[0, P_{CMAX,c} - (10 \\ &\cdot log_{10}(M_{PUSCH,c}(0) + P0_{PUSCH,c}(2) + delta_{msg2}, c + alpha, c(2) \cdot PL \\ &+ deltaTF, c(0) + CL)] \end{aligned}$$

where $M_{PUSCH,c}(0)$ may be the bandwidth of the PUSCH resource assignment expressed as a number of resource blocks valid for the subframe of the first PUSCH transmission in the serving cell c, and deltaTF,c(0) may be a power adjustment of first PUSCH transmission in the serving cell c. $P0_{PUSCH,c}(2)$ may equal the initial preamble power, *e.g.*, preambleInitialReceivedTargetPower, which may be configured by higher layers plus a message3 delta power value that may be configured by higher layers. CL may be an adjustment to compensate for the CE level or the number of repetitions for the PUSCH transmission, which may be included or indicated in the RAR. One or more of the elements of the above equation may be 0 or not included. The message3 delta power may be 0 or not exist.

[0219] The equation above may (*e.g.*, in effect) correspond to a delta $P_{rampup,c}$ value that may result in the initial power being maximum power. $f_c(0)$ and/or delta $P_{rampup,c}$ may be zero.

[0220] The WTRU may use the CE level and/or number of repetitions that it uses for the successful PRACH preamble transmission or transmissions, *e.g.*, the CE level and/or number of repetitions for which the WTRU successfully receives an RAR, as the CE level and/or number of repetitions for a PUSCH transmission, *e.g.*, the first PUSCH transmission, which may correspond to message 3 of the RA procedure.

[0221] A transmission power, such as an initial power, may be associated with a CE level or number of repetitions. This transmission power may be configured, for example, by signaling such as broadcast or higher layer signaling. The WTRU may set the PUSCH power (*e.g.*, the initial PUSCH power or message 3 PUSCH power) to this value and/or may set the PUSCH using or at this power. The power may be a minimum power for a CE level.

[0222] A CE level or number of repetitions may be updated. UL grants and/or TPC commands may include adjustments that may be applied to future UL transmissions and/or to future UL transmit power determinations. For example, an UL grant or TPC command may include a CE level or number of repetitions to use for an upcoming UL transmission. The WTRU may transmit, *e.g.*, may always transmit, the PUSCH at maximum power or may adjust the transmit power based on an open loop component and/or a closed loop component. The WTRU may transmit the PUSCH with a number of repetitions that may be provided with or separately from an UL grant or a TPC command. The WTRU may transmit the PUSCH with a number of repetitions that may correspond to a CE level that may be provided with or separately from an UL grant or a TPC command.

[0223] If the grant or TPC command corresponds to an UL transmission in subframe X or an UL transmission that may begin in subframe X, the WTRU may use the indicated CE level, repetitions, or power adjustment (*e.g.*, to increase or decrease the power) for the UL transmission

in subframe X or for the UL transmission that may begin in subframe X. The TPC command or UL grant may be repeated (*e.g.*, by the eNB) and/or received (*e.g.*, by the WTRU) in a set of subframes that may correspond to UL transmission by the WTRU in subframe X or to UL transmission that may begin in subframe X.

[0224] PUSCH power may be ramped. For example, the WTRU may ramp its PUSCH power if it has not received an ACK from the eNB for a number of PUSCH transmissions. This number may be configured, for example, by the eNB. The WTRU may increase its power by a certain delta value based on a number of unsuccessful transmissions, which may be determined based on the lack of receipt of ACK for the transmissions. The delta value may be configured, for example, by the eNB. The number of unsuccessful transmissions and/or the delta value may be a function of the CE level and/or the number of repetitions. The power may be increased for one or more retransmissions, *e.g.*, each of the retransmissions. The transmission power may not be increased above the maximum power. Increases to the power may be stopped when the maximum power is reached or when an increase would cause the power to exceed the maximum power.

[0225] One or more of the examples disclosed herein for an UL channel or transmission may be applicable to a downlink (DL) channel or transmission. For example, the examples disclosed herein in the context of UL grants may be applicable to DL grants, consistent with the subject matter disclosed herein. For example, a CE level or a number of repetitions to use for PDSCH reception or PUCCH transmission may be included in a DL grant.

[0226] Successful reception of an RAR may be or may include reception of an RAR that may be intended for the WTRU. Transmission of a PRACH or preamble may include transmission of repetitions of a PRACH or preamble. For purposes of illustration and description, PRACH and preamble may be used interchangeably.

[0227] A random access (RA) or RA procedure may be requested or initiated, for example, by a PDCCH order. For example, a WTRU may receive a request or indication, *e.g.*, from an eNB, to perform or initiate an RA or RA procedure. The request or indication may be or may be included in a PDCCH order that may be transmitted in a PDCCH region, for example, in a downlink control information (DCI). A WTRU, such as a low cost or reduced capability WTRU, may not be able to receive a PDCCH in a PDCCH region, *e.g.*, due to a limited capability (*e.g.*, reduced bandwidth and/or limited coverage). PDCCH order in a PDCCH region may not be supported for or by some WTRUs, such as low cost or reduced capability WTRUs or WTRUs that may not be able to receive a PDCCH in a PDCCH region.

[0228] PDCCH order is disclosed by way of example only and not limitation. Another request to perform or initiate an RA or RA procedure may be used and may still be consistent with this disclosure. For example, an RA request may be substituted for a PDCCH order and may still be consistent with this disclosure.

[0229] PDCCH order, M-PDCCH carrying PDCCH order, a DCI that may request or initiate contention-free (or contention-based) RA, a DCI carrying one or more PDCCH orders, and a DCI that may request or initiate RA may be used interchangeably herein.

[0230] CE level, number of repetitions, and repetition number may be substituted for each other and may still be consistent with this disclosure.

[0231] An RA procedure may be initiated on an individual basis or on a group basis. A DCI or PDCCH order or RA request that may indicate (or initiate) an RA, *e.g.*, a contention-free or contention-based RA, may be transmitted via an M-PDCCH. An M-PDCCH may be a downlink control channel that may be monitored and/or received by a WTRU, such as a low cost or reduced capability WTRU.

[0232] For purposes of description and explanation, RA may be replaced with RA procedure, and *vice versa*, and may still be consistent with the examples disclosed herein.

[0233] A DCI, such as a group DCI, may be used to initiate RA for one or more WTRUs. A DCI may include one or more PDCCH orders that may request or initiate an RA or RA procedure for one or more WTRUs. A PDCCH order may be associated with a WTRU. A PDCCH order may be associated with multiple WTRUs. If a PDCCH order requests or initiates RA, WTRUs associated with that PDCCH order (*e.g.*, WTRUs that receive that PDCCH order) may transmit a PRACH preamble, *e.g.*, a selected or assigned PRACH preamble. The assigned PRACH preamble may be configured, *e.g.*, by the eNB, such as by higher layer signaling. For example, a WTRU may be configured with a PRACH preamble for a contention-free RA via higher layer signaling. The PRACH preamble configured via higher layer signaling may be considered as a WTRU-specific PRACH preamble for contention-free RA. The assigned PRACH preamble may be indicated in or with the PDCCH order. A separate PRACH preamble may be indicated for a WTRU (*e.g.*, each WTRU) for which the PDCCH order is intended (or may be intended).

[0234] A PDCCH order may be used to initiate random access for multiple WTRUs, *e.g.*, individually. An eNB may indicate the random access initiation for a WTRU in a WTRU group that may monitor the same PDCCH order. For example, a bit field may include N bits that may be associated with N WTRUs, *e.g.*, in a group. A bit (*e.g.*, each bit) may indicate random access (e.g., a request to initiate random access) or not (*e.g.*, 0 for no initiation of RA, 1 for initiation of

RA). A WTRU (*e.g.*, each WTRU) may be indicated or configured with a bit location (*e.g.*, in the bit field) associated with or in the PDCCH order. A PRACH preamble for the PDCCH order may be configured via higher layer signaling for a WTRU (*e.g.*, each WTRU). A PRACH preamble index corresponding to each bit in the bit field for RA initiation may be transmitted in the PDCCH order.

[0235] Two or more PDCCH orders may be transmitted in a DCI. A (*e.g.*, each) PDCCH order may be associated with a WTRU.

[0236] A DCI or PDCCH may include information for initiating an RA procedure for one or more WTRUs. At least some of the information may be included separately for a WTRU (*e.g.*, each WTRU) for which the PDCCH order may be intended. At least some of the information may be common to one or more WTRUs (*e.g.*, all of the WTRUs) for which the PDCCH order may be intended.

[0237] A DCI or PDCCH order that may initiate an RA procedure may include a PRACH preamble index. A DCI or PDCCH order that may initiate an RA procedure may include a PRACH mask index and/or time resources for the PRACH transmission. A DCI or PDCCH order that may initiate an RA procedure may include a CE level and/or repetition number. A DCI or PDCCH order that may initiate an RA procedure may include a transmission (e.g., power) level and/or power level type (*e.g.*, maximum power or based on DL measurement). A DCI or PDCCH order that may initiate an RA procedure may include frequency resources (*e.g.*, a set of PRBs) for the PRACH transmission.. A DCI or PDCCH order that may initiate an RA procedure may include an on/off indicator (*e.g.*, on to initiate RA, or off for no initiation of RA)..

[0238] A DCI that may carry one or more PDCCH orders may be scrambled with an RNTI, *e.g.*, its CRC may be scrambled with an RNTI. A WTRU may be configured with and/or use one or more RNTIs, such as a WTRU-specific RNTI (*e.g.*, a C-RNTI). The WTRU may use the one or more RNTIs to determine whether a DCI is intended for it.

[0239] An RNTI may be used for the DCI carrying one or more PDCCH orders. The RNTI may be WTRU-specific. The RNTI may be a group RNTI or a common RNTI, such as one that may be used by multiple WTRUs. The RNTI may be referred to as a PDCCH order RNTI. The RNTI may or may not be specific to DCIs carrying one or more PDCCH orders.

[0240] For a WTRU, the PDCCH order RNTI may be the WTRU's C-RNTI. A PDCCH order may be transmitted in a WTRU-specific DCI, which may use C-RNTI.

[0241] The PDCCH order RNTI may be or may be determined as a function of at least one of a WTRU-ID (*e.g.*, C-RNTI), a CE level, and/or a PRACH preamble index. One or more of a C-RNTI, a CE level, and/or a PRACH preamble index may be configured via higher layers.

[0242] The PDCCH order RNTI may be or may be determined as a function of the PRACH preamble and/or resource that may be used for a contention-based RA procedure. For example, the PDCCH order RNTI may be a function of a recent (*e.g.*, the most recent) PRACH preamble and/or PRACH resource that the WTRU used (*e.g.*, successfully) for RRC connection establishment. The PDCCH order RNTI may be a function of a recent (*e.g.*, the most recent) PRACH preamble and/or PRACH resource that the WTRU used (*e.g.*, successfully) for a PDCCH-initiated RA procedure (*e.g.*, a contention-based RA procedure).

[0243] The PDCCH order RNTI may be or may be determined as a function of the time and/or frequency location of the RAR associated with a recent (*e.g.*, the most recent) PRACH preamble and/or PRACH resource that the WTRU used (*e.g.*, successfully) for a contention-based RA procedure (*e.g.*, for RRC connection establishment or PDCCH order initiated). The PDCCH order RNTI may be indicated via higher layers.

[0244] The time and/or frequency location in which a WTRU may monitor PDCCH order may be determined as a function of the PDCCH order RNTI.

[0245] An indication may be used to determine whether a DCI is intended to be used for the scheduling of unicast traffic (*e.g.*, PUSCH/PDSCH) or whether the DCI is intended to be used for a PDCCH order. The indication may be a bit field in the DCI. The indication may be based on the RNTI used for the DCI. A combination of two or more bit field conditions may be used as an indication. The search space of M-PDCCH may be used as an indication.

[0246] A WTRU may transmit PRACH in response to RA procedure initiation, for example, by PDCCH order.

[0247] A WTRU may monitor a search space such as M-PDCCH search space for DCI scrambled (*e.g.*, for DCI with CRC scrambled) with PDCCH order RNTI. A WTRU may receive and/or successfully decode DCI scrambled with PDCCH order RNTI.

[0248] A DCI scrambled with an RNTI may be the same as or may be used to represent a DCI with a CRC scrambled with an RNTI.

[0249] Upon receipt or in response to receipt of the DCI, the WTRU may initiate a RA or RA procedure.

[0250] The WTRU may transmit a PRACH based on information included in the PDCCH order carried by the DCI and/or configured information.

[0251] The WTRU may determine, for example from this information, one or more of (i) the PRACH preamble, (ii) the CE level and/or number of repetitions to use for the preamble transmission and/or the RA procedure, and/or (iii) the time and/or frequency resources for the preamble transmission.

[0252] The WTRU may transmit the determined preamble in the determined time and/or frequency resources with the determined CE level or number of repetitions. For example, the WTRU may transmit the PRACH (or preamble) with or using the CE level or number of repetitions indicated in or by the PDCCH order. The WTRU may transmit the PRACH (or preamble) with or using the CE level or number of repetitions configured via higher layer signaling, for example for contention-free or PDCCH order initiated RA.

[0253] The WTRU may transmit the PRACH (or preamble) with or using its current CE level, which may be the CE level of a recent (*e.g.*, its most recent) successful RA procedure.

[0254] The WTRU may transmit the PRACH (or preamble) with or using the CE level or number of repetitions corresponding to (or determined from or according to) the CE level or number of repetitions of a previous (*e.g.*, previous successful) RA procedure. The previous RA procedure may be a most recent (*e.g.*, most recent successful) contention-based (or contention-free) RA procedure. The previous RA procedure may be the most recent (*e.g.*, most recent successful) contention-based (or contention-free) RA procedure for RRC connection establishment or that was initiated by PDCCH order.

[0255] A successful RA procedure may be one for which the WTRU successfully received an RAR (*e.g.*, successfully received an RAR which it determined was intended for it).

[0256] The CE level that the WTRU may use for the PDCCH order indicated RA procedure may be determined, *e.g.*, by the WTRU, based on a prior RA (*e.g.*, a prior contention-based RA). For example, the CE level may be determined based on the PRACH resource associated with the latest (*e.g.*, most recent) RAR the WTRU received successfully.

[0257] The WTRU may transmit a preamble indicated in the PDCCH order. The WTRU may transmit a preamble configured by higher layers for contention-free or PDCCH order requested RA.

[0258] The WTRU may transmit the PRACH with the power level or type (*e.g.*, maximum power or based on DL measurement) indicated in or by the PDCCH order. The WTRU may transmit the PRACH with the power level or type configured by higher layers. If measurement based power is used, the WTRU may ramp the power and try again if an RAR is not successfully received.

[0259] The WTRU may transmit the PRACH in time and/or frequency resources according to the PRACH mask index indicated in or by the PDCCH order and/or a PRACH mask index configured by higher layers.

[0260] The WTRU may transmit the PRACH in time and/or frequency resources (*e.g.*, PRBs) indicated in or by the PDCCH order.

[0261] The WTRU may transmit the PRACH in time and/or frequency resources configured by higher layers for RACH or contention-free RACH, for example, for the CE level the WTRU may be using for the PRACH transmission.

[0262] A PDCCH order indicated or initiated RA or RA procedure may be an RA or RA procedure indicated, requested, and/or initiated by a DCI and/or PDCCH order, *e.g.*, by an eNB.

[0263] The CE level (or number of repetitions) that the WTRU may use for the PDCCH order indicated RA procedure may be or may be based on the CE level (or number of repetitions) used for the M-PDCCH carrying the PDCCH order. For example, the CE level (or number of repetitions) may be based on (*e.g.*, equal to) the number of repetitions used for M-PDCCH. The CE level (or number of repetitions) may be based on the number of total aggregation levels used for M-PDCCH, which may be referred to as the number of (E)CCEs used over subframes for repetitions.

[0264] If the WTRU does not successfully receive an RAR in response to a preamble it transmitted, the WTRU may try again, for example, until an RAR is successfully received or the maximum number of tries has been reached or exceeded.

[0265] The WTRU may use the same CE level for one or more (*e.g.*, all) preamble transmission attempts, for example for PDCCH order initiated RA. The WTRU may try different CE levels (*e.g.*, successively higher CE levels) and the starting CE level for the RA procedure may be or may be based on the CE level used for the M-PDCCH carrying the PDCCH order.

[0266] Starting CE level and CE level may be substituted for each other and still be consistent with this disclosure.

[0267] Techniques for handling DCI formats, *e.g.*, carrying PDCCH order, with coverage enhancement may be provided and/or used.

[0268] A PDCCH order (*e.g.*, a DCI carrying one or more PDCCH orders) may be transmitted repetitively. For example, a PDCCH order may be transmitted Nrep times (*e.g.*, in or in each of Nrep subframes or TTIs), where Nrep may be the number of repetitions. Nrep may be determined based on the CE level of the WTRU or WTRUs for which the PDCCH order or orders are intended. For example, Nrep may correspond to the CE level of the WTRU (*e.g.*, among the WTRUs for which the PDCCH order or orders may be intended) needing the most coverage enhancement. Nrep may be determined as a function of a group RNTI used for the DCI carrying one or more PDCCH orders. Nrep may be a value configured or provided by high layers and may be specific to a DCI carrying PDCCH order or may be common with the repetition number for other DCIs such as all DCIs

[0269] One or more (*e.g.*, all) DCI formats may have a repetition number, *e.g.*, a number of repetitions, associated with it or them. The repetition number may be configured, for example, in a WTRU-specific manner or cell-specific manner (*e.g.*, broadcast such as in system information). A WTRU may use a DCI format's repetition number (*e.g.*, configured repetition number) to receive or attempt to receive and/or decode that DCI format, for example, regardless of a CE level being used by a WTRU for other purposes, *e.g.*, for data transmission and/or reception. DCI and DCI format may be substituted for each other and still be consistent with this disclosure.

[0270] The number of repetitions of a DCI format may be a function of the maximum number of bits the DCI format may carry.

[0271] The number of repetitions of a DCI format may be a function of the maximum CE level supported by the eNB or cell that may transmit the DCI format.

[0272] The number of repetitions of a DCI format may be a function of the maximum CE level supported for the DCI format by the eNB or cell that may transmit the DCI format.

[0273] CE level use and/or support may be different for different DCI formats, *e.g.*, for an eNB or cell. Maximum CE level use and/or support may be different for different DCI formats, *e.g.*, for an eNB or cell.

[0274] If a WTRU receives a PDCCH order with repetitions and the last (or first) subframe of the repetitions is subframe n, the WTRU may transmit a PRACH preamble in the first PRACH resource (or the first PRACH resource available for the indicated PRACH preamble transmission) in subframe n+k3 or later where k3 may be at least one of following: (i) a fixed positive integer number such as 6, (ii) a positive integer number determined as a function of a CE level (or Nrep) such as the number of repetitions plus a fixed integer, and/or (iii) a configured number provided via higher layer signaling.

[0275] For a PDCCH order transmitted with Nrep repetitions, the WTRU may successfully receive the PDCCH order using fewer than Nrep repetitions, *e.g.*, Nue repetitions. The reference subframe n for determining the start of the preamble transmission may be the last subframe (or a subframe relative to the last subframe) of the Nrep repetitions or the Nue repetitions.

[0276] A PDCCH order to initiate a RA procedure may (or may only) be supported in a subset of CE levels. A WTRU and/or eNB may support two or more CE levels which may include normal coverage (*e.g.*, CE level-0) and one or more enhanced coverage levels (*e.g.*, CE level-1, 2, 3), for example for data transmission and reception. PDCCH order may (or may only) be used for a subset of the CE levels. For exemplary purposes, lower number CE levels may correspond to lower coverage enhancement, *e.g.*, fewer repetitions.

[0277] The PDCCH order may (or may only) be used for and/or by a WTRU in a normal coverage (*e.g.*, CE level-0). The PDCCH order may (or may only) be used for and/or by a WTRU in a normal coverage without bandwidth limitation.

[0278] The PDCCH order, *e.g.*, to initiate RA procedure, may be used for or by a WTRU in some coverage enhancement levels, but not in other coverage enhancement levels.

[0279] For example, the PDCCH order may be used for a WTRU in a low coverage enhancement level (*e.g.*, CE level-1 or CE level-1 and CE level-2). PDCCH order may not be used if a WTRU is in a high coverage enhancement level (*e.g.*, CE level-3 or CE level-2 and CE level-3). A WTRU in a low coverage enhancement level may monitor for and/or respond to a PDCCH order. A WTRU in a high coverage enhancement level may not monitor for and/or respond to a PDCCH order. Low coverage enhancement may be substituted for high coverage enhancement and vice versa and still be consistent with this disclosure.

[0280] The CE level or levels supported (*e.g.*, by the eNB and/or WTRU) for PDCCH order may be predefined, configured, or known. For example, configuration of the CE level, CE levels, or highest CE level supported by the eNB and/or expected to be supported by a WTRU for PDCCH order may be provided via higher layer signaling (*e.g.*, by the eNB) such as via system information, which may be broadcast. A WTRU may monitor for and/or respond to a PDCCH order while in or using a CE level supported or expected to be supported for PDCCH order. A WTRU may not monitor for and/or respond to a PDCCH order while in or using a CE level not supported or expected to be supported for PDCCH order.

[0281] The limit of PDCCH order to a subset of CE levels may be (or may only be) for PDCCH order which initiates contention-free RA. PDCCH order which initiates contention-based RA may be applicable at a larger set of (*e.g.*, all) CE levels supported, *e.g.*, by the eNB.

[0282] If a WTRU receives a PDCCH order indicating a contention-free RA procedure at a CE level not supported (*e.g.*, by the eNB or the WTRU) for contention-free RA, the WTRU may initiate a contention-based RA procedure.

[0283] A RA procedure may be used for CE level change.

[0284] An indication may be transmitted to initiate a RA procedure, which may be a contention-based or contention-free RA procedure. The indication may be transmitted in a PDCCH order. The PDCCH order may be used to change the CE level of the WTRU (*e.g.*, to a level such as a lower level which may need or use fewer repetitions or to a higher level which may need or use more repetitions).

[0285] In an example, a WTRU may receive a PDCCH order that may initiate a contention-based (or contention-free) RA procedure. In response, the WTRU may perform a contention-based (or contention-free) RA procedure.

[0286] The WTRU may perform the same (or a similar) RA procedure as for RRC connection establishment, *e.g.*, for initial access.

[0287] The WTRU may perform the same (or a similar) RA procedure as for RRC connection establishment, *e.g.*, for initial access, except for one or more aspects such as the starting CE level determination.

[0288] The starting CE level for a RA procedure (*e.g.*, a contention-based RA procedure) that may be initiated by a PDCCH order may be indicated in the PDCCH order.

[0289] The WTRU may begin with a starting CE level, and may transmit a preamble using that level (*e.g.*, with the repetitions corresponding to that level). If the WTRU does not successfully receive an RAR, the WTRU may try again using a higher (*e.g.*, next higher) CE level. The WTRU may try at each successively higher CE level until an RAR is successfully received or the RA procedure has failed at the highest CE level supported by the cell and/or the WTRU. Multiple tries at each level may be performed before going to the next higher level. Tries at the same level may be at increasingly higher power.

[0290] For the starting CE level, the WTRU may use the starting CE level provided in the PDCCH order or choose one autonomously, such as based on a DL measurement (*e.g.*, RSRP).

[0291] The WTRU may begin with a starting CE level corresponding to normal mode or to no coverage enhancement, for example based on an indication to do so included in the PDCCH order (*e.g.*, CE level or starting CE level set to a certain value such as 0) or a characteristic of the PDCCH order, such as the DCI format used or the RNTI used. A WTRU may begin with a starting CE level corresponding to normal mode or to no coverage enhancement for a contention-based RA initiated by PDCCH order, for example, always.

[0292] Normal coverage that, for example, may not use techniques such as repetition to enhance coverage, may be considered a CE level such as CE level-0.

[0293] A PDCCH order which may be used in initiate a RA procedure may include at least one of the following information: (i) a CE level or starting CE level, (ii) a PRACH preamble index, (iii) a PRACH preamble group index (*e.g.*, that may select a preconfigured group of preambles provided by higher layer signaling), (iv) a timing advance, (v) time and/or frequency resources (*e.g.*, subframes and/or PRBs) for the preamble transmission, and/or (vi) an indication of a group (*e.g.*, a group configured by higher layer signaling) of time and/or frequency resources (*e.g.*, subframes and/or PRBs) for the preamble transmission.

[0294] For contention-based RA, the PRACH preamble index may be a fixed known value, such as 0 or all zeros. This value may indicate to the WTRU that contention-based RA is requested or is to be performed. The value may indicate that the WTRU should choose the preamble.

[0295] The WTRU may choose the preamble to use from a set of preambles available for the CE level that the WTRU will use for the preamble transmission, for example, for contention-based RA.

[0296] A preamble or preamble group may be indicated in the PDCCH order. The WTRU may use the indicated preamble or select a preamble from the indicated group (*e.g.*, randomly), for example for contention-free RA.

[0297] The WTRU may choose time and/or frequency resources for the preamble transmission based on the time and/or frequency resources available for and/or corresponding to the CE level the WTRU will use for the preamble transmission. Correspondence may be configured and/or indicated in higher layer signaling. The WTRU may use resources indicated in the PDCCH order or select from a group of resources indicated in the PDCCH order.

[0298] After one or more attempts transmitting a preamble (*e.g.*, with repetitions for the CE level of the attempt), the WTRU may successfully receive an RAR. The WTRU may change the preamble for each attempt, for example, if one specific preamble was not indicated in the PDCCH order.

[0299] The WTRU may receive an UL grant, *e.g.*, in the RAR, to transmit a message to the eNB. The WTRU may send a message on the granted resources (*e.g.*, on a PUSCH). The message may indicate that the WTRU successfully received the RAR. The message may be used to perform contention resolution, *e.g.*, for a contention-based RA. For initial access, this message may be or may be referred to as msg3, which may be or include an RRC connection establishment request. For RA initiated by a PDCCH order, the WTRU may already be connected.

[0300] The WTRU may send a message or indication, *e.g.*, on the granted resources, which may indicate a successful RA procedure, RA procedure complete, successful reception of the RAR and/or other information which may indicate to the eNB (or may be interpreted by the eNB) that the RA procedure (*e.g.*, at least through RAR reception by the WTRU) was successful or completed. RA procedure msg3 or a modified version of msg3 may be used, for example, with a new establishment cause. A new message may be used. Message and msg may be used interchangeably.

[0301] The resources the WTRU may use for the PRACH transmission may be unique to a CE level and/or the eNB may be aware or informed that the RA procedure was successful. The eNB may know, *e.g.*, based on the PRACH resource used by the WTRU and/or the success of the RA procedure, what CE level the WTRU used or needed for achieving the successful RA procedure.

[0302] The CE level for the successful RA procedure (*e.g.*, the new CE level) may be lower (or higher) than the one the WTRU was using prior to the RA procedure.

[0303] The WTRU may change its current CE level to the CE level corresponding to the successful RA procedure (*e.g.*, the new CE level). The new CE level may correspond to normal coverage.

[0304] The WTRU may apply the timing advance included in the PDCCH order, for example, when or beginning when transmitting the UL message following successful reception of the RAR, *e.g.*, the UL message for which resources were granted in the RAR.

[0305] The WTRU may continue to use its current CE level until it completes the RA procedure. If the RA procedure results in a change of CE level, the WTRU may begin to use the new CE level when it completes the RA procedure.

[0306] Completion of the RA procedure may correspond to when the WTRU transmits the indication of the success of the RA procedure. The WTRU may use the new CE level when transmitting the indication.

[0307] In another example, a PDCCH order may be used to initiate one of contention-free RA or contention-based RA. An indication such as a bit field in the DCI associated with the PDCCH order may be used to indicate whether the PDCCH order is for contention-based RA or contention-free RA. A different RNTI may be used to indicate a PDCCH order for contention-based RA and a PDCCH order for contention-free RA. A different search space, *e.g.*, a different fallback M-PDCCH search space, may be used to indicate the type of RA indicated by the PDCCH order.

[0308] A search space that may be a fallback search space may be provided and/or used.

[0309] A search space, *e.g.*, of a cell, may have, use or be defined with a certain CE level, which may be a highest CE level which may be supported by the cell. An indication may be transmitted in this search space to a WTRU to initiate a RA procedure. The search space may be known or configured, *e.g.*, by higher layer signaling. The higher level signaling may be from the eNB, such as in system information, which may be broadcast.

[0310] The search space may be or may be used for a fallback control channel. The search space may be referred to as a fallback search space. A fallback control channel, a fallback search space, a common search space, and a fallback M-PDCCH may be used interchangeably.

[0311] A fallback M-PDCCH may be configured with at least one of: a subband or frequency location, a set of time locations, a CE level, and a number of repetitions.

[0312] A specific subband (*e.g.*, a subset of consecutive PRBs which may be within a system bandwidth such as a DL system bandwidth of a cell) and/or a specific time location or set of time locations (*e.g.*, a subset of subframes and/or radio frames) may be used for a fallback M-PDCCH.

[0313] The frequency and/or time locations of the subband may be indicated in higher layer signaling such as broadcast signaling or via a physical broadcasting channel (*e.g.*, MIB). The frequency and/or time locations of the subband may be determined (*e.g.*, by the WTRU) as a function of one or more system parameters. The system parameters may include DL system bandwidth, physical cell-ID, subframe number, SFN number, and MBSFN configuration. The frequency and/or time locations of the subband may change over time. For example, a frequency hopping pattern (*e.g.*, predefined or configured) may be used.

[0314] The number of repetitions for the fallback M-PDCCH may be the same as the maximum number of repetitions for M-PDCCH configured in the cell. The number of repetitions may be indicated via higher layer signaling such as broadcast signaling or via a physical broadcasting channel (*e.g.*, MIB).

[0315] A part of M-PDCCH WTRU-specific search space may be used as a fallback M-PDCCH. For example, M-PDCCH WTRU-specific search space may include one or more CE levels (*e.g.*, repetition numbers). One or more M-PDCCH candidates in the M-PDCCH WTRU-specific search space with a highest CE level may be used as fallback M-PDCCH.

[0316] A WTRU may determine one or more parameters (*e.g.*, transmission and/or reception parameters) for a fallback M-PDCCH which may include one or more of a subband or frequency location, a set of time locations, a CE level, and a number of repetitions. The WTRU may determine the one or more parameters based on at least one of received configuration, system parameters, and otherwise known information.

[0317] The WTRU may monitor fallback M-PDCCH according to at least the determined parameters. The WTRU may monitor fallback M-PDCCH for at least PDCCH order (or DCI format including a PDCCH order for the WTRU) that may indicate, initiate, or request an RA procedure. Upon or in response to successful receipt of a PDCCH order, the WTRU may initiate an RA procedure.

[0318] The fallback M-PDCCH may be used by the eNB to communicate with the WTRU at a certain CE level such as a highest CE level supported by the cell, for example, if communication with the WTRU may need a higher (or lower) CE level than what is currently being used. The eNB may indicate a CE level change to the WTRU in or using the fallback M-PDCCH. The eNB may transmit a PDCCH order and/or a request to initiate a RA procedure to a WTRU, for example to potentially change the CE level of the WTRU such as to a more appropriate or higher (or lower) CE level.

[0319] Paging may be provided and/or used. CE information may be used for paging. When an eNB may page or is to page a WTRU that may be in idle mode, the eNB may not know whether the WTRU may be in coverage enhanced (CE) mode and/or if it may be in CE mode, what the CE level may be. If the eNB may page a CE mode WTRU using normal paging procedures, the WTRU may not receive the page.

[0320] Idle mode may be or include one or more of (*e.g.*, the modes or states of) RRC Idle, ECM Idle, EMM Registered, and/or EMM Deregistered.

[0321] A WTRU may provide CE information that may be for or regarding the WTRU to an eNB and/or an MME. An eNB may provide CE information that may be for or regarding a WTRU to another eNB (*e.g.*, as part of a handover procedure) and/or to an MME. MME may be replaced by another network entity and still be consistent with this disclosure. WTRU and device (*e.g.*, which may be an MTC device or LC-MTC device) may be used interchangeably.

[0322] An MME may store CE information that may be for or regarding a WTRU. The MME may include CE information that may be for or regarding a WTRU in a message to an eNB, for example, when requesting the eNB to page the WTRU, such as when the WTRU may be in idle mode.

[0323] CE information that may be for or regarding a WTRU may include one or more of the mode of the WTRU with respect to coverage enhancements, *e.g.*, CE mode or not CE mode; the CE level of the WTRU; and/or the WTRU's capability to support CE mode. The information included in CE information may be different for different messages and/or purposes.

[0324] The mode of the WTRU with respect to coverage enhancements may be the current and/or last (or most recently) known or stored mode of the WTRU. The CE level of the WTRU may be the current and/or last (or most recently) known or stored CE level of the WTRU.

[0325] CE level may include an indication of CE mode. A certain value or level such as 0 may be used to indicate that the UE may not be in CE mode. For example, 0, 1, 2, and 3 may be used to indicate not in CE mode, and levels 1, 2, and 3 of CE mode, respectively.

[0326] In an example, a WTRU may provide CE information to an MME in a NAS message such as an attach (*e.g.*, ATTACH REQUEST) message and/or a tracking area update (TAU) message.

[0327] The WTRU may provide CE information to an MME during one or more of the network registration actions, such as an attach (*e.g.*, in the "ATTACH REQUEST" message) or during device or WTRU mobility management actions such as tracking area update (TAU) (*e.g.*, in the "TRACKING AREA UPDATE REQUEST" message). For example, the WTRU may include such CE information in one or more of the aforementioned messages itself, or in one or more of its WTRU or device capabilities or network support feature attribute IEs such as "WTRU network capabilities," "MS network capabilities," "MS Classmark 2," MS Classmark 3," "MS network feature support," and the like.

[0328] An eNB may receive CE information (*e.g.*, some CE information) from a WTRU and/or may determine CE information (*e.g.*, some or some other CE information) in one or more other ways (*e.g.*, from a PRACH resource a WTRU may have used which may indicate certain CE information). The WTRU may provide CE information, *e.g.*, to the eNB, in one or more capabilities information elements (IEs) or messages (*e.g.*, a WTRU capabilities IE or message and/or an IE or message that may be specific to CE information and/or or information relating to paging or paging capabilities). The WTRU may autonomously send the message. The eNB may provide CE information to an MME in an S1 (*e.g.*, S1AP) message.

[0329] An eNB may provide CE information to an MME for or regarding a WTRU following determination and/or receipt of this information. An eNB may provide CE information to an MME for or regarding a WTRU following a change or update of this information. An eNB may provide CE information to an MME for or regarding a WTRU when the eNB may release the WTRU (*e.g.*, from its connection such as an RRC connection with the eNB) and/or when the WTRU may go to idle mode.

[0330] An MME may provide CE information (*e.g.*, which it may have stored for a WTRU) to an eNB, for example, in support of certain procedures, for example certain procedures in which the eNB may not have this information. For example, the MME may provide CE information (*e.g.*, which may include one or more items of information that may be provided separately or in combinations such as in one or more IEs), to an eNB in association with paging (*e.g.*, with or in an S1 PAGING message) for a given WTRU or device that may be in idle mode or attached but not connected, or detached or unattached but known to be located in the paging area. The eNB may page the WTRU in a manner consistent with the CE information it may receive, *e.g.*, from the MME.

[0331] A WTRU may provide updated CE information to an eNB and/or MME, for example, when one or more of the components of its CE information may change or in other situations.

[0332] Under certain conditions, *e.g.*, when the WTRU may be in idle mode, the WTRU may perform a RA procedure to connect to an eNB for providing CE information or updated CE information. The WTRU may send an RRC connection request, and the reason may be indicated by the WTRU as mobile originated signaling (mo-signaling).

[0333] Change of CE mode and/or CE level (*e.g.*, in idle and/or connected mode) may be a reason for a WTRU to perform (*e.g.*, trigger) a TAU. Change of CE mode and/or CE level (*e.g.*, in idle and/or connected mode) may be a reason for a WTRU to perform a RA procedure and/or perform (or request) connection establishment and/or send a capabilities message to or with an eNB.

[0334] If a WTRU may change to or from CE mode and/or or may change its CE level, *e.g.*, while in idle mode (or connected mode), the WTRU may connect to an eNB (*e.g.*, RRC connection), *e.g.*, perform an RA procedure to request and/or establish an RRC connection with the eNB where the establishment cause may be mobile originated signaling (mo-signaling).

[0335] If a WTRU may change to or from CE mode and/or may change its CE level, *e.g.*, while in idle mode (or connected mode), the WTRU may perform an RA procedure with an eNB (which may be the same or similar procedure as the one for establishing the connection), which may enable the eNB to determine whether or not the WTRU may be in CE mode and/or what level of CE the WTRU may need or use.

[0336] If a WTRU may change to or from CE mode and/or or may change its CE level, *e.g.*, while in idle mode (or connected mode), and/or for other reasons, the WTRU may provide CE information (*e.g.*, updated CE information) regarding the WTRU to the eNB and/or MME, for example as part of a WTRU message to the eNB and/or a WTRU message (*e.g.*, NAS message) to the MME (*e.g.*, via the eNB). The WTRU may use one or more messages to convey the CE information to the eNB and/or MME. The WTRU may use a NAS procedure and/or message such as TAU (*e.g.*, in the "TRACKING AREA UPDATE REQUEST" message) to provide CE information or updated CE information to the MME. The WTRU may use a capabilities message to provide CE information or updated CE information to the eNB.

[0337] A WTRU may perform an RA procedure to establish a connection with an eNB.

[0338] Following connection establishment, the WTRU may send a NAS message to the MME which may be a TAU message. The message may include an indication of the mode (CE mode or not CE mode) and/or CE level of the WTRU. The WTRU may include the WTRU

capability of supporting CE mode in the TAU message. The CE mode support capability may (*e.g.*, may only) be included in an ATTACH message to the MME.

[0339] The WTRU may send CE information to the MME in a TAU message (*e.g.*, in the "TRACKING AREA UPDATE REQUEST" message). When the WTRU may send such a message, for example for a reason other than a change of CE information, the WTRU may include all or certain of its CE information, *e.g.*, the WTRU may or may only include the CE information that may have changed since the last time the WTRU may have sent CE information to the MME.

[0340] When CE information for a WTRU may change, an eNB may send a message (*e.g.*, an S1AP message) to provide certain (*e.g.*, some or all) of the CE information or at least (or only) the changed information to the MME.

[0341] During or after radio link failure (RLF) or recovery from RLF, a WTRU may provide CE information to an eNB and/or MME such as in accordance with one or more of the solutions or examples described herein, for example for a WTRU in idle mode which may have changed CE mode and/or CE level. The WTRU may act as if CE mode and/or CE level may have changed (*e.g.*, even if it or they have not changed), for example, since before RLF or conditions which may have resulted in RLF may have occurred.

[0342] Paging may be provided for and/or used by a WTRU or WTRUs that may be in CE mode. When an eNB may page or intend to page a WTRU which may support CE mode, the eNB may not know if the WTRU may currently be in CE mode and/or the eNB may not know the current CE level of the WTRU. This may happen, for example, if the CE information which may be stored by the MME may not include CE mode or CE level information or if such information may be stale.

[0343] An eNB may page a WTRU, such as one that may support CE mode, using non-CE paging or using both non-CE paging and CE paging (*e.g.*, simultaneously or sequentially). An eNB may page a WTRU, such as one that may support CE mode, using non-CE paging first and if unsuccessful, then using CE paging. An eNB may page a WTRU, such as one that may support CE mode, using CE paging or only CE paging. An eNB may page a WTRU, such as one that may support CE mode, using CE paging for the worst CE level (*e.g.*, the level which may use the most repetition), *e.g.*, only for the worst CE level. An eNB may page a WTRU, such as one that may support CE mode, using CE paging for one CE level, and if unsuccessful, using CE paging for another (*e.g.*, another higher) or the next (*e.g.*, the next higher) level. An eNB may page a WTRU, such as one that may support CE mode, using CE paging for one or more (*e.g.*, each of the) CE levels (*e.g.*, one at a time or simultaneously), for example, until successful or until the

worst level may have failed. An eNB may page a WTRU, such as one that may support CE mode, using CE paging for the last known or stored CE mode and/or CE level of the WTRU, which may be provided to the eNB in a message (*e.g.*, S1-Paging message), *e.g.*, from the MME. An eNB may page a WTRU, such as one that may support CE mode, using CE paging for the CE mode and/or CE level of the WTRU that may be provided to the eNB in a message (*e.g.*, S1-Paging message), *e.g.*, from the MME. Using non-CE paging may include using legacy paging techniques or paging techniques that may be used for WTRUs that may not need or use coverage enhancement. Using CE paging may include paging using coverage enhancement techniques such as repetition. The number of repetitions may be fixed, configured, or a function of the CE level. Using CE paging may include providing a PDSCH carrying PCH or paging without a DCI format.

[0344] An eNB that may page a WTRU using both non-CE paging and CE paging may cease the CE paging (*e.g.*, the repetitions of the CE paging) if and/or when it may receive (*e.g.*, successfully receive) a response from the WTRU to the non-CE paging. A response to a page from a WTRU may be or include the transmission of a PRACH preamble and/or at least part of an RA procedure. Successful reception of the response by the eNB may include being able to determine that the response was from the WTRU it may have paged.

[0345] An eNB that may page a WTRU using both non-CE paging and CE paging may cease the CE paging (*e.g.*, the repetitions of the CE paging) if and/or when the eNB may receive an indication, *e.g.*, from the MME that the page was successful. An indication that the page was successful may include a request to perform an operation for the WTRU, such as setting up a bearer.

[0346] An eNB that may page or intend to page a WTRU (*e.g.*, one that may support CE mode or that the eNB may know may support CE mode), where the eNB may, for example, not know or may be unsure of the (*e.g.*, the current) CE mode and/or CE level of the WTRU, may try paging the WTRU using non-CE paging (*e.g.*, first). If the eNB may not receive (or successfully receive) a response from the WTRU or an indication (*e.g.*, of paging success) from the MME, for example, within a certain amount of time, the eNB may try paging the WTRU using CE paging.

[0347] The eNB may try CE paging for one or more CE levels until successful or all fail, or may try the worst CE level (*e.g.*, only). A paging attempt by the eNB, *e.g.*, using non-CE mode or CE mode with a CE level (*e.g.*, a certain CE level), may be in response to a paging request from the MME. The paging request may be provided in an S1 paging message. An MME may provide an indication of lack of success of a paging attempt instead of an indication of success.

[0348] An eNB may page a connected mode CE mode WTRU, *e.g.*, using CE mode paging, to inform it of system information changes. The eNB may directly inform these WTRUs of the changes with dedicated signaling.

[0349] CE paging may be provided and/or used. A WTRU may monitor PDCCH and/or EPDCCH to determine if there may be PDSCH carrying PCH (or paging message) that may be intended for it. The WTRU may look for a paging RNTI (*e.g.*, P-RNTI) or DCI format masked with (*e.g.*, with a CRC scrambled with) a paging RNTI (*e.g.*, P-RNTI) that may indicate a PDSCH that may carry PCH or a paging message. PCH and paging message may be used interchangeably. Using a RNTI (*e.g.*, a DCI format using a RNTI) may be the same as being masked with (*e.g.*, the DCI format being masked with) the RNTI or having (*e.g.*, the DCI format having) a (or its) CRC scrambled with the RNTI.

[0350] A WTRU, such as a coverage limited WTRU, may use, need, and/or combine repetitions of a transmission (*e.g.*, PDCCH, EPDCCH, PDSCH, *etc.*) to be able to successfully receive and/or decode the transmission. Rules and/or procedures may be used for PDSCH that may carry PCH or a paging message and/or PDCCH (and/or EPDCCH) that may carry a DCI format that may indicate the presence of (or upcoming presence of) a PDSCH that may carry a PCH or paging message.

[0351] CE paging may use coverage enhancement techniques such as repetition of the PDCCH and/or EPDCCH that may carry a DCI format that may indicate the presence of (or upcoming presence of) a PDSCH that may carry a PCH or paging message and/or repetition of a PDSCH that may carry a PCH or paging message.

[0352] An eNB, such as one that may use CE paging, may transmit PCH in a coverage enhanced manner, for example, when transmitting PCH to a WTRU that may be coverage limited. A WTRU, such as a coverage limited WTRU that may use or respond to CE paging, may receive PCH in a coverage enhanced manner. CE paging may include transmission and/or reception of PCH in a coverage enhanced manner.

[0353] CE paging and/or transmission and/or reception of PCH in a coverage enhanced manner may include transmission of repetitions of PCH, which may include transmission of repetitions of a PDSCH that may carry PCH and/or transmission of repetitions of the associated PDCCH and/or EPDCCH. CE paging and/or transmission and/or reception of PCH in a coverage enhanced manner may include reception and/or combining of repetitions of PCH, which may include reception of and/or combining repetitions of the PDSCH that may carry PCH and/or reception of and/or combining repetitions of the associated PDCCH and/or EPDCCH. CE paging and/or transmission and/or reception of PCH in a coverage enhanced manner may include

transmission of an RNTI for the PCH PDCCH and/or EPDCCH, *e.g.*, legacy P-RNTI or an RNTI, *e.g.*, PCE-RNTI, which may be specific to coverage limited WTRUs, for example, of a coverage enhancement level (*e.g.*, of a certain CE level). CE paging and/or transmission and/or reception of PCH in a coverage enhanced manner may include monitoring and/or reception of an RNTI for the PCH PDCCH and/or EPDCCH, *e.g.*, legacy P-RNTI or an RNTI, *e.g.*, PCE-RNTI, which may be specific to coverage limited WTRUs, for example, of a coverage enhancement level (*e.g.*, of a certain CE level).

[0354] A WTRU and/or eNB (such as a WTRU and/or eNB that may use CE paging) may transmit repetitions of PCH, which may include transmitting repetitions of a PDSCH that may carry PCH and/or transmitting repetitions of the associated PDCCH and/or EPDCCH. A WTRU and/or eNB (such as a WTRU and/or eNB that may use CE paging) may receive and/or combine repetitions of PCH, which may include receiving and/or combining repetitions of the PDSCH that may carry PCH and/or receiving and/or combining repetitions of the associated PDCCH and/or EPDCCH. A WTRU and/or eNB (such as a WTRU and/or eNB that may use CE paging) may transmit an RNTI for the PCH PDCCH and/or EPDCCH, *e.g.*, legacy P-RNTI or an RNTI, *e.g.*, PCE-RNTI, which may be specific to coverage limited WTRUs, for example, of a coverage enhancement level (*e.g.*, of a certain CE level). A WTRU and/or eNB (such as a WTRU and/or eNB that may use CE paging) may monitor and/or receive an RNTI for the PCH PDCCH and/or EPDCCH, *e.g.*, legacy P-RNTI or an RNTI, *e.g.*, PCE-RNTI, which may be specific to coverage limited WTRUs, for example, of a coverage enhancement level (*e.g.*, of a certain CE level).

[0355] P-RNTI or another RNTI may be used for PDCCH and/or EPDCCH associated with PDSCH that may carry PCH, for example, for PCH intended for a WTRU that may be coverage limited and/or bandwidth limited.

[0356] PDCCH and/or EPDCCH associated with PDSCH that may carry PCH may be located in a common search space (*e.g.*, PDCCH common search space and/or EPDCCH common search space), for example, for PCH that may be intended for a WTRU that may be coverage limited and/or bandwidth limited.

[0357] A WTRU, such as one that may be coverage limited, may begin monitoring for the PDCCH and/or EPDCCH associated with PDSCH that may carry PCH at the start of its DRX cycle (*e.g.*, the first subframe of its DRX cycle). The WTRU may monitor for PDCCH and/or EPDCCH using P-RNTI or PCE-RNTI or a PCE-RNTI for its CE level (*e.g.*, current CE level).

[0358] An eNB may transmit a PCH PDSCH in a fixed, known, or determined location and/or with one or more fixed, known, or determined parameters (*e.g.*, transmission parameters such as MCS) such that a DCI format may not be required or used, *e.g.*, for a PCH PDSCH that

may be intended for a WTRU (or at least a WTRU) that may be bandwidth limited and/or coverage limited. The fixed, known, or determined location and/or parameters may be provided by the eNB in signaling, such as broadcast signaling (*e.g.*, in system information). PCH PDSCH may be used to represent a PDSCH which may carry PCH.

[0359] The location and/or one or more transmission parameters of a PCH PDSCH that may be intended for a WTRU (or at least a WTRU) that may be bandwidth limited and/or coverage limited may be a function of a capability (or reduced capability) of the WTRU. For example, PCH PDSCH location and/or one or more PCH PDSCH transmission parameters may be a function of one or more of CE mode, CE level, and/or BW limitation. The capability (or reduced capability) of the WTRU, such as the CE mode and/or CE level and/or BW limitation of the WTRU, may determine (or may be used by the WTRU and/or eNB to determine) the location (*e.g.*, subframes and/or RBs) and/or one or more transmission parameters (*e.g.*, MCS) for the PCH PDSCH that may be intended for a WTRU (or at least a WTRU) that may be bandwidth limited and/or coverage limited. The eNB may transmit and/or the WTRU may receive or attempt to receive the PCH PDSCH in the determined location.

[0360] Determination of the location and/or transmission parameter(s) of a PCH PDSCH that may be intended for a WTRU (or at least a WTRU) that may be bandwidth limited and/or coverage limited, *e.g.*, by the WTRU and/or eNB, may be based at least in part on configuration (*e.g.*, of PCH PDSCH location and/or parameters) for one or more capabilities (or reduced capabilities, such as CE mode or level), which may be provided by the eNB via signaling, such as broadcast signaling. Determination of the location and/or transmission parameter(s) of a PCH PDSCH that may be intended for a WTRU (or at least a WTRU) that may be bandwidth limited and/or coverage limited, *e.g.*, by the WTRU and/or eNB, may be based at least in part on a WTRU parameter or identifier, such as the WTRU IMSI or WTRU ID.

[0361] Location (*e.g.*, of a PCH PDSCH) may be or may include time (*e.g.*, subframe, set of subrames, or pattern of subframes) and/or frequency (*e.g.*, one or more RBs).

[0362] A PCH or PCH PDSCH may be or may represent an instance or repetition of a PCH or PCH PDSCH. Repetitions of a PCH or PCH PDSCH that may be combined by a WTRU, such as a WTRU that may be coverage limited, may be in the same or different locations (*e.g.*, subframes may be different and RBs may be the same or different) and/or may use the same or different parameters.

[0363] A WTRU, such as a bandwidth limited and/or coverage limited WTRU, may monitor for, receive, or attempt to receive PCH PDSCH, *e.g.*, from an eNB. The WTRU and/or the eNB may determine the location of an PCH PDSCH that may be intended for the WTRU (or at least

the WTRU) based at least in part on configuration, *e.g.*, of the relationship or correspondence between PCH PDSCH location and/or parameters and WTRU capability or reduced capability, which may be provided by the eNB via signaling, such as broadcast signaling.

[0364] One or more PCH (or PCH PDSCH) transport block sizes may be configured or fixed and may correspond to a certain number of pages (*e.g.*, to a certain number of WTRUs). Padding may be used, for example, when the number of pages (*e.g.*, actual pages) may be less than the number of pages (*e.g.*, the certain number of pages) that may correspond to a fixed or configured transport block size (TBS). TBS configuration may be by signaling, such as broadcast signaling, which may be from the eNB. There may be a separate PCH (or PCH PDSCH) TBS value (*e.g.*, fixed or configured) for one or more CE levels. There may be one or more PCH (or PCH PDSCH) TBS values for PCH (or PCH PDSCH) that may be intended for (*e.g.*, at least for) a coverage limited and/or bandwidth limited WTRU. A WTRU such as a WTRU that may be coverage limited and/or bandwidth limited may receive or may expect to receive a PCH (or PCH PDSCH) with a fixed or configured TBS. An eNB may transmit a PCH (or PCH PDSCH) that may be intended for (*e.g.*, at least for) a WTRU that may be coverage limited and/or bandwidth limited with a fixed or configured TBS.

[0365] There may be N CE levels, and there may be PCH PDSCH resources (*e.g.*, separate PCH PDSCH resources) for each of the N CE levels. An eNB may transmit and/or a WTRU may receive or may expect to receive a PCH PDSCH in certain time and/or frequency resources (*e.g.*, subframes and/or RBs) that may correspond to the CE mode or level of the WTRU.

[0366] One or more (*e.g.*, a set of) PCH (or PCH PDSCH) transport block (TB) sizes (*e.g.*, possible or candidate TB sizes) may be fixed or configured (*e.g.*, by the eNB) and/or determined (*e.g.*, by the WTRU). A WTRU may try one or more of the TB sizes (*e.g.*, in the set of TB sizes) to try to successfully receive the PCH (or PCH PDSCH), for example, when monitoring for and/or attempting to receive PCH (or PCH PDSCH).

[0367] One or more (*e.g.*, a set of) PCH (or PCH PDSCH) candidates may be fixed or configured (*e.g.*, by the eNB) and/or determined (*e.g.*, by the WTRU). The PCH (or PCH PDSCH) candidates may differ in one or more characteristics that may include time (*e.g.*, subframe), frequency (*e.g.*, RBs), TB size, and one or more transmission parameters, such as MCS. A WTRU may try one or more of the PCH (or PCH PDSCH) candidates to try to successfully receive the PCH (or PCH PDSCH), for example, when monitoring for and/or attempting to receive PCH (or PCH PDSCH).

[0368] PDCCH (and/or EPDCCH) may be repeated a number of times, *e.g.*, M times, for example, for CE paging. The same PDCCH may be repeated (*e.g.*, for one or more (*e.g.*, each) of

the M times) and one or more (*e.g.*, each of the) repetitions may be located in the same place in a search space such as a common search space (CSS), *e.g.*, a PDCCH and/or EPDCCH CSS.

[0369] There may be a gap of G (*e.g.*, 0 or greater) that may follow the PDCCH (and/or EPDCCH) repetitions. G may be or may include a number of subframes (or certain subframes such as POs) and/or frames (or certain frames, such as PFs). The corresponding PDSCH (*e.g.*, PCH PDSCH) may follow after the gap and/or may be repeated P times. M may or may not equal P. One or more of M, G, and P may be a function of a CE level (*e.g.*, the CE level determined for the WTRU to be paged or the worst case CE level). M and/or G may be zero, for example, if no DCI format may be used or needed for paging (*e.g.*, CE paging).

[0370] An eNB may transmit the repetitions of the PDCCH (and/or EPDCCH) and/or the PDSCH in certain subframes and/or frames such as POs and/or PFs.

[0371] An eNB may transmit the repetitions of the PDCCH (and/or EPDCCH) and/or the PDSCH in certain subframes such as designated or configured subframes and/or subframes which may be DL (*e.g.*, any DL) subframes and/or certain (*e.g.*, all) special subframes (*e.g.*, for TDD).

[0372] The subframe of the first PDSCH (*e.g.*, of a set of P repetitions of a PDSCH) that may carry a page (*e.g.*, PCH) for a WTRU, such as a CE mode WTRU, may align with POs and/or PFs and/or may be related to the timing of the PDCCH.

[0373] To page a WTRU, the eNB may transmit a first transmission (or repetition) of a PDCCH (and/or EPDCCH) and/or PDSCH (*e.g.*, PCH PDSCH) according to the starting PO of the WTRU, which may be determined in a same or similar manner to which a PO may be determined by or for a legacy WTRU or according to another rule or calculation.

[0374] Following the first transmission of a PDCCH (and/or EPDCCH) and/or PDSCH (*e.g.*, PCH PDSCH), which may be in a (*e.g.*, a certain) PO (*e.g.*, a starting PO) and/or a (*e.g.*, a certain) PF (*e.g.*, a starting PF), one or more (*e.g.*, each) of the next of the M or P repetitions may be transmitted by the eNB in the next PO (*e.g.*, each of the next M, M-1, P or P-1 POs). A next PO may be in the same or the next PF as a previous PO.

[0375] Following the first transmission of a PDCCH (and/or EPDCCH) and/or PDSCH (*e.g.*, PCH PDSCH), which may be in a (*e.g.*, a certain) PO (*e.g.*, a starting PO) and/or a (*e.g.*, a certain) PF (*e.g.*, a starting PF), one or more (*e.g.*, each) of the next of the M or P repetitions may be transmitted by the eNB in the same PO as the previous transmission in the next PF.

[0376] Following the first transmission of a PDCCH (and/or EPDCCH) and/or PDSCH (*e.g.*, PCH PDSCH), which may be in a (*e.g.*, a certain) PO (*e.g.*, a starting PO) and/or a (*e.g.*, a certain) PF (*e.g.*, a starting PF), one or more (*e.g.*, each) of the next of the M or P repetitions may

be transmitted by the eNB in the next subframe (*e.g.*, each of the next M, M-1, P or P-1 subframes) that may be DL.

[0377] Following the first transmission of a PDCCH (and/or EPDCCH) and/or PDSCH (*e.g.*, PCH PDSCH), which may be in a (*e.g.*, a certain) PO (*e.g.*, a starting PO) and/or a (*e.g.*, a certain) PF (*e.g.*, a starting PF), one or more (*e.g.*, each) of the next of the M or P repetitions may be transmitted by the eNB in the next subframe (*e.g.*, each of the next M, M-1, P or P-1 subframes) that may be either a DL or special subframe where special subframes may apply (*e.g.*, only apply) for TDD.

[0378] Following the first transmission of a PDCCH (and/or EPDCCH) and/or PDSCH (*e.g.*, PCH PDSCH), which may be in a (*e.g.*, a certain) PO (*e.g.*, a starting PO) and/or a (*e.g.*, a certain) PF (*e.g.*, a starting PF), one or more (*e.g.*, each) of the next of the M or P repetitions may be transmitted by the eNB in the next designated or configured subframe, which may be for this purpose. The subframe configuration may be provided via signaling, such as broadcast signaling, for example, in system information. System information may be provided in one or more SIBs.

[0379] Whether or not a subframe may be a DL subframe or a special subframe may be determined according to the cell specific TDD UL/DL configuration of the cell, which may be broadcast by the cell in system information (*e.g.*, in SIB 1).

[0380] The POs and/or PFs that may be used for CE paging and (*e.g.*, at least) non-CE paging (*e.g.*, legacy paging) may be the same or different. The POs and/or PFs that may be used for CE paging may be configured and/or determined separately from the POs and/or PFs that may be used for (*e.g.*, at least) non-CE (*e.g.*, legacy) paging.

[0381] A WTRU, such a WTRU that may be coverage limited, may look for a page using non-CE paging and may use CE paging if non-CE paging may not be successful. For example, the WTRU may monitor for PDCCH which may be masked by P-RNTI in a PO that may be determined according to a legacy calculation. If the WTRU may successfully receive a P-RNTI in this manner and/or a corresponding PDSCH in the PO subframe, the WTRU may not use CE paging, *e.g.*, it may not monitor for repeated PDCCH and/or EPDCCH and/or PDSCH. The WTRU may determine if a PCH it may have received in the PO may be intended for it and, if so, may respond to the page accordingly.

[0382] A WTRU, such a WTRU that may be coverage limited, may determine, *e.g.*, for its paging cycle, one or more of a starting subframe, a starting PF, and/or a starting PO. Such determination may be in a same or similar manner to which a PO may be determined by or for a legacy WTRU or according to a new rule or calculation.

[0383] The starting subframe or starting PO for a page or paging cycle for a CE mode WTRU may be the subframe or PO for or of the first transmission of the PDCCH (and/or EPDCCH) of the M repetitions of the channel. The starting subframe or starting PO for a page or paging cycle for a CE mode WTRU may be the subframe or PO for or of the first transmission of the PCH PDSCH of the P repetitions of the channel.

[0384] A WTRU, such as a WTRU that may be coverage limited, may look for a page using CE paging. According to the subframes in which the starting PO and the M repetitions of the PDCCH (and/or EPDCCH) may be (*e.g.*, as described for eNB transmission), the WTRU may monitor PDCCH (and/or EPDCCH) in those subframes and may combine the signals from those subframes or a subset of those subframes into one PDCCH (and/or EPDCCH) that it may attempt to decode and/or for which it may determine if it may be masked with a paging RNTI such as P-RNTI or PCE-RNTI.

[0385] If the WTRU may determine that there may be a page for the WTRU, for example, if the PDCCH (and/or EPDCCH) was or was determined by the WTRU to be masked with a paging RNTI (*e.g.*, P-RNTI or PCE-RNTI), the WTRU may begin to receive the corresponding P repetitions of PDSCH.

[0386] The WTRU may skip a certain number of subframes and/or frames from the last of the M repetitions to the first of the P repetitions, which may be according to G.

[0387] A WTRU may not monitor for PDCCH and/or EPDCCH in order to receive a PCH PDSCH. According to the subframes in which the starting PO and the P repetitions of the PCH PDSCH may be (*e.g.*, as described for eNB transmission), the WTRU may monitor for PDSCH (*e.g.*, PCH PDSCH) in those subframes and may combine the signals from those subframes or from a subset of those subframes into one PDSCH, which it may attempt to decode and/or receive. The WTRU may monitor for the PCH PDSCH in a known or determined location or locations and/or using one or more known and/or determined parameters of PCH PDSCH. The WTRU may monitor for one or more PCH PDSCH candidates.

[0388] The WTRU may receive the P repetitions or a subset of the P repetitions of the PDSCH or PDSCH candidates and may combine them (or one or more, *e.g.*, each set of repetitions) to a single PDSCH from which it may attempt to (*e.g.*, successfully) receive and/or decode a PCH. If the WTRU may (*e.g.*, successfully) receive and/or decode the PCH, the WTRU may determine if the PCH was intended for the WTRU and, if so, the WTRU may respond to the page.

[0389] One or more of M, G, and P may be a function of a CE level (*e.g.*, the CE level of the WTRU or the worst case CE level).

[0390] Worst case CE level may be the worst or highest CE level supported by the cell or eNB (e.g., the CE level with the highest number of repetitions) which may be indicated in cell-specific signaling, e.g., broadcast signaling such as via a physical broadcast channel (e.g., MIB) or higher layer signaled system information (e.g., SIB).

[0391] G and/or P may be indicated in the PDCCH (and/or EPDCCH), which may be masked by a paging RNTI such as P-RNTI or PCE-RNTI. G and/or P may be indicated in the PDCCH (and/or EPDCCH), which may correspond to the paging PDSCH, which may be repeated P times.

[0392] The subframes of the repetitions and/or the gap may not be consecutive subframes. The subframes of the repetitions and/or the gap may be PO subframes or other particular or designated subframes. The PO subframes may be the PO subframes of a WTRU, such as any WTRU or of a certain WTRU, such as a WTRU for which a page may be intended.

[0393] For example, the repeated PDCCHs (and/or EPDCCHs) and/or PDSCHs that may be used by CE mode WTRUs (and or eNBs for CE paging) may occur in subframes that may be possible paging occasions (POs). For FDD, PO subframes may be certain subframes, such as subframes 0, 4, 5, and 9, for example. Depending on configuration (*e.g.*, by the eNB), the subsets of subframes for POs may be certain subsets, such as [9], [4,9], or [0,4,5,9], for example. For TDD, the PO subframes may be certain subframes, such as subframes 0, 1, 5, and 6, for example. Depending on configuration (*e.g.*, by the eNB), the subsets of subframes for POs may be certain subsets, such as [0], [0,5], or [0,1,5,9], for example.

[0394] A starting subframe of a PO or a starting PO may be in a PF. One or more repetitions of an EPDCCH and/or PDSCH for paging may not be in a PF. One or more of the PDCCHs, EPDCCHs, and/or PDSCHs that may be used for paging may be transmitted and/or received in subframes that may be identified by configuration as subframes that may be used for paging. The configuration may be provided via signaling, such as broadcast signaling, for example, in system information. The system information may be provided, for example, in one or more system information blocks (SIBs).

[0395] A downlink (DL) control channel may be used for paging. For example, an (E)PDCCH common search space (CSS) may include one or more (E)PDCCH candidates and may be configured for paging. A WTRU, such as a WTRU that may be bandwidth limited and/or coverage limited, may decode and/or monitor one or more (E)PDCCH candidates in the (E)PDCCH CSS to receive a DCI that may be masked by a paging RNTI, such as P-RNTI or PCE-RNTI. One or more (E)PDCCH candidates may be transmitted in a time and/or frequency location known to a WTRU that may monitor or may need to monitor or receive the (E)PDCCH

candidates. CSS may be used as a non-limiting example of a search space. The time and/or frequency location of the (E)PDCCH CSS and/or (E)PDCCH candidate or candidates and/or one or more parameters that may enable monitoring and/or decoding of the (E)PDCCH CSS and/or (E)PDCCH candidate or candidates may be provided or configured via signaling, such as broadcast signaling that may be received and/or used by the WTRU. Another search space may be used and may be consistent with the disclosed subject matter.

[0396] Candidates, resources, and PRBs, such as (E)PDCCH candidates, (E)PDCCH resources, and (E)PDCCH PRBs may be used interchangeably or substituted for each other and still be consistent with this disclosure. PRBs and RBs may be used interchangeably.

[0397] The term (E)PDCCH may represent EPDCCH and/or PDCCH. The term (E)CCE may represent a control channel element (CCE) and/or an enhanced control channel element (ECCE).

[0398] An (E)PDCCH candidate may be, may have, and/or may include a combination of an (E)CCE aggregation level and a number of repetitions. For example, an (E)PDCCH candidate may include the (E)CCE aggregation level N_{AL} and the number of repetitions N_{REP}. A total aggregation level (TAL) may correspond to a total number of (E)CCEs that may belong to an (E)PDCCH candidate. The number of (E)CCEs for the total aggregation level N_{TAL} may be determined as a function of N_{AL} and N_{REP}. For example, N_{TAL} may be the product of N_{AL} and N_{REP}.

[0399] An (E)PDCCH candidate that may have a larger total aggregation level (N_{TAL}) may support a higher CE level than an (E)PDCCH candidate that may have a smaller total aggregation level. A higher CE level may provide more or better coverage enhancement than a lower CE level. For example, a higher CE level may provide better signal strength at a receiver than a lower CE level.

[0400] Two or more (E)PDCCH candidates may be configured with a different total aggregation level, for example, to support two or more CE levels. A WTRU may monitor and/or decode a subset of the (E)PDCCH candidates that may be configured. The subset may include one or more (*e.g.*, all) of the (E)PDCCH candidates that may be configured. A WTRU may monitor and/or decode an (E)PDCCH candidate to receive a DCI that may be masked with an RNTI, such as a paging RNTI.

[0401] A WTRU may monitor and/or decode one or more, *e.g.*, all, (E)PDCCH candidates that may be configured, regardless of a CE level used, configured, and/or determined for or by the WTRU.

[0402] For (E)PDCCH candidate monitoring, the WTRU may start from an (E)PDCCH candidate with a first, *e.g.*, smallest total aggregation level. The WTRU may move to an (E)PDCCH candidate with a second, *e.g.*, larger total aggregation level if the WTRU does not receive a DCI that may be masked with a paging RNTI in the first total aggregation level. The WTRU may move or continue to move to another, *e.g.*, larger total aggregation level until it reaches a maximum total aggregation level if the WTRU does not receive a DCI that may be masked with a paging RNTI in a total aggregation level (*e.g.*, a certain total aggregation level). The WTRU may stop monitoring (E)PDCCH candidates and may not move to a next or another total aggregation level if the WTRU receives a DCI that may be masked with a paging RNTI in a total aggregation level, *e.g.*, a certain total aggregation level.

[0403] A WTRU may monitor a subset of (E)PDCCH candidates configured based on the CE level used, configured, and/or determined for or by the WTRU. A paging RNTI that may be associated with a certain subset of (E)PDCCH candidates may be determined based on the CE level. A WTRU may monitor and/or decode one or more (E)PDCCH candidates in the subset of (E)PDCCH candidates to receive a DCI that may be masked with the paging RNTI associated with the CE level used, configured, and/or determined for or by the WTRU.

[0404] The WTRU may determine and/or use a first CE level or a number of repetitions for monitoring and/or decoding an (E)PDCCH candidate, for example, to receive a DCI that may be a paging DCI or a DCI that may be masked by a paging RNTI. The WTRU may determine and/or use a second CE level or number of repetitions for reception of a PDSCH that may carry a paging channel or paging message or paging information. A CE level may be associated with or configured to correspond to a number of repetitions, for example, via signaling from an eNB, such as via broadcast signaling. CE level and number of repetitions may be used interchangeably. The first and second CE levels may be the same or different. The first and/or second CE levels may be determined by the WTRU.

[0405] A WTRU may determine a CE level or CE levels (*e.g.*, the first and/or second CE levels), which may be used or configured for or by the WTRU, for example, for one or more aspects of paging reception. For example, a WTRU may determine one or more CE levels (*e.g.*, for one or more aspects of paging reception) based on a latest or most recent CE level used by or known to the WTRU and/or based on one or more of known, measured, and/or signaled values or information. The determined CE level (or levels) may be specific to paging (*e.g.*, to one or more aspects of paging reception) or may be applicable to other procedures or purposes rather than or in addition to paging (or paging reception). Paging reception aspects may include, but are not limited to, one or more of: monitoring and/or decoding one or more (E)PDCCH candidates,

receiving a paging DCI, and/or receiving a PDSCH carrying a paging channel or paging message or paging information.

[0406] A CE level that may be determined and/or used by the WTRU (*e.g.*, for at least one or more aspects of paging reception) may be or may be based on the latest CE level stored at an MME for the WTRU. The CE level for the WTRU may be signaled from an eNB, such as the serving eNB of the WTRU to the MME. The CE level that may be determined and/or used by the WTRU may be (or may be based on) the latest CE level used (*e.g.*, by the WTRU) for a successful reception of a DCI that may be masked with one or more of a paging RNTI, a system information RNTI, and/or a RA-RNTI, or the like. The CE level that may be determined and/or used by the WTRU may be (or may be based on) the latest CE level used (*e.g.*, by the WTRU) for a successful reception of a DL channel (*e.g.*, from its serving cell or the cell on which it is camped), such as a PDSCH carrying broadcast information (*e.g.*, a SIB), a PDSCH carrying a paging channel or paging message or paging information, a PDSCH carrying a RAR, and/or PBCH.

[0407] A CE level that may be determined and/or used by the WTRU (*e.g.*, for at least one or more aspects of paging reception) may be (or may be based on) the CE level associated with a downlink measurement (*e.g.*, RSRP and/or RSRQ), for example, made by the WTRU. The downlink measurement may be or correspond to a current or most recent downlink measurement. The measurement may be a filtered measurement.

[0408] A CE level that may be determined and/or used by the WTRU (*e.g.*, for at least one or more aspects of paging reception) may be (or may be based on) a CE level that may be indicated from broadcast signaling and/or a broadcasting channel, *e.g.*, SIB, MTC-SIB, LC-SIB, MIB, and/or PBCH. For example, the CE level that may be determined and/or used by the WTRU may be (or may be based on) a paging CE level (*e.g.*, a CE level for paging) that may, for example, be indicated from broadcast signaling and/or a broadcasting channel, *e.g.*, SIB, MTC-SIB, LC-SIB, MIB, and/or PBCH. The broadcast CE level may be used (*e.g.*, for paging) for and/or by some or all WTRUs. For example, the broadcast CE level may be used (*e.g.*, for paging) for and/or by one or more of: one or more (*e.g.*, all) WTRUs in CE mode, one or more (e.g., all) WTRUs that support CE mode, one or more (*e.g.*, all) WTRUs of a certain WTRU type or category (*e.g.*, low cost WTRU), and/or one or more (*e.g.*, all) WTRUs that have a certain capability or reduced capability (*e.g.*, reduced bandwidth WTRU).

[0409] A CE level that may be determined and/or used by the WTRU (*e.g.*, for at least one or more aspects of paging reception) may be (or may be based on) the maximum CE level supported by the cell from which the WTRU may receive paging (*e.g.*, the cell on which the

WTRU may be camped in idle mode). The maximum CE level supported by the cell may be provided in signaling, such as broadcast signaling (*e.g.*, SIB, MIB, and/or PBCH). The WTRU may receive and/or use the signaling to determine the maximum CE level and/or the CE level for paging.

[0410] The WTRU may use the determined CE level to determine the number of aggregation levels and/or the number of repetitions to use for one or more (E)PDCCH candidates that the WTRU may monitor and/or decode to receive a paging DCI. The WTRU may monitor and/or decode one or more (E)PDCCH candidates according to the determined number of aggregation levels and/or the number of repetitions, for example, to receive a paging DCI.

[0411] One or more (E)PDCCH candidates may be configured with a total aggregation level, *e.g.*, a same total aggregation level. The total aggregation level may correspond to a CE level, *e.g.*, a maximum CE level supported in the cell, such as the maximum CE level supported in the cell for paging.

[0412] The time and/or frequency location of the (E)PDCCH candidate or candidates may be known to a WTRU, such as a WTRU that may support enhanced coverage mode and/or that may be in enhanced coverage mode. For example, the configuration of the (E)PDCCH candidate or candidates may be signaled from broadcast signaling and/or a broadcasting channel (*e.g.*, MIB and/or MTC-SIB).

[0413] Enhanced coverage and coverage enhanced may be used interchangeably. Enhanced coverage mode and coverage enhanced mode may be used interchangeably. Enhanced coverage level and coverage enhanced level mode may be used interchangeably.

[0414] For an (E)PDCCH candidate or candidates with M repetitions, the (E)PDCCH candidate or candidates may be transmitted and/or received in M subframes. The M subframes may be M consecutive subframes or M consecutive DL subframes. The M subframes may be M consecutive subframes within the set of subframes that may be used for paging. The subframes that may be used for paging may be signaled (*e.g.*, via broadcast signaling such as via a SIB) or known. For a WTRU, the first of the M subframes may correspond to the WTRU's Paging Occasion, which may be a function of the WTRU-ID. The WTRU may combine the M repetitions to decode the (E)PDCCH candidate or candidates. The WTRU may combine a subset of the M repetitions, *e.g.*, S repetitions or the first S of the M repetitions, to decode the (E)PDCCH candidate or candidates. The WTRU may combine repetitions until it successfully decodes the (E)PDCCH candidate or candidates or until it combines all M repetitions. If the WTRU combines all M repetitions and does not successfully receive a DCI (*e.g.*, for paging), the WTRU may determine there is no page or no page for the WTRU, for example, for the current

paging cycle. If the WTRU successfully receives the DCI, the WTRU may receive or may attempt to receive the corresponding PDSCH, which may carry a paging message. Reception of a PDSCH may include receiving and/or combining repetitions of the PDSCH.

[0415] The frequency location of the (E)PDCCH candidate or candidates for paging may be determined as a function of one or more of a WTRU-ID (*e.g.*, IMSI) and/or a physical cell ID (PCI).

[0416] The frequency location of the (E)PDCCH candidate or candidates for paging may be determined as a function of the configuration of one or more downlink subbands, which may be configured for LC-MTC and/or enhanced coverage. A subband may correspond to a set of consecutive PRBs (*e.g.*, six consecutive PRBs) located within a system bandwidth. When multiple subbands are configured, the subbands may be partially or fully overlapped. The subbands may be mutually orthogonal in the frequency domain. One or more subbands may be used for an (E)PDCCH candidate or candidates for paging. The subband that may be used for or by a WTRU may be a function of one or more of WTRU-ID, PCI, and/or DL system bandwidth.

[0417] Subband configuration, *e.g.*, for an (E)PDCCH candidate or candidates and/or PDSCH for paging may be provided (*e.g.*, by a cell or eNB) in signaling such as broadcast signaling, for example in system information (*e.g.,* in one or more SIBs).

[0418] A WTRU may determine a subband to use for an (E)PDCCH candidate or candidates and/or PDSCH for paging from one or more of a subband configuration provided, a number of subbands configured, paging cycle, PF, PO, SFN, PCI, DL system bandwidth, and/or WTRU-ID. The WTRU may determine the subband to use for a PO, a starting subframe of a PO, and/or a subframe corresponding to a repetition of an (E)PDCCH candidate and/or PDSCH of a PO. The frequency location of the (E)PDCCH candidate or candidates for paging may be predefined or known. A certain subband index (*e.g.*, the first subband) may be used for an (E)PDCCH candidate or candidates for paging if one or more downlink subbands are configured. A starting PRB index for the paging subband may be defined or determined as a function of one or more of downlink system bandwidth, subframe number, frame number, physical cell ID, and/or WTRU-ID. WTRU-ID may be a WTRU IMSI.

[0419] For purposes of description and explanation, the terms paging channel, paging message, and paging information may be used interchangeably.

[0420] A PDSCH may carry a paging message. A PDSCH carrying a paging message (*e.g.*, PCH) for a WTRU that supports or that may be in enhanced coverage mode may be scheduled from an associated (E)PDCCH. A WTRU may monitor or decode a DCI that may be masked with a paging RNTI from the associated (E)PDCCH. The paging message may be intended for a

single WTRU or multiple WTRUs. The paging message may include a system information modification indication. The DCI may include the system information modification indication. For example, a bit or bit field in the DCI may indicate whether the system information has been changed or will be changed (*e.g.*, at the start of the next system information modification period). The bit or bit field may be or include an indication of yes or no or an indication of true or false. The bit field may be or may be used for a value tag, *e.g.*, systemInfoValueTag.

[0421] The DCI may carry one or more of the following information. The DCI may carry a frequency location of the PDSCH (*e.g.*, subband index or starting PRB). The DCI may carry a time location of the PDSCH (*e.g.*, a starting subframe location). The DCI may carry TBS or TBS candidates. The DCI may carry a modulation order. The DCI may carry the repetition number of the associated PDSCH (*e.g.*, P).

[0422] A WTRU may decode and/or receive the PDSCH if the WTRU receives a DCI that may be masked with a paging RNTI. The paging RNTI may be intended for the WTRU. A paging RNTI may be intended for a WTRU if it is intended for a WTRU or WTRUs of a certain type and the WTRU is of that type. For example, the paging RNTI may be intended for WTRUs supporting or in coverage enhanced mode.

[0423] A paging RNTI, for example, for a WTRU of a certain type, may be a function of one or more of a paging cycle, PF, PO, the number of POs per PF, SFN, WTRU-ID, and/or the number of repetitions that may be used for the (E)PDCCH candidates for paging. This may enable repetitions of a DCI beginning in the subframe of a first PO to be repeated in the subframe of a second PO (*e.g.*, in the same frame) without confusing WTRUs that may be looking for a DCI beginning in the second PO.

[0424] The PDSCH may be transmitted repetitively over multiple subframes (*e.g.*, P subframes). The P subframes may be continuous or consecutive within the subframes used for paging transmission. The P subframes may be discontinuous within the subframes used for paging transmission.

[0425] One or more P values may be used to support one or more CE levels. For example, P = {N1, N2, N3} may be used, where P values are positive integer numbers and N1 < N2 < N3. A different P value may be used according to the CE level. The P values may be predefined, *e.g.*, for each CE level supported by the cell. The P values, *e.g.*, for each CE level supported by the cell, may be indicated from a broadcasting channel (*e.g.*, SIB). The CE level or the P value that may be used for transmission of the PDSCH carrying a paging message may be indicated from (or by) the associated (E)PDCCH (*e.g.*, in the DCI). Three values of P are used for exemplary purposes. Another value may be used and still be consistent with this disclosure.

[0426] A starting subframe for a PDSCH carrying a paging message, for example, in a paging cycle or corresponding to a PO, may be the same regardless of the P value. For example, the PDSCH with P = N1 and the PDSCH with P = N2 may have the same starting subframe. The end subframe may be different.

[0427] A WTRU may start to receive the PDSCH with a smallest P value (*e.g.*, N1) and may move to a next level (*e.g.*, a next highest P value, N2) if the WTRU fails to receive the PDSCH carrying the paging message until it may reach a maximum P value (*e.g.*, N3). The WTRU may stop combining repetitions if it successfully receives the PDSCH prior to combining all P repetitions of a level (*e.g.*, N1, N2, or N3).

[0428] A WTRU may receive the PDSCH with a corresponding P value indicated from the associated (E)PDCCH. A WTRU may receive the PDSCH by combining repetitions up to the P value indicated from the associated (E)PDCCH. The WTRU may stop combining repetitions if it successfully receives the PDSCH prior to combining all P repetitions. A WTRU may receive the PDSCH with a P value associated with a current CE level, which may be determined based on a downlink measurement.

[0429] Each P value may be associated with a certain (*e.g.*, separate, unique, or different) paging RNTI. A WTRU may implicitly determine the P value from the paging RNTI when the WTRU receives a DCI that may be masked with a certain paging RNTI. For example, a first P-RNTI may be associated with a first P value (*e.g.*, N1) and a second P-RNTI may be associated with a second P value (*e.g.*, N2), and so on. When checking for a page, *e.g.*, in a PO or its PO, a WTRU may check for a CRC scrambled with one or more of the P-RNTIs. If such a CRC is found, the WTRU may use that P-RNTI to determine the P value with which the PDSCH may be transmitted. The association may be between a P-RNTI and a CE level. The CE level may be associated with the P value. One or more of the associations may be predefined, known, or provided in signaling, such as broadcast signaling. The paging RNTI for each CE level for paging may be a function of the number of CE levels (or the maximum CE level) supported by the eNB or cell. The WTRU may determine the paging RNTI for each CE level based on the number of CE levels (or the maximum CE level) supported by the eNB or cell which may be provided via broadcast signaling such as in a MIB (*e.g.*, PBCH) or SIB.

[0430] A starting subframe of a PDSCH carrying a paging message (*e.g.*, if the PDSCH is transmitted over P subframes repetitively) may be determined as a function of the last subframe of the associated (E)PDCCH. For example, if the last subframe of the associated (E)PDCCH is the subframe n, the starting subframe may be the subframe n+k, where k may be, for example, a gap value G. The subframe n may be the last subframe of a certain (E)PDCCH candidate. If a

different number of repetitions is used for two or more (E)PDCCH candidates, the subframe n may be different according to the (E)PDCCH candidate. The subframe n may be the last subframe of an (E)PDCCH candidate that may have a largest number of repetitions. The value of n may be the same regardless of the (E)PDCCH candidate in which a WTRU may receive a DCI that may be masked with a paging RNTI or that may carry a scheduling information of the PDSCH. The value of k may be determined based on the (E)PDCCH candidate and/or the number of repetitions for an (E)PDCCH candidate.

[0431] (E)PDCCH carrying a DCI masked or scrambled with a P-RNTI that may be intended for a WTRU that may be in CE mode may be transmitted with M repetitions. The value of M may be independent of the CE level of the WTRU. The WTRU may combine one or more repetitions of the EPDCCH up to the maximum of M repetitions to attempt to receive a DCI scrambled with a P-RNTI, *e.g.*, beginning in its PO. The DCI may implicitly or explicitly identify the number of repetitions, P, with which the PDSCH carrying the PCH may be transmitted. If the WTRU successfully receives the DCI, the WTRU may receive and/or may combine up to P repetitions of the PDSCH to receive the page. If the WTRU successfully receives the page and the page is intended for the WTRU (or the WTRU determines that a page intended for the WTRU is included in the paging message), the WTRU may respond, for example, by performing a random access procedure and/or requesting connection establishment for an incoming call. If the WTRU does not successfully receive the DCI, the WTRU may assume there is no page for the WTRU and the WTRU may sleep, for example, until its next PO. If the WTRU successfully receives the DCI and the value of P is lower than what the WTRU determines it needs to receive the PDSCH, the WTRU may not attempt to receive the PDSCH, for example, in order to save battery power. If the WTRU successfully receives the DCI and does not successfully receive the PDSCH after combining the P repetitions, the WTRU may determine its CE level to be higher than that which uses P repetitions and may save that information for use for a next or later PO.

[0432] A WTRU, such a WTRU in coverage enhancement mode, may receive (E)PDCCH carrying a DCI masked or scrambled with an RNTI such as a paging RNTI (*e.g.*, P-RNTI, PCE-RNTI, or another RNTI). The DCI may include an indication that system information (*e.g.*, one or more SIBs) has changed or will change. The indication may be in the form of a bit or bit field. The indication may have a value of True to indicate system information has changed or will change. The indication may be, for example, in the form of a value or a value tag that the WTRU may compare to a previously stored value or value tag. If the value or value tag is different from the previous or stored value tag, the WTRU may understand or infer that one or more SIBs has

changed or will change. If the DCI includes an indication (*e.g.*, a positive indication) regarding or related to system information change, there may not be a PDSCH associated with the DCI and/or the WTRU may not receive or attempt to receive a PDSCH that may be associated with the DCI. The WTRU may receive one or more SIBs (*e.g.*, after the start of the next SIB modification period) to acquire the updated system information, for example, if the indication indicates that system information has been or will be updated.

[0433] If the DCI (*e.g.*, DCI for paging and/or system information update) positively indicates a system information change (*e.g.*, has occurred or will occur), there may be no PDSCH associated with the DCI. If the DCI (*e.g.*, DCI for paging and/or system information update) does not indicate a (*e.g.*, any) system information change or indicates no system information change, there may be a PDSCH associated with the DCI.

[0434] A DCI or DCI format may be used to page or address one or more WTRUs and/or indicate that system information has been or will be updated. The update may occur at or before the start of the next system information modification period. The DCI format may be transmitted with or without an associated PDSCH that may carry a paging message or paging information. The DCI format may include an indication as to whether or not there may be an associated PCH or PDSCH. If the DCI format indicates that there is no associated PCH or PDSCH, one or more (*e.g.*, all) the parameters related to the PDSCH, *e.g.*, the scheduling parameters for the PDSCH, may not be included in the DCI or the parameters may be fixed values (*e.g.*, zeroes) or ignored. The DCI format may be carried by a PDCCH or EPDCCH which may be in CSS. For purposes of illustration and description, DCI and DCI format may be used interchangeably. The DCI format for system information update (*e.g.*, system information update without a paging message or WTRU-specific paging message or record) may be separate or different from the DCI format for paging (*e.g.*, for paging with an associated PCH or PDSCH).

[0435] A WTRU that receives the DCI format may receive or may attempt to receive an associated PDSCH if (*e.g.*, only if) the DCI format indicates an associated PDSCH (*e.g.*, that may carry a paging message) and/or the DCI format corresponds to a DCI format with an associated PDSCH (*e.g.*, that may carry a paging message).

[0436] The DCI format may be intended for use by and/or may be used by WTRUs in connected mode and/or idle mode. The DCI format may be intended for use by and/or may be used by WTRUs that may be in coverage enhanced mode and/or that may be reduced bandwidth WTRUs. The control channel (*e.g.*, PDCCH and/or EPDCCH) that may carry the DCI format and/or the DCI format may be repeated M-SI times or up to M-SI times. The value of M-SI may correspond to the maximum CE level supported by the cell. The value of M-SI may be provided

in broadcast signaling such as system information, *e.g.*, in a SIB which may be intended for use by and/or may be used by WTRUs which may be in coverage enhanced mode and or which may be reduced bandwidth WTRUs. The value of M-SI may be separate from and/or different from the number of repetitions that may be used for a DCI that may be for paging and/or may not indicate a system information update. The value of M-SI may be chosen by the eNB to correspond to the highest CE level (or number or repetitions) that may be needed by its connected mode WTRUs. A WTRU may combine up to M-SI repetitions to receive or successfully receive the DCI format.

[0437] The DCI format may include one or more system information update indications. A system information update indication may indicate update of one or more of: SIBs or system information that may be associated with a value tag; SIBs or system information that may be associated with ETWS; SIBs or system information that may be associated with CMAS; and/or SIBs or system information that may be associated with EAB parameters.

[0438] The CRC of a DCI format that may include one or more system information update indications (*e.g.*, one or more positive indications or one or more indications set to yes or true) may be scrambled with an RNTI that may be different from an RNTI that may be used to scramble the CRC of a DCI format that may not include a system information update indication (*e.g.*, a positive indication or an indication set to yes or true).

[0439] There may be a separate DCI format and/or RNTI for system information update indications to idle mode WTRUs and connected mode WTRUs.

[0440] The RNTI for a DCI format for system information update may be different from the RNTI for a DCI format for paging (*e.g.*, WTRU-specific paging). A separate or different RNTI may be provided and/or used for one or more of a DCI format for system information update, *e.g.*, only; a DCI format for positive system information update and paging (*e.g.*, indicating associated paging PDSCH); and/or a DCI format for paging (*e.g.*, indicating associated paging PDSCH) without a system information update or positive system information update. A WTRU may monitor for one or more of the RNTIs, *e.g.*, in or according to its PO.

[0441] The schedule for a PDCCH, EPDCCH, and/or DCI format that may carry a system information update indication may be separate from the schedule for a PDCCH, EPDCCH, and/or DCI format associated with paging messages. AWTRU may determine a PO per PC to monitor for paging messages. A WTRU may determine and/or may use another schedule for monitoring for system information updates. The occasions for system information updates may be referred to as system information update occasions (SIUOs). An idle mode WTRU may monitor its PO for paging messages (*e.g.*, for the PDCCH, EPDCCH, DCI format, and/or

PDSCH for paging messages). An idle mode and/or connected mode WTRU may monitor SIUOs for system information updates. SIUOs for idle and connected mode WTRUs may be different. A WTRU may monitor for an RNTI for paging in its PO. A WTRU may monitor for an RNTI for system information update in a SIUO. When a PO and SIUO coincide, a WTRU may monitor for a paging and/or a system information update RNTI.

[0442] Following receipt of a system information update indication, a WTRU may acquire the associated system information or one or more SIBs. For some SIBs, *e.g.*, value tag SIBs, the WTRU may wait until the start of the next system information modification period to acquire the SIBs.

[0443] A DCI format may be transmitted by the eNB and/or received by the WTRU in PDCCH or EPDCCH.

[0444] System information and/or a paging configuration may be updated. Configuration information for and/or related to paging may be carried in or at least in a broadcast signaling channel and/or system information, such as in a SIB, *e.g.*, MTC-SIB. Configuration information, for example, for paging, may include configuration information for an (E)PDCCH that may be used to carry a scheduling information of a PDSCH that may carry a paging message. Configuration information, for example, for paging, may include the number of repetitions M for an (E)PDCCH that may be used to carry a scheduling information of a PDSCH that may carry a paging message. Configuration information, for example for paging, may include one or more parameters that may be used for (E)PDCCH and/or PDSCH reception, for example, for paging. Configuration information may include, but is not limited to, a CE level, a maximum CE level, a number of repetitions, and/or a maximum number of repetitions. Configuration information, for example, for paging, may include PDSCH configuration and/or one or more P values that may be used for reception of PDSCH, which may carry a paging message.

[0445] An MTC-SIB may be transmitted and/or may be used if the PBCH or MIB indicates the support of low-cost WTRU and/or enhanced coverage WTRU. There may be one or more MTC-SIBs. An MTC-SIB may be intended for, received by, and/or used by one or more WTRUs that may be a certain type of WTRU. The certain type may be one or more of: MTC-WTRU, LC-MTC-WTRU, reduced BW WTRU, a WTRU supporting coverage enhancements, and/or a WTRU in coverage enhanced mode.

[0446] A first MTC-SIB (*e.g.*, MTC-SIB-0) may be transmitted in a known or determined time and/or frequency location. The time and/or frequency location may be determined, *e.g.*, by the WTRU, based on at least one or more of the system parameters acquired from MIB (*e.g.*, SFN, DL system bandwidth) and/or physical cell-ID.

[0447] The first MTC-SIB (*e.g.*, MTC-SIB-0) may carry an indication of system information modification (*e.g.*, systemInfoValueTag). The first MTC-SIB may carry one or more of the following for the second MTC-SIB (and/or subsequent MTC-SIB(s)): (i) scheduling information (*e.g.*, schedule in time), (ii) a TBS size, (iii) a modulation order, (iv) a repetition cycle (or CE level or repetition number), and/or (v) a frequency location.

[0448] The first MTC-SIB may have one or more properties, for example the first MTC-SIB may have a fixed TBS size. A zero-padding may be used if the actual payload size is smaller than the fixed TBS size. The first MTC-SIB may have a fixed modulation order. For example, QPSK may be used. The first MTC-SIB may be used for system information modification indication and scheduling information for the subsequent (*e.g.*, second) MTC-SIB. For example, the first MTC-SIB may only be used for system information modification indication and scheduling information for the subsequent MTC-SIB. The first MTC-SIB may be transmitted periodically.

[0449] A WTRU, such a WTRU in coverage enhancement mode, may receive the first MTC-SIB, for example, if the WTRU needs to check whether the system information has been or will be updated before it monitors or receives the paging signals. If the first MTC-SIB indicates that the system information has been updated or will be updated prior to the WTRU's PO, the WTRU may receive the subsequent MTC-SIBs (*e.g.*, after the start of the next SIB modification period) to acquire the updated system information, for example, at least related to the paging configuration. If the WTRU cannot acquire the SIBs, *e.g.*, at least the SIBs related to paging, prior to its PO, the WTRU may skip monitoring its PO for paging (*e.g.*, skip monitoring (E)PDCCH for paging), for example, until after it successfully receives the SIBs.

[0450] Techniques for reuse of the P-RNTI (*e.g.*, legacy P-RNTI) may be provided. For example, there may be limited space in CSS, which may make it difficult to page WTRUs (*e.g.*, legacy WTRUs and CE mode WTRUs).

[0451] P-RNTI may be used for CE paging and non-CE paging, for example, without overlap or collision when paging coverage limited WTRUs and non-coverage limited WTRUs.

[0452] PDCCH that may be associated with PDSCH that may carry PCH may be transmitted and/or received in a common search space (CSS). A WTRU may monitor for P-RNTI in CSS.

[0453] PDCCH for CE mode WTRUs may be repeated M times. The same PDCCH may be repeated for one or more of the M times. The same PDCCH may be repeated for each of the M times. One or more (*e.g.*, and possibly all) of the repetitions may be located in the same place, *e.g.*, the same place in the CSS. There may be a gap G that may follow the PDCCH repetitions.

The corresponding PDSCH may follow after the gap and may be repeated P times. P and M may be the same or different values.

[0454] A PDCCH may grant or point to one or more PDSCHs (*e.g.*, in a current or future subframe) which may carry PCH with a certain location and/or with certain parameters or properties (*e.g.*, MCS, *etc.*). A current subframe may be the same subframe as the PDCCH providing the grant. A future subframe may be a subframe after or later than the subframe of the PDCCH providing the grant.

[0455] In the M subframes in which the PDCCH may be transmitted, there may or may not be a corresponding PDSCH. A CE mode WTRU may not look for a PDSCH until after the M repetitions of the PDCCH and after it may successfully receive the PDCCH from combining the (*e.g.*, M) PDCCH repetitions. A non-CE mode and/or legacy WTRU, however, may look for a corresponding PDSCH in one or more (*e.g.*, each) of the M subframes in which there may be a P-RNTI. The PDSCH in these subframes may be used to page non-CE mode and/or legacy WTRUs according to non-CE mode and/or legacy rules. The PDSCHs (*e.g.*, all the PDSCHs) in these subframes may have the same location and parameters. The PDSCHs in these subframes may have the same location and parameters as the PDSCHs that may be repeated P times for a CE mode WTRU after the gap.

[0456] In the subframes of the gap and the P PDSCH subframes for the CE mode WTRU, the CE mode WTRU may not look for or expect a P-RNTI. P-RNTI may be used in those subframes for non-CE mode and/or legacy WTRUs. A PDCCH that may use P-RNTI in those subframes may be used in a non-CE mode and/or legacy manner. In those subframes, the PDCCH that may use P-RNTI may change from subframe to subframe and the PDCCH may point to a PDSCH in a different location and/or with different parameters. The PDCCH that may use P-RNTI in those subframes may not point to a PDSCH in a location that may overlap a PDSCH that may be used by or for CE mode WTRUs.

[0457] A DRX cycle may be provided and/or used. A DRX cycle may not be suitable or sufficient for CE mode WTRUs. DRX and paging cycle may be used interchangeably.

[0458] The DRX or paging cycle for a CE mode WTRU may be the longer of a WTRU specific signaled value and a default value such as the legacy default value. The DRX or paging cycle for a CE mode WTRU may be a CE mode DRX value, which may be cell-specific and may be provided in broadcast signaling, such as system information. The DRX or paging cycle for a CE mode WTRU may be the shorter or longer of a WTRU specific signaled value (*e.g.*, which may be specific to CE mode) and a cell specific value. The DRX or paging cycle for a CE mode WTRU may be independent of WTRU ID and/or IMSI.

[0459] The DRX or paging cycle for CE mode WTRUs may be a function of one or more of the default DRX or paging cycle (*e.g.*, a multiple of it); the legacy DRX or paging cycle (*e.g.*, a multiple of it); the CE level; and/or the number of repetitions of the paging PDCCH and/or PDSCH (*e.g.*, M and/or P) and or the gap (*e.g.*, G) between them.

[0460] Paging may be provided for and/or used by WTRUs that may be bandwidth limited. An eNB that may page or that may intend to page a WTRU may or may not know that the WTRU may be a limited bandwidth WTRU and may or may need to page the WTRU in a way in which the WTRU may receive the page.

[0461] An eNB that may support limited bandwidth WTRUs may or may always page certain WTRUs (*e.g.*, all WTRUs or limited bandwidth WTRUs) in a bandwidth in which limited bandwidth WTRUs may receive the PDSCH (*e.g.*, in or within N RBs such as the center N RBs, where N may be 6).

[0462] For paging a WTRU, such as one that may be a limited bandwidth WTRU, an eNB may use an EPDCCH for the control channel associated with a paging PDSCH (*e.g.*, a PDSCH that may carry PCH), for example, since a PDCCH may not (or may not be able to) be located in a limited bandwidth.

[0463] An eNB, for example one that may not know if a WTRU it may page or intend to page may be a limited bandwidth WTRU, may page the WTRU using PDCCH (*e.g.*, which may not be in a limited bandwidth) and EPDCCH (which may be in a limited bandwidth). The PDCCH and the EPDCCH may be associated with the same PDSCH and the grant that the PDCCH and/or EPDCCH may provide may be the same with respect to at least some (*e.g.*, all) parameters such as one or more of the grant size (*e.g.*, in RBs), grant location, and MCS, among others.

[0464] The PDCCH may be masked with P-RNTI or another paging RNTI that may be used by at least limited bandwidth WTRUs. The EPDCCH may be masked with P-RNTI or another paging RNTI that may be used by at least limited bandwidth WTRUs.

[0465] A WTRU that may be bandwidth limited may monitor EPDCCH in its PO. If the WTRU may receive (*e.g.*, successfully receive) an EPDCCH that may be masked with P-RNTI or a (*e.g.*, another) paging RNTI that may be used by at least limited BW WTRUs, the WTRU may receive or attempt to receive the associated (*e.g.*, granted) PDSCH that may carry PCH. If the PCH may include a page for the WTRU, the WTRU may respond to the page.

[0466] For a WTRU which may be both coverage limited and bandwidth limited, the eNB may apply one or more of the examples disclosed herein for paging a WTRU that may be coverage limited where the PDSCH repetitions which may carry the PCH and/or the associated

EPDCCH repetitions may be located within the limited bandwidth, which may be received by a limited bandwidth WTRU.

[0467] If an eNB may not know if a WTRU may be reduced BW, the eNB may try paging the WTRU as a full bandwidth WTRU one or more times and if unsuccessful may then try to page the WTRU as a limited bandwidth WTRU.

[0468] Paging a WTRU as a full bandwidth WTRU may include using PDCCH for the control channel (*e.g.*, which may be masked with P-RNTI or another paging RNTI), which may be associated with a PDSCH which may carry PCH.

[0469] Paging a WTRU as a limited bandwidth WTRU may include paging the WTRU in accordance with one or more of the examples disclosed herein for limited bandwidth WTRUs such as using EPDCCH and/or limiting the EPDCCH and/or paging PDSCH to locations within the limited bandwidth.

[0470] One or more examples described herein for RAR transmission and/or reception may be applied to PCH transmission and/or reception, for example, for PCH that may be or may be intended for a WTRU that may be bandwidth limited and/or coverage limited.

[0471] An eNB may page a WTRU that may be bandwidth limited and/or coverage limited without the use of a control channel, such as PDCCH or EPDCCH.

[0472] The POs and/or PFs in which a paging PDSCH (*e.g.*, one that may carry PCH) may be located may be known (*e.g.*, by calculations and/or parameters such as legacy and/or new calculations and/or parameters). The grant parameters for the paging PDSCH may be known (*e.g.*, fixed or signaled). Paging PDSCH for limited bandwidth WTRUs may be less often than paging PDSCH for full bandwidth WTRUs.

[0473] In a subframe or PO that may include a PCH intended for a WTRU that may be a bandwidth limited and/or coverage limited WTRU, the WTRU may attempt to receive a paging PDSCH using the known location and/or parameters. The WTRU may determine if it may receive the paging PDSCH successfully based on the CRC of the PDSCH. If the WTRU may successfully receive a PCH that it may determine to be intended for it, the WTRU may respond to the page.

[0474] For a WTRU that may be in CE mode, the WTRU may combine multiple repetitions of the paging PDSCH, which may be in the same location (*e.g.*, in at least frequency resources) and may use the same parameters for one or more (*e.g.*, each) of its repetitions, before attempting to successfully receive the PCH from the PDSCHs. For a WTRU that may be in CE mode but may not be bandwidth limited, the location of the PDSCHs may not be limited to being in or within the limited bandwidth. For a WTRU that may be bandwidth limited or that may behave

like a bandwidth limited WTRU, the location of the PDSCHs may be limited to being in or within the limited bandwidth.

[0475] A location (*e.g.*, time and/or frequency resources) of a PDSCH that may be used for paging and/or parameters (*e.g.*, coding/decoding parameters such as MCS) of the PDSCH may be signaled by the eNB to the WTRU using dedicated signaling and/or broadcast signaling (*e.g.*, in system information or in one or more SIBs). The location (*e.g.*, time and/or frequency resources) and/or certain parameters may be fixed or known (*e.g.*, by specification).

[0476] The processes and instrumentalities described herein may apply in any combination, may apply to other wireless technologies, and for other services.

[0477] A WTRU may refer to an identity of the physical device, or to the user's identity such as subscription related identities, *e.g.*, MSISDN, SIP URI, *etc.* WTRU may refer to application-based identities, *e.g.*, user names that may be used per application.

[0478] The processes described above may be implemented in a computer program, software, and/or firmware incorporated in a computer-readable medium for execution by a computer and/or processor. Examples of computer-readable media include, but are not limited to, electronic signals (transmitted over wired and/or wireless connections) and/or computer-readable storage media. Examples of computer-readable storage media include, but are not limited to, a read only memory (ROM), a random access memory (RAM), a register, cache memory, semiconductor memory devices, magnetic media such as, but not limited to, internal hard disks and removable disks, magneto-optical media, and/or optical media such as CD-ROM disks, and/or digital versatile disks (DVDs). A processor in association with software may be used to implement a radio frequency transceiver for use in a WTRU, UE, terminal, base station, RNC, and/or any host computer.

CLAIMS

What is Claimed:

1. A method for providing communication in a network, the method comprising:

transmitting a preamble using a physical random access channel (PRACH);

determining a location of a random access response (RAR) based on a parameter of the PRACH, the location comprising at least one of a subframe or a frequency resource on which the RAR is transmitted; and

receiving the RAR at the determined location.

2. The method of claim 1, further comprising selecting a PRACH resource based on a coverage enhancement (CE) level.

3. The method of claim 2, receiving the RAR being performed within a response window determined as a function of the CE level.

4. The method of claim 1, further comprising determining a number of repetitions of the RAR based on the parameter of the PRACH.

5. The method of claim 1, the parameter of the PRACH comprising at least one of a subframe, a frequency resource on which the PRACH is transmitted, or the preamble.

6. The method of claim 5, the frequency resource on which the PRACH is transmitted comprising at least one resource block (RB).

7. The method of claim 1, the frequency resource on which the RAR is transmitted comprising at least one resource block (RB).

8. The method of claim 1, further comprising:

receiving an indication to initiate a random access procedure; and

transmitting the preamble based on the received indication.

9. The method of claim 8, the indication comprising at least one of a physical downlink control channel (PDCCH) order or a coverage enhancement (CE) level.

10. The method of claim 9, further comprising selecting a PRACH resource based on the CE level, transmitting the preamble using the selected PRACH resource, and repeating the preamble transmission based on the CE level.

11. The method of claim 1, further comprising receiving a configuration that provides the relationship between the PRACH parameter and the RAR location.

12. The method of claim 11, the configuration being received in system information.

13. A method for providing communication in a network, the method comprising:

receiving a preamble using a physical random access channel (PRACH) associated with at least one of a coverage enhancement (CE) level or a CE mode of a wireless transmit/receive unit (WTRU) from which the preamble is received;

determining a location of a random access response (RAR) based on a parameter of the PRACH, the location comprising at least one of a subframe or a frequency resource on which the RAR is to be transmitted;

determining a number of repetitions of the RAR to transmit based on the CE level or CE mode; and

transmitting the RAR at the determined location with the determined number of repetitions.

14. The method of claim 13, further comprising providing CE information regarding the WTRU to at least one of an evolved node B (eNB) device or a mobility management entity (MME) device.

15. The method of claim 14, the CE information comprising at least one of the CE level, the CE mode, or a capability of the WTRU to support the CE mode.

16. The method of claim 13, further comprising receiving CE information from a mobile management entity (MME) device.

17. A wireless transmit/receive unit (WTRU) comprising:

a transceiver; and

a processor to execute instructions to cause the WTRU to

transmit a preamble using a physical random access channel (PRACH);

determine a location of a random access response (RAR) based on a parameter of the PRACH, the location comprising at least one of a subframe or a frequency resource on which the RAR is transmitted; and

receive the RAR at the determined location.

18. The WTRU of claim 17, the processor configured to select a PRACH resource based on a coverage enhancement (CE) level.

19. The WTRU of claim 17, the processor configured to determine a number of repetitions of the RAR based on the parameter of the PRACH.

20. The WTRU of claim 17, the parameter of the PRACH comprising at least one of a subframe, a frequency resource on which the PRACH is transmitted, or the preamble.

21. The WTRU of claim 20, the frequency resource on which the PRACH is transmitted comprising at least one resource block (RB).

22. The WTRU of claim 17, the frequency resource on which the RAR is transmitted comprising at least one resource block (RB).

23. An evolved node B (eNB) device comprising:

a transceiver; and

a processor to execute instructions to cause the eNB device to

receive a preamble using a physical random access channel (PRACH) associated with at least one of a coverage enhancement (CE) level or a CE mode of a wireless transmit/receive unit (WTRU) from which the preamble is received;

determine a location of a random access response (RAR) based on a parameter of the PRACH, the location comprising at least one of a subframe or a frequency resource on which the RAR is to be transmitted;

determine a number of repetitions of the RAR to transmit based on the CE level or CE mode; and

transmit the RAR at the determined location with the determined number of repetitions.

24. The eNB device of claim 23, the processor configured to cause the transceiver to provide CE information regarding the WTRU to at least one of an evolved node B (eNB) device or a mobile management entity (MME) device.

25. The eNB device of claim 24, the CE information comprising at least one of the CE level, the CE mode, or a capability of the WTRU to support the CE mode.

26. The eNB device of claim 23, the processor configured to cause the transceiver to receive CE information from a mobile management entity (MME) device.

(54) Title: METHOD FOR CSI FEEDBACK IN WIRELESS COMMUNICATION SYSTEM, AND APPARATUS THEREFOR

(54) 발명의 명칭 : 무선 통신 시스템에서 CSI를 피드백하기 위한 방법 및 이를 위한 장치

[도16]

S1610 ... Terminal capability information (first control information and/or second control information)
S1620 ... CSI action-related configuration information
S1630 ... Command measurement of fully activated CSI-RS
S1640 ... Measure fully activated CSI-RS
S1650 ... Report result of measurement
AA ... Terminal
BB ... Base station
CC ... Track partially activated CSI-RS

(57) Abstract: A method for feeding back channel state information (CSI) in a wireless communication system, carried out by a terminal, according to the present specification comprises the steps of: transmitting, to a base station, capability information of the terminal for CSI-related action; receiving configuration information for the CSI-related action from the base station; tracking partially activated CSI reference signal (RS); measuring fully activated CSI-RS; and reporting the results of the measurement to the base station.

(57) 요약서: 본 명세서는 무선 통신 시스템에서 CSI(Channel State Information) 피드백(feedback)을 수행하기 위한 방법에 있어서, 단말에 의해 수행되는 방법은, CSI 관련 동작에 대한 상기 단말의 능력(capability) 정보를 기지국으로 전송하는 단계; CSI 관련 동작 설정(configuration) 정보를 상기 기지국으로부터 수신하는 단계; 부분 활성화 CSI-RS(Reference Signal)를 트래킹(tracking)하는 단계; 완전 활성화 CSI-RS 를 측정하는 단계; 및 상기 측정 결과를 상기 기지국으로 보고(report)하는 단계를 포함하여 이루어지는 것을 특징으로 한다.

명세서

발명의 명칭: 무선 통신 시스템에서 CSI를 피드백하기 위한 방법 및 이를 위한 장치

기술분야

[1] 본 발명은 무선 통신 시스템에 관한 것으로서, 보다 상세하게 단말에서 참조 신호(reference signal)을 기반으로 CSI를 피드백하기 위한 방법 및 이를 지원하는 장치에 관한 것이다.

배경기술

[2] 이동 통신 시스템은 사용자의 활동성을 보장하면서 음성 서비스를 제공하기 위해 개발되었다. 그러나 이동통신 시스템은 음성뿐 아니라 데이터 서비스까지 영역을 확장하였으며, 현재에는 폭발적인 트래픽의 증가로 인하여 자원의 부족 현상이 야기되고 사용자들이 보다 고속의 서비스에 대한 요구하므로, 보다 발전된 이동 통신 시스템이 요구되고 있다.

[3] 차세대 이동 통신 시스템의 요구 조건은 크게 폭발적인 데이터 트래픽의 수용, 사용자 당 전송률의 획기적인 증가, 대폭 증가된 연결 디바이스 개수의 수용, 매우 낮은 단대단 지연(End-to-End Latency), 고에너지 효율을 지원할 수 있어야 한다. 이를 위하여 이중 연결성(Dual Connectivity), 대규모 다중 입출력(Massive MIMO: Massive Multiple Input Multiple Output), 전이중(In-band Full Duplex), 비직교 다중접속(NOMA: Non-Orthogonal Multiple Access), 초광대역(Super wideband) 지원, 단말 네트워킹(Device Networking) 등 다양한 기술들이 연구되고 있다.

발명의 상세한 설명

기술적 과제

[4] 본 명세서는 CSI 동작과 관련된 단말의 능력 정보를 송수신하는 방법을 제공함에 목적이 있다.

[5] 또한, 본 명세서는 CSI 피드백 절차에서 지연을 줄이기 위해 부분 활성화 CSI-RS를 트래킹하고, 완전 활성화 CSI-RS에 대해서만 측정 및 보고를 수행하는 방법을 제공함에 목적이 있다.

[6] 또한, 본 명세서는 CSI 측정 관련 윈도우를 초기화 또는 갱신하는 방법을 제공함에 목적이 있다.

[7] 본 발명에서 이루고자 하는 기술적 과제들은 이상에서 언급한 기술적 과제들로 제한되지 않으며, 언급하지 않은 또 다른 기술적 과제들은 아래의 기재로부터 본 발명이 속하는 기술분야에서 통상의 지식을 가진 자에게 명확하게 이해될 수 있을 것이다.

과제 해결 수단

[8] 본 명세서는 무선 통신 시스템에서 CSI(Channel State Information)

피드백(feedback)을 수행하기 위한 방법에 있어서, 단말에 의해 수행되는 방법은, CSI 관련 동작에 대한 상기 단말의 능력(capability) 정보를 기지국으로 전송하는 단계; CSI 관련 동작 설정(configuration) 정보를 상기 기지국으로부터 수신하는 단계, 상기 CSI 관련 동작 설정 정보는 부분 활성화(partial activation)를 수행하는 CSI 관련 동작을 나타내는 부분 활성화 CSI 관련 동작 인덱스(index) 정보 또는 완전 활성화(full activation)를 수행하는 CSI 관련 동작을 나타내는 완전 활성화 CSI 관련 동작 인덱스 정보 중 적어도 하나를 포함하며; 부분 활성화 CSI-RS(Reference Signal)를 트래킹(tracking)하는 단계; 완전 활성화 CSI-RS를 측정하는 단계; 및 상기 측정 결과를 상기 기지국으로 보고(report)하는 단계를 포함하여 이루어지는 것을 특징으로 한다.

[9] 또한, 본 명세서에서 상기 완전 활성화 CSI-RS를 측정하는 단계는, 상기 완전 활성화 CSI-RS에 대한 측정의 활성화를 지시하는 제 1 메시지를 상기 기지국으로부터 수신하는 단계; 및 상기 제 1 메시지에 의해 활성화된 완전 활성화 CSI-RS를 측정하는 단계를 포함하는 것을 특징으로 한다.

[10] 또한, 본 명세서에서 상기 CSI 관련 동작은 CSI-RS, CSI-IM(Interference Management) 또는 CSI process 중 적어도 하나와 관련 있는 것을 특징으로 한다.

[11] 또한, 본 명세서에서 상기 단말의 능력 정보는 동시에 완전 활성화(full activation) 가능한 상기 CSI 관련 동작의 최대 개수를 나타내는 제 1 제어 정보 및 동시에 부분 활성화(partial activation) 가능한 상기 CSI 관련 동작의 최대 개수를 나타내는 제 2 제어 정보를 포함하는 것을 특징으로 한다.

[12] 또한, 본 명세서에서 상기 부분 활성화 CSI-RS를 트래킹(tracking)하는 단계는, 상기 부분 활성화 CSI-RS에 대해 시간 및/또는 주파수에서 동기를 맞추는 단계를 포함하는 것을 특징으로 한다.

[13] 또한, 본 명세서에서 상기 트래킹은 상기 CSI 관련 동작 설정 정보에 포함된 특정 RS(Reference Signal)과 quasi co-location(QCL) 가정을 적용하여 수행하는 것을 특징으로 한다.

[14] 또한, 본 명세서에서 상기 완전 활성화 CSI-RS는 상기 부분 활성화 CSI-RS에서 선택되는 것을 특징으로 한다.

[15] 또한, 본 명세서에서 상기 제 1 메시지는 MAC(Media Access Control) CE(Control Element) 또는 DCI(Downlink Control Information)인 것을 특징으로 한다.

[16] 또한, 본 명세서는 상기 기지국으로부터 CSI-RS 측정 윈도우(measurement window)와 관련된 제 3 제어 정보를 수신하는 단계를 더 포함하며, 상기 CSI-RS를 측정하는 단계는, 상기 제 1 메시지를 수신하는 경우, 상기 CSI-RS 측정 윈도우를 초기화 또는 갱신하는 단계; 상기 CSI-RS 측정 윈도우가 초기화 또는 갱신되는 시점부터 특정 구간까지 CSI-RS의 측정을 반복적으로 수행하는 단계; 및 상기 측정 결과들을 평균하는(averaging) 단계를 포함하는 것을 특징으로 한다.

[17] 또한, 본 명세서에서 CSI 피드백이 주기적 CSI 피드백인 경우, 상기 CSI-RS 측정 윈도우를 초기화 또는 갱신하는 시점은 상기 특정 구간 이후에 최초로 발생하는 RI(Rank Indicator) 보고에 연관된 특정 기준 자원(reference resource) 시점인 것을 특징으로 한다.

[18] 또한, 본 명세서에서 상기 제 1 메시지는 각 CSI 프로세스 별로 상기 기지국으로부터 수신되는 것을 특징으로 한다.

[19] 또한, 본 명세서에서 상기 제 1 메시지는 빔포밍 관련 매트릭스의 변경을 알리는 빔-변경 지시자(Beam-Change Indicator:BCI) 시그널링(signaling)인 것을 특징으로 한다.

[20] 또한, 본 명세서는 무선 통신 시스템에서 CSI(Channel State Information)을 피드백하기 위한 단말에 있어서, 상기 단말은, 무선 신호를 송수신하기 위한 RF(Radio Frequency) 유닛; 및 상기 RF 유닛을 제어하는 프로세서를 포함하고, CSI 관련 동작에 대한 상기 단말의 능력(capability) 정보를 기지국으로 전송하고; CSI 관련 동작 설정(configuration) 정보를 상기 기지국으로부터 수신하고, 상기 CSI 관련 동작 설정 정보는 부분 활성화(partial activation)를 수행하는 CSI 관련 동작을 나타내는 부분 활성화 CSI 관련 동작 인덱스(index) 정보 또는 완전 활성화(full activation)를 수행하는 CSI 관련 동작을 나타내는 완전 활성화 CSI 관련 동작 인덱스 정보 중 적어도 하나를 포함하며; 부분 활성화 CSI-RS(Reference Signal)를 트래킹(tracking)하고; 완전 활성화 CSI-RS를 측정하며; 및 상기 측정 결과를 상기 기지국으로 보고(report)하도록 제어하는 것을 특징으로 한다.

발명의 효과

[21] 본 명세서는 MAC 레벨 또는 PHY 레벨에서 CSI 설정 관련 정보를 단말로 전송함으로써, CSI 피드백 절차에 있어 지연을 줄일 수 있는 효과가 있다.

[22] 또한, 본 명세서는 CSI 측정 관련 윈도우를 CSI 측정 활성화 지시 시점 또는 CSI 설정 변경 알림 시점에 초기화 또는 갱신하도록 함으로써, 불필요한 과거의 환경을 CSI 측정에 반영시키지 않도록 함으로써 보다 정확한 CSI 피드백을 수행할 수 있는 효과가 있다.

[23] 본 발명에서 얻을 수 있는 효과는 이상에서 언급한 효과로 제한되지 않으며, 언급하지 않은 또 다른 효과들은 아래의 기재로부터 본 발명이 속하는 기술분야에서 통상의 지식을 가진 자에게 명확하게 이해될 수 있을 것이다.

도면의 간단한 설명

[24] 본 발명에 관한 이해를 돕기 위해 상세한 설명의 일부로 포함되는, 첨부 도면은 본 발명에 대한 실시예를 제공하고, 상세한 설명과 함께 본 발명의 기술적 특징을 설명한다.

[25] 도 1은 본 발명이 적용될 수 있는 무선 통신 시스템에서 무선 프레임의 구조를 나타낸다.

[26] 도 2는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하나의 하향링크 슬롯에 대한 자원 그리드(resource grid)를 예시한 도면이다.

[27] 도 3은 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 서브 프레임의 구조를 나타낸다.

[28] 도 4는 본 발명이 적용될 수 있는 무선 통신 시스템에서 상향링크 서브 프레임의 구조를 나타낸다.

[29] 도 5는 일반적인 다중 입출력 안테나(MIMO) 통신 시스템의 구성도이다.

[30] 도 6은 다수의 송신 안테나에서 하나의 수신 안테나로의 채널을 나타낸 도이다.

[31] 도 7은 본 발명이 적용될 수 있는 무선 통신 시스템에서 컴포넌트 캐리어 및 캐리어 병합의 일례를 나타낸다.

[32] 도 8은 본 발명이 적용될 수 있는 무선 통신 시스템에서 경쟁 기반 랜덤 액세스 절차를 설명하기 위한 도면이다.

[33] 도 9는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 자원 블록 쌍에 매핑된 참조 신호 패턴을 예시한다.

[34] 도 10은 본 발명이 적용될 수 있는 무선 통신 시스템에서 CSI-RS 구성을 예시하는 도면이다.

[35] 도 11은 본 발명이 적용될 수 있는 무선 통신 시스템에서 기지국 또는 단말이 AAS 기반의 3D(3-Dimension) 빔 형성이 가능한 다수의 송/수신 안테나를 갖고 있는 시스템을 예시한다.

[36] 도 12는 본 발명의 일 실시예에 따른 RRM-RS의 안테나 포트 별 RSRP를 예시한다.

[37] 도 13은 본 발명의 일 실시예에 따른 RRM-RS 안테나 포트 그룹핑 레벨을 예시한다.

[38] 도 14는 본 발명의 일 실시예에 따른 이차원 인덱스로 배열된 RRM-RS의 안테나 포트와 안테나 포트 그룹을 예시하는 도면이다.

[39] 도 15 내지 17은 본 명세서에서 제안하는 CSI 측정 및 보고 방법의 일례들을 나타낸 도이다.

[40] 도 18은 본 발명의 일 실시예에 따른 무선 통신 장치의 블록 구성도를 예시한다.

발명의 실시를 위한 형태

[41] 이하, 본 발명에 따른 바람직한 실시 형태를 첨부된 도면을 참조하여 상세하게 설명한다. 첨부된 도면과 함께 이하에 개시될 상세한 설명은 본 발명의 예시적인 실시형태를 설명하고자 하는 것이며, 본 발명이 실시될 수 있는 유일한 실시형태를 나타내고자 하는 것이 아니다. 이하의 상세한 설명은 본 발명의 완전한 이해를 제공하기 위해서 구체적 세부사항을 포함한다. 그러나, 당업자는 본 발명이 이러한 구체적 세부사항 없이도 실시될 수 있음을 안다.

[42] 몇몇 경우, 본 발명의 개념이 모호해지는 것을 피하기 위하여 공지의 구조 및 장치는 생략되거나, 각 구조 및 장치의 핵심기능을 중심으로 한 블록도 형식으로

도시될 수 있다.

[43] 본 명세서에서 기지국은 단말과 직접적으로 통신을 수행하는 네트워크의 종단 노드(terminal node)로서의 의미를 갖는다. 본 문서에서 기지국에 의해 수행되는 것으로 설명된 특정 동작은 경우에 따라서는 기지국의 상위 노드(upper node)에 의해 수행될 수도 있다. 즉, 기지국을 포함하는 다수의 네트워크 노드들(network nodes)로 이루어지는 네트워크에서 단말과의 통신을 위해 수행되는 다양한 동작들은 기지국 또는 기지국 이외의 다른 네트워크 노드들에 의해 수행될 수 있음은 자명하다. '기지국(BS: Base Station)'은 고정국(fixed station), Node B, eNB(evolved-NodeB), BTS(base transceiver system), 액세스 포인트(AP: Access Point) 등의 용어에 의해 대체될 수 있다. 또한, '단말(Terminal)'은 고정되거나 이동성을 가질 수 있으며, UE(User Equipment), MS(Mobile Station), UT(user terminal), MSS(Mobile Subscriber Station), SS(Subscriber Station), AMS(Advanced Mobile Station), WT(Wireless terminal), MTC(Machine-Type Communication) 장치, M2M(Machine-to-Machine) 장치, D2D(Device-to-Device) 장치 등의 용어로 대체될 수 있다.

[44] 이하에서, 하향링크(DL: downlink)는 기지국에서 단말로의 통신을 의미하며, 상향링크(UL: uplink)는 단말에서 기지국으로의 통신을 의미한다. 하향링크에서 송신기는 기지국의 일부이고, 수신기는 단말의 일부일 수 있다. 상향링크에서 송신기는 단말의 일부이고, 수신기는 기지국의 일부일 수 있다.

[45] 이하의 설명에서 사용되는 특정 용어들은 본 발명의 이해를 돕기 위해서 제공된 것이며, 이러한 특정 용어의 사용은 본 발명의 기술적 사상을 벗어나지 않는 범위에서 다른 형태로 변경될 수 있다.

[46] 이하의 기술은 CDMA(code division multiple access), FDMA(frequency division multiple access), TDMA(time division multiple access), OFDMA(orthogonal frequency division multiple access), SC-FDMA(single carrier frequency division multiple access), NOMA(non-orthogonal multiple access) 등과 같은 다양한 무선 접속 시스템에 이용될 수 있다. CDMA는 UTRA(universal terrestrial radio access)나 CDMA2000과 같은 무선 기술(radio technology)로 구현될 수 있다. TDMA는 GSM(global system for mobile communications)/GPRS(general packet radio service)/EDGE(enhanced data rates for GSM evolution)와 같은 무선 기술로 구현될 수 있다. OFDMA는 IEEE 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802-20, E-UTRA(evolved UTRA) 등과 같은 무선 기술로 구현될 수 있다. UTRA는 UMTS(universal mobile telecommunications system)의 일부이다. 3GPP(3rd generation partnership project) LTE(long term evolution)은 E-UTRA를 사용하는 E-UMTS(evolved UMTS)의 일부로써, 하향링크에서 OFDMA를 채용하고 상향링크에서 SC-FDMA를 채용한다. LTE-A(advanced)는 3GPP LTE의 진화이다.

[47] 본 발명의 실시예들은 무선 접속 시스템들인 IEEE 802, 3GPP 및 3GPP2 중 적어도 하나에 개시된 표준 문서들에 의해 뒷받침될 수 있다. 즉, 본 발명의

실시예들 중 본 발명의 기술적 사상을 명확히 드러내기 위해 설명하지 않은 단계들 또는 부분들은 상기 문서들에 의해 뒷받침될 수 있다. 또한, 본 문서에서 개시하고 있는 모든 용어들은 상기 표준 문서에 의해 설명될 수 있다.

[48] 설명을 명확하게 하기 위해, 3GPP LTE/LTE-A를 위주로 기술하지만 본 발명의 기술적 특징이 이에 제한되는 것은 아니다.

[49]

[50] **본 발명이 적용될 수 있는 무선 통신 시스템 일반**

[51] 도 1은 본 발명이 적용될 수 있는 무선 통신 시스템에서 무선 프레임의 구조를 나타낸다.

[52] 3GPP LTE/LTE-A에서는 FDD(Frequency Division Duplex)에 적용 가능한 타입 1 무선 프레임(radio frame) 구조와 TDD(Time Division Duplex)에 적용 가능한 타입 2의 무선 프레임 구조를 지원한다.

[53] 도 1에서 무선 프레임의 시간 영역에서의 크기는 T_s=1/(15000*2048)의 시간 단위의 배수로 표현된다. 하향링크 및 상향링크 전송은 T_f=307200*T_s=10ms의 구간을 가지는 무선 프레임으로 구성된다.

[54] 도 1의 (a)는 타입 1 무선 프레임의 구조를 예시한다. 타입 1 무선 프레임은 전이중(full duplex) 및 반이중(half duplex) FDD에 모두 적용될 수 있다.

[55] 무선 프레임(radio frame)은 10개의 서브프레임(subframe)으로 구성된다. 하나의 무선 프레임은 T_slot=15360*T_s=0.5ms 길이의 20개의 슬롯으로 구성되고, 각 슬롯은 0부터 19까지의 인덱스가 부여된다. 하나의 서브프레임은 시간 영역(time domain)에서 연속적인 2개의 슬롯(slot)으로 구성되고, 서브프레임 i는 슬롯 2i 및 슬롯 2i+1로 구성된다. 하나의 서브프레임을 전송하는데 걸리는 시간을 TTI(transmission time interval)이라 한다. 예를 들어, 하나의 서브 프레임은 길이는 1ms이고, 하나의 슬롯의 길이는 0.5ms일 수 있다.

[56] FDD에서 상향링크 전송 및 하향링크 전송은 주파수 도메인에서 구분된다. 전이중 FDD에 제한이 없는 반면, 반이중 FDD 동작에서 단말은 동시에 전송 및 수신을 할 수 없다.

[57] 하나의 슬롯은 시간 영역에서 복수의 OFDM(orthogonal frequency division multiplexing) 심볼을 포함하고, 주파수 영역에서 다수의 자원블록(RB: Resource Block)을 포함한다. 3GPP LTE는 하향링크에서 OFDMA를 사용하므로 OFDM 심볼은 하나의 심볼 구간(symbol period)을 표현하기 위한 것이다. OFDM 심볼은 하나의 SC-FDMA 심볼 또는 심볼 구간이라고 할 수 있다. 자원 블록(resource block)은 자원 할당 단위이고, 하나의 슬롯에서 복수의 연속적인 부반송파(subcarrier)를 포함한다.

[58] 도 1의 (b)는 타입 2 프레임 구조(frame structure type 2)를 나타낸다.

[59] 타입 2 무선 프레임은 각 153600*T_s=5ms의 길이의 2개의 하프 프레임(half frame)으로 구성된다. 각 하프 프레임은 30720*T_s=1ms 길이의 5개의 서브프레임으로 구성된다.

[60] TDD 시스템의 타입 2 프레임 구조에서 상향링크-하향링크 구성(uplink-downlink configuration)은 모든 서브프레임에 대하여 상향링크와 하향링크가 할당(또는 예약)되는지 나타내는 규칙이다.

[61] 표 1은 상향링크-하향링크 구성을 나타낸다.

[62] [표1]

Uplink-Downlink configu-ration	Downlink-to-Uplink Switch-point periodicity	Subframe number

5	10ms	D	S	U	D	D	D	D	D	D	D
6	5ms	D	S	U	U	U	D	S	U	U	D

[63] 표 1을 참조하면, 무선 프레임의 각 서브프레임 별로, 'D'는 하향링크 전송을 위한 서브프레임을 나타내고, 'U'는 상향링크 전송을 위한 서브프레임을 나타내며, 'S'는 DwPTS(Downlink Pilot Time Slot), 보호구간(GP: Guard Period), UpPTS(Uplink Pilot Time Slot) 3가지의 필드로 구성되는 스페셜 서브프레임(special subframe)을 나타낸다.

[64] DwPTS는 단말에서의 초기 셀 탐색, 동기화 또는 채널 추정에 사용된다. UpPTS는 기지국에서의 채널 추정과 단말의 상향링크 전송 동기를 맞추는 데 사용된다. GP는 상향링크와 하향링크 사이에 하향링크 신호의 다중경로 지연으로 인해 상향링크에서 생기는 간섭을 제거하기 위한 구간이다.

[65] 각 서브프레임 i는 각 T_slot=15360*T_s=0.5ms 길이의 슬롯 2i 및 슬롯 2i+1로 구성된다.

[66] 상향링크-하향링크 구성은 7가지로 구분될 수 있으며, 각 구성 별로 하향링크 서브프레임, 스페셜 서브프레임, 상향링크 서브프레임의 위치 및/또는 개수가 다르다.

[67] 하향링크에서 상향링크로 변경되는 시점 또는 상향링크에서 하향링크로 전환되는 시점을 전환 시점(switching point)이라 한다. 전환 시점의 주기성(Switch-point periodicity)은 상향링크 서브프레임과 하향링크 서브프레임이 전환되는 양상이 동일하게 반복되는 주기를 의미하며, 5ms 또는 10ms가 모두 지원된다. 5ms 하향링크-상향링크 전환 시점의 주기를 가지는 경우에는 스페셜 서브프레임(S)은 하프-프레임 마다 존재하고, 5ms 하향링크-상향링크 전환 시점의 주기를 가지는 경우에는 첫번째 하프-프레임에만 존재한다.

[68] 모든 구성에 있어서, 0번, 5번 서브프레임 및 DwPTS는 하향링크 전송만을 위한 구간이다. UpPTS 및 서브프레임 서브프레임에 바로 이어지는 서브프레임은

항상 상향링크 전송을 위한 구간이다.

[69] 이러한, 상향링크-하향링크 구성은 시스템 정보로써 기지국과 단말이 모두 알고 있을 수 있다. 기지국은 상향링크-하향링크 구성 정보가 바뀔 때마다 구성 정보의 인덱스만을 전송함으로써 무선 프레임의 상향링크-하향링크 할당상태의 변경을 단말에 알려줄 수 있다. 또한, 구성 정보는 일종의 하향링크 제어정보로서 다른 스케줄링 정보와 마찬가지로 PDCCH(Physical Downlink Control Channel)를 통해 전송될 수 있으며, 방송 정보로서 브로드캐스트 채널(broadcast channel)을 통해 셀 내의 모든 단말에 공통으로 전송될 수도 있다.

[70] 표 2는 스페셜 서브프레임의 구성(DwPTS/GP/UpPTS의 길이)을 나타낸다.

[71] [표2]

Special subframe configuration	Normal cyclic prefix in downlink			Extended cyclic prefix in downlink		
	DwPTS	UpPTS		DwPTS	UpPTS	
		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink
0	$6592 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$	$7680 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$
1	$19760 \cdot T_s$			$20480 \cdot T_s$

5	$6592 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$	$20480 \cdot T_s$		
6	$19760 \cdot T_s$			$23040 \cdot T_s$		
7	$21952 \cdot T_s$			-	-	-
8	$24144 \cdot T_s$			-	-	-

[72] 도 1의 예시에 따른 무선 프레임의 구조는 하나의 예시에 불과하며, 무선 프레임에 포함되는 부 반송파의 수 또는 서브 프레임에 포함되는 슬롯의 수, 슬롯에 포함되는 OFDM 심볼의 수는 다양하게 변경될 수 있다.

[73] 도 2는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하나의 하향링크 슬롯에 대한 자원 그리드(resource grid)를 예시한 도면이다.

[74] 도 2를 참조하면, 하나의 하향링크 슬롯은 시간 영역에서 복수의 OFDM 심볼을 포함한다. 여기서, 하나의 하향링크 슬롯은 7개의 OFDM 심볼을 포함하고, 하나의 자원 블록은 주파수 영역에서 12개의 부 반송파를 포함하는 것을 예시적으로 기술하나, 이에 한정되는 것은 아니다.

[75] 자원 그리드 상에서 각 요소(element)를 자원 요소(resource element)하고, 하나의 자원 블록(RB: resource block)은 12×7 개의 자원 요소를 포함한다. 하향링크 슬롯에 포함되는 자원 블록들의 수 N^DL은 하향링크 전송 대역폭(bandwidth)에 종속한다.

[76] 상향링크 슬롯의 구조는 하향링크 슬롯의 구조와 동일할 수 있다.

[77] 도 3은 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 서브

프레임의 구조를 나타낸다.

[78] 도 3을 참조하면, 서브 프레임내의 첫번째 슬롯에서 앞의 최대 3개의 OFDM 심볼들이 제어 채널들이 할당되는 제어 영역(control region)이고, 나머지 OFDM 심볼들은 PDSCH(Physical Downlink Shared Channel)이 할당되는 데이터 영역(data region)이다. 3GPP LTE에서 사용되는 하향링크 제어 채널의 일례로 PCFICH(Physical Control Format Indicator Channel), PDCCH(Physical Downlink Control Channel), PHICH(Physical Hybrid-ARQ Indicator Channel) 등이 있다.

[79] PCFICH는 서브 프레임의 첫번째 OFDM 심볼에서 전송되고, 서브 프레임 내에 제어 채널들의 전송을 위하여 사용되는 OFDM 심볼들의 수(즉, 제어 영역의 크기)에 관한 정보를 나른다. PHICH는 상향 링크에 대한 응답 채널이고, HARQ(Hybrid Automatic Repeat Request)에 대한 ACK(Acknowledgement)/NACK(Not-Acknowledgement) 신호를 나른다. PDCCH를 통해 전송되는 제어 정보를 하향링크 제어정보(DCI: downlink control information)라고 한다. 하향링크 제어정보는 상향링크 자원 할당 정보, 하향링크 자원 할당 정보 또는 임의의 단말 그룹에 대한 상향링크 전송(Tx) 파워 제어 명령을 포함한다.

[80] PDCCH는 DL-SCH(Downlink Shared Channel)의 자원 할당 및 전송 포맷(이를 하향링크 그랜트라고도 한다.), UL-SCH(Uplink Shared Channel)의 자원 할당 정보(이를 상향링크 그랜트라고도 한다.), PCH(Paging Channel)에서의 페이징(paging) 정보, DL-SCH에서의 시스템 정보, PDSCH에서 전송되는 랜덤 액세스 응답(random access response)과 같은 상위 레이어(upper-layer) 제어 메시지에 대한 자원 할당, 임의의 단말 그룹 내 개별 단말들에 대한 전송 파워 제어 명령들의 집합, VoIP(Voice over IP)의 활성화 등을 나를 수 있다. 복수의 PDCCH들은 제어 영역 내에서 전송될 수 있으며, 단말은 복수의 PDCCH들을 모니터링할 수 있다. PDCCH는 하나 또는 복수의 연속적인 CCE(control channel elements)의 집합으로 구성된다. CCE는 무선 채널의 상태에 따른 부호화율(coding rate)을 PDCCH에 제공하기 위하여 사용되는 논리적 할당 단위이다. CCE는 복수의 자원 요소 그룹(resource element group)들에 대응된다. PDCCH의 포맷 및 사용 가능한 PDCCH의 비트 수는 CCE들의 수와 CCE들에 의해 제공되는 부호화율 간의 연관 관계에 따라 결정된다.

[81] 기지국은 단말에게 전송하려는 DCI에 따라 PDCCH 포맷을 결정하고, 제어 정보에 CRC(Cyclic Redundancy Check)를 붙인다. CRC에는 PDCCH의 소유자(owner)나 용도에 따라 고유한 식별자(이를 RNTI(Radio Network Temporary Identifier)라고 한다.)가 마스킹된다. 특정의 단말을 위한 PDCCH라면 단말의 고유한 식별자, 예를 들어 C-RNTI(Cell-RNTI)가 CRC에 마스킹될 수 있다. 또는 페이징 메시지를 위한 PDCCH라면 페이징 지시 식별자, 예를 들어 P-RNTI(Paging-RNTI)가 CRC에 마스킹될 수 있다. 시스템 정보, 더욱 구체적으로 시스템 정보 블록(SIB: system information block)를 위한 PDCCH라면 시스템 정보

식별자, SI-RNTI(system information RNTI)가 CRC에 마스킹될 수 있다. 단말의 랜덤 액세스 프리앰블의 전송에 대한 응답인 랜덤 액세스 응답을 지시하기 위하여, RA-RNTI(random access-RNTI)가 CRC에 마스킹될 수 있다.

[82] EPDCCH(enhanced PDCCH)는 단말 특정(UE-specific) 시그널링을 나른다. EPDCCH는 단말 특정하게 설정된 물리 자원 블록(PRB: physical resource block)에 위치한다. 다시 말해, 상술한 바와 같이 PDCCH는 서브 프레임내의 첫번째 슬롯에서 앞의 최대 3개의 OFDM 심볼들에서 전송될 수 있으나, EPDCCH는 PDCCH 이외의 자원 영역에서 전송될 수 있다. 서브프레임 내 EPDCCH가 시작되는 시점(즉, 심볼)은 상위 계층 시그널링(예를 들어, RRC 시그널링 등)을 통해 단말에 설정될 수 있다.

[83] EPDCCH는 DL-SCH와 관련된 전송 포맷, 자원 할당 및 HARQ 정보, UL-SCH와 관련된 전송 포맷, 자원 할당 및 HARQ 정보, SL-SCH(Sidelink Shared Channel) 및 PSCCH(Physical Sidelink Control Channel)과 관련된 자원 할당 정보 등을 나를 수 있다. 다중의 EPDCCH가 지원될 수 있으며, 단말은 EPCCH의 세트를 모니터링할 수 있다.

[84] EPDCCH는 하나 또는 그 이상의 연속된 진보된 CCE(ECCE: enhanced CCE)를 이용하여 전송될 수 있으며, 각 EPDCCH 포맷 별로 단일의 EPDCCH 당 ECCE의 개수가 정해질 수 있다.

[85] 각 ECCE는 복수의 자원 요소 그룹(EREG: enhanced resource element group)으로 구성될 수 있다. EREG는 ECCE의 RE에의 매핑을 정의하기 위하여 사용된다. PRB 쌍 별로 16개의 EREG가 존재한다. 각 PRB 쌍 내에서 DMRS를 나르는 RE를 제외하고, 모든 RE는 주파수가 증가하는 순서대로 그 다음 시간이 증가하는 순서대로 0 내지 15까지의 번호가 부여된다.

[86] 단말은 복수의 EPDCCH를 모니터링할 수 있다. 예를 들어, 단말이 EPDCCH 전송을 모니터링하는 하나의 PRB 쌍 내 하나 또는 두 개의 EPDCCH 세트가 설정될 수 있다.

[87] 서로 다른 개수의 ECCE가 병합됨으로써 EPCCH를 위한 서로 다른 부호화율(coding rate)이 실현될 수 있다. EPCCH는 지역적 전송(localized transmission) 또는 분산적 전송(distributed transmission)을 사용할 수 있으며, 이에 따라 PRB 내 RE에 ECCE의 매핑이 달라질 수 있다.

[88] 도 4는 본 발명이 적용될 수 있는 무선 통신 시스템에서 상향링크 서브 프레임의 구조를 나타낸다.

[89] 도 4를 참조하면, 상향링크 서브 프레임은 주파수 영역에서 제어 영역과 데이터 영역으로 나눌 수 있다. 제어 영역에는 상향링크 제어 정보를 나르는 PUCCH(Physical Uplink Control Channel)이 할당된다. 데이터 영역은 사용자 데이터를 나르는 PUSCH(Physical Uplink Shared Channel)이 할당된다. 단일 반송파 특성을 유지하기 위해 하나의 단말은 PUCCH와 PUSCH을 동시에 전송하지 않는다.

[90] 하나의 단말에 대한 PUCCH에는 서브 프레임 내에 자원 블록(RB: Resource Block) 쌍이 할당된다. RB 쌍에 속하는 RB들은 2개의 슬롯들의 각각에서 서로 다른 부 반송파를 차지한다. 이를 PUCCH에 할당된 RB 쌍은 슬롯 경계(slot boundary)에서 주파수 도약(frequency hopping)된다고 한다.

[91]

[92] **MIMO**(Multi-Input Multi-Output)

[93] MIMO 기술은 지금까지 일반적으로 한 개의 송신안테나와 한 개의 수신안테나를 사용했던 것에서 탈피하여, 다중 송신(Tx) 안테나와 다중 수신(Rx) 안테나를 사용한다. 다시 말해서, MIMO 기술은 무선 통신 시스템의 송신단 또는 수신단에서 다중 입출력 안테나를 사용하여 용량 증대 또는 성능 개성을 꾀하기 위한 기술이다. 이하에서는 'MIMO'를 '다중 입출력 안테나'라 칭하기로 한다.

[94] 더 구체적으로, 다중 입출력 안테나 기술은 하나의 완전한 메시지(total message)를 수신하기 위하여 한 개의 안테나 경로에 의존하지 않으며, 여러 개의 안테나를 통해 수신한 복수의 데이터 조각을 수집하여 완전한 데이터를 완성시킨다. 결과적으로, 다중 입출력 안테나 기술은 특정 시스템 범위 내에서 데이터 전송율을 증가시킬 수 있으며, 또한 특정 데이터 전송율을 통해 시스템 범위를 증가시킬 수 있다.

[95] 차세대 이동통신은 기존 이동통신에 비해 훨씬 높은 데이터 전송률을 요구하므로 효율적인 다중 입출력 안테나 기술이 반드시 필요할 것으로 예상된다. 이와 같은 상황에서 MIMO 통신 기술은 이동통신 단말과 중계기 등에 폭넓게 사용할 수 있는 차세대 이동통신 기술이며, 데이터 통신 확대 등으로 인해 한계 상황에 따라 다른 이동통신의 전송량 한계를 극복할 수 있는 기술로서 관심을 모으고 있다.

[96] 한편, 현재 연구되고 있는 다양한 전송효율 향상 기술 중 다중 입출력 안테나(MIMO) 기술은 추가적인 주파수 할당이나 전력증가 없이도 통신 용량 및 송수신 성능을 획기적으로 향상시킬 수 있는 방법으로서 현재 가장 큰 주목을 받고 있다.

[97] 도 5는 일반적인 다중 입출력 안테나(MIMO) 통신 시스템의 구성도이다.

[98] 도 5를 참조하면, 송신 안테나의 수를 N_T개로, 수신 안테나의 수를 N_R개로 동시에 늘리게 되면, 송신기나 수신기에서만 다수의 안테나를 사용하게 되는 경우와 달리 안테나 수에 비례하여 이론적인 채널 전송 용량이 증가하므로, 전송 레이트(transfer rate)를 향상시키고, 주파수 효율을 획기적으로 향상시킬 수 있다. 이 경우, 채널 전송 용량의 증가에 따른 전송 레이트는 하나의 안테나를 이용하는 경우의 최대 전송 레이트(R_o)에 다음과 같은 레이트 증가율(R_i)이 곱해진 만큼으로 이론적으로 증가할 수 있다.

[99] [수식1]

$$R_i = \min\left(N_T, N_R\right)$$

[100] 즉, 예를 들어, 4개의 송신 안테나와 4개의 수신 안테나를 이용하는 MIMO 통신 시스템에서는 단일 안테나 시스템에 비해 이론상 4배의 전송 레이트를 획득할 수 있다.

[101] 이와 같은 다중 입출력 안테나의 기술은 다양한 채널 경로를 통과한 심볼들을 이용하여 전송 신뢰도를 높이는 공간 다이버시티(spatial diversity) 방식과, 다수의 송신 안테나를 이용하여 다수의 데이터 심볼을 동시에 송신하여 전송률을 향상시키는 공간 멀티플렉싱(spatial multiplexing) 방식으로 나눌 수 있다. 또한 이러한 두 가지 방식을 적절히 결합하여 각각의 장점을 적절히 얻고자 하는 방식에 대한 연구도 최근 많이 연구되고 있는 분야이다.

[102] 각각의 방식에 대해 좀더 구체적으로 살펴보면 다음과 같다.

[103] 첫째로, 공간 다이버시티 방식의 경우에는 시공간 블록 부호 계열과, 다이버시티 이득과 부호화 이득을 동시에 이용하는 시공간 트렐리스(Trelis) 부호 계열 방식이 있다. 일반적으로 비트 오류율 개선 성능과 부호 생성 자유도는 트렐리스 부호 방식이 우수하지만, 연산 복잡도는 시공간 블록 부호가 간단하다. 이와 같은 공간 다이버서티 이득은 송신 안테나 수(N_T)와 수신 안테나 수(N_R)의 곱(N_T × N_R)에 해당되는 양을 얻을 수 있다.

[104] 둘째로, 공간 멀티플렉싱 기법은 각 송신 안테나에서 서로 다른 데이터 열을 송신하는 방법인데, 이때 수신기에서는 송신기로부터 동시에 전송된 데이터 사이에 상호 간섭이 발생하게 된다. 수신기에서는 이 간섭을 적절한 신호처리 기법을 이용하여 제거한 후 수신한다. 여기에 사용되는 잡음 제거 방식은 MLD(maximum likelihood detection) 수신기, ZF(zero-forcing) 수신기, MMSE(minimum mean square error) 수신기, D-BLAST (Diagonal-Bell Laboratories Layered Space-Time), V-BLAST(Vertical-Bell Laboratories Layered Space-Time) 등이 있으며, 특히 송신단에서 채널 정보를 알 수 있는 경우에는 SVD(singular value decomposition) 방식 등을 사용할 수 있다.

[105] 셋째로, 공간 다이버시티와 공간 멀티플렉싱의 결합된 기법을 들 수 있다. 공간 다이버시티 이득만을 얻을 경우 다이버시티 차수의 증가에 따른 성능개선 이득이 점차 포화되며, 공간 멀티플렉싱 이득만을 취하면 무선 채널에서 전송 신뢰도가 떨어진다. 이를 해결하면서 두 가지 이득을 모두 얻는 방식들이 연구되어 왔으며, 이 중 시공간 블록 부호 (Double-STTD), 시공간 BICM(STBICM) 등의 방식이 있다.

[106] 상술한 바와 같은 다중 입출력 안테나 시스템에 있어서의 통신 방법을 보다 구체적인 방법으로 설명하기 위해 이를 수학적으로 모델링하는 경우 다음과 같이 나타낼 수 있다.

[107] 먼저, 도 5에 도시된 바와 같이 N_T개의 송신 안테나와 N_R개의 수신 안테나가 존재하는 것을 가정한다.

[108] 먼저, 송신 신호에 대해 살펴보면, 이와 같이 N_T개의 송신 안테나가 있는 경우 최대 전송 가능한 정보는 N_T개 이므로, 이를 다음과 같은 벡터로 나타낼 수

있다.

[109] [수식2]

$$\mathbf{s} = \left[s_1, s_2, \cdots, s_{N_T}\right]^T$$

[110] 한편, 각각의 전송 정보 s_1, s_2, ..., s_N_T에 있어 전송 전력을 달리 할 수 있으며, 이때 각각의 전송 전력을 P_1, P_2, ..., P_N_T라 하면, 전송 전력이 조정된 전송 정보는 다음과 같은 벡터로 나타낼 수 있다.

[111] [수식3]

$$\hat{\mathbf{s}} = \left[\hat{s}_1, \hat{s}_2, \cdots, \hat{s}_{N_T}\right]^T = \left[P_1 s_1, P_2 s_2, \cdots, P_{N_T} s_{N_T}\right]^T$$

[112] 또한, 수학식 3의 전송 전력이 조정된 전송 정보를 전송 전력의 대각 행렬 P로 다음과 같이 나타낼 수 있다.

[113] [수식4]

$$\hat{\mathbf{s}} = \begin{bmatrix} P_1 & & & 0 \\ & P_2 & & \\ & & \ddots & \\ 0 & & & P_{N_T} \end{bmatrix} \begin{bmatrix} s_1 \\ s_2 \\ \vdots \\ s_{N_T} \end{bmatrix} = \mathbf{Ps}$$

[114] 한편, 수학식 4의 전송 전력이 조정된 정보 벡터는 그 후 가중치 행렬 W가 곱해져 실제 전송되는 N_T개의 전송 신호 x_1, x_2, ..., x_N_T를 구성한다. 여기서, 가중치 행렬은 전송 채널 상황 등에 따라 전송 정보를 각 안테나에 적절히 분배해 주는 역할을 수행한다. 이와 같은 전송 신호 x_1, x_2, ..., x_N_T를 벡터 x를 이용하여 다음과 같이 나타낼 수 있다.

[115] [수식5]

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_i \\ \vdots \\ x_{N_T} \end{bmatrix} = \begin{bmatrix} w_{11} & w_{12} & \cdots & w_{1N_T} \\ w_{21} & w_{22} & \cdots & w_{2N_T} \\ \vdots & & \ddots & \\ w_{i1} & w_{i2} & \cdots & w_{iN_T} \\ \vdots & & \ddots & \\ w_{N_T1} & w_{N_T2} & \cdots & w_{N_TN_T} \end{bmatrix} \begin{bmatrix} \hat{s}_1 \\ \hat{s}_2 \\ \vdots \\ \hat{s}_j \\ \vdots \\ \hat{s}_{N_T} \end{bmatrix} = \mathbf{W}\hat{\mathbf{s}} = \mathbf{WPs}$$

[116] 여기서, w_ij는 i번째 송신 안테나와 j번째 전송 정보간의 가중치를 나타내며, W는 이를 행렬로 나타낸 것이다. 이와 같은 행렬 W를 가중치 행렬(Weight Matrix) 또는 프리코딩 행렬(Precoding Matrix)라 부른다.

[117] 한편, 상술한 바와 같은 전송 신호(x)는 공간 다이버시티를 사용하는 경우와 공간 멀티플랙싱을 사용하는 경우로 나누어 생각해 볼 수 있다.

[118] 공간 멀티플랙싱을 사용하는 경우는 서로 다른 신호를 다중화하여 보내게 되므로, 정보 벡터 s의 원소들이 모두 다른 값을 가지게 되는 반면, 공간

다이버시티를 사용하게 되면 같은 신호를 여러 채널 경로를 통하여 보내게 되므로 정보 벡터 s의 원소들이 모두 같은 값을 갖게 된다.

[119] 물론, 공간 멀티플랙싱과 공간 다이버시티를 혼합하는 방법도 고려 가능하다. 즉, 예를 들어 3 개의 송신 안테나를 통하여 같은 신호를 공간 다이버시티를 이용하여 전송하고, 나머지는 각각 다른 신호를 공간 멀티플랙싱하여 보내는 경우도 고려할 수 있다.

[120] 다음으로, 수신신호는 N_R개의 수신 안테나가 있는 경우, 각 안테나의 수신신호 y_1, y_2, ..., y_N_R을 벡터 y로 다음과 같이 나타내기로 한다.

[121] [수식6]

$$\mathbf{y} = \left[y_1, y_2, \cdots, y_{N_R}\right]^{\mathrm{T}}$$

[122] 한편, 다중 입출력 안테나 통신 시스템에 있어서의 채널을 모델링하는 경우, 각각의 채널은 송수신 안테나 인덱스에 따라 구분할 수 있으며, 송신 안테나 j로부터 수신 안테나 i를 거치는 채널을 h_ij로 표시하기로 한다. 여기서, h_ij의 인덱스의 순서가 수신 안테나 인덱스가 먼저, 송신안테나의 인덱스가 나중임에 유의한다.

[123] 이러한 채널은 여러 개를 한데 묶어서 벡터 및 행렬 형태로도 표시 가능하다. 벡터 표시의 예를 들어 설명하면 다음과 같다.

[124] 도 6은 다수의 송신 안테나에서 하나의 수신 안테나로의 채널을 나타낸 도이다.

[125] 도 6에 도시된 바와 같이 총 N_T개의 송신 안테나로부터 수신안테나 i로 도착하는 채널은 다음과 같이 표현 가능하다.

[126] [수식7]

$$\mathbf{h}_i^T = \left[h_{i1}, h_{i2}, \cdots, h_{iN_T}\right]$$

[127] 또한, 상기 수학식 7과 같은 행렬 표현을 통해 N_T개의 송신 안테나로부터 N_R개의 수신 안테나를 거치는 채널을 모두 나타내는 경우 다음과 같이 나타낼 수 있다.

[128] [수식8]

$$\mathbf{H} = \begin{bmatrix} \mathbf{h}_1^{\mathrm{T}} \\ \mathbf{h}_2^{\mathrm{T}} \\ \vdots \\ \mathbf{h}_i^{\mathrm{T}} \\ \vdots \\ \mathbf{h}_{\mathbf{N_R}}^{\mathrm{T}} \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} & \cdots & h_{1N_T} \\ h_{21} & h_{22} & \cdots & h_{2N_T} \\ \vdots & & \ddots & \\ h_{i1} & h_{i2} & \cdots & h_{iN_T} \\ \vdots & & \ddots & \\ h_{N_R1} & h_{N_R2} & \cdots & h_{N_RN_T} \end{bmatrix}$$

[129] 한편, 실제 채널은 위와 같은 채널 행렬 H를 거친 후에 백색 잡음(AWGN: Additive White Gaussian Noise)가 더해지게 되므로, N_R개의 수신 안테나 각각에 더해지는 백색 잡음 n_1, n_2, ..., n_N_R을 백터로 표현하면 다음과 같다.

[130] [수식9]

$$\mathbf{n} = \left[n_1, n_2, \cdots, n_{N_R}\right]^{\mathrm{T}}$$

[131] 상술한 바와 같은 전송 신호, 수신 신호, 채널, 및 백색 잡음의 모델링을 통해 다중 입출력 안테나 통신 시스템에서의 각각은 다음과 같은 관계를 통해 나타낼 수 있다.

[132] [수식10]

$$\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_i \\ \vdots \\ y_{N_R} \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} & \cdots & h_{1N_T} \\ h_{21} & h_{22} & \cdots & h_{2N_T} \\ \vdots & & \ddots & \\ h_{i1} & h_{i2} & \cdots & h_{iN_T} \\ \vdots & & \ddots & \\ h_{N_R1} & h_{N_R2} & \cdots & h_{N_RN_T} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_j \\ \vdots \\ x_{N_T} \end{bmatrix} + \begin{bmatrix} n_1 \\ n_2 \\ \vdots \\ n_i \\ \vdots \\ n_{N_R} \end{bmatrix} = \mathbf{Hx} + \mathbf{n}$$

[133] 한편, 채널의 상태를 나타내는 채널 행렬 H의 행과 열의 수는 송수신 안테나 수에 의해서 결정된다. 채널 행렬 H는 앞서 살펴본 바와 같이 행의 수는 수신 안테나의 수 N_R과 같아지고, 열의 수는 송신 안테나의 수 N_T와 같아 지게 된다. 즉, 채널 행렬 H는 N_R×N_T 행렬이 된다.

[134] 일반적으로, 행렬의 랭크(rank)는 서로 독립인(independent) 행 또는 열의 개수 중에서 최소 개수로 정의된다. 따라서, 행렬의 랭크는 행 또는 열의 개수보다 클 수 없게 된다. 수식적으로 예를 들면, 채널 행렬 H의 랭크(rank(H))는 다음과 같이 제한된다.

[135] [수식11]

$$rank(\mathbf{H}) \le \min(N_T, N_R)$$

[136] 또한, 행렬을 고유치 분해(Eigen value decomposition)를 하였을 때, 랭크는 고유치(eigen value)들 중에서 0이 아닌 고유치들의 개수로 정의할 수 있다. 비슷한 방법으로, 랭크를 SVD(singular value decomposition) 했을 때 0이 아닌 특이값(singular value)들의 개수로 정의할 수 있다. 따라서, 채널 행렬에서 랭크의 물리적인 의미는 주어진 채널에서 서로 다른 정보를 보낼 수 있는 최대 수라고 할 수 있다.

[137] 본 명세서에 있어, MIMO 전송에 대한 '랭크(Rank)'는 특정 시점 및 특정 주파수 자원에서 독립적으로 신호를 전송할 수 있는 경로의 수를 나타내며, '레이어(layer)의 개수'는 각 경로를 통해 전송되는 신호 스트림의 개수를 나타낸다. 일반적으로 송신단은 신호 전송에 이용되는 랭크 수에 대응하는 개수의 레이어를 전송하기 때문에 특별한 언급이 없는 한 랭크는 레이어 개수와 동일한 의미를 가진다.

[138]

[139] 캐리어 병합(Carrier Aggregation)

[140] 본 발명의 실시예들에서 고려하는 통신 환경은 멀티 캐리어(Multi-carrier) 지원 환경을 모두 포함한다. 즉, 본 발명에서 사용되는 멀티 캐리어 시스템 또는 캐리어 병합(CA: Carrier Aggregation) 시스템이라 함은 광대역을 지원하기 위해서, 목표로 하는 광대역을 구성할 때 목표 대역보다 작은 대역폭(bandwidth)을 가지는 1개 이상의 컴포넌트 캐리어(CC: Component Carrier)를 병합(aggregation)하여 사용하는 시스템을 말한다.

[141] 본 발명에서 멀티 캐리어는 캐리어의 병합(또는, 반송파 집성)을 의미하며, 이때 캐리어의 병합은 인접한(contiguous) 캐리어 간의 병합뿐 아니라 비 인접한(non-contiguous) 캐리어 간의 병합을 모두 의미한다. 또한, 하향링크와 상향링크 간에 집성되는 컴포넌트 캐리어들의 수는 다르게 설정될 수 있다. 하향링크 컴포넌트 캐리어(이하, 'DL CC'라 한다.) 수와 상향링크 컴포넌트 캐리어(이하, 'UL CC'라 한다.) 수가 동일한 경우를 대칭적(symmetric) 집성이라고 하고, 그 수가 다른 경우를 비대칭적(asymmetric) 집성이라고 한다. 이와 같은 캐리어 병합은 반송파 집성, 대역폭 집성(bandwidth aggregation), 스펙트럼 집성(spectrum aggregation) 등과 같은 용어와 혼용되어 사용될 수 있다.

[142] 두 개 이상의 컴포넌트 캐리어가 결합되어 구성되는 캐리어 병합은 LTE-A 시스템에서는 100MHz 대역폭까지 지원하는 것을 목표로 한다. 목표 대역보다 작은 대역폭을 가지는 1개 이상의 캐리어를 결합할 때, 결합하는 캐리어의 대역폭은 기존 IMT 시스템과의 호환성(backward compatibility) 유지를 위해서 기존 시스템에서 사용하는 대역폭으로 제한할 수 있다. 예를 들어서 기존의 3GPP LTE 시스템에서는 {1.4, 3, 5, 10, 15, 20}MHz 대역폭을 지원하며, 3GPP LTE-advanced 시스템(즉, LTE-A)에서는 기존 시스템과의 호환을 위해 상기의 대역폭들만을 이용하여 20MHz보다 큰 대역폭을 지원하도록 할 수 있다. 또한, 본 발명에서 사용되는 캐리어 병합 시스템은 기존 시스템에서 사용하는 대역폭과 상관없이 새로운 대역폭을 정의하여 캐리어 병합을 지원하도록 할 수도 있다.

[143] LTE-A 시스템은 무선 자원을 관리하기 위해 셀(cell)의 개념을 사용한다.

[144] 상술한 캐리어 병합 환경은 다중 셀(multiple cells) 환경으로 일컬을 수 있다. 셀은 하향링크 자원(DL CC)과 상향링크 자원(UL CC) 한 쌍의 조합으로 정의되나, 상향링크 자원은 필수 요소는 아니다. 따라서, 셀은 하향링크 자원 단독, 또는 하향링크 자원과 상향링크 자원으로 구성될 수 있다. 특정 단말이 단 하나의 설정된 서빙 셀(configured serving cell)을 가지는 경우 1개의 DL CC와 1개의 UL CC를 가질 수 있으나, 특정 단말이 2개 이상의 설정된 서빙 셀을 가지는 경우에는 셀의 수만큼의 DL CC를 가지며 UL CC의 수는 그와 같거나 그보다 작을 수 있다.

[145] 또는, 그 반대로 DL CC와 UL CC가 구성될 수도 있다. 즉, 특정 단말이 다수의 설정된 서빙 셀을 가지는 경우 DL CC의 수보다 UL CC가 더 많은 캐리어 병합

환경도 지원될 수 있다. 즉, 캐리어 병합(carrier aggregation)은 각각 캐리어 주파수(셀의 중심 주파수)가 서로 다른 둘 이상의 셀들의 병합으로 이해될 수 있다. 여기서, 말하는 '셀(Cell)'은 일반적으로 사용되는 기지국이 커버하는 영역으로서의 '셀'과는 구분되어야 한다.

[146] LTE-A 시스템에서 사용되는 셀은 프라이머리 셀(PCell: Primary Cell) 및 세컨더리 셀(SCell: Secondary Cell)을 포함한다. P셀과 S셀은 서빙 셀(Serving Cell)로 사용될 수 있다. RRC_CONNECTED 상태에 있지만 캐리어 병합이 설정되지 않았거나 캐리어 병합을 지원하지 않는 단말의 경우, P셀로만 구성된 서빙 셀이 단 하나 존재한다. 반면, RRC_CONNECTED 상태에 있고 캐리어 병합이 설정된 단말의 경우 하나 이상의 서빙 셀이 존재할 수 있으며, 전체 서빙 셀에는 P셀과 하나 이상의 S셀이 포함된다.

[147] 서빙 셀(P셀과 S셀)은 RRC 파라미터를 통해 설정될 수 있다. PhysCellId는 셀의 물리 계층 식별자로 0부터 503까지의 정수값을 가진다. SCellIndex는 S셀을 식별하기 위하여 사용되는 간략한(short) 식별자로 1부터 7까지의 정수값을 가진다. ServCellIndex는 서빙 셀(P셀 또는 S셀)을 식별하기 위하여 사용되는 간략한(short) 식별자로 0부터 7까지의 정수값을 가진다. 0값은 P셀에 적용되며, SCellIndex는 S셀에 적용하기 위하여 미리 부여된다. 즉, ServCellIndex에서 가장 작은 셀 ID (또는 셀 인덱스)을 가지는 셀이 P셀이 된다.

[148] P셀은 프라이머리 주파수(또는, primary CC) 상에서 동작하는 셀을 의미한다. 단말이 초기 연결 설정(initial connection establishment) 과정을 수행하거나 연결 재-설정 과정을 수행하는데 사용될 수 있으며, 핸드오버 과정에서 지시된 셀을 지칭할 수도 있다. 또한, P셀은 캐리어 병합 환경에서 설정된 서빙 셀 중 제어관련 통신의 중심이 되는 셀을 의미한다. 즉, 단말은 자신의 P셀에서만 PUCCH를 할당 받아 전송할 수 있으며, 시스템 정보를 획득하거나 모니터링 절차를 변경하는데 P셀만을 이용할 수 있다. E-UTRAN(Evolved Universal Terrestrial Radio Access)은 캐리어 병합 환경을 지원하는 단말에게 이동성 제어 정보(mobilityControlInfo)를 포함하는 상위 계층의 RRC 연결 재설정(RRCConnectionReconfigutaion) 메시지를 이용하여 핸드오버 절차를 위해 P셀만을 변경할 수도 있다.

[149] S셀은 세컨더리 주파수(또는, Secondary CC) 상에서 동작하는 셀을 의미할 수 있다. 특정 단말에 P셀은 하나만 할당되며, S셀은 하나 이상 할당될 수 있다. S셀은 RRC 연결이 설정이 이루어진 이후에 구성 가능하고 추가적인 무선 자원을 제공하는데 사용될 수 있다. 캐리어 병합 환경에서 설정된 서빙 셀 중에서 P셀을 제외한 나머지 셀들, 즉 S셀에는 PUCCH가 존재하지 않는다. E-UTRAN은 S셀을 캐리어 병합 환경을 지원하는 단말에게 추가할 때, RRC_CONNECTED 상태에 있는 관련된 셀의 동작과 관련된 모든 시스템 정보를 특정 시그널(dedicated signal)을 통해 제공할 수 있다. 시스템 정보의 변경은 관련된 S셀의 해제 및 추가에 의하여 제어될 수 있으며, 이 때 상위 계층의 RRC

연결 재설정 (RRCConnectionReconfigutaion) 메시지를 이용할 수 있다. E-UTRAN은 관련된 S셀 안에서 브로드캐스트하기 보다는 단말 별로 상이한 파라미터를 가지는 특정 시그널링(dedicated signaling) 할 수 있다.

[150] 초기 보안 활성화 과정이 시작된 이후에, E-UTRAN은 연결 설정 과정에서 초기에 구성되는 P셀에 부가하여 하나 이상의 S셀을 포함하는 네트워크를 구성할 수 있다. 캐리어 병합 환경에서 P셀 및 S셀은 각각의 컴포넌트 캐리어로서 동작할 수 있다. 이하의 실시 예에서는 프라이머리 컴포넌트 캐리어(PCC)는 P셀과 동일한 의미로 사용될 수 있으며, 세컨더리 컴포넌트 캐리어(SCC)는 S셀과 동일한 의미로 사용될 수 있다.

[151] 도 7은 본 발명이 적용될 수 있는 무선 통신 시스템에서 컴포넌트 캐리어 및 캐리어 병합의 일례를 나타낸다.

[152] 도 7의 (a)는 LTE 시스템에서 사용되는 단일 캐리어 구조를 나타낸다. 컴포넌트 캐리어에는 DL CC와 UL CC가 있다. 하나의 컴포넌트 캐리어는 20MHz의 주파수 범위를 가질 수 있다.

[153] 도 7의 (b)는 LTE_A 시스템에서 사용되는 캐리어 병합 구조를 나타낸다. 도 7의 (b)의 경우에 20MHz의 주파수 크기를 갖는 3 개의 컴포넌트 캐리어가 결합된 경우를 나타낸다. DL CC와 UL CC가 각각 3 개씩 있으나, DL CC와 UL CC의 개수에 제한이 있는 것은 아니다. 캐리어 병합의 경우 단말은 3개의 CC를 동시에 모니터링할 수 있고, 하향링크 신호/데이터를 수신할 수 있고 상향링크 신호/데이터를 송신할 수 있다.

[154] 만약, 특정 셀에서 N개의 DL CC가 관리되는 경우에는, 네트워크는 단말에 M (M≤N)개의 DL CC를 할당할 수 있다. 이때, 단말은 M 개의 제한된 DL CC 만을 모니터링하고 DL 신호를 수신할 수 있다. 또한, 네트워크는 L (L≤M≤N)개의 DL CC에 우선순위를 주어 주된 DL CC를 단말에 할당할 수 있으며, 이러한 경우 UE는 L 개의 DL CC는 반드시 모니터링해야 한다. 이러한 방식은 상향링크 전송에도 똑같이 적용될 수 있다.

[155] 하향링크 자원의 반송파 주파수(또는 DL CC)와 상향링크 자원의 반송파 주파수(또는, UL CC) 사이의 링키지(linkage)는 RRC 메시지와 같은 상위계층 메시지나 시스템 정보에 의해 지시될 수 있다. 예를 들어, SIB2(System Information Block Type2)에 의해서 정의되는 링키지에 의해서 DL 자원과 UL 자원의 조합이 구성될 수 있다. 구체적으로, 링키지는 UL 그랜트를 나르는 PDCCH가 전송되는 DL CC와 상기 UL 그랜트를 사용하는 UL CC간의 맵핑 관계를 의미할 수 있으며, HARQ를 위한 데이터가 전송되는 DL CC(또는 UL CC)와 HARQ ACK/NACK 신호가 전송되는 UL CC(또는 DL CC)간의 맵핑 관계를 의미할 수도 있다.

[156] 단말이 하나 이상의 S셀이 설정되면, 네트워크는 설정된 S셀(들)을 활성화(activate) 또는 비활성화(deactivate)할 수 있다. P셀은 항상 활성화된다. 네트워크는 활성/비활성(Activation/Deactivation) MAC 제어 요소(MAC control

element)를 전송함으로써 S셀(들)을 활성화 또는 비활성화한다.

[157] 활성/비활성 MAC 제어 요소는 고정된 크기를 가지고, 7개의 C 필드(C-field)와 1개의 R 필드(R-field)를 포함하는 단일의 옥텟(octet)으로 구성된다. C 필드는 각 S셀 인덱스(SCellIndex) 별로 구성되고, S셀의 활성/비활성 상태를 지시한다. C 필드 값이 '1'로 셋팅되면 해당 S셀 인덱스를 가지는 S셀의 활성화되는 것을 지시하고, '0'으로 셋팅되면 해당 S셀 인덱스를 가지는 S셀의 비활성화되는 것을 지시한다.

[158] 또한, 단말은 설정된 S셀 별로 타이머(sCellDeactivationTimer)를 유지하고, 타이머가 만료될 때 관련된 S셀을 비활성화한다. 동일한 초기 타이머 값이 타이머(sCellDeactivationTimer)의 각 인스턴스(instance)에 적용되며, RRC 시그널링에 의해 설정된다. S셀(들)이 추가될 때 또는 핸드오버 이후, 초기 S셀(들)은 비활성화 상태이다.

[159] 단말은 각 TTI에서 각각의 설정된 S셀(들)에 대하여 아래와 같은 동작을 수행한다.

[160] - 단말이 특정 TTI(서브프레임 n)에서 S셀을 활성화하는 활성/비활성 MAC 제어 요소를 수신하면, 단말은 정해진 타이밍에 해당하는 TTI(서브프레임 n+8 또는 그 이후)에서 S셀을 활성화하고, 해당 S셀과 관련된 타이머를 (재)시작시킨다. 단말이 S셀을 활성화한다는 것은 단말이 S셀 상에서 SRS(Sounding Reference Signal) 전송, S셀을 위한 CQI(Channel Quality Indicator)/PMI(Precoding Matrix Indicator)/RI(Rank Indication)/PTI(Precoding Type Indicator) 보고, S셀 상에서 PDCCH 모니터링, S셀을 위한 PDCCH 모니터링과 같은 일반 S셀 동작을 적용한다는 것을 의미한다.

[161] - 단말이 특정 TTI(서브프레임 n)에서 S셀을 비활성화하는 활성/비활성 MAC 제어 요소를 수신하거나 또는 특정 TTI(서브프레임 n) 활성화된 S셀과 관련된 타이머가 만료되면, 단말은 정해진 타이밍에 해당하는 TTI(서브프레임 n+8 또는 그 이후)에서 S셀을 비활성화하고, 해당 S셀의 타이머를 중단하며, 해당 S셀과 관련된 모든 HARQ 버퍼를 비운다(flush).

[162] - 활성화된 S셀 상의 PDCCH가 상향링크 그랜트(uplink grant) 또는 하향링크 승인(downlink assignment)을 지시하거나, 또는 활성화된 S셀을 스케줄링하는 서빙 셀 상의 PDCCH가 활성화된 S셀을 위한 상향링크 그랜트(uplink grant) 또는 하향링크 승인(downlink assignment)을 지시하면, 단말은 해당 S셀과 관련된 타이머를 재시작한다.

[163] - S셀이 비활성화되면, 단말은 S셀 상에서 SRS를 전송하지 않고, S셀을 위한 CQI/PMI/RI/PTI를 보고하지 않으며, S셀 상에서 UL-SCH를 전송하지 않으며, S셀 상에서 PDCCH를 모니터하지 않는다.

[164]

[165] **랜덤 액세스 절차(Random Access Procedure)**

[166] 이하에서는 LTE/LTE-A 시스템에서 제공하는 랜덤 액세스 절차(random access

procedure)에 대해 살펴본다.

[167] 랜덤 액세스 절차는 단말이 기지국과 상향링크 동기를 얻거나 상향링크 무선 자원을 할당 받기 위해 사용된다. 단말의 전원이 켜진 후, 단말은 초기 셀과의 하향링크 동기를 획득하고 시스템 정보를 수신한다. 시스템 정보로부터 사용 가능한 랜덤 액세스 프리앰블(random access preamble)의 집합과 랜덤 액세스 프리앰블의 전송에 사용되는 무선 자원에 관한 정보를 얻는다. 랜덤 액세스 프리앰블의 전송에 사용되는 무선 자원은 적어도 하나 이상의 서브프레임 인덱스와 주파수 영역 상의 인덱스의 조합으로 특정될 수 있다. 단말은 랜덤 액세스 프리앰블의 집합으로부터 임의로 선택한 랜덤 액세스 프리앰블을 전송하고, 상기 랜덤 액세스 프리앰블을 수신한 기지국은 상향링크 동기를 위한 타이밍 정렬(TA: timing alignment) 값을 랜덤 액세스 응답을 통해 단말로 보낸다. 이로써 단말은 상향링크 동기를 획득하는 것이다.

[168] 랜덤 액세스 절차는 FDD(frequency division duplex)와 TDD(time division duplex)에서 공통적인 절차이다. 랜덤 액세스 절차는 셀 사이즈에 무관하며, 캐리어 병합(CA: carrier aggregation)이 설정된 경우 서빙 셀(serving cell)의 개수와도 무관하다.

[169] 먼저, 단말이 랜덤 액세스 절차를 수행하는 경우로는 다음과 같은 경우가 있다.

[170] - 단말이 기지국과의 RRC 연결(RRC Connection)이 없어, RRC 아이들 상태에서 초기 접속 (initial access)을 수행하는 경우

[171] - RRC 연결 재-확립 절차(RRC connection re-establishment procedure)를 수행하는 경우

[172] - 단말이 핸드오버 과정에서, 타겟(target) 셀로 처음 접속하는 경우

[173] - 기지국의 명령에 의해 랜덤 액세스 절차가 요청되는 경우

[174] - RRC 연결 상태 중, 상향링크 시간 동기가 맞지 않은 상황에서(non-synchronized) 하향링크로 전송될 데이터가 발생하는 경우

[175] - RRC 연결 상태 중, 상향링크의 시간 동기가 맞지 않거나(non-synchronized), 무선자원을 요청하기 위해 사용되는 지정된 무선자원이 할당되지 않은 상황에서, 상향링크로 전송할 데이터가 발생하는 경우

[176] - RRC 연결 상태 중, 타이밍 어드밴스(timing advance)가 필요한 상황에서 단말의 위치 결정(positioning)을 수행하는 경우

[177] - 무선 연결 실패(radio link failure) 또는 핸드오버 실패(handover failure) 시 복구 과정을 수행하는 경우

[178] 3GPP Rel-10에서는 캐리어 병합을 지원하는 무선 접속 시스템에서 하나의 특정 셀(예를 들어, P셀)에 적용 가능한 TA(timing advance) 값을 복수의 셀에 공통으로 적용하는 것을 고려하였다. 다만, 단말이 서로 다른 주파수 밴드에 속한(즉, 주파수 상에서 크게 이격된) 복수의 셀들 혹은 전파(propagation) 특성이 다른 복수의 셀들을 병합할 수 있다. 또한 특정 셀의 경우 커버리지 확대 혹은 커버리지 홀의 제거를 위해 RRH(remote radio header)(즉, 리피터), 펨토 셀(femto

cell) 혹은 피코 셀(pico cell) 등과 같은 스몰 셀(small cell) 또는 세컨더리 기지국(SeNB: secondary eNB)이 셀 내에 배치되는 상황에서 단말은 하나의 셀을 통해 기지국(즉, 매크로 기지국(macro eNB))과 통신을 수행하고, 다른 셀을 통해 세컨더리 기지국과 통신을 수행하는 경우 복수의 셀들이 서로 다른 전파 지연 특성을 가지게 될 수 있다. 이 경우, 하나의 TA 값을 복수의 셀들에 공통으로 적용하는 방식으로 사용하는 상향링크 전송을 수행할 경우 복수의 셀들 상에서 전송되는 상향링크 신호의 동기에 심각한 영향을 끼칠 수 있다. 따라서, 복수의 셀들이 병합된 CA 상황에서 복수의 TA를 가지는 것이 바람직할 수 있으며, 3GPP Rel-11에서는 다중 TA(multiple TA)를 지원하기 위하여 특정 셀 그룹 단위로 TA를 독립적으로 할당하는 것을 고려한다. 이를 TA 그룹(TAG: TA group)이라 하며, TAG는 하나 이상의 셀들을 포함할 수 있으며, TAG 내 포함된 하나 이상의 셀에는 동일한 TA가 공통적으로 적용될 수 있다. 이러한 다중 TA를 지원하기 위하여, MAC TA 명령 제어 요소(element)는 2 비트의 TAG 식별자(TAG ID)와 6 비트의 TA 명령 필드로 구성된다.

[179] 캐리어 병합이 설정된 단말은 P셀과 관련되어 앞서 설명한 랜덤 액세스 절차를 수행하는 경우가 발생되면 랜덤 액세스 절차를 수행하게 된다. P셀이 속한 TAG(즉, pTAG: primary TAG)의 경우, 기존과 동일하게 P셀을 기준으로 결정되는, 혹은 P셀에 수반되는 랜덤 액세스 절차를 통해 조정되는 TA를 pTAG 내 모든 셀(들)에 적용할 수 있다. 반면, S셀로만 구성되는 TAG(즉, sTAG: secondary TAG)의 경우, sTAG 내 특정 S셀을 기준으로 결정되는 TA는 해당 sTAG 내 모든 셀(들)에 적용할 수 있으며, 이 때 TA는 기지국에 의해 개시되 랜덤 액세스 절차에 의해 획득될 수 있다. 구체적으로, sTAG 내에서 S셀은 RACH(Random Access Channel) 자원으로 설정되고, 기지국은 TA를 결정하기 위하여 S셀에서 RACH 접속을 요청한다. 즉, 기지국은 P셀에서 전송되는 PDCCH 오더에 의해 S셀들 상에서 RACH 전송을 개시시킨다. S셀 프리앰블에 대한 응답 메시지는 RA-RNTI를 사용하여 P셀을 통해 전송된다. 단말은 랜덤 액세스를 성공적으로 마친 S셀을 기준으로 결정되는 TA는 해당 sTAG 내 모든 셀(들)에 적용할 수 있다. 이와 같이, 랜덤 액세스 절차는 S셀에서도 해당 S셀이 속한 sTAG의 타이밍 정렬(timing alignment)을 획득하기 위하여 S셀에서도 수행될 수 있다.

[180] LTE/LTE-A 시스템에서는 랜덤 액세스 프리앰블(random access preamble, RACH preamble)을 선택하는 과정에서, 특정한 집합 안에서 단말이 임의로 하나의 프리앰블을 선택하여 사용하는 경쟁 기반 랜덤 액세스 절차(contention based random access procedure)과 기지국이 특정 단말에게만 할당해준 랜덤 액세스 프리앰블을 사용하는 비 경쟁 기반 랜덤 액세스 절차(non-contention based random access procedure)을 모두 제공한다. 다만, 비 경쟁 기반 랜덤 액세스 절차는, 상술한 핸드오버 과정, 기지국의 명령에 의해 요청되는 경우, 단말 위치 결정(positioning) 및/또는 sTAG을 위한 타이밍 어드밴스 정렬에 한하여 사용될

수 있다. 랜덤 액세스 절차가 완료된 후에 일반적인 상향링크/하향링크 전송이 발생된다.

[181] 한편, 릴레이 노드(RN: relay node) 또한 경쟁 기반 랜덤 액세스 절차와 비 경쟁 기반 랜덤 액세스 절차를 모두 지원한다. 릴레이 노드가 랜덤 액세스 절차를 수행할 때, 그 시점에서 RN 서브프레임 구성(configuration)을 중단시킨다(suspend). 즉, 이는 일시적으로 RN 서브프레임 구성을 폐기하는 것으로 의미한다. 이후, 성공적으로 랜덤 액세스 절차가 완료되는 시점에서 RN 서브프레임 구성이 재개된다.

[182] 도 8은 본 발명이 적용될 수 있는 무선 통신 시스템에서 경쟁 기반 랜덤 액세스 절차를 설명하기 위한 도면이다.

[183] (1) 제1 메시지(Msg 1, message 1)

[184] 먼저, 단말은 시스템 정보(system information) 또는 핸드오버 명령(handover command)을 통해 지시된 랜덤 액세스 프리앰블의 집합에서 임의로(randomly) 하나의 랜덤 액세스 프리앰블(random access preamble, RACH preamble)을 선택하고, 상기 랜덤 액세스 프리앰블을 전송할 수 있는 PRACH(physical RACH) 자원을 선택하여 전송한다.

[185] 랜덤 액세스 프리앰블은 RACH 전송 채널에서 6비트로 전송되고, 6비트는 RACH 전송한 단말을 식별하기 위한 5비트의 임의 식별자(radom identity)와, 추가 정보를 나타내기 위한 1비트(예를 들어, 제3 메시지(Msg 3)의 크기를 지시)로 구성된다.

[186] 단말로부터 랜덤 액세스 프리엠블을 수신한 기지국은 프리앰블을 디코딩하고, RA-RNTI를 획득한다. 랜덤 액세스 프리앰블이 전송된 PRACH와 관련된 RA-RNTI는 해당 단말이 전송한 랜덤 액세스 프리앰블의 시간-주파수 자원에 따라 결정된다.

[187] (2) 제2 메시지(Msg 2, message 2)

[188] 기지국은 제1 메시지 상의 프리앰블을 통해서 획득한 RA-RNTI로 지시(address)되는 랜덤 액세스 응답(random access response)을 단말로 전송한다. 랜덤 액세스 응답에는 랜덤 액세스 프리앰블 구분자/식별자(RA preamble index/identifier), 상향링크 무선자원을 알려주는 상향링크 승인(UL grant), 임시 셀 식별자(TC-RNTI: Temporary C-RNTI) 그리고 시간 동기 값(TAC: time alignment command)들이 포함될 수 있다. TAC는 기지국이 단말에게 상향링크 시간 정렬(time alignment)을 유지하기 위해 보내는 시간 동기 값을 지시하는 정보이다. 단말은 상기 시간 동기 값을 이용하여, 상향링크 전송 타이밍을 갱신한다. 단말이 시간 동기를 갱신하면, 시간 동기 타이머(time alignment timer)를 개시 또는 재시작한다. UL grant는 후술하는 스케줄링 메시지(제3 메시지)의 전송에 사용되는 상향링크 자원 할당 및 TPC(transmit power command)를 포함한다. TPC는 스케줄링된 PUSCH를 위한 전송 파워의 결정에 사용된다.

[189] 단말은 랜덤 액세스 프리앰블을 전송 후에, 기지국이 시스템 정보 또는 핸드오버 명령을 통해 지시된 랜덤 액세스 응답 윈도우(random access response window) 내에서 자신의 랜덤 액세스 응답(random access response)의 수신을 시도하며, PRACH에 대응되는 RA-RNTI로 마스킹된 PDCCH를 검출하고, 검출된 PDCCH에 의해 지시되는 PDSCH를 수신하게 된다. 랜덤 액세스 응답 정보는 MAC PDU(MAC packet data unit)의 형식으로 전송될 수 있으며, 상기 MAC PDU는 PDSCH을 통해 전달될 수 있다. PDCCH에는 상기 PDSCH를 수신해야 하는 단말의 정보와, 상기 PDSCH의 무선 자원의 주파수 그리고 시간 정보, 그리고 상기 PDSCH의 전송 형식 등이 포함되어 있는 것이 바람직하다. 상술한 바와 같이, 일단 단말이 자신에게 전송되는 PDCCH의 검출에 성공하면, 상기 PDCCH의 정보들에 따라 PDSCH로 전송되는 랜덤 액세스 응답을 적절히 수신할 수 있다.

[190] 랜덤 액세스 응답 윈도우는 프리앰블을 전송한 단말이 랜덤 액세스 응답 메시지를 수신하기 위해서 대기하는 최대 시구간을 의미한다. 랜덤 액세스 응답 윈도우는 프리앰블이 전송되는 마지막 서브프레임에서 3개의 서브프레임 이후의 서브프레임으로부터 시작하여 'ra-ResponseWindowSize'의 길이를 가진다. 즉, 단말은 프리앰블을 전송이 종료된 서브프레임으로부터 3개의 서브프레임 이후부터 확보한 랜덤 액세스 윈도우 동안 랜덤 액세스 응답을 수신하기 위해 대기한다. 단말은 시스템 정보(system information)을 통해 랜덤 액세스 윈도우 사이즈('ra-ResponseWindowsize') 파라미터 값을 획득할 수 있으며, 랜덤 액세스 윈도우 사이즈는 2부터 10 사이의 값으로 결정될 수 있다.

[191] 단말은 기지국에 전송하였던 랜덤 액세스 프리앰블과 동일한 랜덤 액세스 프리앰블 구분자/식별자를 가지는 랜덤 액세스 응답을 성공적으로 수신하면, 랜덤 액세스 응답의 모니터링을 중지한다. 반면, 랜덤 액세스 응답 윈도우가 종료될 때까지 랜덤 액세스 응답 메시지를 수신하지 못하거나, 기지국에 전송하였던 랜덤 액세스 프리앰블과 동일한 랜덤 액세스 프리앰블 구분자를 가지는 유효한 랜덤 액세스 응답을 수신하지 못한 경우 랜덤 액세스 응답의 수신은 실패하였다고 간주되고, 이후 단말은 프리앰블 재전송을 수행할 수 있다.

[192] 상술한 바와 같이 랜덤 액세스 응답에서 랜덤 액세스 프리앰블 구분자가 필요한 이유는, 하나의 랜덤 액세스 응답에는 하나 이상의 단말들을 위한 랜덤 액세스 응답 정보가 포함될 수 있기 때문에, 상기 UL grant, TC-RNTI 그리고 TAC가 어느 단말에게 유효한지를 알려주기 위는 것이 필요하기 때문이다.

[193] (3) 제3 메시지(Msg 3, message 3)

[194] 단말이 자신에게 유효한 랜덤 액세스 응답을 수신한 경우에는, 상기 랜덤 액세스 응답에 포함된 정보들을 각각 처리한다. 즉, 단말은 TAC을 적용시키고, TC-RNTI를 저장한다. 또한, UL grant를 이용하여, 단말의 버퍼에 저장된 데이터 또는 새롭게 생성된 데이터를 기지국으로 전송한다. 단말의 최초 접속의 경우, RRC 계층에서 생성되어 CCCH를 통해 전달된 RRC 연결 요청이 제3 메시지에

포함되어 전송될 수 있으며, RRC 연결 재확립 절차의 경우 RRC 계층에서 생성되어 CCCH를 통해 전달된 RRC 연결 재확립 요청이 제3 메시지에 포함되어 전송될 수 있다. 또한, NAS 접속 요청 메시지를 포함할 수도 있다.

[195] 제3 메시지는 단말의 식별자가 포함되어야 한다. 경쟁 기반 랜덤 액세스 절차에서는 기지국에서 어떠한 단말들이 상기 랜덤 액세스 절차를 수행하는지 판단할 수 없는데, 차후에 충돌 해결을 하기 위해서는 단말을 식별해야 하기 때문이다.

[196] 단말의 식별자를 포함시키는 방법으로는 두 가지 방법이 존재한다. 첫 번째 방법은 단말이 상기 랜덤 액세스 절차 이전에 이미 해당 셀에서 할당 받은 유효한 셀 식별자(C-RNTI)를 가지고 있었다면, 단말은 상기 UL grant에 대응하는 상향링크 전송 신호를 통해 자신의 셀 식별자를 전송한다. 반면에, 만약 랜덤 액세스 절차 이전에 유효한 셀 식별자를 할당 받지 못하였다면, 단말은 자신의 고유 식별자(예를 들면, S-TMSI 또는 임의 값(random number))를 포함하여 전송한다. 일반적으로 상기의 고유 식별자는 C-RNTI보다 길다. UL-SCH 상의 전송에서는 단말 특정 스크램블링이 사용된다. 다만, 단말이 아직 C-RNTI를 할당받지 못한 경우라면, 스크램블링은 C-RNTI에 기반할 수 없으며 대신 랜덤 액세스 응답에서 수신한 TC-RNTI가 사용된다. 단말은 상기 UL grant에 대응하는 데이터를 전송하였다면, 충돌 해결을 위한 타이머(contention resolution timer)를 개시한다.

[197] (4) 제4 메시지(Msg 4, message 4)

[198] 기지국은 단말로부터 제3 메시지를 통해 해당 단말의 C-RNTI를 수신한 경우 수신한 C-RNTI를 이용하여 단말에게 제4 메시지를 전송한다. 반면, 단말로부터 제3 메시지를 통해 상기 고유 식별자(즉, S-TMSI 또는 임의 값(random number))를 수신한 경우, 랜덤 액세스 응답에서 해당 단말에게 할당한 TC-RNTI를 이용하여 제4 메시지를 단말에게 전송한다. 여기서, 제4 메시지는 C-RNTI를 포함하는 RRC 연결 설정 메시지(RRC connection setup)가 해당될 수 있다.

[199] 단말은 랜덤 액세스 응답에 포함된 UL grant를 통해 자신의 식별자를 포함한 데이터를 전송한 이후, 충돌 해결을 위해 기지국의 지시를 기다린다. 즉, 특정 메시지를 수신하기 위해 PDCCH의 수신을 시도한다. 상기 PDCCH를 수신하는 방법에 있어서도 두 가지 방법이 존재한다. 앞에서 언급한 바와 같이 상기 UL grant에 대응하여 전송된 제3 메시지가 자신의 식별자가 C-RNTI인 경우, 자신의 C-RNTI를 이용하여 PDCCH의 수신을 시도하고, 상기 식별자가 고유 식별자(즉, S-TMSI 또는 임의 값(random number))인 경우에는, 랜덤 액세스 응답에 포함된 TC-RNTI를 이용하여 PDCCH의 수신을 시도한다. 그 후, 전자의 경우, 만약 상기 충돌 해결 타이머가 만료되기 전에 자신의 C-RNTI를 통해 PDCCH를 수신한 경우에, 단말은 정상적으로 랜덤 액세스 절차가 수행되었다고 판단하고, 랜덤 액세스 절차를 종료한다. 후자의 경우에는 상기 충돌 해결 타이머가 만료되기 전에 TC-RNTI를 통해 PDCCH를 수신하였다면, 상기 PDCCH가 지시하는

PDSCH이 전달하는 데이터를 확인한다. 만약 상기 데이터의 내용에 자신의 고유 식별자가 포함되어 있다면, 단말은 정상적으로 랜덤 액세스 절차가 수행되었다고 판단하고, 랜덤 액세스 절차를 종료한다. 제4 메시지를 통해 단말은 C-RNTI를 획득하고, 이후 단말과 네트워크는 C-RNTI를 이용하여 단말 특정 메시지(dedicated message)를 송수신하게 된다.

[200] 다음은 랜덤 액세스에서 충돌 해결을 위한 방법에 대하여 설명한다.

[201] 랜덤 액세스를 수행함에 있어서 충돌이 발생하는 이유는 기본적으로 랜덤 액세스 프리앰블의 수가 유한하기 때문이다. 즉, 기지국은 모든 단말들에게 단말 고유의 랜덤 액세스 프리앰블을 부여할 수 없기 때문에, 단말은 공통의 랜덤 액세스 프리앰블들 중에서 임의적으로 하나를 선택해서 전송하게 된다. 이에 따라 동일한 무선 자원(PRACH 자원)을 통해 둘 이상의 단말들이 같은 랜덤 액세스 프리앰블을 선택하여 전송하게 되는 경우가 발생하지만, 기지국에서는 하나의 단말에게서 전송되는 하나의 랜덤 액세스 프리앰블로 판단하게 된다. 이로 인해, 기지국은 랜덤 액세스 응답을 단말에게 전송하고 랜덤 액세스 응답은 하나의 단말이 수신할 것으로 예측한다. 하지만, 상술한 바와 같이 충돌이 발생할 수 있기 때문에, 둘 이상의 단말들이 하나의 랜덤 액세스 응답을 수신하게 되며, 이에 따라 단말마다 각각 랜덤 액세스 응답의 수신에 따른 동작을 수행하게 된다. 즉, 랜덤 액세스 응답에 포함된 하나의 UL Grant를 이용하여, 둘 이상의 단말들이 서로 다른 데이터를 동일한 무선자원에 전송하게 되는 문제점이 발생하게 된다. 이에 따라, 상기 데이터의 전송은 모두 실패할 수도 있고, 단말들의 위치 또는 전송파워에 따라 특정 단말의 데이터만을 기지국에서 수신할 수도 있다. 후자의 경우, 둘 이상의 단말들은 모두 자신의 데이터의 전송이 성공했다고 가정하기 때문에, 기지국은 경쟁에서 실패한 단말들에게 실패 사실에 대한 정보를 알려주어야 한다. 즉, 상기 경쟁의 실패 또는 성공에 대한 정보를 알려주는 것이 충돌 해결(contention resolution)라 한다.

[202] 충돌 해결 방법에는 두 가지 방법이 있는데 한 가지 방법은, 충돌 해결 타이머(contention resolution timer)를 이용하는 방법과, 다른 한가지 방법은 성공한 단말의 식별자를 단말들에게 전송하는 방법이다. 전자의 경우는, 단말이 랜덤 액세스 과정 전에 이미 고유의 C-RNTI를 가지고 있는 경우에 사용된다. 즉, 이미 C-RNTI를 가지고 있는 단말은 랜덤 액세스 응답에 따라 자신의 C-RNTI를 포함한 데이터를 기지국으로 전송하고, 충돌 해결 타이머를 작동한다. 그리고, 충돌 해결 타이머가 만료되기 전에, 자신의 C-RNTI에 의해 지시되는 PDCCH 정보가 수신되면, 단말은 자신이 경쟁에서 성공했다고 판단하고, 랜덤 액세스를 정상적으로 마치게 된다. 반대로, 만약 충돌 해결 타이머가 만료되기 전에, 자신의 C-RNTI에 의해 지시되는 PDCCH를 전송 받지 못한 경우는, 자신이 경쟁에서 실패했다고 판단하고, 랜덤 액세스 과정을 다시 수행하거나, 상위 계층으로 실패 사실을 통보할 수 있다. 충돌 해소 방법 중 후자의 경우, 즉 성공한 단말의 식별자를 전송하는 방법은, 단말이 랜덤 액세스 과정 전에 고유의 셀

식별자가 없는 경우에 사용된다. 즉, 단말 자신이 셀 식별자가 없는 경우, 랜덤 액세스 응답에 포함된 UL Grant 정보에 따라 데이터에 셀 식별자 보다 상위 식별자(S-TMSI 또는 random number)를 포함하여 전송하고, 단말은 충돌 해결 타이머를 작동시킨다. 충돌 해결 타이머가 만료되기 전에, 자신의 상위 식별자를 포함한 데이터가 DL-SCH로 전송된 경우, 단말은 랜덤 액세스 과정이 성공했다고 판단한다. 반면에, 충돌 해결 타이머가 만료되기 전에, 자신의 상위 식별자를 포함한 데이터를 DL-SCH로 전송 받지 못하는 경우에는, 단말은 랜덤 액세스 과정이 실패했다고 판단하게 되는 것이다.

[203] 한편, 비경쟁 기반 임의접속 과정에서의 동작은 도 8에 도시된 경쟁 기반 임의접속 과정과 달리 제1 메시지 전송 및 제2 메시지 전송만으로 임의접속 절차가 종료되게 된다. 다만, 제1 메시지로서 단말이 기지국에 임의접속 프리엠블을 전송하기 전에 단말은 기지국으로부터 임의접속 프리엠블을 할당받게 되며, 이 할당받은 임의접속 프리엠블을 기지국에 제1 메시지로서 전송하고, 기지국으로부터 임의접속 응답을 수신함으로써 임의접속 절차가 종료되게 된다.

[204]

[205] <u>참조 신호(RS: Reference Signal)</u>

[206] 무선 통신 시스템에서 데이터는 무선 채널을 통해 전송되기 때문에, 신호는 전송 중에 왜곡될 수 있다. 수신단에서 왜곡된 신호를 정확하게 수신하기 위하여, 수신된 신호의 왜곡은 채널 정보를 이용하여 보정되어야 한다. 채널 정보를 검출하기 위하여 송신측과 수신측 모두 알고 있는 신호 전송 방법과 신호가 채널을 통해 전송될 때 왜곡된 정도를 이용하여 채널 정보를 검출하는 방법을 주로 이용한다. 상술한 신호를 파일럿 신호 또는 참조 신호(RS: reference signal)라고 한다.

[207] 또한 최근 대부분의 이동통신 시스템에서 패킷을 전송할 때, 지금까지 한 개의 송신안테나와 한 개의 수신안테나를 사용했던 것에서 탈피, 다중송신안테나와 다중수신안테나를 채택해 송수신 데이터 효율을 향상시킬 수 있는 방법을 사용한다. 다중 입출력 안테나를 이용하여 데이터를 송수신할 때, 신호를 정확하게 수신하기 위하여 송신 안테나와 수신 안테나 간의 채널 상태가 검출되어야 한다. 따라서 각 송신 안테나는 개별적인 참조 신호를 가져야 한다.

[208] 이동 통신 시스템에서 RS는 그 목적에 따라 크게 두 가지로 구분될 수 있다. 채널 정보 획득을 위한 목적의 RS와 데이터 복조를 위해 사용되는 RS가 있다. 전자는 UE가 하향 링크로의 채널 정보를 획득하는데 그 목적이 있으므로, 광대역으로 전송되어야 하고, 특정 서브 프레임에서 하향 링크 데이터를 수신하지 않는 UE라도 그 RS를 수신하고 측정할 수 있어야 한다. 또한 이는 핸드오버 등의 측정 등을 위해서도 사용된다. 후자는 기지국이 하향링크를 보낼 때 해당 리소스에 함께 보내는 RS로서, UE는 해당 RS를 수신함으로써 채널 추정을 할 수 있고, 따라서 데이터를 복조할 수 있게 된다. 이 RS는 데이터가 전송되는

영역에 전송되어야 한다.

[209] 하향 참조 신호는 셀 내 모든 단말이 공유하는 채널 상태에 대한 정보 획득 및 핸드오버 등의 측정 등을 위한 하나의 공통 참조 신호(CRS: common RS)와 특정 단말만을 위하여 데이터 복조를 위해 사용되는 전용 참조 신호(dedicated RS)가 있다. 이와 같은 참조 신호들을 이용하여 복조(demodulation)와 채널 측정(channel measurement)을 위한 정보를 제공할 수 있다. 즉, DRS는 데이터 복조용으로만 사용되며 CRS는 채널 정보 획득 및 데이터 복조의 두 가지 목적으로 다 사용된다.

[210] 수신 측(즉, 단말)은 CRS로부터 채널 상태를 측정하고, CQI(Channel Quality Indicator), PMI(Precoding Matrix Index) 및/또는 RI(Rank Indicator)와 같은 채널 품질과 관련된 지시자를 송신 측(즉, 기지국)으로 피드백한다. CRS는 셀 특정 기준신호(cell-specific RS)라고도 한다. 반면, 채널 상태 정보(CSI: Channel State Information)의 피드백과 관련된 참조 신호를 CSI-RS라고 정의할 수 있다.

[211] DRS는 PDSCH 상의 데이터 복조가 필요한 경우 자원 요소들을 통해 전송될 수 있다. 단말은 상위 계층을 통하여 DRS의 존재 여부를 수신할 수 있으며, 상응하는 PDSCH가 매핑되었을 때만 유효하다. DRS를 단말 특정 참조 신호(UE-specific RS) 또는 복조 참조 신호(DMRS: Demodulation RS)라고 할 수 있다.

[212] 도 9는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 자원 블록 쌍에 매핑된 참조 신호 패턴을 예시한다.

[213] 도 9를 참조하면, 참조 신호가 매핑되는 단위로 하향링크 자원 블록 쌍은 시간 영역에서 하나의 서브 프레임 × 주파수 영역에서 12개의 부 반송파로 나타낼 수 있다. 즉, 시간 축(x축) 상에서 하나의 자원 블록 쌍은 일반 순환 전치(normal CP: normal Cyclic Prefix) 인 경우 14개의 OFDM 심볼의 길이를 가지고(도 9(a)의 경우), 확장 순환 전치(extended CP: extended Cyclic Prefix)인 경우 12개의 OFDM 심볼의 길이를 가진다(도 9(b)의 경우). 자원 블록 격자에서 '0', '1', '2' 및 '3'으로 기재된 자원 요소들(REs)은 각각 안테나 포트 인덱스 '0', '1', '2' 및 '3'의 CRS의 위치를 의미하며, 'D'로 기재된 자원 요소들은 DRS의 위치를 의미한다.

[214] 이하 CRS에 대하여 좀 더 상세하게 기술하면, CRS는 물리적 안테나의 채널을 추정하기 위해 사용되고, 셀 내에 위치한 모든 단말에 공통적으로 수신될 수 있는 참조 신호로써 전체 주파수 대역에 분포된다. 즉, 이 CRS는 cell-specific한 시그널로, 광대역에 대해서 매 서브 프레임마다 전송된다. 또한, CRS는 채널 품질 정보(CSI) 및 데이터 복조를 위해 이용될 수 있다.

[215] CRS는 전송 측(기지국)에서의 안테나 배열에 따라 다양한 포맷으로 정의된다. 3GPP LTE 시스템(예를 들어, 릴리즈-8)에서는 기지국의 전송 안테나 개수에 따라서 최대 4개의 안테나 포트에 대한 RS가 전송된다. 하향링크 신호 송신 측은 단일의 송신 안테나, 2개의 송신 안테나 및 4개의 송신 안테나와 같이 3 종류의 안테나 배열을 가진다. 예를 들어 기지국의 송신 안테나의 개수가 두 개일 경우,

0번과 1번 안테나 포트에 대한 CRS가 전송되고, 네 개인 경우 0~3 번 안테나 포트에 대한 CRS가 각각 전송된다. 기지국의 송신 안테나가 4개일 경우 한 RB에서의 CRS 패턴은 도 9와 같다.

[216] 기지국이 단일의 송신 안테나를 사용하는 경우, 단일 안테나 포트를 위한 참조 신호가 배열된다.

[217] 기지국이 2개의 송신 안테나를 사용하는 경우, 2개의 송신 안테나 포트를 위한 참조 신호는 시분할 다중화(TDM: Time Division Multiplexing) 및/또는 주파수 분할 다중화(FDM Frequency Division Multiplexing) 방식을 이용하여 배열된다. 즉, 2개의 안테나 포트를 위한 참조 신호는 각각이 구별되기 위해 서로 다른 시간 자원 및/또는 서로 다른 주파수 자원이 할당된다.

[218] 게다가, 기지국이 4개의 송신 안테나를 사용하는 경우, 4개의 송신 안테나 포트를 위한 참조 신호는 TDM 및/또는 FDM 방식을 이용하여 배열된다. 하향링크 신호의 수신 측(단말)에 의하여 측정된 채널 정보는 단일의 송신 안테나 전송, 송신 다이버시티, 폐쇄 루프 공간 다중화(closed-loop spatial multiplexing), 개방 루프 공간 다중화(open-loop spatial multiplexing) 또는 다중 사용자-다중 입출력 안테나(Multi-User MIMO)와 같은 전송 방식을 이용하여 전송된 데이터를 복조하기 위하여 사용될 수 있다.

[219] 다중 입출력 안테나가 지원되는 경우 참조 신호가 특정의 안테나 포트로부터 전송될 때, 상기 참조 신호는 참조 신호의 패턴에 따라 특정된 자원 요소들의 위치에 전송되며, 다른 안테나 포트를 위해 특정된 자원 요소들의 위치에 전송되지 않는다. 즉, 서로 다른 안테나 사이의 참조 신호는 서로 겹치지 않는다.

[220] 이하 DRS에 대하여 좀 더 상세하게 기술하면, DRS는 데이터를 복조하기 위하여 사용된다. 다중 입출력 안테나 전송에서 특정의 단말을 위해 사용되는 선행 부호화(precoding) 가중치는 단말이 참조 신호를 수신하였을 때 각 송신 안테나에서 전송된 전송 채널과 결합되어 상응하는 채널을 추정하기 위하여 변경 없이 사용된다.

[221] 3GPP LTE 시스템(예를 들어, 릴리즈-8)은 최대로 4개의 전송 안테나를 지원하고, 랭크 1 빔포밍(beamforming)을 위한 DRS가 정의된다. 랭크 1 빔포밍을 위한 DRS는 또한 안테나 포트 인덱스 5 를 위한 참조 신호를 나타낸다.

[222] LTE 시스템의 진화 발전된 형태의 LTE-A 시스템에서 기지국의 하향 링크로 최대 8개의 송신 안테나를 지원할 수 있도록 디자인되어야 한다. 따라서 최대 8개 송신 안테나에 대한 RS 역시 지원되어야 한다. LTE 시스템에서 하향 링크 RS는 최대 4개의 안테나 포트에 대한 RS만 정의되어 있으므로, LTE-A 시스템에서 기지국이 4개 이상 최대 8개의 하향 링크 송신 안테나를 가질 경우 이들 안테나 포트에 대한 RS가 추가적으로 정의되고 디자인되어야 한다. 최대 8개의 송신 안테나 포트에 대한 RS는 위에서 설명한 채널 측정을 위한 RS와 데이터 복조를 위한 RS 두 가지가 모두 디자인되어야 한다.

[223] LTE-A 시스템을 디자인 함에 있어서 중요한 고려 사항 중 하나는 하위

호환성(backward compatibility), 즉 LTE 단말이 LTE-A 시스템에서도 아무 무리 없이 잘 동작해야 하고, 시스템 또한 이를 지원해야 한다는 것이다. RS 전송 관점에서 보았을 때, LTE에서 정의되어 있는 CRS가 전 대역으로 매 서브 프레임마다 전송되는 시간-주파수 영역에서 추가적으로 최대 8개의 송신 안테나 포트에 대한 RS가 추가적으로 정의되어야 한다. LTE-A 시스템에서 기존 LTE의 CRS와 같은 방식으로 최대 8개의 송신 안테나에 대한 RS 패턴을 매 서브 프레임마다 전 대역에 추가하게 되면 RS 오버헤드가 지나치게 커지게 된다.

[224] 따라서 LTE-A 시스템에서 새로이 디자인되는 RS는 크게 두 가지 분류로 나누게 되는데, MCS, PMI 등의 선택을 위한 채널 측정 목적의 RS (CSI-RS: Channel State Information-RS, Channel State Indication-RS 등)와 8개의 전송 안테나로 전송되는 데이터 복조를 위한 RS(DM-RS: Data Demodulation-RS)이다.

[225] 채널 측정 목적의 CSI-RS는 기존의 CRS가 채널 측정, 핸드 오버 등의 측정 등의 목적과 동시에 데이터 복조를 위해 사용되는 것과 달리 채널 측정 위주의 목적을 위해서 디자인되는 특징이 있다. 물론 이 또한 핸드 오버 등의 측정 등의 목적으로도 사용될 수도 있다. CSI-RS가 채널 상태에 대한 정보를 얻는 목적으로만 전송되므로 CRS와 달리 매 서브 프레임마다 전송되지 않아도 된다. CSI-RS의 오버헤드를 줄이기 위하여 CSI-RS는 시간 축 상에서 간헐적으로 전송된다.

[226] 데이터 복조를 위해서 해당 시간-주파수 영역에서 스케줄링 된 UE에게 전용적(dedicated)으로 DM-RS가 전송된다. 즉, 특정 UE의 DM-RS는 해당 UE가 스케줄링 된 영역, 즉 데이터를 수신 받는 시간-주파수 영역에만 전송되는 것이다.

[227] LTE-A 시스템에서 eNB는 모든 안테나 포트에 대한 CSI-RS를 전송해야 한다. 최대 8개의 송신 안테나 포트에 대한 CSI-RS를 매 서브 프레임마다 전송하는 것은 오버헤드가 너무 큰 단점이 있으므로, CSI-RS는 매 서브 프레임마다 전송되지 않고 시간 축에서 간헐적으로 전송되어야 그 오버헤드를 줄일 수 있다. 즉, CSI-RS는 한 서브 프레임의 정수 배의 주기를 가지고 주기적으로 전송되거나 특정 전송 패턴으로 전송될 수 있다. 이 때 CSI-RS가 전송되는 주기나 패턴은 eNB가 설정할 수 있다.

[228] CSI-RS를 측정하기 위해서 UE는 반드시 자신이 속한 셀의 각각의 CSI-RS 안테나 포트에 대한 CSI-RS의 전송 서브 프레임 인덱스, 전송 서브 프레임 내에서 CSI-RS 자원 요소(RE) 시간-주파수 위치, 그리고 CSI-RS 시퀀스 등에 대한 정보를 알고 있어야 한다.

[229] LTE-A 시스템에 eNB는 CSI-RS를 최대 8개의 안테나 포트에 대해서 각각 전송해야 한다. 서로 다른 안테나 포트의 CSI-RS 전송을 위해 사용되는 자원은 서로 직교(orthogonal)해야 한다. 한 eNB가 서로 다른 안테나 포트에 대한 CSI-RS를 전송할 때 각각의 안테나 포트에 대한 CSI-RS를 서로 다른 RE에 맵핑함으로써 FDM/TDM방식으로 이들 자원을 orthogonal하게 할당할 수 있다.

또는 서로 다른 안테나 포트에 대한 CSI-RS를 서로 orthogonal한 코드에 맵핑시키는 CDM방식으로 전송할 수 있다.

[230] CSI-RS에 관한 정보를 eNB가 자기 셀 UE에게 알려줄 때, 먼저 각 안테나 포트에 대한 CSI-RS가 매핑되는 시간-주파수에 대한 정보를 알려줘야 한다. 구체적으로, CSI-RS가 전송되는 서브 프레임 번호들, 또는 CSI-RS가 전송되는 주기, CSI-RS가 전송되는 서브 프레임 오프셋이며, 특정 안테나의 CSI-RS RE가 전송되는 OFDM 심볼 번호, 주파수 간격(spacing), 주파수 축에서의 RE의 오프셋 또는 쉬프트 값 등이 있다.

[231] CSI-RS는 1개, 2개, 4개 또는 8개의 안테나 포트를 통해 전송된다. 이때, 사용되는 안테나 포트는 각각 p=15, p=15,16, p=15,...,18, p=15,...,22이다. CSI-RS는 서브캐리어 간격 Δf=15kHz에 대해서만 정의될 수 있다.

[232] (k',l')(여기서, k'는 자원 블록 내 부반송파 인덱스이고, l'는 슬롯 내 OFDM 심볼 인덱스를 나타낸다.) 및 n_s의 조건은 아래 표 4 또는 표 5와 같은 CSI-RS 설정(configuration)에 따라 결정된다.

[233] 표 3은 일반 CP에서 CSI-RS 구성으로부터 (k',l')의 매핑을 예시한다.

[234] [표3]

	CSI reference signal configuration	Number of CSI reference signals configured					
		1 or 2		4		8	
		(k',l')	n_s mod 2	(k',l')	n_s mod 2	(k',l')	n_s mod 2
Frame structure type 1 and 2	0	(9,5)	0	(9,5)	0	(9,5)	0
	1	(11,2)	1	(11,2)	1	(11,2)	1
	2	(9,2)	1	(9,2)	1	(9,2)	1

[237] 표 3 및 표 4를 참조하면, CSI-RS의 전송에 있어서, 이종 네트워크(HetNet: heterogeneous network) 환경을 포함하여 멀티 셀 환경에서 셀간 간섭(ICI: inter-cell interference)을 줄이기 위하여 최대 32개(일반 CP 경우) 또는 최대 28개(확장 CP 경우)의 서로 다른 구성(configuration)이 정의된다.

[238] CSI-RS 구성은 셀 내의 안테나 포트의 개수 및 CP에 따라 서로 다르며, 인접한 셀은 최대한 서로 다른 구성을 가질 수 있다. 또한, CSI-RS 구성은 프레임 구조에 따라 FDD 프레임과 TDD 프레임에 모두 적용하는 경우와 TDD 프레임에만 적용하는 경우로 나눠질 수 있다.

[239] 표 3 및 표 4를 기반으로 CSI-RS 구성에 따라 (k',l') 및 n_s가 정해지고, 각 CSI-RS 안테나 포트가 CSI-RS 전송에 이용하는 시간-주파수 자원이 결정된다.

[240] 도 10은 본 발명이 적용될 수 있는 무선 통신 시스템에서 CSI-RS 구성을 예시하는 도면이다.

[241] 도 10(a)는 1개 또는 2개의 CSI-RS 안테나 포트들에 의한 CSI-RS 전송에 사용

가능한 20가지 CSI-RS 구성들을 나타낸 것이고, 도 10(b)는 4개의 CSI-RS 안테나 포트들에 의해 사용 가능한 10가지 CSI-RS 구성들을 나타낸 것이며, 도 10(c)는 8개의 CSI-RS 안테나 포트들에 의해 CSI-RS 전송에 사용 가능한 5가지 CSI-RS 구성들을 나타낸 것이다.

[242] 이와 같이, 각 CSI-RS 구성에 따라 CSI-RS가 전송되는 무선 자원(즉, RE 쌍)이 결정된다.

[243] 특정 셀에 대하여 CSI-RS 전송을 위해 1개 혹은 2개의 안테나 포트가 설정되면, 도 10(a)에 도시된 20가지 CSI-RS 구성들 중 설정된 CSI-RS 구성에 따른 무선 자원 상에서 CSI-RS가 전송된다.

[244] 마찬가지로, 특정 셀에 대하여 CSI-RS 전송을 위해 4개의 안테나 포트가 설정되면, 도 10(b)에 도시된 10가지 CSI-RS 구성들 중 설정된 CSI-RS 구성에 따른 무선 자원 상에서 CSI-RS가 전송된다. 또한, 특정 셀에 대하여 CSI-RS 전송을 위해 8개의 안테나 포트가 설정되면, 도 10(c)에 도시된 5가지 CSI-RS 구성들 중 설정된 CSI-RS 구성에 따른 무선 자원 상에서 CSI-RS가 전송된다.

[245] 2개의 안테나 포트 별(즉, {15,16}, {17,18}, {19,20}, {21,22})로 각각의 안테나 포트에 대한 CSI-RS는 동일한 무선 자원에 CDM되어 전송된다. 안테나 포트 15 및 16를 예를 들면, 안테나 포트 15 및 16에 대한 각각의 CSI-RS 복소 심볼은 동일하나, 서로 다른 직교 코드(예를 들어, 왈시 코드(walsh code)가 곱해져서 동일한 무선 자원에 매핑된다. 안테나 포트 15에 대한 CSI-RS의 복소 심볼에는 [1, 1]이 곱해지고, 안테나 포트 16에 대한 CSI-RS의 복소 심볼에는 [1 -1]이 곱해져서 동일한 무선 자원에 매핑된다. 이는 안테나 포트 {17,18}, {19,20}, {21,22}도 마찬가지이다.

[246] UE는 전송된 심볼에 곱해진 코드를 곱하여 특정 안테나 포트에 대한 CSI-RS를 검출할 수 있다. 즉, 안테나 포트 15에 대한 CSI-RS를 검출하기 위해서 곱해진 코드 [1 1]을 곱하고, 안테나 포트 16에 대한 CSI-RS를 검출하기 위해서 곱해진 코드 [1 -1]을 곱한다.

[247] 도 10(a) 내지 (c)를 참조하면, 동일한 CSI-RS 구성 인덱스에 해당하게 되면, 안테나 포트 수가 많은 CSI-RS 구성에 따른 무선 자원은 CSI-RS 안테나 포트 수가 적은 CSI-RS 구성에 따른 무선 자원을 포함한다. 예를 들어, CSI-RS 구성 0의 경우, 8개 안테나 포트 수에 대한 무선 자원은 4개 안테나 포트 수에 대한 무선 자원과 1 또는 2개의 안테나 포트 수에 대한 무선 자원을 모두 포함한다.

[248] 하나의 셀에서 복수의 CSI-RS 구성이 사용될 수 있다. 넌-제로 전력(NZP: non-zero power) CSI-RS는 0개 또는 1개 CSI-RS 구성만이 이용되고, 제로 전력(ZP: zero power) CSI-RS는 0개 또는 여러 개의 CSI-RS 구성이 이용될 수 있다.

[249] 상위 계층에 의해 설정되는 16 비트의 비트맵인 ZP CSI-RS(ZeroPowerCSI-RS)에서 1로 설정된 각 비트 별로, UE는 위의 표 3 및 표 4의 4개의 CSI-RS 열(column)에 해당하는 RE들에서(상위 계층에 의해 설정된

NZP CSI-RS를 가정하는 RE와 중복되는 경우를 제외) 제로 전송 전력을 가정한다. 최상위 비트(MSB: Most Significant Bit)는 가장 낮은 CSI-RS 구성 인덱스에 해당하고, 비트맵 내에서 그 다음의 비트는 순서대로 다음의 CSI-RS 구성 인덱스에 해당한다.

[250] CSI-RS는 위의 표 3 및 표 4에서 (n_s mod 2)의 조건을 만족하는 하향링크 슬롯 및 CSI-RS 서브프레임 구성을 만족하는 서브프레임에서만 전송된다.

[251] 프레임 구조 타입 2(TDD)의 경우, 스페셜 서브프레임, 동기 신호(SS), PBCH 또는 SIB 1(SystemInformationBlockType1) 메시지 전송과 충돌되는 서브프레임 또는 페이징 메시지 전송을 위해 설정된 서브프레임에서 CSI-RS는 전송되지 않는다.

[252] 또한, 안테나 포트 세트 S(S={15}, S={15,16}, S={17,18}, S={19,20} 또는 S={21,22}) 내 속하는 어떠한 안테나 포트에 대한 CSI-RS가 전송되는 RE는 PDSCH 또는 다른 안테나 포트의 CSI-RS 전송에 사용되지 않는다.

[253] CSI-RS 전송에 사용되는 시간-주파수 자원들은 데이터 전송에 사용될 수 없으므로, CSI-RS 오버헤드가 증가할수록 데이터 처리량(throughput)이 감소하게 된다. 이를 고려하여 CSI-RS는 매 서브프레임마다 전송되도록 구성되지 않고, 다수의 서브프레임에 해당하는 소정의 전송 주기마다 전송되도록 구성된다. 이 경우, 매 서브프레임마다 CSI-RS가 전송되는 경우에 비하여 CSI-RS 전송 오버헤드가 많이 낮아질 수 있다.

[254] CSI-RS 전송을 위한 서브프레임 주기(이하, 'CSI 전송 주기'로 지칭함)(T_CSI-RS) 및 서브프레임 오프셋(Δ_CSI-RS)은 아래 표 5과 같다.

[255] 표 5은 CSI-RS 서브프레임 구성을 예시한다.

[256] [표5]

CSI-RS-SubframeConfig I_{CSI-RS}	CSI-RS periodicity T_{CSI-RS} (subframes)	CSI-RS subframe offset Δ_{CSI-RS} (subframes)
0 - 4	5	I_{CSI-RS}
5 - 14	10	$I_{CSI\ RS}-5$
15 - 34	20	$I_{CSI-RS}-15$
35 - 74	40	$I_{CSI-RS}-35$
75 - 154	80	$I_{CSI-RS}-75$

[257] 표 5을 참조하면, CSI-RS 서브프레임 구성(I_CSI-RS)에 따라 CSI-RS 전송 주기(T_CSI-RS) 및 서브프레임 오프셋(Δ_CSI-RS)이 결정된다.

[258] 표 5의 CSI-RS 서브프레임 구성은 앞서 'SubframeConfig' 필드 및 'zeroTxPowerSubframeConfig' 필드 중 어느 하나로 설정될 수 있다. CSI-RS 서브프레임 구성은 NZP CSI-RS 및 ZP CSI-RS에 대하여 개별적으로(separately) 설정될 수 있다.

[259] CSI-RS를 포함하는 서브프레임은 아래 수학식 12를 만족한다.

[260] [수식12]

$$(10n_f + \lfloor n_s/2 \rfloor - \Delta_{CSI-RS}) \bmod T_{CSI-RS} = 0$$

[261] 수학식 12에서 T_CSI-RS는 CSI-RS 전송 주기, Δ_CSI-RS는 서브프레임 오프셋 값, n_f는 시스템 프레임 넘버, n_s는 슬롯 넘버를 의미한다.

[262] 서빙 셀에 대해 전송 모드 9(transmission mode 9)가 설정된 UE의 경우, UE는 하나의 CSI-RS 자원 구성이 설정될 수 있다. 서빙 셀에 대해 전송 모드 10(transmission mode 10)이 설정된 UE의 경우, UE는 하나 또는 그 이상의 CSI-RS 자원 구성(들)이 설정될 수 있다.

[263] 각 CSI-RS 자원 구성을 위한 아래와 같이 파라미터가 상위 계층 시그널링을 통해 설정된다.

[264] - 전송 모드 10이 설정된 경우, CSI-RS 자원 구성 식별자

[265] - CSI-RS 포트 개수

[266] - CSI-RS 구성 (표 3 및 표 4 참조)

[267] - CSI-RS 서브프레임 구성(I_CSI-RS) (표 5 참조)

[268] - 전송 모드 9가 설정된 경우, CSI 피드백을 위한 전송 파워(P_C)

[269] - 전송 모드 10이 설정된 경우, 각 CSI 프로세스에 대하여 CSI 피드백을 위한 전송 파워(P_C). CSI 프로세스에 대하여 CSI 서브프레임 세트들 C_CSI,0 및 C_CSI,1가 상위 계층에 의해 설정되면, P_C는 CSI 프로세스의 각 CSI 서브프레임 세트 별로 설정된다.

[270] - 임의 랜덤(pseudo-rnadom) 시퀀스 발생기 파라미터(n_ID)

[271] - 전송 모드 10이 설정된 경우, QCL(QuasiCo-Located) 타입 B UE 가정을 위한 QCL 스크램블링 식별자(qcl-ScramblingIdentity-r11), CRS 포트 카운트(crs-PortsCount-r11), MBSFN 서브프레임 설정 리스트(mbsfn-SubframeConfigList-r11) 파라미터를 포함하는 상위 계층 파라미터('qcl-CRS-Info-r11')

[272] UE가 도출한 CSI 피드백 값이 [-8, 15] dB 범위 내의 값을 가질 때, P_C는 CSI-RS EPRE에 대한 PDSCH EPRE의 비율로 가정된다. 여기서, PDSCH EPRE는 CRS EPRE에 대한 PDSCH EPRE의 비율이 ρ_A인 심볼에 해당한다.

[273] 서빙 셀의 동일한 서브프레임에서 CSI-RS와 PMCH이 함께 설정되지 않는다.

[274] 프레임 구조 타입 2에서 4개의 CRS 안테나 포트가 설정된 경우, UE는 일반 CP의 경우 [20-31] 세트(표 3 참조) 또는 확장 CP의 경우 [16-27] 세트(표 4 참조)에 속하는 CSI-RS 구성 인덱스가 설정되지 않는다.

[275] UE는 CSI-RS 자원 구성의 CSI-RS 안테나 포트가 지연 확산(delay spread), 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift), 평균 이득(average gain) 및 평균 지연(average delay)에 대하여 QCL 관계를 가진다고 가정할 수 있다.

[276] 전송 모드 10 그리고 QCL 타입 B가 설정된 UE는 CSI-RS 자원 구성에 해당하는

안테나 포트 0-3과 CSI-RS 자원 구성에 해당하는 안테나 포트 15-22가 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift)에 대하여 QCL 관계라고 가정할 수 있다.

[277] 전송 모드 10이 설정된 UE의 경우, 서빙 셀에 대하여 하나 또는 그 이상의 CSI-IM(Channel-State Information - Interference Measurement) 자원 구성이 설정될 수 있다.

[278] 상위 계층 시그널링을 통해 각 CSI-IM 자원 구성을 위한 아래와 같은 파라미터가 설정될 수 있다.

[279] - ZP CSI-RS 구성 (표 3 및 표 4 참조)

[280] - ZP CSI RS 서브프레임 구성(I_CSI-RS) (표 5 참조)

[281] CSI-IM 자원 구성은 설정된 ZP CSI-RS 자원 구성 중 어느 하나와 동일하다.

[282] 서빙 셀의 동일한 서브프레임 내 CSI-IM 자원과 PMCH가 동시에 설정되지 않는다.

[283] 전송 모드 1-9가 설정된 UE의 경우, 서빙 셀에 대하여 UE는 하나의 ZP CSI-RS 자원 구성이 설정될 수 있다. 전송 모드 10이 설정된 UE의 경우, 서빙 셀에 대하여 UE는 하나 또는 그 이상의 ZP CSI-RS 자원 구성이 설정될 수 있다.

[284] 상위 계층 시그널링을 통해 ZP CSI-RS 자원 구성을 위한 아래와 같은 파라미터가 설정될 수 있다.

[285] - ZP CSI-RS 구성 리스트 (표 3 및 표 4 참조)

[286] - ZP CSI-RS 서브프레임 구성(I_CSI-RS) (표 5 참조)

[287] 서빙 셀의 동일한 서브프레임에서 ZP CSI-RS와 PMCH가 동시에 설정되지 않는다.

[288]

[289] **셀 측정(Cell Measurement)/측정 보고(Measurement Report)**

[290] 단말의 이동성(mobility) 보장을 위한 여러 방법들(핸드오버, 랜덤 액세스, 셀 탐색 등) 중 하나 또는 그 여러 방법들을 위하여 UE는 셀 측정(cell measurement)한 결과를 기지국(혹은 네트워크)에 보고한다.

[291] 3GPP LTE/LTE-A 시스템에서 셀 특정 참조 신호(CRS)는 시간 축으로 각 서브프레임 내의 0, 4, 7, 11 번째 OFDM 심볼을 통해 전송되고, 이는 셀 측정(cell measurement)를 위해 기본적으로 사용된다. 즉, 단말은 서빙 셀(serving cell)과 이웃 셀(neighbor cell)로부터 각각 수신되는 CRS를 이용하여, 셀 측정을 수행한다.

[292] 셀 측정(cell measurement)은 서빙 셀 및 이웃 셀의 신호 세기 혹은 총 수신 전력 대비 신호 세기 등을 측정하는 참조 신호 수신 전력(RSRP: Reference signal receive power), 수신신호강도(RSSI: Received signal strength indicator), 참조신호수신품질(RSRQ: Reference signal received quality) 등의 RRM(Radio resource management) 측정과 서빙 셀과의 링크 품질을 측정하여 라디오 링크 실패(radio link failure) 여부를 평가할 수 있는 RLM(Radio Link Monitoring)

측정을 포함하는 개념이다.

[293] RSRP는 측정 주파수 대역 내에서 CRS가 전송되는 RE의 전력 분배의 선형 평균이다. RSRP 결정을 위해, 안테나 포트 '0'에 해당하는 CRS(R0)가 사용될 수 있다. 또한, RSRP 결정을 위해, 안테나 포트 '1'에 해당하는 CRS(R1)가 추가로 사용될 수도 있다. RSRP를 결정하기 위하여 UE에 의해 이용되는 측정 주파수 대역 및 측정 구간 내에서 이용하는 RE들의 수는 해당 측정 정확도 요구(accuracy requirements)가 만족되는 한도에서 UE가 결정할 수 있다. 또한, RE 당 전력은 순환 전치(CP)를 제외한 심볼의 나머지 부분 내에서 수신한 에너지로부터 결정될 수 있다.

[294] RSSI는 측정 대역 내에서 안테나 포트 '0'에 해당하는 RS를 포함하는 OFDM 심볼들에서 동일 채널(co-channel)의 서빙 셀(serving cell)과 넌-서빙 셀(non-serving cell), 인접 채널로부터의 간섭, 열 잡음(thermal noise) 등을 포함하는 해당 UE에 의해 모든 소스들로부터 감지된 총 수신 전력의 선형 평균으로 도출된다. 상위 계층 시그널링에 의하여 RSRQ 측정을 수행하기 위한 특정 서브프레임들이 지시되는 경우, RSSI는 지시된 서브프레임들 내의 모든 OFDM 심볼에 통해 측정된다.

[295] RSRQ는 N×RSRP/RSSI로 도출된다. 여기서, N은 RSSI 측정 대역폭의 RB 개수를 의미한다. 또한, 위의 식에서 분자 및 분모의 측정은 동일한 RB의 세트에서 구해질 수 있다.

[296] 기지국은 상위 계층 시그널링(예를 들어, RRC 연결 재구성(RRC Connection Reconfiguration) 메시지)을 통해 UE에게 측정(measurement)을 위한 설정 정보를 전달할 수 있다.

[297] RRC 연결 재구성 메시지는 무선 자원 구성 전용('radioResourceConfigDedicated') 정보 요소(IE: Information Element)와, 측정 설정('measConfig') IE를 포함한다.

[298] 'measConfig' IE는 UE에 의해 수행되어야 하는 측정을 특정하고, 측정 갭(measurement gap)의 구성 뿐만 아니라 인트라-주파수(intra-frequency) 이동성, 인터-주파수(inter-frequency) 이동성, 인터-RAT(inter-RAT) 이동성을 위한 설정 정보를 포함한다.

[299] 특히, 'measConfig' IE는 측정에서 제거될 측정 대상('measObject')의 리스트를 나타내는 'measObjectToRemoveList'와 새로이 추가되거나 수정될 리스트를 나타내는 'measObjectToAddModList'가 포함된다. 또한, 'measObject'에는 통신 기술에 따라 'MeasObjectCDMA2000', 'MeasObjctEUTRA', 'MeasObjectGERAN' 등이 포함된다.

[300] 'RadioResourceConfigDedicated' IE는 무선 베어러(Radio Bearer)를 설정/변경/해제(setup/modify/release) 하거나, MAC 메인 구성을 변경하거나, 반정적 스케줄링(SPS: Semi-Persistent Scheduling) 설정을 변경하거나 및 전용 물리적 설정(dedicated physical configuration)을 변경하기 위하여 사용된다.

[301] 'RadioResourceConfigDedicated' IE는 서빙 셀 측정을 위한 시간 영역 측정 자원 제한 패턴(time domain measurement resource restriction pattern)을 지시하는 'measSubframePattern-Serv' 필드를 포함한다. 또한, UE에 의해 측정될 이웃 셀을 지시하는 'measSubframeCellList' 와 이웃 셀 측정을 위한 시간 영역 측정 자원 제한 패턴을 지시하는 'measSubframePattern-Neigh'를 포함한다.

[302] 측정 셀(서빙 셀 및 이웃 셀 포함)을 위해 설정된 시간 영역 측정 자원 제한 패턴(time domain measurement resource restriction pattern)은 RSRQ 측정을 수행하기 위한 무선 프레임 당 적어도 하나의 서브프레임을 지시할 수 있다. 측정 셀을 위해 설정된 시간 영역 측정 자원 제한 패턴에 의하여 지시된 서브프레임 이외에서는 RSRQ 측정이 수행되지 않는다.

[303] 이와 같이, UE(예를 들어, 3GPP Rel-10)는 서빙 셀 측정을 위한 서브프레임 패턴('measSubframePattern-Serv') 및 이웃 셀 측정을 위한 서브프레임 패턴('measSubframePattern-Neigh')에 의해 설정된 구간에서만 RSRQ가 측정되어야 한다.

[304] 다만, RSRP는 이러한 패턴 내 측정이 제약되어 있지 않지만, 정확도 요구(accuracy requirement)를 위해서는 이러한 패턴 내에서만 측정되는 것이 바람직하다.

[305]

[306] <u>안테나 포트 간 QCL(quasi co-located)</u>

[307] QC/QCL(quasi co-located 혹은 quasi co-location)은 다음과 같이 정의될 수 있다.

[308] 두 개의 안테나 포트가 QC/QCL 관계에 있다(혹은 QC/QCL 되었다)고 하면, 하나의 안테나 포트를 통해 전달되는 신호의 광범위 특성(large-scale property)이 다른 하나의 안테나 포트를 통해 전달되는 신호로부터 암시(infer)될 수 있다고 단말이 가정할 수 있다. 여기서, 상기 광범위 특성은 지연 확산(Delay spread), 도플러 확산(Doppler spread), 주파수 쉬프트(Frequency shift), 평균 수신 파워(Average received power), 수신 타이밍(Received Timing) 중 하나 이상을 포함한다.

[309] 또한, 다음과 같이 정의될 수도 있다. 두 개의 안테나 포트가 QC/QCL 관계에 있다(혹은 QC/QCL 되었다)고 하면, 하나의 안테나 포트를 통해 일 심볼이 전달되는 채널의 광범위 특성(large-scale property)이 다른 하나의 안테나 포트를 통해 일 심볼이 전달되는 무선 채널로부터 암시(infer)될 수 있다고 단말이 가정할 수 있다. 여기서, 상기 광범위 특성은 지연 확산(delay spread), 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift), 평균 이득(average gain) 및 평균 지연(average delay) 중 하나 이상을 포함한다.

[310] 즉, 두 개의 안테나 포트들이 QC/QCL 관계에 있다(혹은 QC/QCL 되었다)고 함은, 하나의 안테나 포트로부터의 무선 채널의 광범위 특성이 나머지 하나의 안테나 포트로부터의 무선 채널의 광범위 특성과 같음을 의미한다. RS가 전송되는 복수의 안테나 포트를 고려하면, 서로 다른 두 종류의 RS가 전송되는

안테나 포트들이 QCL 관계에 있으면, 한 종류의 안테나 포트로부터의 무선 채널의 광범위 특성을 다른 한 종류의 안테나 포트로부터의 무선 채널의 광범위 특성으로 대체할 수 있을 것이다.

[311] 본 명세서에서 위 QC/QCL 관련 정의들을 구분하지 않는다. 즉, QC/QCL 개념은 위 정의들 중에 하나를 따를 수 있다. 혹은 유사한 다른 형태로, QC/QCL 가정이 성립하는 안테나 포트 간에는 마치 동일 위치(co-location)에서 전송하는 것처럼 가정할 수 있다는 형태 (예를 들어, 동일 전송 포인트(transmission point)에서 전송하는 안테나 포트라고 단말이 가정할 수 있다는 등)으로 QC/QCL 개념 정의가 변형될 수도 있으며, 본 발명의 사상은 이와 같은 유사 변형예들을 포함한다. 본 발명에서는 설명의 편의상 위 QC/QCL 관련 정의들을 혼용하여 사용한다.

[312] 상기 QC/QCL의 개념에 따라, 단말은 비-QC/QCL(Non-QC/QCL) 안테나 포트들에 대해서는 해당 안테나 포트들로부터의 무선 채널 간에 동일한 상기 광범위 특성을 가정할 수 없다. 즉, 이 경우 단말은 타이밍 획득 및 트랙킹(tracking), 주파수 오프셋 추정 및 보상, 지연 추정 및 도플러 추정 등에 대하여 각각의 설정된 비-QC/QCL 안테나 포트 별로 독립적인 프로세싱을 수행하여야 한다.

[313] QC/QCL을 가정할 수 있는 안테나 포트들간에 대해서, 단말은 다음과 같은 동작을 수행할 수 있다는 장점이 있다:

[314] - 지연 확산 및 도플러 확산에 대하여, 단말은 어떤 하나의 안테나 포트로부터의 무선 채널에 대한 전력-지연-프로파일(power-delay profile), 지연 확산 및 도플러 스펙트럼(Doppler spectrum), 도플러 확산 추정 결과를, 다른 안테나 포트로부터의 무선 채널에 대한 채널 추정 시 사용되는 위너 필터(Wiener filter) 등에 동일하게 적용할 수 있다.

[315] - 주파수 쉬프트(shift) 및 수신된 타이밍에 대하여, 단말은 어떤 하나의 안테나 포트에 대한 시간 및 주파수 동기화 수행한 후, 동일한 동기화를 다른 안테나 포트의 복조에 적용할 수 있다.

[316] - 평균 수신 전력에 대하여, 단말은 둘 이상의 안테나 포트들에 대하여 RSRP(Reference Signal Received Power) 측정을 평균할 수 있다.

[317] 예를 들어, 단말이 하향링크 데이터 채널 복조를 위한 DMRS 안테나 포트가 서빙 셀의 CRS 안테나 포트와 QC/QCL 되었다면, 단말은 해당 DMRS 안테나 포트를 통한 채널 추정 시 자신의 CRS 안테나 포트로부터 추정했던 무선 채널의 광범위 특성들(large-scale properties)을 동일하게 적용하여 DMRS 기반 하향링크 데이터 채널 수신 성능을 향상시킬 수 있다.

[318] 왜냐하면, CRS는 매 서브프레임 그리고 전체 대역에 걸쳐 상대적으로 높은 밀도(density)로 브로드캐스팅되는 참조 신호이므로, 광범위 특성에 관한 추정치는 CRS로부터 보다 안정적으로 획득이 가능하기 때문이다. 반면, DMRS는 특정 스케줄링된 RB에 대해서는 단말 특정하게 전송되며, 또한

PRG(precoding resource block group) 단위가 기지국이 전송에 사용하는 프리코딩 행렬(precoding matrix)가 변할 수 있으므로 단말에게 수신되는 유효 채널은 PRG 단위로 달라질 수 있어 다수의 PRG를 스케줄링 받은 경우라고 하더라도 넓은 대역에 걸쳐 DMRS를 무선 채널의 광범위 특성 추정용으로 사용 시에 성능 열화가 발생할 수 있다. 또한, CSI-RS도 그 전송 주기가 수~수십 ms가 될 수 있고, 자원 블록 당 평균적으로 안테나 포트 당 1 자원 요소의 낮은 밀도를 가지므로 CSI-RS도 마찬가지로 무선 채널의 광범위 특성 추정용으로 사용할 경우 성능 열화가 발생할 수 있다.

[319] 즉, 안테나 포트 간의 QC/QCL 가정을 함으로써 단말은 하향링크 참조 신호의 검출/수신, 채널 추정, 채널 상태 보고 등에 활용할 수 있다.

[320]

[321] 제한된 RLM 및 RRM/CSI 측정

[322] 간섭 조정(Interference coordination)의 한 방법으로서, 공격 셀(aggressor cell)이 일부 물리 채널의 전송 파워(transmission power)/동작(activity)를 줄이는 (여기서, 전송 파워/동작을 줄이는 것은 제로 파워로 설정하는 동작까지 포함할 수 있음) 침묵 서브프레임(silent subframe)(또는, ABS(almost blank subframe)으로 지칭될 수 있음)을 사용하고, 희생 셀(victim cell)이 이를 고려하여 UE를 스케줄링하는 시간 도메인 셀 간 간섭 조정(scheduling하는 time domain inter-cell interference coordination)이 가능하다.

[323] 이 경우, 희생 셀(victim cell) UE의 입장에서는 간섭 레벨(interference level)이 서브프레임에 따라서 크게 변화할 수 있다.

[324] 이러한 상황에서 각 서브프레임에서의 보다 정확한 무선 링크 모니터링(RLM: radio link monitoring)이나 RSRP/RSRQ 등을 측정하는 무선 자원 관리(RRM: radio resource management) 동작을 수행하거나 링크 적응(link adaptation)을 위해서 채널 상태 정보(CSI: channel state information)를 측정하기 위해서, 상기 모니터링/측정은 균일한 간섭 특성을 지니는 서브프레임의 세트들로 제한되어야 한다. 3GPP LTE 시스템에서는 아래와 같이 제한된 RLM 및 RRM/CSI 측정을 정의한다.

[325] UE는 Pcell의 하향링크 무선 링크 품질(downlink link quality)을 감지하기 위하여 셀 특정 참조 신호(CRS)에 기반하여 하향링크 링크 품질을 모니터한다. 단말은 하향링크 무선 링크 품질을 추정하고, Pcell의 하향링크 무선 링크 품질을 모니터링하기 위하여 임계치 Q_out 및 Q_in와 추정치를 비교한다.

[326] 임계치 Q_out은 하향링크 무선 링크가 신뢰있게(reliably) 수신될 수 없는 레벨로 정의되고, 아래 표 6에서 명시된 전송 파라미터에 기반하여 PCFICH 에러를 고려한 가상의(hypothetical) PDCCH 전송의 10% 블록 에러율(BER: block error rate)에 해당한다.

[327] 임계치 Q_in는 하향링크 무선 링크 품질이 Q_out에서의 하향링크 무선 링크 품질 보다 현저하게 신뢰있게 수신될 수 있는 레벨로 정의되고, 아래 표 7에서

명시된 전송 파라미터에 기반하여 PCFICH 에러를 고려한 가상의(hypothetical) PDCCH 전송의 2% BER에 해당한다.

[328] 상위 계층 시그널링이 제한된 RLM을 위한 특정 서브프레임을 지시할 때, 무선 링크 품질이 모니터링된다.

[329] RLM 측정을 수행하기 위한 시간 도메인 측정 자원 제한 패턴이 상위 계층에 의해 설정될 때, 또한 측정되는 셀을 위해 설정된 시간 도메인 측정 자원 제한 패턴이 RLM 측정을 수행하기 위한 무선 프레임 당 적어도 하나의 서브프레임을 지시한다면, 일정한 요구 사항이 적용된다.

[330] CRS 지원(assistance) 정보가 제공되는 경우, CRS 지원 정보가 제공된 하나 또는 그 이상의 셀의 전송 안테나 포트(transmit antenna port)의 개수가 RLM이 수행되는 셀의 전송 안테나 포트의 개수와 상이할 때 상기 요구 사항이 만족될 수 있다.

[331] 만약, 단말이 CRS 지원 정보를 제공받지 않거나 CRS 지원 데이터가 전체 평가 기간 동안에 유효하지 않으면, CRS와 논-MBSFN(multicast broadcast single frequency network) 서브프레임 내에서 설정된 ABS의 충돌 하에 시간 도메인 측정 제한이 적용될 수 있다.

[332] 표 6은 동기가 맞지 않은 상태(out-of-sync)에 대한 PDCCH/PCFICH 전송 파라미터를 예시한다.

[333] [표6]

속성(Attribute)	값(Value)
DCI 포맷	1A
제어 OFDM 심볼의 수	2; 대역폭 ≥ 10 MHz 3; 3 MHz ≤ 대역폭 ≤ 10 MHz 4; 대역폭 = 1.4 MHz
병합 레벨(Aggregation level) (CCE)	4; 대역폭 = 1.4 MHz 8; 대역폭 ≥ 3 MHz
PDCCH RE 에너지 대 평균 RS RE 에너지의 비 (Ratio of PDCCH RE energy to average RS RE energy)	4 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 1 dB; Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우
PCFICH RE 에너지 대 평균 RS RE 에너지의 비 (Ratio of PCFICH RE energy to average RS RE energy)	4 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 1 dB: Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우

[334] 표 7은 동기가 맞는 상태(in-sync)에 대한 PDCCH/PCFICH 전송 파라미터를 예시한다.

[335] [표7]

속성(Attribute)	값(Value)
DCI 포맷	1C
제어 OFDM 심볼의 수	2; 대역폭 ≥ 10 MHz 3; 3 MHz ≤ 대역폭 ≤ 10 MHz 4; 대역폭 = 1.4 MHz
병합 레벨(Aggregation level) (CCE)	4
PDCCH RE 에너지와 평균 RS RE 에너지 간 비율 (Ratio of PDCCH RE energy to average RS RE energy)	0 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 -3 dB; Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우
PCFICH RE 에너지 대 평균 RS RE 에너지의 비 (Ratio of PCFICH RE energy to average RS RE energy)	4 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 1 dB; Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우

[336] Pcell에 대한 하향링크 무선 링크 품질은 UE에 의해 상위 계층에 동기가 맞지 않은 상태(out-of-sync status)/동기가 맞는 상태(in-sync status)를 지시하기 위하여 모니터된다.

[337] 비-DRX(non-DRX) 모드 동작에서, UE의 물리 계층은 매 무선 프레임에서 임계치(Q_out 및 Q_in)를 고려하여 이전 시간 구간 동안 평가된 무선 링크 품질을 측정(assess)한다.

[338] 상위 계층 시그널링이 제한된 RLM을 위한 특정 서브프레임을 지시하면, 무선 링크 품질의 측정은 상위 계층 시그널링에서 지시되지 않는 이외 다른 서브프레임에서 수행되지 않는다.

[339] 무선 링크 품질이 임계치 Q_out 보다 불량하면, UE의 물리 계층은 무선 링크 품질이 측정된 무선 프레임 내에서 상위 계층에게 out-of-sync를 지시한다. 무선 링크 품질이 임계치 Q_in 보다 양호하면, UE의 물리 계층은 무선 링크 품질이 측정된 무선 프레임 내에서 상위 계층에게 in-sync를 지시한다.

[340]

[341] <u>매시브 MIMO(Massive MIMO)</u>

[342] LTE 릴리즈(Rel: release)-12 이후의 무선 통신 시스템에서는 능동 안테나 시스템(AAS: Active Antenna System)의 도입이 고려되고 있다.

[343] 신호의 위상 및 크기를 조정할 수 있는 증폭기와 안테나가 분리되어 있는 기존의 수동 안테나 시스템과 달리, AAS는 각각의 안테나가 증폭기와 같은 능동 소자를 포함하도록 구성된 시스템을 의미한다.

[344] AAS는 능동 안테나 사용에 따라 증폭기와 안테나를 연결하기 위한 별도의 케이블, 커넥터, 기타 하드웨어 등이 필요하지 않고, 따라서 에너지 및 운용 비용 측면에서 효율성이 높은 특징을 갖는다. 특히, AAS는 각 안테나 별 전자식 빔 제어(electronic beam control) 방식을 지원하기 때문에 빔 방향 및 빔 폭을 고려한

정교한 빔 패턴 형성 또는 3차원 빔 패턴을 형성하는 등의 진보된 MIMO 기술을 가능하게 한다.

[345] AAS 등의 진보된 안테나 시스템의 도입으로 다수의 입출력 안테나와 다차원 안테나 구조를 갖는 대규모 MIMO 구조 또한 고려되고 있다. 일례로, 기존의 일자 형 안테나 배열과 달리 2차원 안테나 배열을 형성할 경우, AAS의 능동 안테나에 의해 3차원 빔 패턴을 형성할 수 있다. 송신 안테나 관점에서 상기 3차원 빔 패턴을 활용할 경우, 빔의 수평 방향뿐만 아니라 수직 방향으로의 준-정적 또는 동적인 빔 형성을 수행할 수 있으며 일례로 수직 방향의 섹터 형성 등의 응용을 고려할 수 있다.

[346] 또한, 수신 안테나 관점에서는 대규모 수신 안테나를 활용하여 수신 빔을 형성할 때, 안테나 배열 이득(antenna array gain)에 따른 신호 전력 상승 효과를 기대할 수 있다. 따라서, 상향링크의 경우, 기지국이 다수의 안테나를 통해 단말로부터 전송되는 신호를 수신할 수 있으며, 이때 단말은 간섭 영향을 줄이기 위해 대규모 수신 안테나의 이득을 고려하여 자신의 송신 전력을 매우 낮게 설정할 수 있는 장점이 있다.

[347] 도 11은 본 발명이 적용될 수 있는 무선 통신 시스템에서 기지국 또는 단말이 AAS 기반의 3D(3-Dimension) 빔 형성이 가능한 다수의 송/수신 안테나를 갖고 있는 시스템을 예시한다.

[348] 도 11은 앞서 설명한 예를 도식화한 것으로서, 2차원 안테나 배열(즉, 2D-AAS)를 이용한 3D MIMO 시스템을 예시한다.

[349]

[350] <u>매시브 MIMO의 셀 커버리지(Cell coverage of massive MIMO)</u>

[351] 다중 안테나 시스템, 일례로서 N개의 전송 안테나를 갖는 시스템은 단일 안테나 시스템에 비교해서 전체 전송 전력을 동일하게 전송한다고 가정하면, 특정 지점에 수신 파워가 최대 N배 높도록 빔포밍(beamforming) 해줄 수 있다.

[352] 다중 안테나를 갖는 기지국에서도 CRS, PSS/SSS, PBCH 및 브로드캐스트(broadcast) 정보를 전달하는 채널은 기지국 커버리지 영역내의 모든 UE들이 수신할 수 있도록 특정 방향으로 beamforming을 해주지는 않는다.

[353] 이와 달리, 특정 UE에게 유니캐스트(unicast) 정보를 전달하는 채널인 PDSCH는 해당 UE의 위치 및 링크 상황에 맞추어 beamforming을 해주어 전송 효율을 높이도록 한다. 즉, PDSCH의 전송 데이터 스트림은 특정 방향으로 빔을 형성하기 위하여 프로코딩(precoding)되어 다중의 안테나 포트를 통해 전송된다. 그러므로 대표적으로 CRS와 PDSCH의 전송 전력이 동일한 경우에, 특정 UE에게 CRS의 평균 수신 전력과 비교해서 해당 UE를 향해 beamforming 된 프로코딩된(precoded) PDSCH의 수신 전력은 최대 N배까지 높을 수 있다.

[354] 현재까지 LTE Rel-11 시스템에서 최대 8개의 전송 안테나를 갖는 기지국을 고려하는데, 이는 CRS 평균 수신 전력에 비해서 precoded PDSCH 수신 전력이 8배 클 수 있음을 의미한다. 그러나, 향후에 매시브 MIMO 시스템의 도입으로

기지국의 전송 안테나가 100개 이상 되는 경우에 CRS와 precoded PDSCH의 수신 전력은 100배 이상 차이를 나타낼 수 있다. 결론적으로 massive MIMO 시스템의 도입으로 특정 기지국에서 전송하는 CRS의 커버리지 영역과 DM-RS 기반 PDSCH의 커버리지 영역이 일치하지 않게 된다.

[355] 특히, 이러한 현상은 인접한 두 개의 기지국의 전송 안테나 개수의 차이가 많을 때 크게 나타날 수 있다. 대표적으로 64개의 전송 안테나를 갖는 매크로 셀(macro cell)과 단일 전송 안테나를 갖는 마이크로 셀(micro cell)(예를 들어, 피코 셀(pico cell))이 인접하고 있는 경우를 예로 들 수 있다. Massive MIMO의 초기 배치(deployment) 과정에서 서빙받는(served) UE가 많은 macro cell부터 먼저 안테나 개수를 늘릴 것으로 기대하고 있기 때문에 macro cell, micro cell 그리고 pico cell이 혼재되어 있는 이종의 네트워크(heterogeneous network)의 경우에 인접한 기지국간에 전송 안테나의 개수가 크게 차이 나게 된다.

[356] 예를 들어, 단일 전송 안테나를 갖는 pico cell의 경우에 CRS와 PDSCH의 커버리지 영역이 일치하게 된다. 그러나 64개의 전송 안테나를 갖는 macro cell의 경우에 CRS의 커버리지 영역보다 PDSCH의 커버리지 영역이 더 크게 된다. 그러므로 macro cell과 pico cell의 경계에서 CRS의 수신 품질인 RSRP 또는 RSRQ에만 의존하여 초기접속 및 핸드오버를 결정하게 되면 PDSCH의 최대 품질을 제공해 줄 기지국을 서빙 셀(serving cell)로 선택할 수 없게 된다. 이에 대한 단순한 해결책으로 N개의 전송 안테나를 갖는 기지국의 PDSCH 수신 전력은 N배 클 것으로 가정할 수 있으나, 기지국이 가능한 모든 방향으로 beamforming을 다 해줄 수 없는 경우를 고려할 때 최적 해결책은 아니다.

[357]

[358] **RRM-RS**

[359] 본 특허에서는 프리코딩된 RS(precoded RS)를 전송하고 이에 대한 RRM 측정(measurement)를 수행하는 방법을 제안한다. 이하, 본 명세서에서는 이러한 목적의 precoded RS를 'RRM-RS'라고 명칭하도록 한다. RRM-RS는 다수개의 안테나 포트로 구성되어 있으며 각 안테나 포트 별로 beamforming을 다르게 설정하여 각 전송 빔(beam) 별로 UE가 RSRP를 측정할 수 있도록 한다. 일례로, 기지국에서 M개의 방향으로 beamforming이 가능한 경우에 M 포트(M-port)로 구성된 RRM-RS를 설정하도록 한다.

[360]

[361] **RRM-RS의 주기 및 다중화(multiplexing)**

[362] M-port RRM-RS는 동일 서브프레임에서 CDM되거나 또는 FDM/TDM으로 구분되어 전송될 수 있다. 즉, M-port RRM-RS의 각 안테나 포트 별 전송 신호는 동일 서브프레임에서 다른 전송 RE를 사용하여 전송되거나, 또는 동일 RE를 사용하여 전송되는 경우에 안테나 포트 간에 직교 스크램블링 코드(orthogonal scrambling code)를 사용하여 상호간에 간섭 없이 구분할 수 있도록 한다.

[363] 이와 달리 하나의 서브프레임에서 동시에 전송 가능한 RRM-RS의 안테나 포트

수를 K로 설정하고 (M/K)개의 서브프레임에 나누어 전송할 수 있다.

[364] 이 경우, RRM-RS의 설정 파라미터는 전체 안테나 포트의 개수 M과 하나의 서브프레임에서 동시 전송되는 안테나 포트 수 K를 포함한다. RRM-RS의 설정 파라미터로써 RRM-RS 전송 주기 P와 오프셋 O를 포함한다. 여기서, RRM-RS 전송 주기는 RRM-RS가 전송되는 서브프레임의 간격으로 정의한다. 예로써 P=10, O=5, M=64, K=32인 경우에 RRM-RS는 서브프레임 인덱스(SFI: subframe index)가 5, 15, 25, 35, ... 인 서브프레임에서 전송되며, SFI=5인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 전송되고, SFI=15인 서브프레임에서 안테나 포트 32에서 63의 RRM-RS가 전송되고, SFI=25인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 또다시 전송된다.

[365] 이와 달리 RRM-RS 전송 주기를 동일 안테나 port의 RS가 전송되는 서브프레임의 간격으로 정의하고, (M/K)개의 서브프레임에 RRM-RS의 안테나 포트들을 나누어 전송하는 방식에서 (M/K)개의 연속된 서브프레임에 나누어 전송하도록 한다. 예로써 P=20, O=5, M=64, K=32인 경우에 RRM-RS는 SFI가 5, 6, 25, 26, 45, 46, ...인 서브프레임에서 전송되며, SFI=5인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 전송되고, SFI=6인 서브프레임에서 안테나 포트 32에서 63의 RRM-RS가 전송되고, SFI=25인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 또다시 전송된다.

[366]

[367] **RSRP** 측정 및 보고

[368] RRM-RS의 RSRP는 안테나 포트 별로 측정하여 보고하도록 한다. UE는 다수개의 RRM-RS를 설정 받을 수 있다.

[369] 각 셀에서 RRM-RS를 하나씩 전송하는 경우에, UE는 서빙 셀 및 인접 셀들이 전송하는 RRM-RS들의 설정을 지정 받을 수 있다. 하나의 셀이 다수개의 RRM-RS를 전송할 수도 있다. UE는 RRM-RS의 RSRP를 보고할 때 해당 RSRP가 몇 번째 RRM-RS의 몇 번째 안테나 포트의 RSRP 측정결과인지 함께 알려준다.

[370] RRM-RS의 RSRP를 계산하기 위하여 각 안테나 포트의 수신 신호 레벨의 평균을 취하는데, 평균을 취하는 시간 윈도우(window)를 기지국이 지정해 줄 수 있거나, 또는 미리 정해진 시간 (예를 들어, 200ms) 동안 RRM-RS의 각 안테나 포트 별 수신 신호 레벨의 평균을 취하여 RSRP를 얻도록 한다. 또는 각각의 시간 윈도우에서 얻은 평균 수신 파워를 다시 필터링하여 보고할 RSRP를 얻을 수 있다.

[371] 다수개의 RRM-RS를 설정 받은 UE는 각 RRM-RS의 각 안테나 포트별 RSRP를 측정한다. RRM-RS를 R개 설정 받고 r번째 RRM-RS의 안테나 포트 수가 M_r인 경우에, r번째 RRM-RS의 m번째 안테나 포트의 RSRP를 RSRP(r,m)로 정의한다. UE는 RSRP(r,m)을 정렬하고 그 중에서 강하게 수신되는 L개 안테나 포트의 RSRP를 선택하여 보고하도록 한다.

[372] 위 방식을 약간 변형하여 UE는 RSRP(r,m)을 정렬하고 그 중에서 가장 강하게

수신되는 안테나 port를 선택하고 선택된 안테나 포트의 RSRP, 즉 max(RSRP(r,m))와 대비하여 일정 차이 내로 들어오는 포트의 RSRP들로 보고를 한정시킨다. 즉, 다음과 같이 RSRP 비율(ratio) 또는 dB 스케일(scale) 표현에서 RSRP의 차이가 일정 임계치 보다 높은 최대 L개의 안테나 포트의 RSRP를 보고하도록 한다.

[373] [수식13]

```
RSRP(r,m) - max(RSRP(r,m)) > Threshold
```

[374] 다른 일례로, UE는 참조(reference) 안테나 포트를 지정 받을 수 있다. 참조 안테나 포트로써 해당 UE에게 설정된 프리코딩된(precoded) CSI-RS와 빔 방향이 유사한 서빙 셀이 전송하는 RRM-RS의 안테나 포트를 지정해 주는 것이 바람직하다. UE는 r_0번째 RRM-RS의 m_0번째 안테나 포트를 참조 안테나 포트로 지정 받은 경우에, 참조 안테나 포트의 RSRP에 비해 다른 안테나 포트의 RSRP가 일정 차이 내로 들어오는 경우에 보고하도록 한다. 즉 다음과 같이 RSRP 비율(ratio) 또는 dB 스케일(scale) 표현에서 RSRP의 차이가 일정 임계치를 넘는 경우에 보고하도록 한다.

[375] [수식14]

```
RSRP(r,m) - RSRP(r_0,m_0) > Threshold
```

[376] 도 12는 본 발명의 일 실시예에 따른 RRM-RS의 안테나 포트 별 RSRP를 예시한다.

[377] 도 12에서는 32 안테나 포트로 구성된 RRM-RS의 각 안테나 포트별 RSRP의 일 예시를 나타내고 있다.

[378] 최대 RSRP를 갖는 안테나 포트에 비교해서 5dB이내의 RSRP를 갖는 안테나 포트들의 RSRP를 보고하도록 설정된 경우, 도 12와 같이 안테나 포트 13이 최대 RSRP 40dB를 가지므로 RSRP가 35dB를 넘는 안테나 포트에 대해 보고하도록 한다. 즉, 안테나 포트 13을 포함하여 안테나 포트 24, 25, 26의 RSRP가 기지국에 보고된다.

[379]

[380] <u>안테나 포트 그룹핑(Antenna port grouping)</u>

[381] 안테나 포트 별로 빔 포밍을 다르게 설정할 수 있으므로, 이 경우 안테나 포트와 빔은 일대일 대응 관계를 갖는다.

[382] 그러므로 안테나 포트 인덱스 (i)는 빔 인덱스(beam index) (i)와 일대일로 매핑시킬 수 있다. (i)번째 빔과 (i+1)번째 빔의 방향이 서로 인접하도록 빔들을 인덱싱하는 경우, 앞서 도 12의 예시에서처럼 인접한 안테나 포트들간의 RSRP는 서로 유사한 특징을 보이게 된다. 이러한 유사도는 (i)번째 빔과 (i+c)번째 빔 사이에서도 나타나지만 c가 커질수록 유사도는 떨어진다. 몇 개의 연속된 인접 빔들 사이에서 높은 유사도가 나올지는, 빔의 간격 및 빔의 폭(width), 그리고 다중-경로(multipath)들의 분산(scattering) 정도에 따라서 좌우된다.

[383] RRM-RS에 기반한 RSRP 측정 결과를 보고 받은 기지국은 해당 UE의 대략적 위치를 파악하고 해당 지점으로 향하여 전송되는 프리코딩된(precoded) CSI-RS 설정을 UE에게 알려주어 UE가 CSI-RS를 측정하여 PDSCH 스케줄링을 위한 CSI(RI, PMI, CQI 등)를 피드백 할 수 있도록 한다. 또한, 다수의 셀에서 전송하는 RRM-RS들에 기반한 RSRP 측정 결과를 보고 받은 기지국은 RSRP 측정 결과에 기반하여 해당 UE를 어떤 셀로 핸드오버 시킬지 그리고 타겟 셀에서 어떤 프리코딩된(precoded) CSI-RS를 UE에게 설정해 줄지 결정한다. 즉, RRM-RS에 기반한 RSRP 측정 결과는 해당 UE에게 향후에 어떤 프리코딩된(precoded) CSI-RS를 설정해 줄지를 판단하는데 필요한 중요 정보를 기지국에 제공한다.

[384] 앞서 도 12의 예시와 같은 RSRP 측정 결과를 바탕으로 해당 UE에게 최대 4개의 데이터 스트림 전송이 가능하도록 하거나 또는 페이딩(fading)의 변화에 맞추어 빠르게 최상의 빔 스위칭(best beam switching)을 하기 위하여 4-포트 CSI-RS를 설정해주는 경우에, RSRP가 가장 큰 RRM-RS 포트 13, 24, 25, 26의 빔 방향과 동일한 4-포트 CSI-RS를 생성하여 설정해 주는 것이 최적일 것으로 예상된다. 하지만 CSI-RS가 UE 별로 최적화하여 생성하고 전송하기에는 오버헤드(overhead)가 너무 크다. 그러므로 동일 환경에 있는 많은 UE들이 CSI-RS를 공유하는 것이 CSI-RS 전송 오버헤드를 줄일 수 있는 방법이다. 이러한 목적을 달성하기 위하여 하나의 CSI-RS 설정내의 CSI-RS 안테나 포트들의 프리코딩은 인접 방향으로 전송되는 빔의 특징을 나타내도록 프리코딩되어야 한다. 즉, 다른 서빙 받는 UE(served UE)들을 고려하여 미리 RRM-RS 포트 12, 13, 14, 15의 빔 방향과 동일한 4-포트 CSI-RS1과 RRM-RS 포트 24, 25, 26, 27의 빔 방향과 동일한 4-포트 CSI-RS2가 미리 설정되어 있는 경우에, 해당 UE에게 어떤 CSI-RS를 설정해주는 것이 좋을지를 RRM-RS의 RSRP 보고를 통해 판단할 수 있어야 한다.

[385] 본 발명의 또 다른 실시예로서 안테나 포트 그룹(antenna port group)에 대해서 RSRP를 측정 보고하도록 한다. 제안 방식에서 안테나 포트들을 그룹핑하고 그룹에 속하는 안테나 포트의 RSRP들을 평균 취하여 해당 안테나 포트 그룹의 RSRP를 얻도록 한다. 그룹은 미리 정해져 있거나 또는 기지국이 정해서 알려 줄 수 있다. 또는 UE가 그룹핑 방식을 정하고 이를 보고 할 수 있다.

[386] 앞서 도 12의 예시에서처럼 32-포트로 구성된 RRM-RS의 경우에 4 포트 씩 그룹핑 될 수 있다. 각 그룹들간에 분리(disjoint)하여 8(=32/4)개의 그룹으로 그룹핑될 수 있다. 이 경우에 (i)번째 포트 그룹은 RRM-RS 포트 (4i), (4i+1), (4i+2), (4i+3)로 구성된다. (i)번째 포트 그룹의 RSRP는 안테나 포트 (4i), (4i+1), (4i+2), 그리고 (4i+3)의 RSRP의 평균으로 정의한다.

[387] 또 다른 실시예로서, 그룹간의 중첩을 허용하여 그룹핑할 수 있다. 32-포트로 구성된 RRM-RS을 4 포트씩 그룹핑하는 경우에 15개의 그룹으로 그룹핑하도록 한다. 이 경우에 (i)번째 포트 그룹은 RRM-RS 포트 (2i), (2i+1), (2i+2), (2i+3)로 구성된다. 제안 방식을 일반화하여 A 개의 포트씩 그룹핑하고, 인접 그룹간의

포트 간격을 B로 설정하면, (i)번째 포트 그룹은 RRM-RS 포트 (B*i), (B*i+1), ..., (B*i+A-1)로 구성된다. 파라미터 A와 B의 설정은 기지국이 UE에게 지정해 주거나, 또는 UE가 채널 환경 및 UE 능력(capability)을 고려하여 선정하여 보고할 수 있다.

[388] 제안 방식의 변형으로 UE는 보고할 안테나 포트 그룹을 선택하는 방식으로 RSRP보다 해당 안테나 포트 그룹으로 얻을 수 있는 능력(capability)을 고려할 수 있다. 이 경우에 UE는 안테나 포트 그룹내의 다수의 안테나로부터 다중-계층(multi-layer) 데이터 전송을 고려하여 능력을 계산하도록 한다.

[389]

[390] <u>안테나 포트 그룹핑 레벨(Antenna port grouping level)</u>

[391] 제안 방식에서 크기가 다른 다수개의 그룹핑 방법을 사용할 수 있다. 즉, A1 포트씩 그룹핑하는 방법과 A2 포트씩 그룹핑하는 방법을 동시에 사용할 수 있다. 이하, A_i 포트씩 그룹핑하는 방법을 그룹핑 레벨(grouping level) i로 명칭하도록 한다.

[392] 도 13은 본 발명의 일 실시예에 따른 RRM-RS 안테나 포트 그룹핑 레벨을 예시한다.

[393] 도 13에서는 16 포트 RRM-RS를 4단계의 그룹핑 레벨을 적용하여 그룹핑하는 방식의 일례를 보여주고 있다. 예시에서 그룹핑 레벨 1은 1 포트씩 그룹핑하는 방법으로 그룹핑을 하지 않지 않는 방식을 나타낸다. 그리고 그룹핑 레벨 2, 3, 4는 각각 2 포트, 4 포트, 8 포트씩 그룹핑하고 있다. 그림의 예시에서는 동일 레벨의 안테나 포트 그룹들이 분히(disjoint)하여 설정된 경우를 나타내고 있다.

[394] 이러한 다중 그룹핑 방식에서 UE는 그룹핑 레벨 별로 RSRP를 보고한다. 즉 각 그룹핑 레벨 별로 RSRP가 높은 안테나 그룹을 선택하여 보고하도록 한다. 또는 레벨이 다른 안테나 그룹간에 RSRP를 비교하여 최상의(best) 그룹과 그룹 레벨을 보고할 수 있다. 레벨1이 다른 안테나 그룹간의 RSRP를 비교하기 위하여 각 레벨의 그룹 RSRP에 일정 오프셋만큼 보정하고 비교하도록 한다. RRM-RS를 R개 설정 받은 경우에, (r)번째 RRM-RS의 (l)번째 그룹핑 레벨의 (g)번째 안테나 포트 그룹의 RSRP를 GRSRP(r,l,g)로 정의하면, 다음과 같이 기지국으로부터 (r)번째 RRM-RS의 (l)번째 그룹핑 레벨을 위해 지정 받은 offset(r,l)만큼을 보정하여 Adj_GRSRP(r,l,g)를 계산하고 이를 비교하도록 한다.

[395] [수식15]

```
Adj_GRSRP(r,l,g) = GRSRP(r,l,g) + offset(r,l)
```

[396] 추가적으로, 그룹핑 레벨 별로 또는 전체 그룹핑 방식에서 최상의(best) L개의 포트 그룹 RSRP를 보고하는 방식에서 보고되는 최상의(best) L에 대한 잦은 변동을 줄이기 위해 히스테리시스 파라미터(Hysteresis parameter), Hy를 추가하여 RSRP를 보정할 수 있다.

[397] [수식16]

$$Adj_GRSRP(r,l,g) = GRSRP(r,l,g) + offset(r,l) \pm Hy$$

[398] 여기서, Hy는 해당 포트 그룹이 이전 보고에서 최상의(best) L GRSRP에 포함되는지 여부에 따라서 Hy를 더할지 뺄지 결정된다. 해당 포트 그룹이 이전 보고에서 최상의(best) L GRSRP에 포함되어 있는 경우에 Hy를 더하여 높은 Adj_RSRP를 갖도록 바이어스를 줘서 최상의(best) L Adj_GRSRP를 갖는 포트 그룹이 자주 바뀌는 것을 줄여 주도록 한다.

[399] 제안 방식으로 UE는 참조(reference) 안테나 포트 그룹을 지정 받을 수 있다. 기지국은 해당 UE에게 설정된 프리코딩된(precoded) CSI-RS와 빔 방향이 동일한 서빙 셀이 전송하는 RRM-RS의 안테나 포트 그룹을 참조 안테나 포트 그룹으로 지정해 주는 것이 바람직하다. UE는 그룹핑 레벨 별로 참조 안테나 포트 그룹을 지정 받을 수 있다. 또는 전체 그룹핑 레벨에서 하나의 참조 안테나 포트 그룹을 지정 받을 수 있다. UE는 r_0번째 RRM-RS의 l_0번째 그룹핑 레벨의 m_0번째 안테나 포트 그룹을 참조 안테나 포트 그룹으로 지정 받은 경우에, 참조 안테나 포트 그룹의 Adj_GRSRP에 비해 다른 안테나 포트 그룹의 Adj_GRSRP가 일정 임계츠를 넘는 경우에 보고하도록 한다. 즉 다음과 같이 Adj_GRSRP 비율(ratio) 또는 dB 스케일(scale) 표현에서 RSRP의 차이가 일정 임계치를 넘는 경우에 보고하도록 한다.

[400] [수식17]

$$Adj_GRSRP(r,l,g) - Adj_GRSRP(r_0, l_0, m_0) > Threshold$$

[401] 또는 제안 방식의 변형으로 참조 RSRP를 현재 설정되어 있는 CSI-RS를 통해 특정하여 CSI-RS 기반 RSRP에 비해 RRM-RS 기반 RSRP 결과를 비교하여 선택 보고하도록 한다.

[402]

[403] **3차원(3D: 3-Dimension)을 위한 RRM-RS**

[404] 앞서 본 발명에서 제안하는 방식은 빔(beam)의 방향성이 2차원 공간에서 3차원 공간으로 확장되는 경우에도 변형하여 적용 가능하다. 3차원 공간상에서 빔의 방향성은 상하각(수직각)과 좌우각(수평각)의 두 개의 각도의 의해 조절된다. 그러므로 인접 빔 여부를 파악하기 위하여 빔들을 두 개의 인덱스, 즉 수평 인덱스와 수직 인덱스로 인덱스하는 것이 효율적이다. 본 발명의 특징에 따라 빔 인덱스와 RRM-RS 포트 인덱스와 일대일 대응 관계를 갖기 위하여 RRM-RS 포트도 수평 인덱스와 수직 인덱스로 인덱싱되는 것이 바람직하다.

[405] 수직 방향으로 M_v개의 빔을 갖고 수평 방향으로 M_h개의 빔을 갖는 3D MIMO 시스템의 경우에 전체 (M_v×M_h)개의 빔이 가능하다. 본 발명에서는 (M_v×M_h)-포트 RRM-RS를 설정하고 각 안테나 포트에 수평 인덱스 j_h(j_h=0, ..., M_h-1)와 수직 인덱스 j_v(j_v=0, ..., M_v-1)를 부여하도록 한다. (M_v×M_h)-포트 RRM-RS의 자원 매핑을 고려하여 각 안테나 포트들은 일차원

인덱스 i(i=0, ..., M_v×M_h-1)와 이차원 인덱스 j_h와 j_v를 부여 받게 되는데, (i) = f(j_h, j_v)의 관계를 갖게 된다.

[406] 도 14는 본 발명의 일 실시예에 따른 이차원 인덱스로 배열된 RRM-RS의 안테나 포트와 안테나 포트 그룹을 예시하는 도면이다.

[407] 도 14를 참조하면, 각 안테나 포트들은 (j_h, j_v)로 인덱싱되어 있다. 본 발명에서 제안하는 방식을 적용하여 A_h×A_v 개의 포트씩 그룹핑하고, 인접 그룹간의 포트 간격을 B_h와 B_v로 설정하면, (i_h, i_v)번째 포트 그룹은 RRM-RS port (B_h×i_h+j_h, B_v×i_v+j_v), (j_h=0, ..., A_h-1), (j_v=0, ..., A_v-1)로 구성된다. 파라미터 A_h, A_v와 B_h, B_v의 설정은 기지국이 UE에게 지정해 주거나, 또는 UE가 채널 환경 및 UE 능력(capability)를 고려하여 선정하여 보고할 수 있다.

[408]

[409] **RRM-RS과 CSI-RS의 차이점**

[410] 기존 LTE/LTE-A 시스템에서는 CSI 보고의 목적으로 CSI-RS를 전송한다. UE는 CSI로써 RI, PMI, CQI 등을 보고한다. 이와 달리 본 발명에서 제안하는 RRM-RS는 안테나 포트 별로 RSRP를 측정하기 위해 사용된다. RRM-RS의 전송 자원을 새롭게 정의하기 보다는 기존의 CSI-RS가 설정 가능한 자원을 사용하는 것이 바람직하다. 이는 레가시(legacy) UE들의 전송 효율을 떨어뜨리지 않기 때문이다. 새로운 자원에 RRM-RS를 전송하는 경우에 레가시(legacy) UE들은 이를 인식하지 못하므로, RRM-RS이 전송되는 서브프레임에서 전송 효율이 떨어지거나 또는 스케줄링하지 못하게 된다. 그러므로 기존의 CSI-RS가 설정 가능한 자원을 사용하여 RRM-RS를 전송하는 방식은 레가시(legacy) UE에게 해당 자원을 포함하여 CSI-RS 설정을 해주어 해당 자원에 데이터 매핑이 되지 않음을 알려줄 수 있다.

[411] UE에게 CSI 보고를 위해 설정된 다수개의 CSI-RS에는 데이터 매핑이 이루어지지 않는다. 즉 CSI-RS가 매핑되는 RE를 제외하고 PDSCH를 매핑한다. 본 발명의 제안 방식에서 RRM-RS는 CSI-RS 마찬가지로 RRM-RS가 매핑되는 RE를 제외하고 PDSCH를 매핑하도록 할 수 있다. 그러나 변형된 방식으로 RRM-RS와 무관하게 PDSCH를 매핑하도록 할 수 있다. 이 경우에 UE는 동일 RE에서 RRM-RS와 PDSCH를 동시에 수신할 수 있어야 한다. 또는 기지국이 RRM-RS의 안전한 수신을 보장하기 위하여 해당 자원을 ZP-CSI-RS로 설정하여 PDSCH가 매핑되지 않도록 할 수 있다.

[412]

[413] **RRM-RS의 QCL 설정**

[414] 각 셀에서 RRM-RS를 전송하는 경우에, UE는 서빙 셀 및 인접 셀들이 전송하는 RRM-RS들의 설정을 지정 받을 수 있다. 이를 통하여 UE는 서빙 셀의 빔포밍(beamforming)에 따른 이득 및 인접 셀의 beamforming에 따른 이득을 측정하여 네트워크에 보고하고 핸드오버의 판단 기준으로 활용하도록 해준다.

RRM-RS는 전송 밀도(density)가 매우 낮게 설정되므로 신호의 트래킹(tracking) 목적으로 부족할 수 있다. 그러므로 밀도(density)가 높아 신뢰(reliable)있게 수신되는 신호 대표적으로 CRS를 트래킹(tracking)하고 RRM-RS의 검출하는데 트래킹(tracking) 결과를 활용하도록 한다. 즉, 서빙 셀과 인접 셀의 반송파 주파수를 발생하는 오실레이터의 오차에 의하여 서빙 셀의 CRS에 의해 트래킹(tracking)된 결과를 인접 셀에서 전송된 RRM-RS를 위해 사용하기에는 부적합하다. 그러므로 각각의 RRM-RS 별로 RRM-RS를 검출할 때 사용할 QCL(Quasi Co-Located)된 CRS (혹은 CSI-RS 등 특정 다른 RS)를 알려주도록 한다. UE는 QCL된 CRS (혹은 CSI-RS 등 특정 다른 RS)로부터 추정된 채널의 광범위 특성(large-scale) 특성을 RRM-RS의 검출에 사용한다. 여기서 채널의 광범위 특성(large-scale) 특성은 지연 확산(Delay spread), 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift), 평균 이득(average gain), 그리고 평균 지연(average delay) 중에 하나 이상을 포함할 수 있다.

[415]

[416] **RSRQ로 확장**

[417] 본 발명의 제안 방식들은 RRM-RS의 각 안테나 포트 별로 RSRQ를 측정하는 방식으로 확장 적용될 수 있다. RSRQ는 RSRP와 RSSI의 비율로 정의된다. 그러므로 추가적으로 RSSI의 측정이 추가된다. RSSI의 측정 자원은 동일 반송파 주파수를 갖는, 즉 동일 컴포넌트 캐리어(component carrier)에 설정된 모든 RRM-RS들에 있어서 동일하게 설정될 수 있다. 이 경우에 동일 컴포넌트 캐리어 내의 RRM-RS들의 포트들 간의 비교는 RSRP을 사용하나 RSRQ를 사용하나 동일하다. 그러나 이종 동일 컴포넌트 캐리어 내의 RRM-RS들의 포트들간의 비교는 RSRP을 사용할지 RSRQ를 사용할지에 따라 달라진다. 그러므로 기지국은 UE에게 RRM-RS에 기반한 RRM 보고를 수행함에 있어서 RSRP을 사용할지 RSRQ를 사용할지를 지정해 주도록 한다.

[418] 이와 달리 각각의 RRM-RS들 개별적으로 RSSI 측정 자원을 따로 설정해 줄 수 있다. 이 경우에는 동일 컴포넌트 캐리어 내에서도 RRM-RS들의 포트들간의 비교는 RSRP을 사용할지 RSRQ를 사용할지에 따라 달라진다. 그러므로 기지국은 UE에게 RRM-RS에 기반한 RRM 보고를 수행함에 있어서 RSRP을 사용할지 RSRQ를 사용할지를 지정해 주도록 한다.

[419]

[420] **RRM-RS RSRP와 CRS RSRP의 연관성**

[421] 본 발명의 RRM-RS에 기반한 RSRP는 다중 안테나를 가지고 있는 기지국의 beamforming 이득을 서빙 셀 선택에 반영함을 목적으로 하고 있다. RRM-RS의 RSRP에 근거하여 특정 인접 셀의 beamforing이 가장 좋다고 판단되어도, 해당 셀에서 브로드캐스트하는 채널들, 즉 CRS 기반 복조(demodulation)를 하는 채널이 안정적으로 수신되지 않으면 해당 인접 셀로 UE를 핸드오버 시킬 수 없다. 그러므로 UE에게 특정 기지국에서 전송하는 RRM-RM와 CRS 모두 좋은

품질을 갖는지 보고 받고 이를 근거를 핸드오버 결정 및 빔 선택(beam selection을 수행해야 한다. 이를 위하여 UE는 설정 받은 i번째 RRM-RS의 j번째 안테나 포트 또는 포트그룹의 RSRP를 보고하면서 i번째 RRM-RS과 연결된 CRS의 RSRP를 같이 보고 하도록 한다. 여기서 RRM-RS와 연결된 CRS는 RRM-RS와 QCL된 CRS일 수 있다.

[422]

[423] 이하, 본 명세서에서 제안하는 지연(latency)을 줄이기 위한 단말의 CSI 측정 및 보고 동작 방법에 대해 살펴본다.

[424] 본 명세서에서 제안하는 방법은 3D-MIMO, massive MIMO 등의 시스템뿐만 아니라 amorphous cell(비정형 셀) 환경 등에서도 확장되어 적용 가능할 수 있음은 물론이다.

[425] 먼저, 3D-MIMO 시스템에 대해 간략히 살펴본다.

[426] 3D-MIMO 시스템은 LTE 표준(Rel-12)을 기반으로 하여 앞서 살핀 도 11과 같은 single-cell 2D-AAS(Adaptive Antenna System) 기지국에 적합한 최적의 전송 방식 중 하나이며, 다음과 같은 동작을 고려할 수 있다.

[427] 도 11에 도시된 바와 같이, 8-by-8(8X8)의 antenna array로부터 CSI-RS ports를 구성하는 예를 들어 살펴보면, 세로로 각각 8개의 안테나에 대해서는 특정 target UE에게 최적화된 'UE-dedicated beam coefficients'를 적용한 precoded CSI-RS port 하나씩을 구성하도록 함으로써, 가로로 총 8-port (vertically precoded) CSI-RS를 설정/전송하도록 한다.

[428] 이를 통해, 단말은 종래와 같은 8-port에 대한 CSI feedback을 수행할 수 있게 된다.

[429] 결국, 기지국은 개별 단말 (또는 특정 단말 그룹)에 최적화된 수직 방향 beam gain이 이미 적용된 (precoded) CSI-RS 8 ports를 단말로 전송한다.

[430] 따라서, 상기 단말은 무선 채널을 겪은 CSI-RS를 측정(measure)하기 때문에, 상기 단말은 종래의 수평 방향 코드북에 의한 동일한 피드백 방식을 수행하더라도 상기 (vertically precoded) CSI-RS에 대한 CSI 측정 및 보고(measurement and reporting) 동작을 통해 이미 무선 채널의 수직 방향의 beam gain 효과를 얻을 수 있게 된다.

[431] 이 때, 개별 단말에 최적화된 수직 방향의 beam을 결정하기 위한 방법으로 (1) (vertically precoded) small-cell discovery RS (DRS)에 의한 RRM report 결과를 이용하는 방법, (2) 단말의 sounding RS (SRS)를 기지국이 최적의 수신 beam 방향으로 수신하고, 해당 수신 beam 방향을 채널 상호 관계(channel reciprocity)에 의해 DL 최적 beam 방향으로 변환하여 적용하는 방법 등이 있다.

[432] 만일 기지국이 단말의 이동성으로 인해 상기 UE-dedicated best V-beam 방향이 바뀌었다고 판단할 경우, 종래 동작에 의하면 기지국은 CSI-RS 및 연관 CSI process 등과 관련된 RRC 설정을 모두 재구성(re-configure)하였다.

[433] 이와 같이 RRC 재구성(reconfiguration) 과정을 수행해야 하는 경우, RRC

레벨의 지연(latency)(e.g., 수십 ~ 수백 ms단위) 발생은 불가피하다.

[434] 즉, 네트워크 차원에서는 사전에 타겟 V-beam 방향을 예를 들어, 4개로 분할해 놓고, 각각의 V-방향에 precoding이 걸린 별도의 8 port CSI-RS를 해당 별도의 전송 자원 위치에서 전송하게 된다.

[435] 또한, 각 UE는 8 port CSI-RS 중에서 특정 하나의 CSI-RS 설정에 대한 CSI 측정 및 보고(measurement and reporting)을 해야 하므로, 타겟 V-방향이 바뀔 때에는 변경될 CSI-RS 설정으로 네트워크와 RRC reconfiguration 절차를 수행할 수 밖에 없게 된다.

[436]

[437] 따라서, 이하에서는 본 명세서에서 제안하는 RRC 레벨의 지연(latency)를 없애거나 또는 대폭 줄이기 위한 CSI 측정 및 보고(measurement and reporting) 방법에 대해 구체적으로 살펴본다.

[438] 즉, 본 명세서에서 제안하는 방법은 UE에게 단일 CSI process와 단일 상향링크(UL) 피드백 자원만을 할당해 놓고, measure 대상이 되는 CSI-RS index (그리고/또는 CSI-IM index)가 무엇인지를 RRC 레벨이 아니 MAC 레벨 (또는 PHY 레벨)에서 지시하여 주는 방법에 관한 것이다.

[439] MAC 레벨 지시는 MAC CE를 이용할 수 있고, PHY 레벨 지시는 DCI를 이용할 수 있다.

[440] 즉, 본 명세서에서 제안하는 방법은 기지국(또는 네트워크)가 RRC signaling을 이용하여 다수의 후보 CSI-RS들에 대한 CSI-RS 설정들을 단말에게 설정해주고, 다수의 후보 CSI-RS들 중에 CSI-RS 측정 및 보고를 수행하는 적어도 하나의 CSI-RS에 대해 단말로 '활성화' 지시를 명시적 또는 암시적으로 알려준다.

[441] 예를 들어, CSI-RS 1이 활성화된 상태였을 때, CSI-RS 1에서 CSI-RS 2로 옮길지가 고려되는 상황인 경우, 기지국은 실제로 CSI-RS 2로 옮기라고 re-activate 명령을 지시하기 이전에, 단말에게 CSI-RS 2에 대한 트래킹(tracking)을 미리 하고 있을 수 있도록 사전 활성화(pre-activate)를 먼저 지시할 수 있다.

[442] 여기서, 상기 CSI-RS에 대한 트래킹(tracking)은 단말이 CSI-RS를 측정할 수 있도록 CSI-RS에 대해 시간 및/또는 주파수 동기를 맞추는 동작을 의미할 수 있다.

[443] 즉, 사전-활성화(pre-activate)된 CSI-RS x는 (특정 타이머 시간 이내에서) 실제로 활성화될 수도 있거나 또는 활성화가 되지 않을 수도 있다.

[444] 여기서, 상기 단말은 기지국으로부터 CSI-RS x의 활성화를 지시하는 활성화 메시지를 기지국으로부터 수신한 후, 특정 y ms 이후에 온전한 CSI reporting을 상기 기지국으로 피드백(feedback)할 수 있다.

[445] 여기서, 온전한 CSI reporting을 피드백한다는 의미는 단말이 기지국으로 의미 있는 CSI feedback을 수행하는 것으로 해석될 수 있다.

[446] 상기 CSI feedback은 측정되는 sample의 수에 따라 의미있는 것인지 아니면

의미없는 것인지 판단될 수 있다.

[447]

[448] **능력(capability) 정보 전송**

[449] 보다 구체적으로, 본 명세서에서는 먼저 단말이 특정 능력 시그널링(capability signaling)을 기지국으로 전송함으로써 사전에 (예:초기 접속 시) 상기 기지국으로 자신의 CSI 동작 관련 능력(capability) 정보를 알려준다.

[450] 상기 CSI 동작 관련 단말의 능력 정보는 아래 정보들 중 적어도 하나를 포함할 수 있다.

[451] 여기서, CSI 관련 동작은 CSI-RS, CSI-IM 및/또는 CSI process와 관련된 동작을 의미할 수 있다.

[452] 'A 및/또는 B'의 기재는 'A 또는 B 중 적어도 하나'로 해석될 수 있다.

[453] 1. 최대 몇 개까지의 CSI-RS (Nc개), CSI-IM(Interference Measurement) (Ni개), 및/또는 CSI process (Np개)가 동시에 '완전 활성화(full activation)'가 될 수 있는지에 대한 능력 정보

[454] 여기서, 'full activation (configuration)'으로 표현한 이유는 예를 들어 Nc=3, Ni=3, Np=4인 단말의 경우에는, 실제 기지국이 총 Nc=3 CSI-RSs, Ni=3 CSI-IMs, Np=4 CSI processes를 모두 동시에 설정 가능하다는 의미이며, 이 경우 종래의 Rel-11 표준에서의 CoMP 동작들이 모두 지원 가능하다.

[455] 즉, 단말은 Nc=3 CSI-RSs를 모두 channel measurement하여야 하고, Ni=3 CSI-IMs을 모두 간섭 측정(interference measurement:IM)하여야 하고, Np=4 CSI processes에 대한 CSI feedback을 모두 수행하여야 함을 의미한다.

[456] 2. 최대 몇 개까지의 CSI-RS (Nc'개), CSI-IM (Ni'개), 및/또는 CSI process (Np'개)가 동시에 '일부 활성화(partial activation)'가 될 수 있는지에 대한 능력 정보

[457] 여기서, '일부 활성화(partial activation)'으로 표현한 이유는 상기 'full activation'시에 단말이 수행할 수 있는 동작들 중에 특정 일부 동작(e.g., CSI-RS tracking)만으로 한정되거나 또는 별도의 추가 동작이 포함될 수도 있다.

[458] 예를 들어, 특정 단말은 상기 1.에서의 파라미터는 Nc=1, Ni=1, Np=1임과 동시에 2.에서의 파라미터는 Nc'=3, Ni'=1, Np'=1일 수 있다.

[459] 즉, Nc=1이고, Nc'=3이라는 차이만 가지고 있다.

[460] 이 의미는 상기 특정 단말은 Nc'=3개의 일부 활성화(partial activation)된 CSI-RS에 대해서는 time/frequency synchronization/tracking을 유지하고 있으며, 이 중에서 특정 Nc=1개의 '완전 활성화(full activation)'되는 CSI-RS를 지정받을 수 있다는 의미로 해석될 수 있다.

[461] 이와 같은 Nc=1개의 CSI-RS를 지정 받을 수 있는 대표적인 방법으로, (1) MAC CE command 등을 통해 MAC layer에서 지시를 받을 수 있는 방법, (2) DCI signaling을 통해 PHY layer에서 보다 dynamic indication을 받을 수 있는 방법 등이 있을 수 있다.

[462] 이와 같은 방법을 통해, 단말은 단일 Np=Np'=1개의 CSI process에 대한 (특정 CC에서) 단일 CSI feedback만 수행하면 되기 때문에, CSI feedback에 대한 복잡도 및 overhead는 항상 동일하게 유지될 수 있다.

[463] 그리고, 본 명세서에서 제안하는 방법을 통해 단말이 측정해야 하는 CSI-RS index만을 MAC layer 또는 PHY layer의 signaling을 통해 동적으로 스위칭(dynamic switching)해줄 수 있다는 장점이 있다.

[464] 즉, 본 명세서는 RRC signaling에 의한 즉, CSI-RS reconfiguration latency 보다 작은 latency를 갖는 signaling을 통해 measure 대상이 되는 자원만 switching해주는 방법을 제공한다.

[465] 본 명세서에서는 설명의 편의를 위해, CSI-RS를 중심으로 설명하나 본 명세서에서 제안하는 방법은 CSI-IM index (또는 CSI process index)를 dynamic switching하는 데에도 동일하게 확장 적용할 수 있음은 자명하다.

[466] 추가적으로, 앞의 1. 및 2.에서 파라미터들 간에 Nc <= Nc', Ni <= Ni', 및/또는 Np <= Np' 형태로 추가적인 제한이 있을 수도 있다.

[467] 이 경우, 단말은 이러한 조건을 만족하는 한에서 상기 능력 시그널링(capability signaling)을 전송해야 한다.

[468]

[469] 기지국이 상기 CSI 동작 관련 단말의 능력 정보를 포함하는 capability signaling을 단말로부터 수신하는 경우, 상기 기지국은 추후 해당 단말을 설정할 때, 앞서 살핀 capability 특성 조합에 위배되지 않는 형태로 상기 단말에게 RRC signaling을 전송해야 한다.

[470] 상기 단말은 상기 capability 특성에 위배되는 경우에 대해서는 기대하지 않으며, error case로 간주할 수 있다.

[471]

[472] 앞서 살핀 것처럼, 단말은 기지국으로부터 Nc'=3에 해당하는 CSI-RS 3개를 모두 RRC signaling을 통해 설정받을 수 있다고 가정한다.

[473] 다만, 이때 상기 단말은 각 CSI-RS index별로 'partical activation' 상태로 설정하는 것임을 식별할 수 있는 별도의 식별자 또는 특정 implicit indication에 의해 이를 인지할 수 있는 signaling을 상기 기지국으로부터 수신할 수 있다.

[474] 이 경우, 상기 단말은 상기 RRC signaling을 수신한 시점부터 상기 3개의 CSI-RS에 대해 각각 time/frequency synchronization/tracking을 수행하도록 한다.

[475] 이는 각 CSI-RS 설정에 포함되어 있는 quasi co-location(QCL) 가정을 적용하도록 하는 특정 RS(e.g., CRS)등의 정보에 입각하여 synchronization/tracking을 수행할 수 있다.

[476] 이 때, 상기 별도의 식별자 형태로 Nc'=3개의 CSI-RS 중에 특정 Nc=1개의 CSI-RS만 '완전 활성화(full activation)'임을 추가로 (또는 동시에) 설정 또는 지시 받을 수 있다.

[477] 또는, 암시적으로(implicit하게) 상기 Nc=1개의 CSI-RS는 항상 lowest(highest)

indexed CSI-RS로 규정되는 등 특정 index로 사전에 규정될 수도 있다.

[478] 그러면, 단말은 상기 Nc=1개의 'full activation'된 CSI-RS에 대해서만 CSI feedback을 위한 channel measurement를 수행하면 된다.

[479] 즉, 단말은 나머지 Nc'-Nc=2개의 CSI-RS에 대해서는 channel measurement를 수행하지 않고, tracking만 수행한다.

[480] 이와 같이, Nc=1개의 특정 CSI-RS에 대해서만 channel measurement를 수행하고, 상기 측정을 통해 feedback contents(e.g., RI/PMI/CQI)를 derive하는 방법은 이것과 함께 설정되는 특정 CSI process에 대해 상기 feedback contents를 계산하는 동작이 규정/설정될 수 있다.

[481] 예를 들어, 단말은 특정 Np=1개의 CSI process도 RRC signaling을 통해 기지국으로부터 수신하게 되고, 이러한 CSI process는 특정 개수의 CSI-RS와 CSI-IM 인덱스 간의 조합으로 정의된다.

[482] 하지만, 여기서의 CSI-RS는 상기 full activation되는 Nc=1개의 CSI-RS가 무엇이냐에 따라 상기 full activation되는 CSI-RS가 자동 반영되어 해당 CSI process의 채널 측정(channel measure)의 대상이 되는 CSI-RS로 인식되도록 하는 동작이 정의/설정될 수 있다.

[483] 또 다른 일례로서, CSI process도 예를 들어, Np'=3으로 partial activation 상태로 3가지를 설정 받고, 각각의 CSI process 내 상기 Nc'=3개의 CSI-RS 인덱스가 설정될 수 있다.

[484] 이후, 기지국은 Np=1개의 full activation되는 특정 CSI process를 상기 MAC 또는 PHY signaling을 통해 단말로 dynamic indication을 줄 수 있다.

[485] 그러면, 단말은 상기 full activation되는 특정 CSI process에 대한 CSI feedback을 기지국으로 전송할 수 있다.

[486] 결국, 특정 CSI process 별로 여기에 연동되어 지시되는 특정 CSI-RS 및/또는 CSI-IM 인덱스는 이것이 고정된 인덱스인지, 앞서 살핀 것처럼 자동으로 가변 가능한 인덱스인지를 식별할 수 있는 별도의 식별자 또는 특정 implicit signaling 방법이 정의될 수 있다.

[487] 만일 상기 특정 CSI-RS 및/또는 CSI-IM 인덱스가 특정 인덱스로 고정되어 지시되는 경우, 단말은 상기 고정된 CSI-RS 및/또는 CSI-IM 인덱스에 해당하는 자원에 대한 측정(measurement)를 수행한다.

[488] 만일 상기 특정 CSI-RS 및/또는 CSI-IM 인덱스가 가변 가능한 인덱스 형태로 설정되어 있는 경우, 앞서 살핀 것처럼 특정 Nc=1개의 CSI-RS가 별도의 MAC 또는 PHY signaling으로 'full activation'되는 경우, 해당 인덱스를 자동으로 적용하도록 하는 형태로 적용될 수 있다.

[489] 여기서, full activation되는 Nc개가 2개 이상일 수도 있다.

[490] 예를 들면, 2D-AAS 구조에서의 multiple CSI-RS resources를 Kronecker 연산 등을 통해 함께 measure하도록 하는 목적 등의 경우에 full activation되는 Nc개는 2개 이상일 수 있다.

[491] 이 경우에도 상기 full activation되는 Nc개가 무엇인지가 별도로 dynamic indication되는 경우, 이러한 인덱스들을 자동으로 적용되도록 할 수 있다.

[492] 결국, 이러한 CSI process 설정에 있어서는 해당 설정에서 지시될 수 있는 CSI-RS 및/또는 CSI-IM 인덱스가 어떠한 후보 set 중에서 설정될 수 있는지 RRC 설정 단계에서부터 규정되는 것이 바람직할 수 있다.

[493] 마찬가지로, 상기 CSI-IM에 대해서도 Ni' 및 Ni 개수에 따른 상기 설정 또는 지시 동작이 적용될 수 있음은 자명하다.

[494] 도 15는 본 명세서에서 제안하는 CSI 측정 및 보고 방법의 일례를 나타낸 도이다.

[495] 도 15를 참조하면, 단말은 기지국으로 CSI 동작 관련 상기 단말의 능력 정보를 포함하는 능력 시그널링(capability signaling)을 전송한다(S1510).

[496] 상기 단말의 능력 정보는 동시에 완전 활성화(full activation) 가능한 상기 CSI 관련 동작의 최대 개수를 나타내는 제 1 제어 정보 및 동시에 부분 활성화(partial activation) 가능한 상기 CSI 관련 동작의 최대 개수를 나타내는 제 2 제어 정보를 포함한다.

[497] 이후, 상기 기지국은 CSI 동작과 관련된 설정이 변경되는 경우, 상기 기지국은 상기 단말로 CSI 동작 관련 설정 정보(또는 CSI 관련 동작 설정 정보)를 전송한다(S1520).

[498] 상기 CSI 동작 관련 설정 정보는 부분 활성화(partial activation)를 수행하는 CSI 관련 동작을 나타내는 부분 활성화 CSI 관련 동작 인덱스(index) 정보 또는 완전 활성화(full activation)를 수행하는 CSI 관련 동작을 나타내는 완전 활성화 CSI 관련 동작 인덱스 정보 중 적어도 하나를 포함한다.

[499] 이후, 상기 단말은 상기 CSI 동작 관련 설정 정보에 기초하여 완전 활성화 CSI를 측정한다(S1530).

[500] S1530 단계 이전에 상기 단말은 부분 활성화 CSI-RS에 대해서는 트래킹을 수행한다.

[501] CSI-RS 트래킹에 대한 구체적인 설명은 앞의 내용을 참조한다.

[502] 이후, 상기 단말은 상기 측정 결과를 상기 기지국으로 보고한다(S1540).

[503]

[504] 도 16은 본 명세서에서 제안하는 CSI 측정 및 보고 방법의 또 다른 일례를 나타낸 도이다.

[505] S1610 및 S1620, S1640 및 S1650은 도 15의 S1510 내지 S1540과 동일하므로 구체적인 설명은 생략한다.

[506] S1620 단계 이후(CSI 동작 관련 설정 정보를 기지국이 단말로 전송한 이후), 기지국은 단말로 완전 활성화 CSI-RS에 대한 측정을 지시하는 지시 메시지를 전송한다(S1630).

[507] 상기 지시 메시지는 MAC CE 또는 DCI일 수 있다.

[508] 또한, 상기 완전 활성화 CSI-RS는 부분 활성화 CSI-RS에서 선택되는 것이

바람직할 수 있다.

[509]

[510] **CSI 측정** 윈도우(measurement window) 초기화/갱신 시점

[511] 단말이 MAC signaling 또는 PHY signaling을 통해, 기지국으로부터 특정 CSI-RS, CSI-IM, 및/또는 CSI process index(들)의 full activation되는 signaling을 SF(sufbrame) #n 시점에 수신한 경우, 상기 단말은 해당 시점(subframe #n)으로부터 특정 y ms부터 즉, SF #(n+y) 시점부터 CSI measurement 및 reporting을 하도록 적용할 수 있다.

[512] 만일 periodic CSI reporting의 경우, 상기 SF #(n+y) 시점 이후에 최초로 나오는 RI reporting instance에 연동된 특정 reference resource 시점부터 새롭게 full activation된 특정 CSI-RS, CSI-IM, 및/또는 CSI process index(들)에 대한 CSI measurement 및 reporting을 개시하도록 한다.

[513] 즉, SF #(n+y) 시점 이후에 존재하는 유효한 reference resource 시점들에 대해, 상기 reference resource 시점에 계산되는 CSI(e.g., RI/PMI/CQI)가 최초로 RI가 reporting되는 시점부터 이러한 새로운 CSI contents를 report하도록 정의할 수 있다.

[514] 즉, 상기 최초의 RI reporting 시점 이전에는 PMI/CQI reporting instance가 존재한다 하더라도 상기 새롭게 full activation된 설정에 입각하면 안되고, 그 직전에 따르고 있는 설정에 입각한 CSI feedback contents가 지속해서 reporting되어야 함을 의미한다.

[515] 결국, 새로운 RI reporting instance 시점부터 상기 full activation된 설정에 입각하여 단말의 CSI reporting을 수행하도록 한다.

[516]

[517] 위 동작들에 있어서, CSI measurement를 averaging하는 window와 관련된 설정 정보도 별도로 또는 함께 RRC signaling을 통해 제공되도록 규정될 수 있다.

[518] 또한 이와 같은 동작은 상기 full/partial activation과 같은 형태의 설정을 지원하는 enhanced 단말에 대해서만 규정될 수 있다.

[519] 즉, 종래의 unrestricted observation을 허용하는 것이 아닌, 특정 [d1, d2] ms 시간 구간 안에서만 measurement를 averaging하도록 한다.

[520] 이는 measure 대상이 되는 CSI-RS 및/또는 CSI-IM의 자원 설정 정보가 MAC 또는 PHY signaling을 통해 dynamic switching될 수 있기 때문에 특정 bounded된 구간 내에서만 measurement averaging을 수행하도록 규정하는 것이 바람직할 수 있기 때문이다.

[521] 일례로, 측정(measure) 대상이 되는 CSI-RS 그리고/또는 CSI-IM의 자원 설정 정보가 MAC 또는 PHY signaling(e.g., by DCI)을 통해 dynamic switching/indication되는 signaling을 단말이 기지국으로부터 수신한 경우, 단말은 이에 연동하여 상기 CSI-RS-based channel measurement의 measurement averaging window를 초기화 또는 갱신하도록 규정/설정될 수 있다.

[522] 또한, 단말은 상기 (dynamic switching/indication 되는) signaling에 연동하여 해당 CSI-IM-based interference measurement의 measurement averaging window를 초기화 또는 갱신할 수 있다.

[523] 여기서, measurement averaging window가 초기화 또는 갱신된다는 의미는, 현재 표준에 따른 CSI 측정을 위한 'unrestricted observation'에 의해 예를 들어, 과거 임의의 시점부터 현재까지 반복적으로 측정된 해당 CSI-RS ports로부터의 채널 측정치들을 단말 구현에 따라 averaging하는 종래 동작 대신에, 상기 '임의의 시점부터'라는 'measurement window의 시작점'을 상기 (dynamic switching/indication 되는) signaling을 수신한 시점 #n (또는 특정 설정/지시된 시점 후, e.g., #n+k)부터로 다시 초기화 또는 갱신하도록 하는 것이다.

[524] 또는, 상기 signaling을 통해 어느 시점부터 해당 measurement window가 초기화 또는 갱신되는지의 시점 정보를 (e.g., timestamp형태) 함께 explicit signaling해주는 방식도 적용 가능하다.

[525] 예를 들어, SFN, slot number 등 절대 시간 파라미터 값들에 대한 시간 정보 지시 방법, 또는 상기 signaling을 단말이 수신한 시점부터 특정 +/-Delta값 형태로 지시해주는 방식 등이 있을 수 있다.

[526] 다시 말해, 상기 signaling은 오직 measurement averaging window의 시작 시점만 갱신/리셋 해주는 역할을 하는 것으로 한정될 수 있다.

[527] 그러면, 해당 시점부터 시작하여 이후에 추가적인 상기 signaling이 수신되기 이전까지 단말은 CSI 측정치들을 (단말 구현에 따라) 평균화할 수 있다.

[528] 상기 signaling은 각 CSI process별로 별도로 (독립적으로) signaling될 수 있다. 이를 통해, 각 process별로 measurement window reset이 독립적으로 적용될 수 있도록 한다.

[529] 상기 signaling은 특정 CSI-IM 자원에 대한 interference measurement averaging window를 리셋하는 용도로도 함께 적용될 수도 있다.

[530] 이 경우에는, 특정 CSI process에 속한 CSI-RS 및 CSI-IM에 대한 measurement averaging window를 함께 초기화하는 역할을 하게 된다.

[531] 또는, CSI-IM 자원에 대한 interference measurement averaging window를 리셋하기 위한 별도의 (독립적인) indicator를 signaling하는 방식도 적용 가능하다.

[532] 이는, 간섭 환경의 변화가 존재하는 환경(e.g., eICIC, eIMTA, LAA 등)에서 예를 들어 기지국이 예측/감지 가능한 간섭 환경의 변화가 존재하는 경우, 단말에게 상기 특정 CSI process에 대한 measurement averaging window를 초기화하도록 알려줌으로써, 과거의 간섭 환경을 더 이상 현 시점부터 간섭 측정치에 반영하지 않도록 분리해줄 수 있다는 효과가 있다.

[533] 도 17은 본 명세서에서 제안하는 CSI 측정 및 보고 방법의 또 다른 일례를 나타낸 도이다.

[534] S1710 내지 S1730, S1750 및 S1760은 도 16의 S1610 내지 S1630, S1640 및

S1650과 동일하므로 구체적인 설명은 생략한다.

[535] 도 17을 참조하면, S1730 단계 이후, 단말은 CSI 측정 윈도우를 초기화 또는 갱신한다(S1740).

[536] 이후, 상기 단말은 초기화 또는 갱신된 CSI 측정 윈도우 구간에서 완전 활성화 CSI-RS를 반복적으로 측정하고, 상기 측정 결과를 평균하여, 상기 평균값을 기지국으로 보고한다(S1750~S1760).

[537] S1740 단계 이전에 기지국은 단말로 CSI 측정 윈도우 관련 설정 정보를 전송할 수 있다.

[538]

[539] 상기 (dynamic switching/indication 되는) signaling과 유사한 형태의 또 다른 실시예로서, 본 명세서는 아래와 같이 beamformed CSI-RS 기반의 방식에 대해서도 앞서 살핀 측정 윈도우(measurement window) 설정 관련 동작이 적용될 수 있다.

[540] Elevation beamforming 및 FD-MIMO 동작을 위해서 아래와 같은 PMI feedback scenario들이 고려될 수 있다.

[541] 1. EBF(Elevation Beamforming)/FD-MIMO에 대한 프리코딩 정의

[542] (1) 프리코딩 매트릭스/벡터(Precoding matrix/vector)

[543] - P_1: 와이드밴드(wideband); 자주 업데이트되지 않음(updated less frequently)

[544] - P_2: 서브밴드(subband) 또는 와이드밴드(wideband); 더 자주 업데이트됨(updated more frequently)

[545] - P is a function of P_1 and P_2, applied to 1D or 2D antenna array(P는 1D 또는 2D 안테나 어레이에 적용되는 P_1 및 P_2의 함수이다.)

[546] - PMI(s) are to be specified w.r.t. the above definition

[547] (2) CSI 피드백 시나리오들(Scenarios for CSI feedback)

[548] 1) 시나리오 1

[549] - UE measures CSI-RS ports beamformed with P_1(P_1 transparent to UE).

[550] - PMI report(s) for P_2

[551] 2) 시나리오 2

[552] - UE measures non-precoded 1-D or 2-D CSI-RS ports

[553] Note:P_1 not applied to CSI-RS at eNB

[554] - PMI report(s) for P_1 and P_2

[555] 3) 시나리오 3

[556] - UE measures both non-precoded 1- or 2-D CSI-RS ports (lower duty cycle) and CSI-RS beamformed with P_1

[557] - PMI report(s) for P_1 and P_2

[558] 4) 시나리오 4

[559] - UE measures non-precoded 1- or 2-D CSI-RS ports

[560] Note: P_1 not applied to CSI-RS at eNB(P_1 indicated to UE).

[561] - PMI report(s) for P_2

[562]

[563] 상기 시나리오 1 내지 시나리오 4 중에, 예를 들어 scenario 1 및 scenario 3과 같은 beamformed CSI-RS를 활용하는 방법은 단말이 행렬 P1 자체는 알 필요가 없다고 하더라도, 만일 해당 CSI-RS ports에 기지국이 beamforming을 적용한 P1이 변경된 경우, 상기 기지국은 상기 P1의 변경 시점 관련 정보를 단말로 사전에 알려주어야 한다.

[564] 그래야, 상기 단말은 CSI measurement and calculation 시에 적절한 measurement averaging window를 설정/적용할 수가 있다.

[565] 즉, 현재 표준에 따르면 단말이 해당 CSI-RS ports에 대한 channel measurement 시에는 'unrestricted observation'에 의해 과거 임의의 시점부터 현재까지 반복적으로 측정된 해당 CSI-RS ports로부터의 채널 측정치들을 단말 구현에 따라 averaging하여 신뢰도를 높일 수 있었다(e.g., noise suppression 효과).

[566] 하지만, 상기 시나리오 1 내지 4에서는 P1 자체가 단말에게 알려지지 않는 beamformed CSI-RS ports를 활용하므로, 기지국이 임의의 시점에 P1 자체를 변경할 수 있고, 기지국이 상기 P1이 변경되었음을 단말에게 알려주지 않으면 단말은 변경 이전의 P1과 변경 이후의 P1'에 대한 채널 측정치를 함께 averaging할 수 있으므로 해당 CSI measurement and reporting의 정확도에 문제가 발생할 수 있다.

[567] 따라서, 본 명세서는 이러한 문제점을 해결하기 위해, 기지국이 단말에게 일종의 'beam-change notification' 또는 'beam-change indicator (BCI) signaling을 전송하는 방법을 제공한다.

[568] 이하에서는 'beam-change indicator'를 간단히 'BCI'로 호칭하기로 한다.

[569] BCI signaling은 RRC signaling형태로 지시될 수도 있다.

[570] 그러나 보다 바람직하게는, MAC CE를 통한 signaling이나 DCI 등을 통한 dynamic indication으로 제공될 수 있다.

[571] 즉, 단말은 기지국으로부터 BCI signaling을 수신하는 경우, 해당 CSI process에서의 CSI derivation시에 적용하는 measurement averaging window의 시작점을 해당 BCI signaling 수신 시점(또는 이로부터 특정 지시된 시점, 또는 별도의 timestamp 등으로 explicit indication된 시점)으로 갱신한다.

[572] 즉, 상기 BCI 정보와 함께 (또는 연계된 정보로서), 어느 시점부터 해당 measurement window가 초기화 또는 갱신되는지의 시점 정보를(e.g., timestamp형태) 함께 explicit signaling해주는 방식도 적용 가능하다.

[573] 예를 들어, SFN, slot number등 절대 시간 파라미터 값들에 대한 시간 정보 지시 방법, 또는 상기 signaling을 단말이 수신한 시점부터 특정 +/-Delta값 형태로 지시해주는 방식 등이 있을 수 있다.

[574] 즉, 이러한 BCI signaling은 오직 measurement averaging window의 시작 시점만 갱신/리셋 해주는 역할을 하는 것으로 한정될 수 있다.

[575] 그러면, 이 시점(BCI signaling 수신 시점)부터 시작하여 이후에 추가적인 BCI가

수신되기 이전까지 단말은 CSI 측정치들을 (단말 구현에 따라) 평균화할 수 있다.

[576] 결국, 단말이 상기 갱신된 행렬 P1자체는 알지 못하지만, P1이 갱신되었음을 상기 BCI를 통해 지시받았으므로, 이 시점부터 다시 새롭게 CSI 측정치들을 평균화하도록 함으로써 갱신된 P1이 적용된 CSI-RS ports에 대해서만 해당 CSI process에 대한 CSI calculation and reporting(e.g., P1, P2, RI, CQI 등)을 수행할 수 있다.

[577] 상기 BCI는 각 CSI process별로 별도로 (독립적으로) signaling될 수 있다.

[578] 이를 통해, 각 process별로 measurement window reset이 독립적으로 적용될 수 있도록 한다.

[579] 상기 BCI는 특정 CSI-IM 자원에 대한 interference measurement averaging window를 리셋하는 용도로도 함께 적용될 수도 있다.

[580] 이 경우에는, 특정 CSI process에 속한 CSI-RS 및 CSI-IM에 대한 measurement averaging window를 함께 초기화하는 역할을 하게 된다.

[581] 또는, CSI-IM 자원에 대한 interference measurement averaging window를 리셋하기 위한 별도의 (독립적인) indicator를 signaling하는 방식도 적용 가능하다.

[582] 이는, 간섭 환경의 변화가 존재하는 환경(e.g., eICIC, eIMTA, LAA 등)에서 예를 들어 기지국이 예측/감지 가능한 간섭 환경의 변화가 존재하는 경우, 단말에게 상기 특정 CSI process에 대한 measurement averaging window를 초기화하도록 알려줌으로써, 과거의 간섭 환경을 더 이상 현 시점부터 간섭 측정치에 반영하지 않도록 분리해줄 수 있다는 효과가 있다.

[583]

[584] **본 발명이 적용될 수 있는 장치 일반**

[585] 도 18은 본 발명의 일 실시예에 따른 무선 통신 장치의 블록 구성도를 예시한다.

[586] 도 18를 참조하면, 무선 통신 시스템은 기지국(1810)과 기지국(1810) 영역 내에 위치한 다수의 단말(1820)을 포함한다.

[587] 기지국(1810)은 프로세서(processor, 1811), 메모리(memory, 1812) 및 RF부(radio frequency unit, 1813)을 포함한다. 프로세서(1811)는 앞서 도 1 내지 도 17에서 제안된 기능, 과정 및/또는 방법을 구현한다. 무선 인터페이스 프로토콜의 계층들은 프로세서(1811)에 의해 구현될 수 있다. 메모리(1812)는 프로세서(1811)와 연결되어, 프로세서(1811)를 구동하기 위한 다양한 정보를 저장한다. RF부(1813)는 프로세서(1811)와 연결되어, 무선 신호를 송신 및/또는 수신한다.

[588] 단말(1820)은 프로세서(1821), 메모리(1822) 및 RF부(1823)을 포함한다. 프로세서(1821)는 앞서 도 1 내지 도 17에서 제안된 기능, 과정 및/또는 방법을 구현한다. 무선 인터페이스 프로토콜의 계층들은 프로세서(1821)에 의해 구현될 수 있다. 메모리(1822)는 프로세서(1821)와 연결되어, 프로세서(1821)를

구동하기 위한 다양한 정보를 저장한다. RF부(1823)는 프로세서(1821)와 연결되어, 무선 신호를 송신 및/또는 수신한다.

[589] 메모리(1812, 1822)는 프로세서(1811, 1821) 내부 또는 외부에 있을 수 있고, 잘 알려진 다양한 수단으로 프로세서(1811, 1821)와 연결될 수 있다. 또한, 기지국(1810) 및/또는 단말(1820)은 한 개의 안테나(single antenna) 또는 다중 안테나(multiple antenna)를 가질 수 있다.

[590] 이상에서 설명된 실시예들은 본 발명의 구성요소들과 특징들이 소정 형태로 결합된 것들이다. 각 구성요소 또는 특징은 별도의 명시적 언급이 없는 한 선택적인 것으로 고려되어야 한다. 각 구성요소 또는 특징은 다른 구성요소나 특징과 결합되지 않은 형태로 실시될 수 있다. 또한, 일부 구성요소들 및/또는 특징들을 결합하여 본 발명의 실시예를 구성하는 것도 가능하다. 본 발명의 실시예들에서 설명되는 동작들의 순서는 변경될 수 있다. 어느 실시예의 일부 구성이나 특징은 다른 실시예에 포함될 수 있고, 또는 다른 실시예의 대응하는 구성 또는 특징과 교체될 수 있다. 특허청구범위에서 명시적인 인용 관계가 있지 않은 청구항들을 결합하여 실시예를 구성하거나 출원 후의 보정에 의해 새로운 청구항으로 포함시킬 수 있음은 자명하다.

[591] 본 발명에 따른 실시예는 다양한 수단, 예를 들어, 하드웨어, 펌웨어(firmware), 소프트웨어 또는 그것들의 결합 등에 의해 구현될 수 있다. 하드웨어에 의한 구현의 경우, 본 발명의 일 실시예는 하나 또는 그 이상의 ASICs(application specific integrated circuits), DSPs(digital signal processors), DSPDs(digital signal processing devices), PLDs(programmable logic devices), FPGAs(field programmable gate arrays), 프로세서, 콘트롤러, 마이크로 콘트롤러, 마이크로 프로세서 등에 의해 구현될 수 있다.

[592] 펌웨어나 소프트웨어에 의한 구현의 경우, 본 발명의 일 실시예는 이상에서 설명된 기능 또는 동작들을 수행하는 모듈, 절차, 함수 등의 형태로 구현될 수 있다. 소프트웨어 코드는 메모리에 저장되어 프로세서에 의해 구동될 수 있다. 상기 메모리는 상기 프로세서 내부 또는 외부에 위치하여, 이미 공지된 다양한 수단에 의해 상기 프로세서와 데이터를 주고 받을 수 있다.

[593] 본 발명은 본 발명의 필수적 특징을 벗어나지 않는 범위에서 다른 특정한 형태로 구체화될 수 있음은 당업자에게 자명하다. 따라서, 상술한 상세한 설명은 모든 면에서 제한적으로 해석되어서는 아니 되고 예시적인 것으로 고려되어야 한다. 본 발명의 범위는 첨부된 청구항의 합리적 해석에 의해 결정되어야 하고, 본 발명의 등가적 범위 내에서의 모든 변경은 본 발명의 범위에 포함된다.

산업상 이용가능성

[594] 본 발명의 무선 통신 시스템에서 CSI 피드백하는 방안은 3GPP LTE/LTE-A 시스템에 적용되는 예를 중심으로 설명하였으나, 3GPP LTE/LTE-A 시스템 이외에도 다양한 무선 통신 시스템에 적용하는 것이 가능하다.

청구범위

[청구항 1] 무선 통신 시스템에서 CSI(Channel State Information) 피드백(feedback)을 수행하기 위한 방법에 있어서, 단말에 의해 수행되는 방법은,
CSI 관련 동작에 대한 상기 단말의 능력(capability) 정보를 기지국으로 전송하는 단계;
CSI 관련 동작 설정(configuration) 정보를 상기 기지국으로부터 수신하는 단계,
상기 CSI 관련 동작 설정 정보는 부분 활성화(partial activation)를 수행하는 CSI 관련 동작을 나타내는 부분 활성화 CSI 관련 동작 인덱스(index) 정보 또는 완전 활성화(full activation)를 수행하는 CSI 관련 동작을 나타내는 완전 활성화 CSI 관련 동작 인덱스 정보 중 적어도 하나를 포함하며;
부분 활성화 CSI-RS(Reference Signal)를 트래킹(tracking)하는 단계;
완전 활성화 CSI-RS를 측정하는 단계; 및
상기 측정 결과를 상기 기지국으로 보고(report)하는 단계를 포함하여 이루어지는 것을 특징으로 하는 방법.

[청구항 2] 제 1항에 있어서,
상기 완전 활성화 CSI-RS를 측정하는 단계는,
상기 완전 활성화 CSI-RS에 대한 측정의 활성화를 지시하는 제 1 메시지를 상기 기지국으로부터 수신하는 단계; 및
상기 제 1 메시지에 의해 활성화된 완전 활성화 CSI-RS를 측정하는 단계를 포함하는 것을 특징으로 하는 방법.

[청구항 3] 제 1항에 있어서,
상기 CSI 관련 동작은 CSI-RS, CSI-IM(Interference Management) 또는 CSI process 중 적어도 하나와 관련 있는 것을 특징으로 하는 방법.

[청구항 4] 제 1항에 있어서,
상기 단말의 능력 정보는 동시에 완전 활성화(full activation) 가능한 상기 CSI 관련 동작의 최대 개수를 나타내는 제 1 제어 정보 및 동시에 부분 활성화(partial activation) 가능한 상기 CSI 관련 동작의 최대 개수를 나타내는 제 2 제어 정보를 포함하는 것을 특징으로 하는 방법.

[청구항 5] 제 1항에 있어서,
상기 부분 활성화 CSI-RS를 트래킹(tracking)하는 단계는,
상기 부분 활성화 CSI-RS에 대해 시간 및/또는 주파수에서 동기를 맞추는 단계를 포함하는 것을 특징으로 하는 방법.

[청구항 6] 제 1항에 있어서,
상기 트래킹은 상기 CSI 관련 동작 설정 정보에 포함된 특정 RS(Reference Signal)과 quasi co-location(QCL) 가정을 적용하여 수행하는 것을 특징으로

하는 방법.

[청구항 7] 제 1항에 있어서,
상기 완전 활성화 CSI-RS는 상기 부분 활성화 CSI-RS에서 선택되는 것을 특징으로 하는 방법.

[청구항 8] 제 2항에 있어서,
상기 제 1 메시지는 MAC(Media Access Control) CE(Control Element) 또는 DCI(Downlink Control Information)인 것을 특징으로 하는 방법.

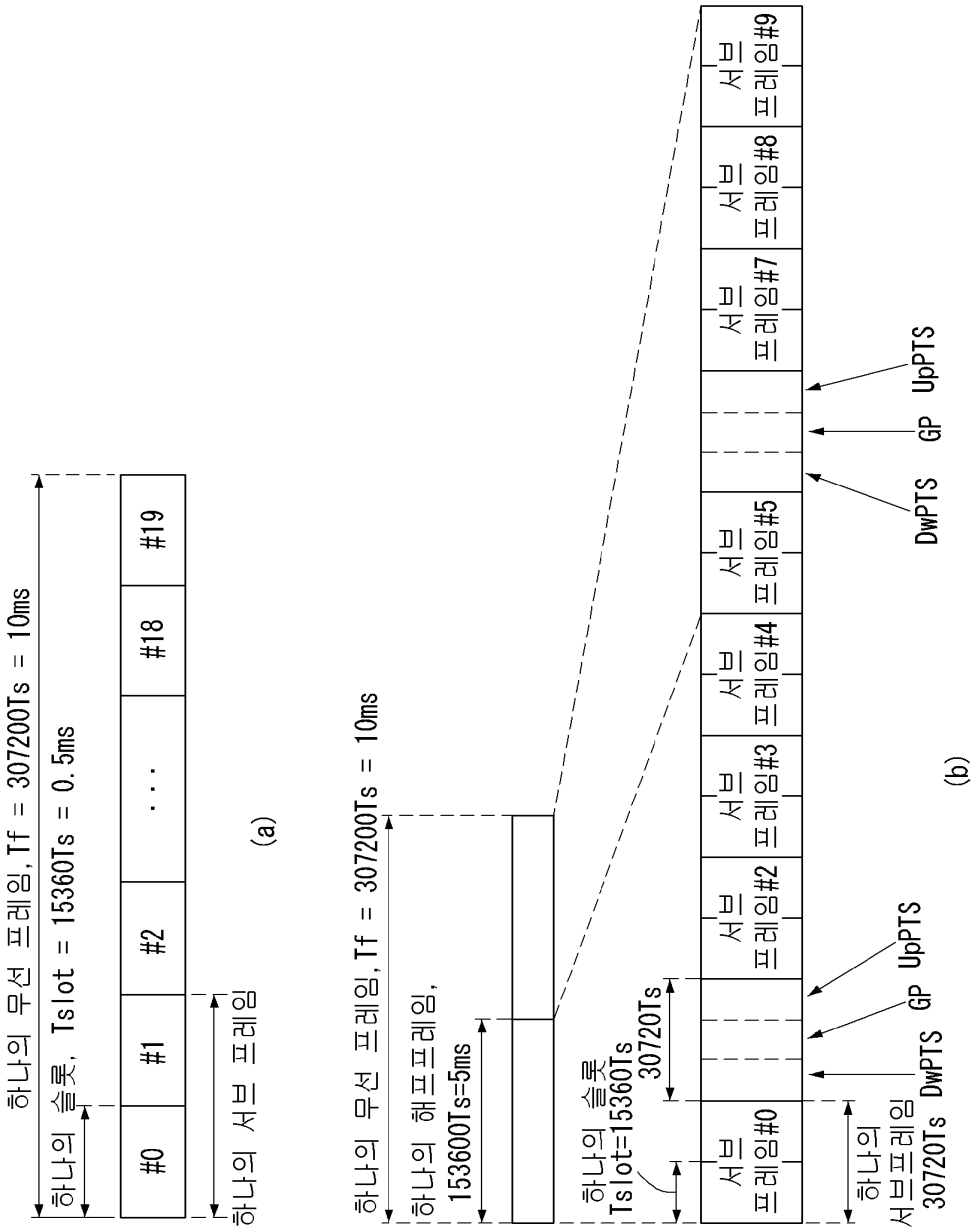
[청구항 9] 제 2항에 있어서,
상기 기지국으로부터 CSI-RS 측정 윈도우(measurement window)와 관련된 제 3 제어 정보를 수신하는 단계를 더 포함하며,
상기 CSI-RS를 측정하는 단계는,
상기 제 1 메시지를 수신하는 경우, 상기 CSI-RS 측정 윈도우를 초기화 또는 갱신하는 단계;
상기 CSI-RS 측정 윈도우가 초기화 또는 갱신되는 시점부터 특정 구간까지 CSI-RS의 측정을 반복적으로 수행하는 단계; 및
상기 측정 결과들을 평균하는(averaging) 단계를 포함하는 것을 특징으로 하는 방법.

[청구항 10] 제 9항에 있어서,
CSI 피드백이 주기적 CSI 피드백인 경우, 상기 CSI-RS 측정 윈도우를 초기화 또는 갱신하는 시점은 상기 특정 구간 이후에 최초로 발생하는 RI(Rank Indicator) 보고에 연관된 특정 기준 자원(reference resource) 시점인 것을 특징으로 하는 방법.

[청구항 11] 제 2항에 있어서,
상기 제 1 메시지는 각 CSI 프로세스 별로 상기 기지국으로부터 수신되는 것을 특징으로 하는 방법.

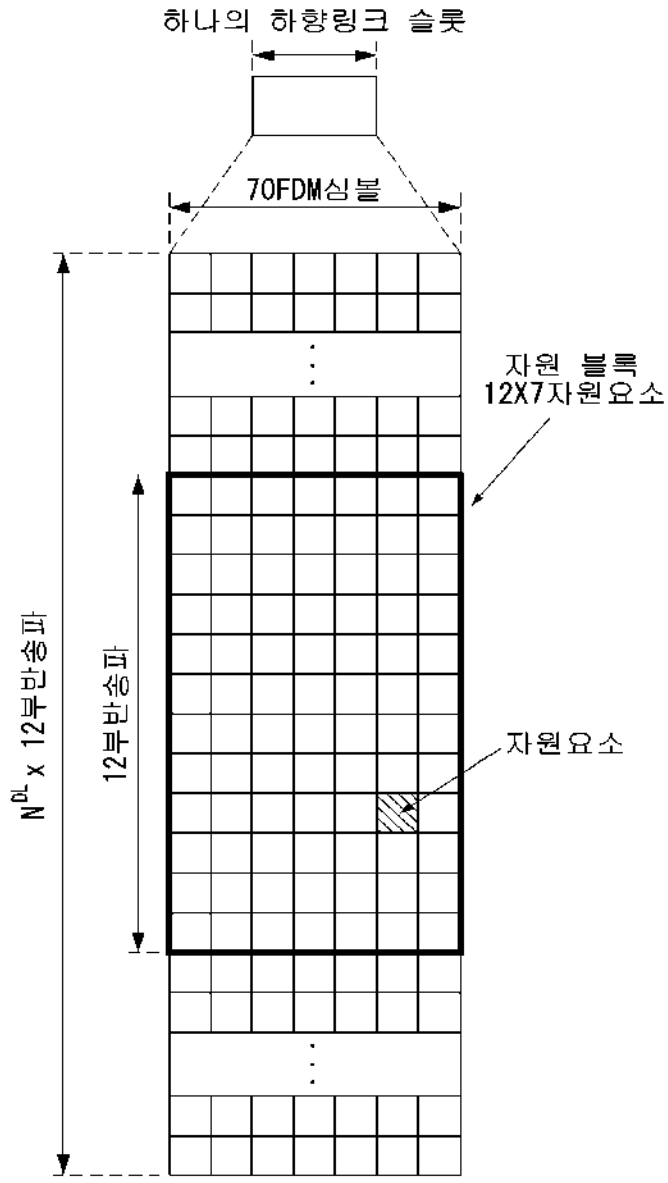
[청구항 12] 제 2항에 있어서,
상기 제 1 메시지는 빔포밍 관련 매트릭스의 변경을 알리는 빔-변경 지시자(Beam-Change Indicator:BCI) 시그널링(signaling)인 것을 특징으로 하는 방법.

[청구항 13] 무선 통신 시스템에서 CSI(Channel State Information)을 피드백하기 위한 단말에 있어서, 상기 단말은,
무선 신호를 송수신하기 위한 RF(Radio Frequency) 유닛; 및
상기 RF 유닛을 제어하는 프로세서를 포함하고,
CSI 관련 동작에 대한 상기 단말의 능력(capability) 정보를 기지국으로 전송하고;
CSI 관련 동작 설정(configuration) 정보를 상기 기지국으로부터 수신하고,
상기 CSI 관련 동작 설정 정보는 부분 활성화(partial activation)를 수행하는 CSI 관련 동작을 나타내는 부분 활성화 CSI 관련 동작



인덱스(index) 정보 또는 완전 활성화(full activation)를 수행하는 CSI 관련 동작을 나타내는 완전 활성화 CSI 관련 동작 인덱스 정보 중 적어도 하나를 포함하며;

부분 활성화 CSI-RS(Reference Signal)를 트래킹(tracking)하고;



완전 활성화 CSI-RS를 측정하며; 및

상기 측정 결과를 상기 기지국으로 보고(report)하도록 제어하는 것을 특징으로 하는 단말.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/KR2016/001177

A. CLASSIFICATION OF SUBJECT MATTER

H04B 7/06(2006.01)i, H04B 17/24(2014.01)i, H04L 5/00(2006.01)i

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
H04B 7/06; H04B 7/26; H04W 72/12; H04B 7/02; H04W 56/00; H04W 24/10; H04B 17/24; H04L 5/00

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched
Korean Utility models and applications for Utility models: IPC as above
Japanese Utility models and applications for Utility models: IPC as above

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
eKOMPASS (KIPO internal) & Keywords: partial activation, full activation, CSI, CSI-RS, motion configuration information, terminal capacity

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	WO 2014-081262 A1 (LG ELECTRONICS INC.) 30 May 2014 See paragraphs [0046], [0052]-[0061], [0072], [0111]-[0118], [0126]; claims 2-3; and figure 5.	1,3,5-6,13
A		2,4,7-12
Y	HUAWEI et al., "On the Support of TM10 with CA in Rel-11", R1-131154, 3GPP TSG RAN WG1 Meeting #72bis, Chicago, USA, 06 April 2013 See pages 1-3; and tables 1-2.	1,3,5-6,13
A	US 2014-0219115 A1 (ETEMAD, Kamran et al.) 07 August 2014 See paragraphs [0039], [0057], [0064]-[0068]; and figure 10.	1-13
A	US 2015-0030037 A1 (LG ELECTRONICS INC.) 29 January 2015 See paragraphs [0009]-[0010], [0085]-[0109]; claim 1; and figure 5.	1-13
A	KR 10-2014-0124356 A (LG ELECTRONICS INC.) 24 October 2014 See paragraphs [0104]-[0120]; and figures 14-15.	1-13

☐ Further documents are listed in the continuation of Box C. ☒ See patent family annex.

* Special categories of cited documents:
"A" document defining the general state of the art which is not considered to be of particular relevance
"E" earlier application or patent but published on or after the international filing date
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O" document referring to an oral disclosure, use, exhibition or other means
"P" document published prior to the international filing date but later than the priority date claimed
"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"&" document member of the same patent family

Date of the actual completion of the international search	Date of mailing of the international search report
25 MAY 2016 (25.05.2016)	**25 MAY 2016 (25.05.2016)**
Name and mailing address of the ISA/KR Korean Intellectual Property Office Government Complex-Daejeon, 189 Seonsa-ro, Daejeon 302-701, Republic of Korea Facsimile No. 82-42-472-7140	Authorized officer Telephone No.

Form PCT/ISA/210 (patent family annex) (January 2015)

국 제 조 사 보 고 서

국제출원번호
PCT/KR2016/001177

A. 발명이 속하는 기술분류(국제특허분류(IPC))

H04B 7/06(2006.01)i, H04B 17/24(2014.01)i, H04L 5/00(2006.01)i

B. 조사된 분야

조사된 최소문헌(국제특허분류를 기재)

H04B 7/06; H04B 7/26; H04W 72/12; H04B 7/02; H04W 56/00; H04W 24/10; H04B 17/24; H04L 5/00

조사된 기술분야에 속하는 최소문헌 이외의 문헌

한국등록실용신안공보 및 한국공개실용신안공보: 조사된 최소문헌란에 기재된 IPC

일본등록실용신안공보 및 일본공개실용신안공보: 조사된 최소문헌란에 기재된 IPC

국제조사에 이용된 전산 데이터베이스(데이터베이스의 명칭 및 검색어(해당하는 경우))

eKOMPASS(특허청 내부 검색시스템) & 키워드: 부분 활성화, 완전 활성화, CSI, CSI-RS, 동작 설정 정보, 단말 능력

C. 관련 문헌

카테고리*	인용문헌명 및 관련 구절(해당하는 경우)의 기재	관련 청구항
Y	WO 2014-081262 A1 (LG ELECTRONICS INC.) 2014.05.30 단락 [0046], [0052]-[0061], [0072], [0111]-[0118], [0126]; 청구항 2-3; 및 도면 5 참조.	1,3,5-6,13
A		2,4,7-12
Y	HUAWEI 등, `On the support of TM10 with CA in Rel-11`, R1-131154, 3GPP TSG RAN WG1 Meeting #72bis, Chicago, USA, 2013.04.06 페이지 1-3; 및 테이블 1-2 참조.	1,3,5-6,13
A	US 2014-0219115 A1 (KAMRAN ETEMAD 등) 2014.08.07 단락 [0039], [0057], [0064]-[0068]; 및 도면 10 참조.	1-13
A	US 2015-0030037 A1 (LG ELECTRONICS INC.) 2015.01.29 단락 [0009]-[0010], [0085]-[0109]; 청구항 1; 및 도면 5 참조.	1-13
A	KR 10-2014-0124356 A (엔시신사 주식회사) 2014.10.24 단락 [0104]-[0120]; 및 도면 14-15 참조.	1-13

☐ 추가 문헌이 C(계속)이 기재되어 있습니다.

☒ 대응특허에 관한 별지를 참조하십시오.

* 인용된 문헌의 특별 카테고리

"A" 특별히 관련이 없는 것으로 보이는 일반적인 기술수준을 정의한 문헌

"B" 국제출원일보다 빠른 출원일 또는 우선일을 가지나 국제출원일 이후에 공개된 선출원 또는 특허 문헌

"L" 우선권 주장에 이문을 제기하는 문헌 또는 다른 인용문헌의 공개일 또는 다른 특별한 이유(이유를 명시)를 밝히기 위하여 인용된 문헌

"O" 구두 개시, 사용, 전시 또는 기타 수단을 언급하고 있는 문헌

"P" 우선일 이후에 공개되었으나 국제출원일 이전에 공개된 문헌

"T" 국제출원일 또는 우선일 후에 공개된 문헌으로, 출원과 상충하지 않으며 발명의 기초가 되는 원리나 이론을 이해하기 위해 인용된 문헌

"X" 특별한 관련이 있는 문헌. 해당 문헌 하나만으로 청구된 발명의 신규성 또는 진보성이 없는 것으로 본다.

"Y" 특별한 관련이 있는 문헌. 해당 문헌이 하나 이상의 다른 문헌과 조합하는 것으로 그 조합이 당업자에게 자명한 경우 청구된 발명은 진보성이 없는 것으로 본다.

"&" 동일한 대응특허문헌에 속하는 문헌

국제조사의 실제 완료일	국제조사보고서 발송일

(54) Title: PAGING FOR LOW COMPLEXITY USER EQUIPMENT AND/OR USER EQUIPMENT IN COVERAGE ENHANCEMENT MODE

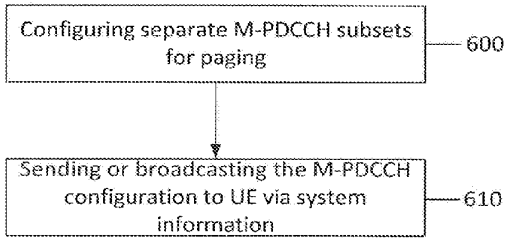

Fig. 6a

(57) Abstract: Systems, methods, apparatuses, and computer program products for paging of low complexity UE and/or UE in coverage enhancement mode are provided. One method includes producing a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration by configuring separate M-PDCCH subsets for paging. One of the subsets may be for low complexity user equipment, and another one of the subsets may be for user equipment operating in coverage enhancement mode.

PAGING FOR LOW COMPLEXITY USER EQUIPMENT AND/OR USER EQUIPMENT IN COVERAGE ENHANCEMENT MODE

BACKGROUND:

Field:

[0001] Embodiments of the invention generally relate to wireless or mobile communications networks, such as, but not limited to, the Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access Network (UTRAN), Long Term Evolution (LTE) Evolved UTRAN (E-UTRAN), LTE-Advanced (LTE-A), future 5G radio access technology, and/or High Speed Packet Access (HSPA). In particular, some embodiments may relate to paging.

Description of the Related Art:

[0002] Universal Mobile Telecommunications System (UMTS) Terrestrial Radio Access Network (UTRAN) refers to a communications network including base stations, or Node Bs, and for example radio network controllers (RNC). UTRAN allows for connectivity between the user equipment (UE) and the core network. The RNC provides control functionalities for one or more Node Bs. The RNC and its corresponding Node Bs are called the Radio Network Subsystem (RNS). In case of E-UTRAN (enhanced UTRAN), no RNC exists and radio access functionality is provided in the enhanced Node B (eNodeB or eNB) or many eNBs. Multiple eNBs are involved for a single UE connection, for example, in case of Coordinated Multipoint Transmission (CoMP) and in dual connectivity.

[0003] Long Term Evolution (LTE) or E-UTRAN provides a new radio access technology and refers to the improvements of UMTS through improved efficiency and services, lower costs, and use of new spectrum opportunities. In particular, LTE is a 3GPP standard that provides for uplink peak rates of at least, for example, 75 megabits per second (Mbps) per carrier and downlink peak rates of at least, for example, 300 Mbps per carrier. LTE supports scalable

carrier bandwidths from 20 MHz down to 1.4 MHz and supports both Frequency Division Duplexing (FDD) and Time Division Duplexing (TDD).

[0004] As mentioned above, LTE may also improve spectral efficiency in networks, allowing carriers to provide more data and voice services over a given bandwidth. Therefore, LTE is designed to fulfill the needs for high-speed data and media transport in addition to high-capacity voice support. Advantages of LTE include, for example, high throughput, low latency, FDD and TDD support in the same platform, an improved end-user experience, and a simple architecture resulting in low operating costs.

[0005] Certain releases of 3GPP LTE (e.g., LTE Rel-10, LTE Rel-11, LTE Rel-12, LTE Rel-13) are targeted towards international mobile telecommunications advanced (IMT-A) systems, referred to herein for convenience simply as LTE-Advanced (LTE-A).

[0006] LTE-A is directed toward extending and optimizing the 3GPP LTE radio access technologies. A goal of LTE-A is to provide significantly enhanced services by means of higher data rates and lower latency with reduced cost. LTE-A is a more optimized radio system fulfilling the international telecommunication union-radio (ITU-R) requirements for IMT-Advanced while keeping the backward compatibility. One of the key features of LTE-A, introduced in LTE Rel-10, is carrier aggregation, which allows for increasing the data rates through aggregation of two or more LTE carriers, e.g., to the transmission bandwidth of up to 100 MHz. LTE-A in later releases may include even wider bandwidths as specified so far. Further, aggregating or interworking on the radio access level with the wireless LAN (WLAN) access network is foreseen.

SUMMARY:

[0007] One embodiment is directed to a method, which may include configuring, by a network node, separate machine type communication (MTC)

physical downlink control channel (M-PDCCH) subsets for paging. One of the subsets is for low complexity user equipment and another one of the subsets is for user equipment operating in coverage enhancement mode.

[0008] Another embodiment is directed to an apparatus that includes at least one processor and at least one memory comprising computer program code. The at least one memory and the computer program code are configured, with the at least one processor, to cause the apparatus at least to configure separate machine type communication (MTC) physical downlink control channel (M-PDCCH) subsets for paging. One of the subsets is for low complexity user equipment and another one of the subsets is for user equipment operating in coverage enhancement mode.

[0009] Another embodiment is directed to an apparatus that may include configuring means for configuring separate machine type communication (MTC) physical downlink control channel (M-PDCCH) subsets for paging. One of the subsets is for low complexity user equipment and another one of the subsets is for user equipment operating in coverage enhancement mode.

[00010] Another embodiment is directed to a method, which may include calculating, by a user equipment, a paging occasion/paging frame (PO/PF). The method may also include deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration. The M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

[00011] Another embodiment is directed to an apparatus that includes at least one processor and at least one memory comprising computer program code. The at least one memory and the computer program code are configured, with the at least one processor, to cause the apparatus at least to calculate a paging occasion/paging frame (PO/PF), and derive a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration. The M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

[00012] Another embodiment is directed to an apparatus that may include calculating means for calculating a paging occasion/paging frame (PO/PF), and deriving means for deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration. The M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

[00013] Another embodiment is directed to a method, which may include calculating a paging occasion/paging frame (PO/PF) according to a new paging cycle definition that links the PO/PF with a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration, and deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration. The M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

[00014] Another embodiment is directed to an apparatus that includes at least one processor and at least one memory comprising computer program code. The at least one memory and the computer program code are configured, with the at least one processor, to cause the apparatus at least to calculate a paging occasion/paging frame (PO/PF) according to a new paging cycle definition that links the PO/PF with a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration, and to derive a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration. The M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission..

[00015] Another embodiment is directed to an apparatus that may include calculating means for calculating a paging occasion/paging frame (PO/PF) according to a new paging cycle definition that links the PO/PF with a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration, and deriving means for deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH)

configuration. The M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

BRIEF DESCRIPTION OF THE DRAWINGS:

[00016] For proper understanding of the invention, reference should be made to the accompanying drawings, wherein:

[00017] Fig. 1 illustrates an example M-PDCCH transmission and PO/PF, according to an embodiment;

[00018] Fig. 2 illustrates a M-PDCCH common search space configuration, according to an embodiment;

[00019] Fig. 3 illustrates an example M-PDCCH monitoring with paging cycle, according to an embodiment;

[00020] Fig. 4 illustrates an example of an enhanced paging cycle configuration, according to an embodiment;

[00021] Fig. 5a illustrates a block diagram of an apparatus, according to an embodiment;

[00022] Fig. 5b illustrates a block diagram of an apparatus, according to another embodiment;

[00023] Fig. 6a illustrates a flow diagram of a method, according to one embodiment;

[00024] Fig. 6b illustrates a flow diagram of a method, according to another embodiment;

[00025] Fig. 6c illustrates a flow diagram of a method, according to another embodiment;

[00026] Fig. 7a illustrates a block diagram of an apparatus, according to one embodiment; and

[00027] Fig. 7b illustrates a block diagram of an apparatus, according to another embodiment.

DETAILED DESCRIPTION:

[00028] It will be readily understood that the components of the invention, as generally described and illustrated in the figures herein, may be arranged and designed in a wide variety of different configurations. Thus, the following detailed description of embodiments of systems, methods, apparatuses, and computer program products for paging of low complexity UE and/or UE in coverage enhancement mode, as represented in the attached figures, is not intended to limit the scope of the invention, but is merely representative of some selected embodiments of the invention.

[00029] The features, structures, or characteristics of the invention described throughout this specification may be combined in any suitable manner in one or more embodiments. For example, the usage of the phrases "certain embodiments," "some embodiments," or other similar language, throughout this specification refers to the fact that a particular feature, structure, or characteristic described in connection with the embodiment may be included in at least one embodiment of the present invention. Thus, appearances of the phrases "in certain embodiments," "in some embodiments," "in other embodiments," or other similar language, throughout this specification do not necessarily all refer to the same group of embodiments, and the described features, structures, or characteristics may be combined in any suitable manner in one or more embodiments.

[00030] Additionally, if desired, the different functions discussed below may be performed in a different order and/or concurrently with each other. Furthermore, if desired, one or more of the described functions may be optional or may be combined. As such, the following description should be considered as merely illustrative of the principles, teachings and embodiments of this invention, and not in limitation thereof.

[00031] Certain embodiments of the invention relate to paging. Paging may be used to notify user equipment (UE) in idle state about incoming data connections. It may be transmitted on the physical downlink shared channel (PDSCH) which is scheduled by the physical downlink control channel

(PDCCH) over air interface. A UE in radio resource control (RRC) Idle mode uses discontinuous reception (DRX) to reduce power consumption, which determines how frequently the UE check for paging messages and wakes from specific paging occasion/paging frame (PO/PF) to monitor PDCCH for potential paging message.

[00032] 3GPP Rel-13 includes a work item entitled "Further LTE Physical Layer Enhancements for MTC" [RP-150492]. The purpose of this work item is to specify a new low-complexity UE for machine type communications (MTC) operation in LTE, to support coverage enhancement (CE) for both Rel-13 low-complexity UE and UE operating in CE compared to existing LTE networks. RAN1 #81 agreed that the paging message is scheduled by MTC PDCCH (M-PDCCH) and a starting subframe of an M-PDCCH UE-specific search space is configured at least for enhanced coverage.

[00033] More specifically, the work item looks at the issue whereby, for MTC, the M-PDCCH has to be repeated numerous times depending on the specific coverage enhancement requirements of UEs. However, if there is a misalignment between the paging cycle and the M-PDCCH, the M-PDCCH may be incorrectly decoded. For example, such incorrect decoding may occur when the PO is not the starting subframe of the M-PDCCH transmission and the UE starts detecting M-PDCCH for paging from the PO which happens in the middle of the M-PDCCH repetitions. Fig. 1 illustrates an example M-PDCCH transmission and PO/PF, where the PO is not the starting subframe of the M-PDCCH transmission and the UE starts detecting M-PDCCH for paging from the PO. Therefore, it would be desirable to match the M-PDCCH and paging cycle setting to the extent possible.

[00034] Thus, embodiments of the invention aim to match the settings of both the paging cycle and the M-PDCCH. One embodiment is for the eNB to configure the M-PDCCH common search space for paging so that separate search subset spaces are formed: one for low complexity UEs, and one for enhanced mode UEs and broadcasted to all UEs in the cell.

[00035] Certain embodiments are directed to solutions for configuring the M-PDCCH common searching space for paging message and enhanced paging monitoring procedure for low complexity UEs and UEs in coverage enhancement mode. The M-PDCCH common search space is made up of multiple search units from the beginning of each M-PDCCH repetition period. One search unit includes a group of subframes, the length of which is determined, for example, by the minimum of supported number of repetitions for transmitting an M-PDCCH downlink control information (DCI) for CE mode UEs.

[00036] The common search space and the UE specific search space can be overlapped in time domain. Fig. 2 illustrates a M-PDCCH common search space configuration, where M-PDCCH CSS is comprised of four search units. In the example of Fig. 2, four candidates (candidate 0-3) are defined with the same number of repetitions, with each mapped to one respective search unit. Candidates 4-6 are mapped to two or more search units respectively. That is to say, there are candidates mapped to different number of repetitions. The length of M-PDCCH CSS can be configured through broadcasting signaling.

[00037] In an embodiment, the eNB configures separate M-PDCCH subset {L,R} for paging, one {L,R} subset for low complexity UEs and another {L,R} subset for UE operating in coverage enhancement mode, where L is enhanced control channel element (eCCE) aggregation level and R is the number of repetitions. The eNB may also configure the starting subframe of a M-PDCCH UE-specific search space at least for UE in enhanced coverage. The M-PDCCH configuration may also be broadcast to UE via system information. In an embodiment, a subset may be considered to be equivalent to a UE search space (either UE-specific or common).

[00038] Therefore, according to certain embodiments, a subset may contain multiple {L,R} values that comprises the UE search space (e.g., {24,8}, {24,16}, {24,32}). As such, in this embodiment, a subset equals the UE search space.

[00039] According to an embodiment, a UE starts monitoring M-PDCCH from the nearest configured M-PDCCH allocation (starting subframe of this M-PDCCH repetitions) after the calculated PO/PF. For example, in this embodiment, the UE may calculate the PO/PF with the existing equation specified in 3GPP TS 36.304, and derive the M-PDCCH configuration (starting subframe and the repetition number of the M-PDCCH transmission) from system information. Unlike existing paging monitoring procedure, in this embodiment, the UE wakes up from the nearest M-PDCCH configuration (starting subframe of this M-PDCCH repetition) after the calculated PO/PF. Fig. 3 illustrates an example M-PDCCH monitoring with paging cycle, according to this embodiment. It is noted that the M-PDCCH starting subframes may be different for different coverage enhancement levels and also for different UEs (e.g., to provide load balancing and reduce blocking probability).

[00040] In addition, a window containing multiple M-PDCCH decoding opportunities (i.e., {L, R} search spaces) in time may be defined. This can help reduce blocking probability but may require the UE to perform additional blind decodings which may increase power consumption. This window size may be configured by the eNB.

[00041] According to another embodiment, a new paging cycle definition is introduced by using one M-PDCCH repetition period as the minimum unit. One example is the paging cycle being: {32pr, 64pr, 128pr, 256pr}, where pr represents the M-PDCCH repetition period. The existing paging cycle range is {32rf, 64rf, 128rf, 256rf}, where value 32rf corresponds to 32 radio frames, 64rf corresponds to 64 radio frames, and so on. However, the repetition of M-PDCCH may occupy 10rf (100 subframes) in the worst case (i.e., the M-PDCCH may need to repeat more than 100 subframes in the worst case), so the paging cycle may need to be extended accordingly to guarantee the desired power saving.

[00042] Therefore, considering the repetition requirement of M-PDCCH, in this embodiment, a new parameter is introduced to count the bundle of M-PDCCH repetitions (or the repetition period of M-PDCCH). This new parameter may be named, for example, as MPN. However, other naming conventions may be used, and MPN is used herein as one example for the sake of simplicity. The MPN could be derived from the system frame number (SFN). For example, where each repetition period of M-PDCCH has M system frame(s) (M could be 2, 4, 8, 16), then MPN = SFN/M.

[00043] An embodiment extends the paging cycle to {32pr, 64pr, 128pr, 256pr}, where pr refers to the M-PDCCH repetition period, such that 32pr equals 32 M-PDCCH repetition periods and so on. The UE may then derive the M-PDCCH repetition period from the existing equation with following update: MPN mod T= (T div N) × (UE_ID mod N), where T is the DRX cycle duration in the number of M-PDCCH repetition period, N is given by Min(T, nB), nB belongs to the set {4T, 2T, T, T/2, T/4, T/8, T/16, T/32}, and UE_ID = IMSI mod (1024/M) (M is the duration of the repetition period of M-PDCCH, could be 2,4, 8 ...). The paging occasion (PO) may be determined by the starting subframe of the M-PDCCH repetition period, and the UE starts receiving M-PDCCH for potential paging from this subframe.

[00044] Fig. 4 illustrates an example of an enhanced paging cycle configuration, where the paging cycle is configured as 32pr which means one paging cycle contains 32 M-PDCCH repetition periods and each modification period contains 4 system frames (which means M = 4). The MPN of the M-PDCCH repetition period for monitoring paging is 4, 36, ..., and the PO is the starting subframe within each M-PDCCH repetition period for paging. It is noted that the M-PDCCH repetition pattern is preconfigured and the starting subframe is not necessarily the subframe# 0 of a system frame, in Fig. 4, the PO of MPN #4 is subframe #5 of SFN #20.

[00045] Fig. 5a illustrates an example of an apparatus 10 according to an embodiment. In an embodiment, apparatus 10 may be a node, host, or server

in a communications network or serving such a network. For example, in certain embodiments, apparatus 10 may be a network node or access node for a radio access network, such as a base station in UMTS or eNB in LTE or LTE-A. However, in other embodiments, apparatus 10 may be other components within a radio access network. It should be noted that one of ordinary skill in the art would understand that apparatus 10 may include components or features not shown in Fig. 5a.

[00046] As illustrated in Fig. 5a, apparatus 10 includes a processor 22 for processing information and executing instructions or operations. Processor 22 may be any type of general or specific purpose processor. While a single processor 22 is shown in Fig. 5a, multiple processors may be utilized according to other embodiments. In fact, processor 22 may include one or more of general-purpose computers, special purpose computers, microprocessors, digital signal processors (DSPs), field-programmable gate arrays (FPGAs), application-specific integrated circuits (ASICs), and processors based on a multi-core processor architecture, as examples.

[00047] Apparatus 10 may further include or be coupled to a memory 14 (internal or external), which may be coupled to processor 22, for storing information and instructions that may be executed by processor 22. Memory 14 may be one or more memories and of any type suitable to the local application environment, and may be implemented using any suitable volatile or nonvolatile data storage technology such as a semiconductor-based memory device, a magnetic memory device and system, an optical memory device and system, fixed memory, and removable memory. For example, memory 14 can be comprised of any combination of random access memory (RAM), read only memory (ROM), static storage such as a magnetic or optical disk, or any other type of non-transitory machine or computer readable media. The instructions stored in memory 14 may include program instructions or computer program code that, when executed by processor 22, enable the apparatus 10 to perform tasks as described herein.

[00048] In some embodiments, apparatus 10 may also include or be coupled to one or more antennas 25 for transmitting and receiving signals and/or data to and from apparatus 10. Apparatus 10 may further include or be coupled to a transceiver 28 configured to transmit and receive information. For instance, transceiver 28 may be configured to modulate information on to a carrier waveform for transmission by the antenna(s) 25 and demodulate information received via the antenna(s) 25 for further processing by other elements of apparatus 10. In other embodiments, transceiver 28 may be capable of transmitting and receiving signals or data directly.

[00049] Processor 22 may perform functions associated with the operation of apparatus 10 which may include, for example, precoding of antenna gain/phase parameters, encoding and decoding of individual bits forming a communication message, formatting of information, and overall control of the apparatus 10, including processes related to management of communication resources.

[00050] In an embodiment, memory 14 may store software modules that provide functionality when executed by processor 22. The modules may include, for example, an operating system that provides operating system functionality for apparatus 10. The memory may also store one or more functional modules, such as an application or program, to provide additional functionality for apparatus 10. The components of apparatus 10 may be implemented in hardware, or as any suitable combination of hardware and software.

[00051] In one embodiment, apparatus 10 may be a network node or access node, such as a base station in UMTS or an eNB in LTE or LTE-A, for example. According to certain embodiments, apparatus 10 may be controlled by memory 14 and processor 22 to produce or generate a M-PDCCH configuration by configuring separate M-PDCCH subsets for paging. In an embodiment, one of the subsets is for low complexity user equipment and

another one of the subsets is for user equipment operating in coverage enhancement mode.

[00052] According to one embodiment, each of the subsets may include an enhanced control channel element (eCCE) aggregation level and a number of repetitions. In some embodiments, apparatus 10 may be further controlled by memory 14 and processor 22 to broadcast the M-PDCCH configuration to UE(s) via system information. Also, in an embodiment, apparatus 10 may be further controlled by memory 14 and processor 22 to configure a starting subframe of the M-PDCCH UE-specific search space at least for UE(s) in enhanced coverage.

[00053] Fig. 5b illustrates an example of an apparatus 20 according to another embodiment. In an embodiment, apparatus 20 may be a node or element in a communications network or associated with such a network, such as a UE, mobile device, mobile unit, a machine type UE or other device. For instance, in some embodiments, apparatus 20 may be UE in LTE or LTE-A. It should be noted that one of ordinary skill in the art would understand that apparatus 20 may include components or features not shown in Fig. 5b.

[00054] As illustrated in Fig. 5b, apparatus 20 includes a processor 32 for processing information and executing instructions or operations. Processor 32 may be any type of general or specific purpose processor. While a single processor 32 is shown in Fig. 5b, multiple processors may be utilized according to other embodiments. In fact, processor 32 may include one or more of general-purpose computers, special purpose computers, microprocessors, digital signal processors (DSPs), field-programmable gate arrays (FPGAs), application-specific integrated circuits (ASICs), and processors based on a multi-core processor architecture, as examples.

[00055] Apparatus 20 may further include or be coupled to a memory 34 (internal or external), which may be coupled to processor 32, for storing information and instructions that may be executed by processor 32. Memory 34 may be one or more memories and of any type suitable to the local

application environment, and may be implemented using any suitable volatile or nonvolatile data storage technology such as a semiconductor-based memory device, a magnetic memory device and system, an optical memory device and system, fixed memory, and removable memory. For example, memory 34 can be comprised of any combination of random access memory (RAM), read only memory (ROM), static storage such as a magnetic or optical disk, or any other type of non-transitory machine or computer readable media. The instructions stored in memory 34 may include program instructions or computer program code that, when executed by processor 32, enable the apparatus 20 to perform tasks as described herein.

[00056] In some embodiments, apparatus 20 may also include or be coupled to one or more antennas 35 for transmitting and receiving signals and/or data to and from apparatus 20. Apparatus 20 may further include a transceiver 38 configured to transmit and receive information. For instance, transceiver 38 may be configured to modulate information on to a carrier waveform for transmission by the antenna(s) 35 and demodulate information received via the antenna(s) 35 for further processing by other elements of apparatus 20. In other embodiments, transceiver 38 may be capable of transmitting and receiving signals or data directly.

[00057] Processor 32 may perform functions associated with the operation of apparatus 20 including, without limitation, precoding of antenna gain/phase parameters, encoding and decoding of individual bits forming a communication message, formatting of information, and overall control of the apparatus 20, including processes related to management of communication resources.

[00058] In an embodiment, memory 34 stores software modules that provide functionality when executed by processor 32. The modules may include, for example, an operating system that provides operating system functionality for apparatus 20. The memory may also store one or more functional modules, such as an application or program, to provide additional functionality for

apparatus 20. The components of apparatus 20 may be implemented in hardware, or as any suitable combination of hardware and software.

[00059] As mentioned above, according to one embodiment, apparatus 20 may be a mobile device, such as a UE in LTE or LTE-A. In one embodiment, apparatus 20 may be controlled by memory 34 and processor 32 to calculate a paging occasion/paging frame (PO/PF) according to legacy equations (e.g., the equations defined in TS 36.304), and to derive a M-PDCCH configuration. The M-PDCCH configuration may include a starting subframe and repetition period of the M-PDCCH transmission.

[00060] In an embodiment, apparatus 20 may be controlled to derive the M-PDCCH configuration from system information. In some embodiments, apparatus 20 may also be controlled by memory 34 and processor 32 to wake up from nearest M-PDCCH configuration after the calculated paging occasion/paging frame (PO/PF).

[00061] According to another embodiment, apparatus 20 may be controlled by memory 34 and processor 32 to calculate PO/PF according to a new paging cycle definition that links the PO/PF with M-PDCCH configuration (that is, the DRX cycle is associated with the M-PDCCH period and the PO is actually the starting subframe within a M-PDCCH period). Apparatus 20 may be controlled, for example, to derive the M-PDCCH repetition period for potential paging according to the following formula: MPN mod T = (T div N) x (UE_ID mod N), where MPN is a parameter for counting the repetition period of M-PDCCH, T is the discontinuous reception cycle duration in the number of M-PDCCH repetition period, N is given by Min(T, nB), nB belongs to the set {4T, 2T, T, T/2, T/4, T/8, T/16, T/32}, and UE_ID = International Mobile Subscriber Identity (IMSI) mod (1024/M), and where M is a duration of the repetition period of M-PDCCH. In one embodiment, MPN = SFN/M, where SFN is system frame number and M is the number of system frames.

[00062] According to certain embodiments, apparatus 20 may be controlled by memory 34 and processor 32 to extend a paging cycle range. In one

embodiment, the paging cycle may be extended to {32pr, 64pr, 128pr, 256pr}, where pr refers to the M-PDCCH repetition period.

[00063] According to certain embodiments, apparatus 20 may be controlled to determine the paging occasion (PO) by starting subframe of M-PDCCH repetition period. In an embodiment, apparatus 20 may then be controlled to start receiving M-PDCCH for potential paging from the starting subframe.

[00064] Fig. 6a illustrates an example flow diagram of a method for producing or generating a M-PDCCH configuration, according to one embodiment of the invention. In certain embodiments, the method of Fig. 6a may be performed by a network node, such as a base station or eNB. As illustrated in Fig. 6a, the method may include, at 600, configuring separate M-PDCCH subsets for paging. One of the subsets may be for low complexity user equipment and another one of the subsets may be for user equipment operating in coverage enhancement mode. According to some embodiments, each of the subsets may include an enhanced control channel element (eCCE) aggregation level and a number of repetitions. In an embodiment, the method may further include, at 610, sending or broadcasting the M-PDCCH configuration to UE via system information. In certain embodiments, the method may also include configuring a starting subframe of a M-PDCCH UE-specific search space at least for UE(s) in enhanced coverage.

[00065] Fig. 6b illustrates an example flow diagram of a method for producing or generating a M-PDCCH configuration, according to one embodiment of the invention. In certain embodiments, the method of Fig. 6b may be performed by a device, such as a UE in LTE or LTE-A. As illustrated in Fig. 6b, the method may include, at 620, calculating a paging occasion/paging frame (PO/PF) according to the legacy PO/PF calculation (e.g., as defined in TS 36.304) and, at 630, deriving a M-PDCCH configuration. The M-PDCCH configuration may include a starting subframe and repetition period of the M-PDCCH transmission.

[00066] In certain embodiments, the deriving step may further include deriving the M-PDCCH configuration from system information. In an embodiment, the method of Fig. 6b may also include, at 640, waking up at the nearest M-PDCCH configuration after the calculated paging occasion/paging frame (PO/PF).

[00067] Fig. 6c illustrates an example flow diagram of a method, according to another embodiment. In certain embodiments, the method of Fig. 6c may be performed by a device, such as a UE in LTE or LTE-A. As illustrated in Fig. 6c, the method may include, at 650, calculating PO/PF according to a new paging cycle definition that links the PO/PF with M-PDCCH configuration and, at 655, deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration. The M-PDCCH configuration may include a starting subframe and repetition period of the M-PDCCH transmission.

[00068] In this embodiment, the DRX cycle is associated with the M-PDCCH period and the PO is actually the starting subframe within a M-PDCCH period. In one example, the M-PDCCH repetition period for potential paging may be derived according to the following formula: MPN mod T = (T div N) x (UE_ID mod N), where MPN is a parameter for counting the repetition period of M-PDCCH, T is the discontinuous reception cycle duration in the number of M-PDCCH repetition period, N is given by Min(T, nB), nB belongs to the set {4T, 2T, T, T/2, T/4, T/8, T/16, T/32}, and UE_ID = International Mobile Subscriber Identity (IMSI) mod (1024/M), and where M is a duration of the repetition period of M-PDCCH. According to some embodiments, the MPN may be equal to SFN/M, where SFN is system frame number and M is the number of system frames.

[00069] According to an embodiment, the method of Fig. 6c may also include extending a paging cycle range. In one embodiment, the extending of the paging cycle range may include extending the paging cycle to {32pr, 64pr, 128pr, 256pr}, where pr refers to the M-PDCCH repetition period.

[00070] According to some embodiments, the calculating step may further include determining the paging occasion (PO) by starting subframe of M-PDCCH repetition period. The method may then include, at 660, starting receiving M-PDCCH for potential paging from the starting subframe.

[00071] Fig. 7a illustrates an example block diagram of an apparatus 700, according to an embodiment. In certain embodiments, apparatus 700 may be a base station or eNB, for example. As illustrated in the example of Fig. 7a, apparatus 700 may include a configuring unit or means 710 and a transceiving unit or means 720 for receiving or transmitting information. In some embodiments, apparatus 700 may also include a storage unit or means, which is not shown.

[00072] According to an embodiment, configuring unit 710 may configure separate machine type communication (MTC) physical downlink control channel (M-PDCCH) subsets for paging. One of the subsets may be for low complexity UE and another one of the subsets may be for UE operating in coverage enhancement mode. Each of the subsets may include an enhanced control channel element (eCCE) aggregation level and a number of repetitions.

[00073] In an embodiment, transceiving unit 720 may send or broadcast M-PDCCH configuration to UE via system information. In some embodiments, configuring unit 710 may also configure a starting subframe of a M-PDCCH UE-specific search space at least for UE in enhanced coverage.

[00074] Fig. 7b illustrates an example block diagram of an apparatus 701, according to another embodiment. In certain embodiments, apparatus 701 may be a mobile device or UE, for example. As illustrated in the example of Fig. 7b, apparatus 701 may include a calculating unit or means 730, a deriving unit or means 740, an extending unit or means 750, a waking unit or means 760, and a transceiving unit or means 770 for receiving or transmitting information. In some embodiments, apparatus 701 may also include a storage unit or means, which is not shown.

[00075] According to an embodiment, calculating unit 730 may calculate a paging occasion/paging frame (PO/PF), for example, according to legacy equation(s), and deriving unit 740 may derive a M-PDCCH configuration. The M-PDCCH configuration may include a starting subframe and repetition period of the M-PDCCH transmission.

[00076] In one embodiment, deriving unit 740 may derive the M-PDCCH configuration from system information. According to some embodiments, waking unit 760 may wake up at the nearest M-PDCCH configuration after the calculated paging occasion/paging frame (PO/PF).

[00077] In another embodiment, calculating unit 730 may calculate a paging occasion/paging frame (PO/PF) according to a new paging cycle definition that links the PO/PF with M-PDCCH configuration, and deriving unit 740 may derive a M-PDCCH configuration. For example, in this embodiment, the DRX cycle is associated with the M-PDCCH period and the PO is actually the starting subframe within a M-PDCCH period. In this embodiment, deriving unit 740 may derive the M-PDCCH repetition period for potential paging according to the following formula: MPN mod T = (T div N) x (UE_ID mod N), where MPN is a parameter for counting the repetition period of M-PDCCH, T is the discontinuous reception cycle duration in the number of M-PDCCH repetition period, N is given by Min(T, nB), nB belongs to the set {4T, 2T, T, T/2, T/4, T/8, T/16, T/32}, and UE_ID = International Mobile Subscriber Identity (IMSI) mod (1024/M), and where M is a duration of the repetition period of M-PDCCH. In an embodiment, MPN may be equal to SFN/M, where SFN is system frame number and M is the number of system frames.

[00078] In certain embodiments, extending unit 750 may extend a paging cycle range. In one embodiment, the paging cycle may be extended to {32pr, 64pr, 128pr, 256pr}, where pr refers to the M-PDCCH repetition period. In one embodiment, calculating unit 730 may determine the paging occasion by starting subframe of M-PDCCH repetition period. Transceiving unit 770 may start receiving M-PDCCH for potential paging from the starting subframe.

[00079] In view of the above, embodiments of the invention may provide several advantages and technical improvements. For example, certain embodiments ensure the reliable M-PDCCH reception for detecting paging message for 3GPP Rel-13 low complexity UEs and UEs in coverage enhancement mode.

[00080] According to embodiments, programs, also called program products or computer programs, including software routines, applets and macros, may be stored in any apparatus-readable data storage medium and they include program instructions to perform particular tasks. A computer program product may comprise one or more computer-executable components which, when the program is run, are configured to carry out embodiments. The one or more computer-executable components may be at least one software code or portions of it. Modifications and configurations required for implementing functionality of an embodiment may be performed as routine(s), which may be implemented as added or updated software routine(s). Software routine(s) may be downloaded into the apparatus.

[00081] Software or a computer program code or portions of it may be in a source code form, object code form, or in some intermediate form, and it may be stored in some sort of carrier, distribution medium, or computer readable medium, which may be any entity or device capable of carrying the program. Such carriers include a record medium, computer memory, read-only memory, photoelectrical and/or electrical carrier signal, telecommunications signal, and software distribution package, for example. Depending on the processing power needed, the computer program may be executed in a single electronic digital computer or it may be distributed amongst a number of computers. The computer readable medium or computer readable storage medium may be a non-transitory medium.

[00082] In other embodiments, the functionality of any method or apparatus described herein may be performed by hardware, for example through the use of an application specific integrated circuit (ASIC), a programmable gate

array (PGA), a field programmable gate array (FPGA), or any other combination of hardware and software. In yet another embodiment, the functionality may be implemented as a signal, a non-tangible means that may be carried by an electromagnetic signal downloaded from the Internet or other network.

[00083] According to an embodiment, an apparatus, such as a node, device, or a corresponding component, may be configured as a computer or a microprocessor, such as single-chip computer element, or as a chipset, including at least a memory for providing storage capacity used for arithmetic operation and an operation processor for executing the arithmetic operation.

[00084] One having ordinary skill in the art will readily understand that the invention as discussed above may be practiced with steps in a different order, and/or with hardware elements in configurations which are different than those which are disclosed. Therefore, although the invention has been described based upon these preferred embodiments, it would be apparent to those of skill in the art that certain modifications, variations, and alternative constructions would be apparent, while remaining within the spirit and scope of the invention. In order to determine the metes and bounds of the invention, therefore, reference should be made to the appended claims.

WHAT IS CLAIMED IS:

1. A method, comprising:

configuring, by a network node, separate machine type communication (MTC) physical downlink control channel (M-PDCCH) subsets for paging,

wherein one of the subsets is for low complexity user equipment and another one of the subsets is for user equipment operating in coverage enhancement mode.

2. The method according to claim 1, wherein each of the subsets comprise a plurality of pairs that are each comprised of enhanced control channel element (eCCE) aggregation level and a number of repetitions.

3. The method according to any one of claims 1 or 2, further comprising broadcasting the machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration to user equipment via system information.

4. The method according to any one of claims 1-3, further comprising configuring a starting subframe of a machine type communication (MTC) physical downlink control channel (M-PDCCH) user equipment-specific search space at least for user equipment in enhanced coverage.

5. An apparatus, comprising:

at least one processor; and

at least one memory comprising computer program code,

the at least one memory and the computer program code are configured, with the at least one processor, to cause the apparatus at least to

configure separate machine type communication (MTC) physical downlink control channel (M-PDCCH) subsets for paging,

wherein one of the subsets is for low complexity user equipment and another one of the subsets is for user equipment operating in coverage enhancement mode.

6. An apparatus, comprising:

configuring means for configuring separate machine type communication (MTC) physical downlink control channel (M-PDCCH) subsets for paging,

wherein one of the subsets is for low complexity user equipment and another one of the subsets is for user equipment operating in coverage enhancement mode.

7. The apparatus according to claim 6, wherein each of the subsets comprise an enhanced control channel element (eCCE) aggregation level and a number of repetitions.

8. The apparatus according to any one of claims 6 or 7, further comprising broadcasting means for broadcasting the machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration to user equipment via system information.

9. The apparatus according to any one of claims 6-8, further comprising configuring means for configuring a starting subframe of a machine type communication (MTC) physical downlink control channel (M-PDCCH) user equipment-specific search space at least for user equipment in enhanced coverage.

10. A method, comprising:

calculating, by a user equipment, a paging occasion/paging frame (PO/PF); and

deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

wherein the M-PDCCH configuration comprises at least one of a starting subframe or repetition period of the M-PDCCH transmission.

11. The method according to 10, further comprising waking up at nearest M-PDCCH configuration after the calculated paging occasion/paging frame (PO/PF).

12. The method according to claim 10, wherein the deriving comprises deriving the M-PDCCH configuration from system information.

13. A method, comprising:

calculating a paging occasion/paging frame (PO/PF) according to a paging cycle definition that links the PO/PF with a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

wherein the M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

14. The method according to claim 13, wherein the deriving further comprises deriving the M-PDCCH repetition period for potential paging according to the following formula:

$$MPN \bmod T = (T \operatorname{div} N) \times (UE_ID \bmod N),$$

where MPN is a parameter for counting the repetition period of M-PDCCH, T is the discontinuous reception cycle duration in the number of M-PDCCH repetition period, N is given by Min(T, nB), nB belongs to the set {4T, 2T, T, T/2, T/4, T/8, T/16, T/32}, and UE_ID = International Mobile Subscriber

Identity (IMSI) mod (1024/M), where M is a duration of the repetition period of M-PDCCH.

15. The method according to claim 14, wherein MPN = SFN/M, where SFN is system frame number and M is the number of system frames contained in one repetition period of M-PDCCH.

16. The method according to claim 13, further comprising extending a paging cycle range.

17. The method according to claim 16, wherein the extending further comprises extending the paging cycle to {32pr, 64pr, 128pr, 256pr}, where pr refers to the M-PDCCH repetition period.

18. The method according to claim 13, wherein the calculating further comprises determining the paging occasion by starting subframe of M-PDCCH repetition period.

19. The method according to claim 18, further comprising starting receiving M-PDCCH for potential paging from the starting subframe.

20. An apparatus, comprising:

at least one processor; and

at least one memory comprising computer program code,

the at least one memory and the computer program code are configured, with the at least one processor, to cause the apparatus at least to

calculate a paging occasion/paging frame (PO/PF); and

derive a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

wherein the M-PDCCH configuration comprises a starting subframe and

repetition period of the M-PDCCH transmission.

21. An apparatus, comprising:

calculating means for calculating a paging occasion/paging frame (PO/PF); and

deriving means for deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

wherein the M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

22. The apparatus according to 21, further comprising waking means for waking up from nearest M-PDCCH configuration after the calculated paging occasion/paging frame (PO/PF).

23. The apparatus according to claim 20, wherein the deriving means comprises means for deriving the M-PDCCH configuration from system information.

24. An apparatus, comprising:

calculating means for calculating a paging occasion/paging frame (PO/PF) according to a paging cycle definition that links the PO/PF with a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

deriving means for deriving a machine type communication (MTC) physical downlink control channel (M-PDCCH) configuration,

wherein the M-PDCCH configuration comprises a starting subframe and repetition period of the M-PDCCH transmission.

25. The apparatus according to claim 24, further comprising deriving means for deriving the M-PDCCH repetition period for potential paging according to the following formula:

MPN mod T = (T div N) x (UE_ID mod N),

where MPN is a parameter for counting the repetition period of M-PDCCH, T is the discontinuous reception cycle duration in the number of M-PDCCH repetition period, N is given by Min(T, nB), nB belongs to the set {4T, 2T, T, T/2, T/4, T/8, T/16, T/32}, and UE_ID = International Mobile Subscriber Identity (IMSI) mod (1024/M), where M is a duration of the repetition period of M-PDCCH.

26. The apparatus according to claim 25, wherein MPN = SFN/M, where SFN is system frame number and M is the number of system frames.

27. The apparatus according to claim 24, further comprising extending means for extending a paging cycle range.

28. The apparatus according to claim 27, wherein the extending means further comprises means for extending the paging cycle to {32pr, 64pr, 128pr, 256pr}, where pr refers to the M-PDCCH repetition period.

29. The apparatus according to claim 24, wherein the calculating means further comprises means for determining the paging occasion by starting subframe of M-PDCCH repetition period.

30. The apparatus according to claim 29, further comprising receiving means for starting receiving M-PDCCH for potential paging from the starting subframe.

31. A computer program, embodied on a non-transitory computer readable medium, the computer program configured to control a processor to perform a process according to any one of claims 1-4 or 10-19.

(54) Title: METHOD AND DEVICE FOR INDICATING NUMEROLOGY

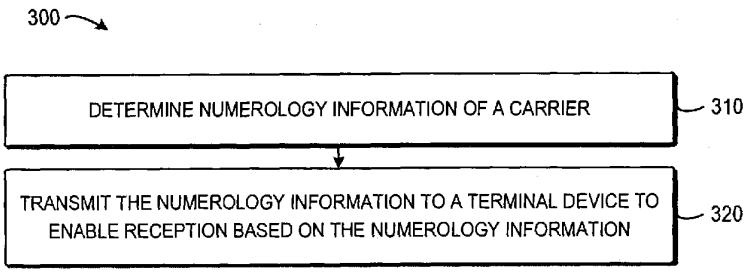

FIG. 3

(57) Abstract: Embodiments of the disclosure provide a method and device for indicating numerology. The method comprises: determining numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and transmitting the numerology information to a terminal device to enable reception based on the numerology information.

WO 2018/081913 A1

METHOD AND DEVICE FOR INDICATING NUMEROLOGY

FIELD OF THE INVENTION

[0001] Embodiments of the present disclosure generally relate to communication techniques. More particularly, embodiments of the present disclosure relate to a method and device for indicating numerology.

BACKGROUND OF THE INVENTION

[0002] Newly-developed mobile standards call for higher data transfer speeds, greater numbers of connections, and better coverage, among other improvements. The 5G standard, according to the Next Generation Mobile Networks Alliance, is expected to provide data rates of several tens of megabits per second to each of tens of thousands of users, with 1 gigabit per second to tens of workers on an office floor. Several hundreds of thousands of simultaneous connections should be supported in order to support large sensor deployments. Consequently, the spectral efficiency is expected to be enhanced to meet more requirements of the new standards.

[0003] Conventionally, for a single carrier, there is one numerology. Therefore, terminal devices have to employ the same numerology in communication with a network device. This inevitably brings undesired, delays, low spectral efficiency for some kind of traffic.

[0004] Accordingly, there is a need for development of better transmission/processing techniques for wireless data transmission to meet different requirements of different applications/users at the same time.

SUMMARY OF THE INVENTION

[0005] The present disclosure proposes a solution for indicating numerology.

[0006] According to a first aspect of embodiments of the present disclosure, embodiments of the disclosure provide a method performed by a network device. The network device determines numerology information of a carrier. The numerology information indicates numerologies of one or more basic units for the

CONFIRMATION COPY

carrier. Then the network device transmits the numerology information to a terminal device to enable reception based on the numerology information.

[0007] According to a second aspect of embodiments of the present disclosure, embodiments of the disclosure provide method performed by a terminal device. The terminal device receives numerology information of a carrier from a network device. The numerology information indicates numerologies of one or more basic units for the carrier. Then the terminal device decodes a signal based on the numerology information.

[0008] According to a third aspect of embodiments of the present disclosure, embodiments of the disclosure provide a network device. The network device comprises: a controller configured to determine numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and a transmitter the numerology information to a terminal device to enable reception based on the numerology information.

[0009] According to a fourth aspect of embodiments of the present disclosure, embodiments of the disclosure provide a terminal device. The terminal device comprises: a receiver configured to receive numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and a decoder configured to decode a signal based on the numerology information.

[0010] Other features and advantages of the embodiments of the present disclosure will also be apparent from the following description of specific embodiments when read in conjunction with the accompanying drawings, which illustrate, by way of example, the principles of embodiments of the disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] Embodiments of the disclosure are presented in the sense of examples and their advantages are explained in greater detail below, with reference to the accompanying drawings, where

[0012] FIG. 1 illustrates a schematic diagram of a communication system 100 according to embodiments of the present disclosure;

[0013] FIG. 2A illustrates a diagram 200 of a basic unit in accordance with embodiments of the present disclosure;

[0014] FIG. 2B illustrates a diagram 260 of a basic unit in accordance with further embodiments of the present disclosure;

[0015] FIG. 3 illustrates a flow chart of a method 300 for performing communication according to embodiments of the present disclosure;

[0016] FIG. 4 illustrates a diagram 400 of the distributed indication according to embodiments of the present disclosure;

[0017] FIG. 5 illustrates a diagram 500 of the centralized indication according to embodiments of the present disclosure;

[0018] FIG. 6 illustrates a diagram 600 of a guard band 610 according to embodiments of the present disclosure;

[0019] FIG. 7 illustrates a diagram 700 of indication of a guard band according to embodiments of the present disclosure;

[0020] FIG. 8 illustrates a diagram 800 of indication of a guard band according to embodiments of the present disclosure;

[0021] FIG. 9 illustrates a diagram 900 of a resource unit 910 according to embodiments of the present disclosure;

[0022] FIG. 10 illustrates a diagram 1000 of information transmission according to embodiments of the present disclosure;

[0023] FIG. 11 illustrates a flow chart of a method 1100 for performing communication according to embodiments of the present disclosure;

[0024] FIG. 12 illustrates a schematic diagram of a network device 1200 according to an embodiment of the present disclosure; and

[0025] FIG. 13 illustrates a schematic diagram of a terminal device 1300 according to an embodiment of the present disclosure.

[0026] Throughout the figures, same or similar reference numbers indicate same or similar elements.

DETAILED DESCRIPTION OF EMBODIMENTS

[0027] The subject matter described herein will now be discussed with reference to several example embodiments. It should be understood these embodiments are discussed only for the purpose of enabling those skilled persons in the art to better understand and thus implement the subject matter described herein, rather than suggesting any limitations on the scope of the subject matter.

[0028] The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of example embodiments. As used herein, the singular forms "a," "an" and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms "comprises," "comprising," "includes" and/or "including," when used herein, specify the presence of stated features, integers, steps, operations, elements and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components and/or groups thereof.

[0029] It should also be noted that in some alternative implementations, the functions/acts noted may occur out of the order noted in the figures. For example, two functions or acts shown in succession may in fact be executed concurrently or may sometimes be executed in the reverse order, depending upon the functionality/acts involved.

[0030] As used herein, the term "communication network" refers to a network following any suitable communication standards, such as Long Term Evolution (LTE), LTE-Advanced (LTE-A), Wideband Code Division Multiple Access (WCDMA), High-Speed Packet Access (HSPA), and so on. Furthermore, the communications between a terminal device and a network device in the communication network may be performed according to any suitable generation communication protocols, including, but not limited to, the first generation (1G), the second generation (2G), 2.5G, 2.75G, the third generation (3G), the fourth generation (4G), 4.5G, the future fifth generation (5G) communication protocols, and/or any other protocols either currently known or to be developed in the future.

[0031] Embodiments of the present disclosure may be applied in various communication systems. Given the rapid development in communications, there

will of course also be future type communication technologies and systems with which the present disclosure may be embodied. It should not be seen as limiting the scope of the present disclosure to only the aforementioned system.

[0032] The term "network device" includes, but not limited to, a base station (BS), a gateway, a management entity, and other suitable device in a communication system. The term "base station" or "BS" represents a node B (NodeB or NB), an evolved NodeB (eNodeB or eNB), a Remote Radio Unit (RRU), a radio header (RH), a remote radio head (RRH), a relay, a low power node such as a femto, a pico, and so forth.

[0033] The term "terminal device" includes, but not limited to, "user equipment (UE)" and other suitable end device capable of communicating with the network device. By way of example, the "terminal device" may refer to a terminal, a Mobile Terminal (MT), a Subscriber Station (SS), a Portable Subscriber Station, a Mobile Station (MS), or an Access Terminal (AT).

[0034] Now some exemplary embodiments of the present disclosure will be described below with reference to the figures. Reference is first made to FIG. 1, which illustrates schematic diagram of a communication system 100 according to embodiments of the present disclosure.

[0035] In the communication system 100, there illustrate a network device (for example, an eNB) 110 that communicates with a terminal device (for example, a UE) 120 by using a certain transmission pattern. The network device 110 sends numerology information to the terminal device 120, wherein the numerology information indicates numerologies of one or more basic units for a carrier. As such, the terminal device 120 is enabled to receive signals from the network device 110 based on the numerology information.

[0036] In the context of the present disclosure, the term "numerology" refers to a set of parameters. In an Orthogonal Frequency Division Multiplexing (OFDM)-based system, the parameters include, for example, but not limited to, a subcarrier spacing, a symbol length, a length of a cyclic prefix (CP), and so on. For instance, a numerology for a subcarrier spacing of 15KHz may include 14 symbols in one subframe, a normal CP, and so on. A numerology for a subcarrier spacing of 30KHz may include 28 symbols in one subframe, a normal CP, and so on. Such a numerology is different from the numerology for the subcarrier spacing of 15KHz.

[0037] The term "basic unit" refers to a block of time-frequency resource. The size of a basic unit may depend on the employed numerology. The basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier. In a frequency domain, the basic unit may be decided by the largest subcarrier spacing. For example, a physical resource block (PRB) with the largest subcarrier spacing may be the frequency size of a basic unit, and/or the largest symbol length may be the time size of the basic unit.

[0038] FIG. 2A illustrates a diagram of a basic unit 240 in accordance with embodiments of the present disclosure. There are three subcarriers, Sc1-Sc3, illustrated in the example of FIG. 2A. In the frequency domain, the basic unit 240 is determined based on the largest subcarrier spacing, 60KHz. That is, the frequency size of the basic unit 240 equals to one PRB of the subcarrier Sc1 of 60KHz, 2 PRBs of the subcarrier Sc2 of 30KHz, and 4 PRBs of the subcarrier Sc3 of 15KHz.

[0039] In the time domain, the basic unit 240 is determined based on the largest symbol length. Thus, the time size of the basic unit 240 equals to a symbol of Sc3 of 15KHz, which has a largest symbol length among Sc1 to Sc3.

[0040] In addition to the above, the basic unit according embodiments of the present disclosure may be implemented in other suitable forms, for example, multiples of the largest symbol length in time domain, and/or multiples of the largest subcarrier spacing, multiples of a PRB, one or multiples of the smallest subcarrier spacing. FIG. 2B illustrates a diagram 200 of another basic unit 270 in accordance with further embodiments of the present disclosure. In the example shown in FIG. 2B, the basic unit 270 is defined based on the smallest subcarrier spacing in frequency domain. The time domain duration may be indicated by other ways explicitly or implicitly. For instance, the basic unit 270 may have the same duration as the basic unit 240 in the time domain, or the time duration may be multiples of the time duration of the basic unit 240.

[0041] It is to be understood that, the above examples are discussed for purpose of illustration, rather than limitation. Those skilled in the art would appreciate that the basic unit can be implemented other suitable forms with the scope of the subject matter of the present disclosure.

[0042] Conventionally, a carrier employs a single numerology, thus spectrum

utilization may be inefficient when terminal devices have different communication demands. To solve this problem, embodiments of the present disclosure propose a solution as discussed below to employ multiple numerologies in a single carrier. By receiving numerology information indicating numerologies of one or more basic units for the carrier, the terminal devices can receive signals based on the numerology information.

[0043] Now some exemplary embodiments of the present disclosure will be described below with reference to the following figures. FIG. 3 illustrates a flow chart of a method 300 for indicating numerology according to embodiments of the present disclosure. The method 300 may be implemented by the network device 110, for example, an eNB or other suitable device.

[0044] The method 300 is entered at 310, where the network device determines numerology information of a carrier. The numerology information indicates numerologies of one or more basic units for the carrier. At 320, the network device transmits the numerology information to a terminal device to enable reception based on the numerology information.

[0045] According to embodiments of the present disclosure, there may be a variety of ways to indicate numerology. In some embodiments, the numerology information may be indicated in a distributed way, which is also referred to as "distributed indication". In this case, the numerology of each basic unit is indicated. For purpose of illustration, the basic unit 240 of FIG. 2A is discussed in these embodiments. Thus, at 310, the network device may determine numerologies for all the basic units. In some implementations, a bitmap may be used to indicate the numerologies of the basic units, that is, one or more bits may be used to indicate the numerology for each basic unit. For example, two bits may be used to indicate subcarrier spacing 15KHz, 30KHz, 60KHz, and 120KHz, respectively. If the bits are "00", it means that the subcarrier of the numerology is 15KHz *1, and if the bits are "01", it means that the subcarrier of the numerology is 15KHz *2 = 30KHz. At 320, the network device may transmit information about the numerologies for all the basic units to the terminal device. FIG. 4 illustrates a diagram 400 of the distributed indication according to embodiments of the present disclosure. As shown in FIG. 4, there are six basic units in a carrier, namely, basic units 1 to 6, and there are 6

numerology indications are used for each of the basic units 1 to 6. In this way, the numerologies may be indicated in a flexible way.

[0046] In some other embodiments, if the basic unit is defined as the basic unit 270 as discussed with reference to FIG. 2B, when the numerology is changed from a small subcarrier spacing to a larger one, numerologies of at least multiple basic units need to be the same. For example, if the basic unit is based on 15KHz subcarrier spacing, and the numerology is changed from 15KHz to 30KHz, then numerology of at least two adjacent basic units should be same; if the numerology is changed to be 60KHz, then numerology of at least four adjacent basic units should be the same.

[0047] Alternatively, in some embodiments, the numerology information may be indicated in a centralized way, which is also referred to as "centralized indication." In this case, the carrier bandwidth may be divided into several groups, and each group may have a group-specific numerology. One group may include one or more basic units. Details of group division may be defined by a pattern, for example, referred to as a grouping pattern. The grouping pattern may be predefined in several ways, for example, according to the traffic characteristics, similar as Time Division Duplex (TDD) configuration. The grouping pattern may be alternatively defined in specification. In some implementations, the grouping pattern may be carried by system information and/or a Physical broadcast channel (PBCH). In the embodiments, the network device may inform the terminal device the grouping pattern and/or the group-specific numerology. The number of groups may be decided by the grouping pattern. The number may change due to different grouping patterns. The maximum group number may be reserved. In this case, the terminal device may need to firstly decode the grouping pattern, and then decode the corresponding numerology for each group based on the pattern.

[0048] In these embodiments, at 310, the network device may determine a grouping pattern indicating groups of the basic units, and then determine a numerology for each of the groups. At 320, the network device may transmit information about the grouping pattern and/or the numerology for each of the groups to the terminal device. FIG. 5 illustrates a diagram 500 of the centralized indication according to embodiments of the present disclosure. In the example of FIG. 5, there are six basic units in a carrier, namely, basic units 1 to 6, and they are divided into three groups,

namely, groups 1 to 3. As shown, group 1 includes basic units 1 and 2, group 2 includes basic unit 3, and group 3 includes basic units 4-6. A numerology is determined for each of the groups. As such, there are three numerology indications for groups 1, 2 and 3, respectively.

[0049] In some other embodiments, if the basic unit is defined as the basic unit 270 as discussed with reference to FIG. 2B, when the numerology is changed from a small subcarrier spacing to a larger one, the basic units may be divided into groups to guarantee basic units in each group have the same numerology. Still referring to FIG. 5, if basic units 1 to 6 are each defined as the basic unit 270, and basic units 1 and 2 correspond to numerology 1, basic unit 3 corresponds to numerology 2 and basic units 4, 5 and 6 correspond to numerology 3, then the basic units 1 to 6 may be divided into three groups to guarantee basic units in each group have the same numerology when the numerology is changed from 15KHz to 30KHz.

[0050] As a further alternative, the indication may be from a numerology perspective. That is to say, one or more basic units may be indicated for a specific numerology. The indication may be similar to a legacy approach of LTE resource allocation. The basic units corresponding to a numerology may be continuous or discontinuous. In some embodiments, the numerology information may be determined as below. At 310, the network device may determine numerologies for the basic units and determine an association between the numerologies and the basic units. Then, at 320, the network device may transmit information about the numerologies and/or the association to the terminal device. In an embodiment, the numerology information may be implemented in the form of the following table 1.

	NUMEROLOGY ID	BASIC UNIT ID
1	Numerology 1	Basic unit 1, 2
2	Numerology 2	Basic unit 3
3	Numerology 3	Basic unit 4, 5, 6

[0051] Upon receipt of the numerology information, the terminal device would understand that three numerologies (i.e., Numerology 1, 2 and 3) are designed for the carrier, Basic units 1 and 2 are associated with Numerology 1, Basic unit 3 is associated with Numerology 2, and Basic units 4, 5 and 6 are associated with

Numerology 3.

[0052] As a still further alternative, the bandwidth of the carrier may be divided into groups, and each group has the same numerology distribution pattern. A numerology distribution pattern indicating numerologies for basic units in one of the groups. For example, if in a group, the ith basic unit (also referred to as basic unit i, i=1,...M, and M indicates the total number of basic units in the group) has a numerology corresponding to 15KHz, and basic unit i+4 has a numerology corresponding to 60KHz, and basic units i and i+4 within another group share the same numerology 15KHz and 60KHz, respectively, then the numerology distribution patterns are the same for these two groups. In this case, the network device may indicate the numerology distribution pattern for a single group to the terminal device, and/or information about the group division, and/or the like. The numerology distribution pattern and/or information about the group division may be specified by specification, by RRC configuration, or in other suitable ways. The numerology distribution pattern for each group can also be indicated dynamically in downlink control information. In some embodiments, the numerology information may be determined as below. At 310, the network device may divide the basic units into groups and determine a numerology distribution pattern indicating numerologies for basic units in one of the groups. Then, at 320, the network device may transmit information about the numerology distribution pattern and/or information about the groups to the terminal device.

[0053] In accordance with embodiments of the present disclosure, for different adjacent numerologies, puncturing of one or more subcarriers may be used if a guard band is necessary. From efficiency point of view, the smaller subcarrier spacing may be punctured. In some embodiments, if new waveform design can mitigate the necessity of a guard band, then the puncturing may be unnecessary. According to embodiments of the present disclosure, the guard band may be indicated in a variety of ways. A size for a unit of the guard band (also referred to as a "guard band unit" hereafter) in the frequency domain may be a subcarrier, a PRB, or other suitable length, depending on the adjacent numerologies and/or numerology bandwidth and/or transmission direction. One or more guard band units may be indicated as a guard band.

[0054] FIG. 6 illustrates a diagram 600 of a guard band 610 according to embodiments of the present disclosure. As shown in FIG. 6, there is a guard band 610 between different subcarrier spacings, Sc2 of 30KHz and Sc3 of 15 KHz. The size of the guard band unit is a subcarrier/PRB, and the guard band in this example includes 3 guard band units.

[0055] According to embodiments of the present disclosure, optionally, after 320, the network device may further determines guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units, and transmits the guard band information to the terminal device for each basic unit.

[0056] According to further embodiments of the present disclosure, optionally, after 320, the network device may further determine guard band information about a guard band between adjacent basic units based on transmission directions of the basic units. For example, a basic unit is used for downlink transmission and the adjacent basic unit is uplink transmission, then there will be a guard band between them. If the transmission direction is changed semi-statically, then the guard band information may be indicated to the terminal device in RRC signaling or PBCH. If the transmission direction, for example, downlink or uplink, is changed dynamically, then the guard band information may be indicated to a terminal device in downlink control information.

[0057] In the determination of the guard band information, the network device may detect whether there is a change between numerologies of the adjacent basic units and then determine occurrence of a guard band between the adjacent basic units based on the detection. In some embodiments, the guard band information may include: a number of subcarriers occupied by the guard band, a number of physical resource blocks occupied by the guard band, a basic unit where the guard band is located, and/or the like. The guard band information may indicate whether a guard band exists. From signaling point of view, even the guard band is to be decided not existent, it can be expressed by indicating the guard band to be 0.

[0058] After determining the guard band information, the network device may transmit the guard band information to the terminal device. In an embodiment, the guard band information may be transmitted together with the numerology information. Referring back to the embodiments of FIG. 4, the guard band information may be transmitted together with the numerology information for each basic unit. In another

embodiment, referring back to the embodiments of FIG. 5, the guard band information may be transmitted together with the numerology information for each group of basic units. More details about the indication of the guard band information will be discussed with the following embodiments with reference to FIGs. 7 and 8.

[0059] In some embodiments, the guard band may be defined by specification. In this case, the guard band may be impacted by adjacent numerology combination, and may be located in the side of the lower subcarrier spacing. For example, when a subcarrier spacing of 30KHz and a subcarrier spacing of 60KHz are located adjacently, no matter the detailed bandwidth for each subcarrier spacing, the guard band is the same and is always located in the 30KHz side. FIG. 7 illustrates a diagram 700 of indication of a guard band according to embodiments of the present disclosure. As shown in FIG. 7, there are two change points of numerologies of basic units 1-6, and two guard bands 710 and 720 defined by specification are located at the change points. In this case, the network device may inform the terminal device information about the numerology, and based on the derived numerology, the terminal device may deduce that there are guard bands 710 and 720.

[0060] Alternatively, in some embodiments, the guard band information and/or the numerology information may be transmitted or indicated by system information/PBCH or Dynamic Control Information (DCI). The indication of the guard band information may be according to the numerology distribution pattern, similar to the indication of the numerology information. In this case, the guard band may be impacted by both the adjacent numerology combination and the bandwidth of each numerology.

[0061] In an embodiment, there is a guard band for each basic unit. The guard band may be zero if no numerology change between adjacent basic units or new wave form adoption. Such guard band information may be transmitted together with the numerology information as discussed with reference to FIG. 4. For each basic unit, the numerology and the guard band are indicated. Both independent indication and joint encoding may be employed. FIG. 8 illustrates a diagram 800 of indication of a guard band according to such an embodiment.

[0062] In an alternative embodiment, there is a guard band for each numerology change. In this case, the guard band information may be transmitted together with

the numerology information as discussed with reference to FIG. 5. For example, the guard band information and/or the numerology information may indicate the numerology distribution pattern. Thus, upon receipt of the information, the terminal device may obtain a change point of numerologies based thereon, and then determine the position of the guard band according to the change point. In this embodiment, the guard band information is transmitted when numerologies of two adjacent basic units change. As such, overhead of transmitting the guard band information is reduced.

[0063] In accordance with embodiments of the present disclosure, the network device may further inform the terminal device information about resource allocation. The allocated resource may be indicated by a common index irrespectively of numerology. Thus, the terminal device may understand the resource allocated to it. In some embodiments, the network device may allocate a resource to one or more terminal devices, and then transmit information about the allocated resource to the terminal device. The information about the allocated resource may include one or more of: an index of a basic unit allocated to the terminal devices, an index of a physical resource block in a basic unit allocated to the terminal devices, and other suitable information.

[0064] In some embodiments, the basic units may be indexed from 0 to N-1, where N is a total number of the basic units. The total number may be determined in several ways. For example, if the carrier bandwidth is B and the bandwidth of the basic frequency variation units is W, then the total number may be calculated below:

$$N = \text{ceil}(B/W),$$

where "ceil" indicates an operation of rounding up.

[0065] The total PRB number (denoted as N_p) within a basic unit may be calculated as:

$$N_p = W/Sc/N_Sc$$

where Sc represents the subcarrier spacing for this basic unit, and N_Sc represents the subcarrier number within a PRB.

[0066] The network device may determine which PRB(s) and/or which basic unit(s) are allocated to terminal devices, and transmit the information about the allocated

resource to the terminal devices. The information may include index of the basic unit(s). A terminal device, for example, the terminal device 120, upon receipt of the information about the allocated resource, may identify the index of the basic unit(s) first. Then, the terminal device may determine which PRBs in the allocated basic unit(s) can be used.

[0067] In some implementations, one or more bits may be used to indicate the index of the basic unit(s). Then, one or more additional bits may be used to indicate PRBs within the basic unit. These bits may be used in both downlink and uplink to indicate the corresponding allocated frequency domain resource.

[0068] Alternatively, in some embodiments, the resource allocation information may be indicated by resource unit(s). The resource unit may be defined based on the smallest subcarrier spacing in frequency domain. For a larger subcarrier spacing, resources allocated to a single UE should consider the relationship between the smallest subcarrier spacing and the larger subcarrier spacing. By way of example, if the resource unit is based on 15KHz subcarrier spacing, and for a 60KHz resource allocation, the allocated resources may be multiple of 4, where 4 is obtained by dividing 60KHz by 15KHz. The time domain duration may be indicated by other ways explicitly or implicitly. For instance, the resource unit may have the same duration as the basic unit discussed above in the time domain, or the time duration may be multiples of the time duration of the basic unit.

[0069] FIG. 9 illustrates a diagram 900 of a resource unit 910 according to embodiments of the present disclosure. In the frequency domain, the resource unit 910 corresponds to the PRB of the smallest subcarrier spacing, namely, Sc3 of 15KHz. In the time domain, the resource unit 910 corresponds to a symbol of the smallest subcarrier spacing.

[0070] With respect the above embodiments, if different channel coding schemes are used for different information block sizes, or if the time domain transmission duration may change due to multi-subframe or mini-slot scheduling, the corresponding Modulation and Coding Scheme (MCS)/Transmission Block Size (TBS) table may change. The chosen of MCS/TBS table may be configured by Radio resource configuration (RRC) signaling.

[0071] In accordance with embodiments of the present disclosure, the network device may transmit the numerology information, and/or the guard band information, and/or the information about resource allocation in a variety of ways. In some embodiments, the network device may transmit the numerology information/guard band information in a region of the carrier corresponding to a reference numerology, and transmit the information about the allocated resource in one or more of the basic units, the region of the carrier for transmitting the reference numerology, and/or the like.

[0072] In some embodiments, the numerology information, the guard band information, and/or the information about resource allocation may be carried by PDCCH/Enhanced PDCCH (ePDCCH). The PDCCH carrying the numerology information and/or guard band information may be shared by a group of UEs, and may be scrambled by a cell specific/beam specific sequence. And the PDCCH carrying the resource allocation information may be scrambled in a UE-specific way. With respect to the terminal device, for example, a UE, it may decode received signals to obtain the numerology information and/or the guard band information. Then, the UE may decode the information about resource allocation to obtain allocated resources, MCS/TBS, transmission duration, and/or the like, which are collectively called as UE specific control information hereafter.

[0073] In some embodiments, the UE specific control information may be located at a time-frequency resource corresponding to a specific numerology. Alternatively, the UE specific control information may also be located at the time-frequency resource corresponding to the reference numerology, combined with the cell/beam-specific control information to be carried in a single PDCCH or scrambled independently to form an independent PDCCH. In some implementations, the PDCCH may occur in a periodical way or in aperiodical way. In the case of the aperiodical implementation, the UE may perform blind detection to identify the PDCCH.

[0074] In some alternative embodiments, the control information may also be carried by PBCH or RRC signaling. As a further alternative, the control information may be carried by a combination of RRC signaling and physical layer control information. In such a case, RRC signaling may be used to indicate a subset of possible

numerologies/guard band configurations, and physical layer control information may be used to indicate the numerology within the subset dynamically.

[0075] FIG. 10 illustrates a diagram 1000 of transmission of UE specific control information 1010 and numerology information/guard band 1020 according to embodiments of the present disclosure. As shown in the example of FIG. 10, the UE specific control information 1010 is transmitted via basic unit 1, and the numerology information/guard band information are transmitted in a region 1030 of the carrier corresponding to the reference numerology.

[0076] Reference is now made to FIG. 11, which illustrates a flow chart of a method 1100 for performing communication according to embodiments of the present disclosure. The method 1100 may be implemented by the terminal device 120, for example, a UE or other suitable device.

[0077] The method 1100 is entered at 1110, where the terminal device receives numerology information of a carrier from a network device. The numerology information may indicate numerologies of one or more basic units for the carrier. The basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier. For example, in the frequency domain, the basic unit may be determined based on the largest subcarrier spacing. In the time domain, the basic unit 240 may be determined based on the largest symbol length. In another example, the basic unit may also be determined based on the smallest subcarrier spacing in frequency domain, and/or determined based on the smallest symbol length in time domain.

[0078] In some embodiments, at 1110, the terminal device may receive information about numerologies for all the basic units. Alternatively, the terminal device may receive information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups. As a further alternative, the terminal device may receive information about numerologies for the basic units and/or an association between the numerologies and the basic units. As a still further alternative, the basic units are divided into groups, and the basic units in each of the groups having the same numerology distribution pattern. In this case, the terminal device may receive at least one of information about a numerology distribution

pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups.

[0079] At 1120, the terminal device decodes a signal based on the numerology information.

[0080] In some embodiments, optionally, the terminal device may further receive guard band information about a guard band between adjacent basic units. In this case, at 1120, the terminal device may decode the signal based on the numerology information and the guard band information.

[0081] In some embodiments, optionally, the terminal device may further information about allocated resource of one or more terminal devices from the network device. The information about allocated resource may include an index of a basic unit allocated to the terminal devices, an index of a physical resource block in a basic unit allocated to the terminal devices, and/or the like. In this case, at 1120, the terminal device may decode the signal based on the numerology information and the information about allocated resource (also referred to as "information about resource allocation").

[0082] In some embodiments, the numerology information may be received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource may be received in one or more of the basic units, or in the region of the carrier for transmitting the reference numerology, or other suitable regions.

[0083] FIG. 12 illustrates a schematic diagram of a network device 1200 according to an embodiment of the present disclosure. According to embodiments of the present disclosure, the network device 1200 may be implemented as the network device 110 or other suitable device in the communication system.

[0084] As shown in FIG. 12, the network device 1200 comprises: a controller 1210 configured to determine numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and a transmitter 1220 configured to transmit the numerology information to a terminal device to enable reception based on the numerology information.

[0085] In some embodiments, the basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

[0086] In some embodiments, the controller 1210 may be further configured to determine numerologies for all the basic units, and wherein the transmitter 1220 may be further configured to transmit information about the numerologies for all the basic units to the terminal device.

[0087] In some embodiments, the controller 1210 may be further configured to: determine a grouping pattern indicating groups of the basic units; and determine a numerology for each of the groups, and wherein the transmitter may be further configured to transmit information about the grouping pattern and/or the numerology for each of the groups to the terminal device.

[0088] In some embodiments, the controller 1210 may be further configured to: determine numerologies for the basic units; and determine an association between the numerologies and the basic units, and wherein the transmitter 1220 may be further configured to transmit information about the numerologies and/or the association to the terminal device.

[0089] In some embodiments, the controller 1210 may be further configured to: divide the basic units into groups; and determine a numerology distribution pattern indicating numerologies for basic units in one of the groups, and wherein the transmitter may be further configured to transmit information about the numerology distribution pattern and/or information about the groups to the terminal device.

[0090] In some embodiments, the controller 1210 may be further configured to: determine guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units; and wherein the transmitter may be further configured to transmit the guard band information to the terminal device.

[0091] In some embodiments, the controller 1210 may be further configured to: detect whether there is a change between numerologies of the adjacent basic units; and determine occurrence of a guard band between the adjacent basic units based on the detection.

[0092] In some embodiments, the guard band information may further include one or more of: a number of subcarriers occupied by the guard band, a number of physical resource blocks occupied by the guard band, and a basic unit where the guard band is located.

[0093] In some embodiments, the transmitter 1220 may be further configured to transmit the guard band information to the terminal device based on the numerology information.

[0094] In some embodiments, the controller 1210 may be further configured to allocate a resource to one or more terminal devices, and wherein the transmitter 1220 may be further configured to transmit information about the allocated resource to the terminal device, wherein the information about the allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

[0095] In some embodiments, the transmitter 1220 may be further configured to: transmit the numerology information in a region of the carrier for transmitting a reference numerology; and transmit the information about the allocated resource in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

[0096] FIG. 13 illustrates a schematic diagram of a terminal device 1300 according to an embodiment of the present disclosure. According to embodiments of the present disclosure, the terminal device 1300 may be implemented as the network device 120 or other suitable device in the communication system.

[0097] As shown in FIG. 13, the terminal device 1300 comprises: a receiver 1310 configured to receive numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and a decoder 1320 configured to decode a signal based on the numerology information.

[0098] In some embodiments, the basic unit may be determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

[0099] In some embodiments, the receiver 1310 may be further configured to receive at least one of: information about numerologies for all the basic units; information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups; information about numerologies for the basic units and/or an association between the numerologies and the basic units; and at least one of information about a numerology distribution pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups, the basic

units in the groups having the same numerology distribution pattern.

[00100] In some embodiments, the receiver 1310 may be further configured to receive guard band information about a guard band between adjacent basic units, wherein the decoder 1320 may be further configured to decode the signal based on the numerology information and the guard band information.

[00101] In some embodiments, the receiver 1310 may be further configured to receive information about allocated resource of one or more terminal devices from the network device, wherein the information about allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

[00102] In some embodiments, wherein the numerology information may be received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource may be received in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

[00103] It is also to be noted that the device 1200 or 1300 may be respectively implemented by any suitable technique either known at present or developed in the future. Further, a single device shown in FIG. 12 or 13 may be alternatively implemented in multiple devices separately, and multiple separated devices may be implemented in a single device. The scope of the present disclosure is not limited in these regards.

[00104] It is noted that the device 1200 or 1300 may be configured to implement functionalities as described with reference to FIGs. 3-10 or FIG. 11. Therefore, the features discussed with respect to the method 300 may apply to the corresponding components of the device 1200, and the features discussed with respect to the method 1100 may apply to the corresponding components of the device 1300. It is further noted that the components of the device 1200 or 1300 may be embodied in hardware, software, firmware, and/or any combination thereof. For example, the components of the device 1200 or 1300may be respectively implemented by a circuit, a processor or any other appropriate device. Those skilled in the art will appreciate that the aforesaid examples are only for illustration not limitation.

[00105] In some embodiment of the present disclosure, the device 1200 or 1300 may

comprise at least one processor. The at least one processor suitable for use with embodiments of the present disclosure may include, by way of example, both general and special purpose processors already known or developed in the future. The device 1200 or 1300 may further comprise at least one memory. The at least one memory may include, for example, semiconductor memory devices, e.g., RAM, ROM, EPROM, EEPROM, and flash memory devices. The at least one memory may be used to store program of computer executable instructions. The program can be written in any high-level and/or low-level compliable or interpretable programming languages. In accordance with embodiments, the computer executable instructions may be configured, with the at least one processor, to cause the device 1200 to at least perform according to the method 300 as discussed above and to cause the device 1300 to at least perform according to the method 1100 as discussed above.

[00106] Based on the above description, the skilled in the art would appreciate that the present disclosure may be embodied in an apparatus, a method, or a computer program product. In general, the various exemplary embodiments may be implemented in hardware or special purpose circuits, software, logic or any combination thereof. For example, some aspects may be implemented in hardware, while other aspects may be implemented in firmware or software which may be executed by a controller, microprocessor or other computing device, although the disclosure is not limited thereto. While various aspects of the exemplary embodiments of this disclosure may be illustrated and described as block diagrams, flowcharts, or using some other pictorial representation, it is well understood that these blocks, apparatus, systems, techniques or methods described herein may be implemented in, as non-limiting examples, hardware, software, firmware, special purpose circuits or logic, general purpose hardware or controller or other computing devices, or some combination thereof.

[00107] The various blocks shown in FIG. 3 or 11 may be viewed as method steps, and/or as operations that result from operation of computer program code, and/or as a plurality of coupled logic circuit elements constructed to carry out the associated function(s). At least some aspects of the exemplary embodiments of the disclosures may be practiced in various components such as integrated circuit chips and modules, and that the exemplary embodiments of this disclosure may be realized in an apparatus that is embodied as an integrated circuit, FPGA or ASIC that is configurable

to operate in accordance with the exemplary embodiments of the present disclosure.

[00108] While this specification contains many specific implementation details, these should not be construed as limitations on the scope of any disclosure or of what may be claimed, but rather as descriptions of features that may be specific to particular embodiments of particular disclosures. Certain features that are described in this specification in the context of separate embodiments can also be implemented in combination in a single embodiment. Conversely, various features that are described in the context of a single embodiment can also be implemented in multiple embodiments separately or in any suitable sub-combination. Moreover, although features may be described above as acting in certain combinations and even initially claimed as such, one or more features from a claimed combination can in some cases be excised from the combination, and the claimed combination may be directed to a sub-combination or variation of a sub-combination.

[00109] Similarly, while operations are depicted in the drawings in a particular order, this should not be understood as requiring that such operations be performed in the particular order shown or in sequential order, or that all illustrated operations be performed, to achieve desirable results. In certain circumstances, multitasking and parallel processing may be advantageous. Moreover, the separation of various system components in the embodiments described above should not be understood as requiring such separation in all embodiments, and it should be understood that the described program components and systems can generally be integrated together in a single software product or packaged into multiple software products.

[00110] Various modifications, adaptations to the foregoing exemplary embodiments of this disclosure may become apparent to those skilled in the relevant arts in view of the foregoing description, when read in conjunction with the accompanying drawings. Any and all modifications will still fall within the scope of the non-limiting and exemplary embodiments of this disclosure. Furthermore, other embodiments of the disclosures set forth herein will come to mind to one skilled in the art to which these embodiments of the disclosure pertain having the benefit of the teachings presented in the foregoing descriptions and the associated drawings.

[00111] Therefore, it is to be understood that the embodiments of the disclosure are not to be limited to the specific embodiments disclosed and that modifications and

other embodiments are intended to be included within the scope of the appended claims. Although specific terms are used herein, they are used in a generic and descriptive sense only and not for purpose of limitation.

WHAT IS CLAIMED IS:

1. A method performed by a network device, comprising:

determining numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and

transmitting the numerology information to a terminal device to enable reception based on the numerology information.

2. The method according to Claim 1, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

3. The method according to Claim 1, wherein determining the numerology information comprises: determining numerologies for all the basic units, and

wherein transmitting the numerology information comprises: transmitting information about the numerologies for all the basic units to the terminal device.

4. The method according to Claim 1, wherein determining the numerology information comprises:

determining a grouping pattern indicating groups of the basic units; and

determining a numerology for each of the groups, and

wherein transmitting the numerology information comprises: transmitting information about the grouping pattern and/or the numerology for each of the groups to the terminal device.

5. The method according to Claim 1, wherein determining the numerology information comprises:

determining numerologies for the basic units; and

determining an association between the numerologies and the basic units, and

wherein transmitting the numerology information comprises: transmitting information about the numerologies and/or the association to the terminal device.

6. The method according to Claim 1, wherein determining the numerology information comprises:

dividing the basic units into groups; and

determining a numerology distribution pattern indicating numerologies for basic units in one of the groups, and

wherein transmitting the numerology information comprises: transmitting information about the numerology distribution pattern and/or information about the groups to the terminal device.

7. The method according to Claim 1, further comprising:

determining guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units; and

transmitting the guard band information to the terminal device.

8. The method according to Claim 7, wherein determining the guard band information comprises:

detecting whether there is a change between numerologies of the adjacent basic units; and

determining occurrence of a guard band between the adjacent basic units based on the detection.

9. The method according to Claim 7 or 8, wherein the guard band information further includes one or more of:

a number of subcarriers occupied by the guard band,

a number of physical resource blocks occupied by the guard band, and

a basic unit where the guard band is located.

10. The method according to Claim 7, wherein transmitting the guard band information to the terminal device comprises:

transmitting the guard band information to the terminal device based on the numerology information.

11. The method according to Claim 1, further comprising:

allocating a resource to one or more terminal devices; and

transmitting information about the allocated resource to the terminal device,

wherein the information about the allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

12. The method according to Claim 11, wherein transmitting the numerology information comprises:

transmitting the numerology information in a region of the carrier for transmitting a reference numerology; and

transmitting the information about the allocated resource in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

13. A method performed by a terminal device, comprising:

receiving numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and

decoding a signal based on the numerology information.

14. The method according to Claim 13, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

15. The method according to Claim 13, wherein receiving the numerology information comprises at least one of:

receiving information about numerologies for all the basic units;

receiving information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups;

receiving information about numerologies for the basic units and/or an association between the numerologies and the basic units; and

receiving at least one of information about a numerology distribution pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups, the basic units in the groups having the same numerology distribution pattern.

16. The method according to Claim 13, further comprising:

receiving guard band information about a guard band between adjacent basic units,

wherein decoding the signal comprises: decoding the signal based on the numerology information and the guard band information.

17. The method according to Claim 13, further comprising:

receiving information about allocated resource of one or more terminal devices from the network device, wherein the information about allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

18. The method according to Claim 17, wherein the numerology information is received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource is received in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

19. A network device, comprising:

a controller configured to determine numerology information of a carrier, the numerology information indicating numerologies of one or more basic units for the carrier; and

a transmitter configured to transmit the numerology information to a terminal device to enable reception based on the numerology information.

20. The network device according to Claim 19, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

21. The network device according to Claim 19, wherein the controller is further configured to determine numerologies for all the basic units, and

wherein the transmitter is further configured to transmit information about the numerologies for all the basic units to the terminal device.

22. The network device according to Claim 19, wherein the controller is further configured to:

determine a grouping pattern indicating groups of the basic units; and

determine a numerology for each of the groups, and

wherein the transmitter is further configured to transmit information about the grouping pattern and/or the numerology for each of the groups to the terminal device.

23. The network device according to Claim 19, wherein the controller is further configured to:

determine numerologies for the basic units; and

determine an association between the numerologies and the basic units, and

wherein the transmitter is further configured to transmit information about the numerologies and/or the association to the terminal device.

24. The network device according to Claim 19, wherein the controller is further configured to:

divide the basic units into groups; and

determine a numerology distribution pattern indicating numerologies for basic units in one of the groups, and

wherein the transmitter is further configured to transmit information about the numerology distribution pattern and/or information about the groups to the terminal device.

25. The network device according to Claim 19, wherein the controller is further configured to:

determine guard band information about a guard band between adjacent basic units based on numerologies of the adjacent basic units; and

wherein the transmitter is further configured to transmit the guard band information to the terminal device.

26. The network device according to Claim 25, wherein the controller is further configured to:

detect whether there is a change between numerologies of the adjacent basic units; and

determine occurrence of a guard band between the adjacent basic units based on the detection.

27. The network device according to Claim 25 or 26, wherein the guard band information further includes one or more of:

a number of subcarriers occupied by the guard band,

a number of physical resource blocks occupied by the guard band, and

a basic unit where the guard band is located.

28. The network device according to Claim 25, wherein the transmitter is further configured to transmit the guard band information to the terminal device based on the numerology information.

29. The network device according to Claim 19, wherein the controller is further configured to allocate a resource to one or more terminal devices, and wherein the transmitter is further configured to transmit information about the allocated resource to the terminal device,

wherein the information about the allocated resource includes at least one of: an index of a basic unit allocated to the terminal devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

30. The network device according to Claim 29, wherein the transmitter is further configured to:

transmit the numerology information in a region of the carrier for transmitting a reference numerology; and

transmit the information about the allocated resource in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

31. A terminal device, comprising:

a receiver configured to receive numerology information of a carrier from a network device, the numerology information indicating numerologies of one or more basic units for the carrier; and

a decoder configured to decode a signal based on the numerology information.

32. The terminal device according to Claim 31, wherein the basic unit is determined based on a subcarrier spacing and a symbol length used by subcarriers of the carrier.

33. The terminal device according to Claim 31, wherein the receiver is further configured to receive at least one of:

information about numerologies for all the basic units;

information about a grouping pattern indicating groups of the basic units and/or a numerology for each of the groups;

information about numerologies for the basic units and/or an association between the numerologies and the basic units; and

at least one of information about a numerology distribution pattern indicating numerologies for basic units in one of groups of basic units and/or information about the groups, the basic units in the groups having the same numerology distribution pattern.

34. The terminal device according to Claim 31, wherein the receiver is further configured to receive guard band information about a guard band between adjacent basic units,

wherein the decoder is further configured to decode the signal based on the numerology information and the guard band information.

35. The terminal device according to Claim 31, wherein the receiver is further configured to receive information about allocated resource of one or more terminal devices from the network device, wherein the information about allocated resource includes at least one of: an index of a basic unit allocated to the terminal

devices, and an index of a physical resource block in a basic unit allocated to the terminal devices.

36. The terminal device according to Claim 35, wherein the numerology information is received in a region of the carrier for transmitting a reference numerology, and the information about the allocated resource is received in at least one of: one or more of the basic units, and the region of the carrier for transmitting the reference numerology.

(54) Title: RADIO LINK MONITORING METHOD IN WIRELESS COMMUNICATION SYSTEM AND DEVICE THEREFOR

(54) 발명의 명칭 : 무선 통신 시스템에서 무선 링크 모니터링 방법 및 이를 위한 장치

[도18]

S1801 ... Perform first RLM for cell on basis of CRS
S1802 ... Perform second RLM for cell on basis of particular reference signal except for CRS
S1803 ... Determine RLM for cell, on basis of first RLM and second RLM or on basis of second RLM

(57) **Abstract**: Disclosed are a radio link monitoring method in a wireless communication system and a device therefor. Specifically, the method for performing radio link monitoring (RLM) by a terminal in a wireless communication system comprises the steps of: performing second RLM for a cell, on the basis of a reference signal except for a cell-specific reference signal (CRS); and determining a radio link failure (RLF) for the cell, on the basis of the second RLM, wherein a determination condition for RLF determination applied to the second RLM may be different from a determination condition for RLF determination applied to CRS-based first RLM.

(57) **요약서**: 무선 통신 시스템에서 무선 링크 모니터링 방법 및 이를 위한 장치가 개시된다. 구체적으로, 무선 통신 시스템에서 단말이 무선 링크 모니터링(RLM: radio link monitoring)을 수행하는 방법에 있어서, 셀 특정 참조 신호(CRS: cell-specific reference signal) 이외 참조 신호를 기반으로 셀에 대한 제 2 RLM 을 수행하는 단계 및 상기 제 2 RLM 을 기반으로 상기 셀에 대한 무선 링크 실패(RLF: radio link failure)를 판단하는 단계를 포함하고, 상기 제 2 RLM 에 적용되는 RLF 판단을 위한 판단 조건은 CRS 기반 제 1 RLM 에 적용되는 RLF 판단을 위한 판단 조건과 상이할 수 있다.

WO 2016/122232 A1

명세서

발명의 명칭: 무선 통신 시스템에서 무선 링크 모니터링 방법 및 이를 위한 장치

기술분야

[1] 본 발명은 무선 통신 시스템에 관한 것으로서, 보다 상세하게 단말에서 참조 신호(reference signal)을 기반으로 무선 링크 모니터링을 수행하기 위한 방법 및 이를 지원하는 장치에 관한 것이다.

배경기술

[2] 이동 통신 시스템은 사용자의 활동성을 보장하면서 음성 서비스를 제공하기 위해 개발되었다. 그러나 이동통신 시스템은 음성뿐 아니라 데이터 서비스까지 영역을 확장하였으며, 현재에는 폭발적인 트래픽의 증가로 인하여 자원의 부족 현상이 야기되고 사용자들이 보다 고속의 서비스에 대한 요구하므로, 보다 발전된 이동 통신 시스템이 요구되고 있다.

[3] 차세대 이동 통신 시스템의 요구 조건은 크게 폭발적인 데이터 트래픽의 수용, 사용자 당 전송률의 획기적인 증가, 대폭 증가된 연결 디바이스 개수의 수용, 매우 낮은 단대단 지연(End-to-End Latency), 고에너지 효율을 지원할 수 있어야 한다. 이를 위하여 이중 연결성(Dual Connectivity), 대규모 다중 입출력(Massive MIMO: Massive Multiple Input Multiple Output), 전이중(In-band Full Duplex), 비직교 다중접속(NOMA: Non-Orthogonal Multiple Access), 초광대역(Super wideband) 지원, 단말 네트워킹(Device Networking) 등 다양한 기술들이 연구되고 있다.

발명의 상세한 설명

기술적 과제

[4] 본 발명의 목적은 무선 통신 시스템에서 단말이 셀 특정 참조 신호(CRS: Cell-specific Reference Signal)과는 별도로 설정되는 무선 자원 무선 자원 관리(RRM: Radio Resource Management) 측정을 위한 참조 신호(RRM-RS)를 기반으로 단말이 셀을 (재)선택하는 방법을 제안한다.

[5] 또한, 본 발명의 목적은 RRM-RS 기반으로 선택된 최적의 셀로 초기 접속(initial access) 과정을 수행하기 위한 방법을 제안한다.

[6] 또한, 본 발명의 목적은 CRS 이외의 참조 신호를 기반으로 무선 링크 모니터링(radio link monitoring)을 수행하는 방법을 제안한다.

[7] 본 발명에서 이루고자 하는 기술적 과제들은 이상에서 언급한 기술적 과제들로 제한되지 않으며, 언급하지 않은 또 다른 기술적 과제들은 아래의 기재로부터 본 발명이 속하는 기술분야에서 통상의 지식을 가진 자에게 명확하게 이해될 수 있을 것이다.

과제 해결 수단

[8] 본 발명의 일 양상은, 무선 통신 시스템에서 단말이 무선 링크 모니터링(RLM: radio link monitoring)을 수행하는 방법에 있어서, 셀 특정 참조 신호(CRS: cell-specific reference signal) 이외 참조 신호를 기반으로 셀에 대한 제2 RLM을 수행하는 단계 및 상기 제2 RLM을 기반으로 상기 셀에 대한 무선 링크 실패(RLF: radio link failure)를 판단하는 단계를 포함하고, 상기 제2 RLM에 적용되는 RLF 판단을 위한 판단 조건은 CRS 기반 제1 RLM에 적용되는 RLF 판단을 위한 판단 조건과 상이할 수 있다.

[9] 본 발명의 다른 일 양상은, 무선 통신 시스템에서 무선 링크 모니터링(RLM: radio link monitoring)을 수행하는 단말에 있어서, 무선 신호를 송수신하기 위한 RF(Radio Frequency) 유닛 및 상기 RF 유닛을 제어하는 프로세서를 포함하고, 상기 셀 특정 참조 신호(CRS: cell-specific reference signal) 이외 참조 신호를 기반으로 셀에 대한 제2 RLM을 수행하고, 상기 제2 RLM을 기반으로 상기 셀에 대한 무선 링크 실패(RLF: radio link failure)를 판단하도록 구성되고, 상기 제2 RLM에 적용되는 RLF 판단을 위한 판단 조건은 CRS 기반 제1 RLM에 적용되는 RLF 판단을 위한 판단 조건과 상이할 수 있다.

[10] 바람직하게, 상기 CRS 기반으로 상기 제1 RLM을 수행하는 단계를 더 포함하고, 상기 셀에 대한 RLF는 상기 제1 RLM 및 상기 제2 RLM을 기반으로 판단될 수 있다.

[11] 바람직하게, 상기 RLF 판단을 위한 판단 조건은 제어 채널 전송 파라미터, 비동기(out-of-sync)/동기(in-sync) 상태 판단을 위한 임계값 및 RLF 타이머 중 적어도 어느 하나를 포함할 수 있다.

[12] 바람직하게, 상기 제2 RLM의 경우, 상기 제2 모니터링을 위한 하향링크 제어 정보(DCI: Downlink Control Information)가 소정의 진보된 물리 하향링크 제어 채널(EPDCCH: Enhanced Physical Downlink Control Channel) 세트로부터 전송된다고 가정될 수 있다.

[13] 바람직하게, 상기 단말이 풀 차원 다중 입력 다중 출력(FD-MIMO: full dimension-Multi Input Multi Output) 지원 가능한 경우, 상기 제2 RLM이 수행될 수 있다.

[14] 바람직하게, 상기 단말이 FD-MIMO 지원 가능하고 상기 단말이 FD-MIMO 모드가 활성화된 경우, 상기 제2 RLM이 수행될 수 있다.

[15] 바람직하게, 상기 셀에 대한 RLF가 상기 제1 RLM 및 상기 제2 RLM을 기반으로 판단되는 경우, 상기 제1 RLM 및 상기 제2 RLM 중 적어도 어느 하나에 의해 상기 셀에 대한 RLF가 결정되면, 상기 셀에 대한 RLF가 결정될 수 있다.

[16] 바람직하게, 상기 제1 RLM 및 상기 제2 RLM 중 어느 하나가 상기 셀에 대한 RLF 판단에 있어서 높은 우선 순위를 가질 수 있다.

[17] 바람직하게, 상기 셀에 대한 RLF가 상기 제1 RLM 및 상기 제2 RLM을 기반으로 판단되는 경우, 상기 제1 RLM 및 상기 제2 RLM 모두에 의해 상기 셀에 대한 RLF가 결정되면, 상기 셀에 대한 RLF가 결정될 수 있다.

[18] 바람직하게, 상기 제2 RLM은 상기 제1 RLM에 의해 소정의 조건이 만족되는 경우 수행될 수 있다.

[19] 바람직하게, 상기 제1 RLM에 의한 RLF 타이머가 가동된 시점으로부터 소정의 오프셋 시간 이후 상기 제2 RLM이 개시될 수 있다.

[20] 바람직하게, 상기 제1 RLM에 의한 RLF 타이머가 가동된 시점으로부터 상기 단말에 의한 다른 셀의 선택(selection) 또는 재선택(reselection) 절차가 완료되기까지 구간 동안, 상기 제2 RLM과 연계된 EPDCCH 세트를 통해 DCI가 수신되고, 상기 DCI에 의해 스케줄링된 물리 하향링크 공유 채널(PDSCH: Physical Downlink Shared Channel)를 통해 하향링크 데이터가 수신될 수 있다.

[21] 바람직하게, 미리 정해진 무선 네트워크 임시 식별자(RNTI: Radio Network Temporary Identifier)로 마스킹된 DCI만 상기 EPDCCH 세트를 통해 수신될 수 있다.

[22] 바람직하게, 상기 CSI 이외 참조 신호는 채널 상태 정보 참조 신호(CSI-RS: Channel State Information-Reference Signal), 디스커버리 참조 신호(DRS: Discovery Reference Signal), 프리코딩된(precoded) 참조 신호 및 셀 (재)선택 관련 동작 시에 적용하도록 설정된 참조 서로 다른 셀 또는 전송 포인트(TP: Transmission Point)의 개수로 구성되는 무정형 셀(amorphous cell)에서 전송되는 참조 신호 중 어느 하나일 수 있다.

발명의 효과

[23] 본 발명의 실시예에 따르면, 무선 통신 시스템에서, 특히 풀-차원-MIMO(full-dimension MIMO)를 사용하거나 진보된 무정형 셀(amorphous cell)을 지원하는 환경에서, 단말에게 가장 효율이 좋은 최적의 셀이 선택될 수 있다.

[24] 또한, 본 발명의 실시예에 따르면, 단말에게 가장 효율이 좋은 최적의 셀로 초기 접속(initial access)함으로써 단말의 초기 셀 접속 과정에서의 지연(latency)을 최소화할 수 있다.

[25] 또한, 본 발명의 실시예에 따르면, 단말에게 가장 효율이 좋은 최적의 셀로 초기 접속(initial access)함으로써, 단말의 추가적인 핸드오버(hand-over)나 셀 재선택(cell re-selection) 과정 없이 빠르게 정상 동작 상태에 진입할 수 있도록 하는 장점이 있다.

[26] 또한, 본 발명의 실시예에 따르면, (CRS 기반 무선 링크 모니터링과 함께) CRS 이외 참조 신호 기반 무선 링크 모니터링에 의해 무선 링크 실패를 판단함으로써 빔포밍된 채널(예를 들어, 풀 차원 다중 입출력(FD-MIMO: Full Dimension Multi-Input Multi-Output) 등이 적용된 채널)에 따른 무선 링크 품질을 고려할 수 있다.

[27] 또한, 본 발명의 실시예에 따르면, 빔포밍된 채널에 따른 무선 링크 품질을 고려함으로써, 빔포밍된 채널 환경이 좋은 상태에서 통신 링크가 단절되는

현상을 줄이며, 또한 빔포밍된 채널을 통한 송수신 동작을 유지함에 따른 성능 이득을 얻을 수 있다.

[28] 본 발명에서 얻을 수 있는 효과는 이상에서 언급한 효과로 제한되지 않으며, 언급하지 않은 또 다른 효과들은 아래의 기재로부터 본 발명이 속하는 기술분야에서 통상의 지식을 가진 자에게 명확하게 이해될 수 있을 것이다.

도면의 간단한 설명

[29] 본 발명에 관한 이해를 돕기 위해 상세한 설명의 일부로 포함되는, 첨부 도면은 본 발명에 대한 실시예를 제공하고, 상세한 설명과 함께 본 발명의 기술적 특징을 설명한다.

[30] 도 1은 본 발명이 적용될 수 있는 무선 통신 시스템에서 무선 프레임의 구조를 나타낸다.

[31] 도 2는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하나의 하향링크 슬롯에 대한 자원 그리드(resource grid)를 예시한 도면이다.

[32] 도 3은 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 서브 프레임의 구조를 나타낸다.

[33] 도 4는 본 발명이 적용될 수 있는 무선 통신 시스템에서 상향링크 서브 프레임의 구조를 나타낸다.

[34] 도 5는 일반적인 다중 입출력 안테나(MIMO) 통신 시스템의 구성도이다.

[35] 도 6은 다수의 송신 안테나에서 하나의 수신 안테나로의 채널을 나타낸 도이다.

[36] 도 7은 본 발명이 적용될 수 있는 무선 통신 시스템에서 컴포넌트 캐리어 및 캐리어 병합의 일례를 나타낸다.

[37] 도 8은 본 발명이 적용될 수 있는 무선 통신 시스템에서 경쟁 기반 랜덤 액세스 절차를 설명하기 위한 도면이다.

[38] 도 9는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 자원 블록 쌍에 매핑된 참조 신호 패턴을 예시한다.

[39] 도 10은 본 발명이 적용될 수 있는 무선 통신 시스템에서 CSI-RS 구성을 예시하는 도면이다.

[40] 도 11은 본 발명이 적용될 수 있는 무선 통신 시스템에서 기지국 또는 단말이 AAS 기반의 3D(3-Dimension) 빔 형성이 가능한 다수의 송/수신 안테나를 갖고 있는 시스템을 예시한다.

[41] 도 12는 본 발명의 일 실시예에 따른 RRM-RS의 안테나 포트 별 RSRP를 예시한다.

[42] 도 13은 본 발명의 일 실시예에 따른 RRM-RS 안테나 포트 그룹핑 레벨을 예시한다.

[43] 도 14는 본 발명의 일 실시예에 따른 이차원 인덱스로 배열된 RRM-RS의 안테나 포트와 안테나 포트 그룹을 예시하는 도면이다.

[44] 도 15는 본 발명의 일 실시예에 따른 RRM-RS 기반 셀 선택 방법을 예시하는

도면이다.

[45] 도 16은 본 발명의 일 실시예에 따른 RRM 측정 방법을 예시하는 도면이다.

[46] 도 17은 본 발명의 일 실시예에 따른 랜덤 액세스 절차를 예시하는 도면이다.

[47] 도 18은 본 발명의 일 실시예에 따른 무선 링크 모니터링을 위한 방법을 예시하는 도면이다.

[48] 도 19는 본 발명의 일 실시예에 따른 무선 통신 장치의 블록 구성도를 예시한다.

발명의 실시를 위한 형태

[49] 이하, 본 발명에 따른 바람직한 실시 형태를 첨부된 도면을 참조하여 상세하게 설명한다. 첨부된 도면과 함께 이하에 개시될 상세한 설명은 본 발명의 예시적인 실시형태를 설명하고자 하는 것이며, 본 발명이 실시될 수 있는 유일한 실시형태를 나타내고자 하는 것이 아니다. 이하의 상세한 설명은 본 발명의 완전한 이해를 제공하기 위해서 구체적 세부사항을 포함한다. 그러나, 당업자는 본 발명이 이러한 구체적 세부사항 없이도 실시될 수 있음을 안다.

[50] 몇몇 경우, 본 발명의 개념이 모호해지는 것을 피하기 위하여 공지의 구조 및 장치는 생략되거나, 각 구조 및 장치의 핵심기능을 중심으로 한 블록도 형식으로 도시될 수 있다.

[51] 본 명세서에서 기지국은 단말과 직접적으로 통신을 수행하는 네트워크의 종단 노드(terminal node)로서의 의미를 갖는다. 본 문서에서 기지국에 의해 수행되는 것으로 설명된 특정 동작은 경우에 따라서는 기지국의 상위 노드(upper node)에 의해 수행될 수도 있다. 즉, 기지국을 포함하는 다수의 네트워크 노드들(network nodes)로 이루어지는 네트워크에서 단말과의 통신을 위해 수행되는 다양한 동작들은 기지국 또는 기지국 이외의 다른 네트워크 노드들에 의해 수행될 수 있음은 자명하다. '기지국(BS: Base Station)'은 고정국(fixed station), Node B, eNB(evolved-NodeB), BTS(base transceiver system), 액세스 포인트(AP: Access Point) 등의 용어에 의해 대체될 수 있다. 또한, '단말(Terminal)'은 고정되거나 이동성을 가질 수 있으며, UE(User Equipment), MS(Mobile Station), UT(user terminal), MSS(Mobile Subscriber Station), SS(Subscriber Station), AMS(Advanced Mobile Station), WT(Wireless terminal), MTC(Machine-Type Communication) 장치, M2M(Machine-to-Machine) 장치, D2D(Device-to-Device) 장치 등의 용어로 대체될 수 있다.

[52] 이하에서, 하향링크(DL: downlink)는 기지국에서 단말로의 통신을 의미하며, 상향링크(UL: uplink)는 단말에서 기지국으로의 통신을 의미한다. 하향링크에서 송신기는 기지국의 일부이고, 수신기는 단말의 일부일 수 있다. 상향링크에서 송신기는 단말의 일부이고, 수신기는 기지국의 일부일 수 있다.

[53] 이하의 설명에서 사용되는 특정 용어들은 본 발명의 이해를 돕기 위해서 제공된 것이며, 이러한 특정 용어의 사용은 본 발명의 기술적 사상을 벗어나지 않는 범위에서 다른 형태로 변경될 수 있다.

[54] 이하의 기술은 CDMA(code division multiple access), FDMA(frequency division multiple access), TDMA(time division multiple access), OFDMA(orthogonal frequency division multiple access), SC-FDMA(single carrier frequency division multiple access), NOMA(non-orthogonal multiple access) 등과 같은 다양한 무선 접속 시스템에 이용될 수 있다. CDMA는 UTRA(universal terrestrial radio access)나 CDMA2000과 같은 무선 기술(radio technology)로 구현될 수 있다. TDMA는 GSM(global system for mobile communications)/GPRS(general packet radio service)/EDGE(enhanced data rates for GSM evolution)와 같은 무선 기술로 구현될 수 있다. OFDMA는 IEEE 802.11 (Wi-Fi), IEEE 802.16 (WiMAX), IEEE 802-20, E-UTRA(evolved UTRA) 등과 같은 무선 기술로 구현될 수 있다. UTRA는 UMTS(universal mobile telecommunications system)의 일부이다. 3GPP(3rd generation partnership project) LTE(long term evolution)은 E-UTRA를 사용하는 E-UMTS(evolved UMTS)의 일부로써, 하향링크에서 OFDMA를 채용하고 상향링크에서 SC-FDMA를 채용한다. LTE-A(advanced)는 3GPP LTE의 진화이다.

[55] 본 발명의 실시예들은 무선 접속 시스템들인 IEEE 802, 3GPP 및 3GPP2 중 적어도 하나에 개시된 표준 문서들에 의해 뒷받침될 수 있다. 즉, 본 발명의 실시예들 중 본 발명의 기술적 사상을 명확히 드러내기 위해 설명하지 않은 단계들 또는 부분들은 상기 문서들에 의해 뒷받침될 수 있다. 또한, 본 문서에서 개시하고 있는 모든 용어들은 상기 표준 문서에 의해 설명될 수 있다.

[56] 설명을 명확하게 하기 위해, 3GPP LTE/LTE-A를 위주로 기술하지만 본 발명의 기술적 특징이 이에 제한되는 것은 아니다.

[57]

[58] **본 발명이 적용될 수 있는 무선 통신 시스템 일반**

[59] 도 1은 본 발명이 적용될 수 있는 무선 통신 시스템에서 무선 프레임의 구조를 나타낸다.

[60] 3GPP LTE/LTE-A에서는 FDD(Frequency Division Duplex)에 적용 가능한 타입 1 무선 프레임(radio frame) 구조와 TDD(Time Division Duplex)에 적용 가능한 타입 2의 무선 프레임 구조를 지원한다.

[61] 도 1에서 무선 프레임의 시간 영역에서의 크기는 $T_s=1/(15000*2048)$의 시간 단위의 배수로 표현된다. 하향링크 및 상향링크 전송은 $T_f=307200*T_s=10ms$의 구간을 가지는 무선 프레임으로 구성된다.

[62] 도 1의 (a)는 타입 1 무선 프레임의 구조를 예시한다. 타입 1 무선 프레임은 전이중(full duplex) 및 반이중(half duplex) FDD에 모두 적용될 수 있다.

[63] 무선 프레임(radio frame)은 10개의 서브프레임(subframe)으로 구성된다. 하나의 무선 프레임은 $T_{slot}=15360*T_s=0.5ms$ 길이의 20개의 슬롯으로 구성되고, 각 슬롯은 0부터 19까지의 인덱스가 부여된다. 하나의 서브프레임은 시간 영역(time domain)에서 연속적인 2개의 슬롯(slot)으로 구성되고, 서브프레임 i는 슬롯 2i 및 슬롯 2i+1로 구성된다. 하나의 서브프레임을 전송하는데 걸리는 시간을

TTI(transmission time interval)이라 한다. 예를 들어, 하나의 서브 프레임은 길이는 1ms이고, 하나의 슬롯의 길이는 0.5ms일 수 있다.

[64] FDD에서 상향링크 전송 및 하향링크 전송은 주파수 도메인에서 구분된다. 전이중 FDD에 제한이 없는 반면, 반이중 FDD 동작에서 단말은 동시에 전송 및 수신을 할 수 없다.

[65] 하나의 슬롯은 시간 영역에서 복수의 OFDM(orthogonal frequency division multiplexing) 심볼을 포함하고, 주파수 영역에서 다수의 자원블록(RB: Resource Block)을 포함한다. 3GPP LTE는 하향링크에서 OFDMA를 사용하므로 OFDM 심볼은 하나의 심볼 구간(symbol period)을 표현하기 위한 것이다. OFDM 심볼은 하나의 SC-FDMA 심볼 또는 심볼 구간이라고 할 수 있다. 자원 블록(resource block)은 자원 할당 단위이고, 하나의 슬롯에서 복수의 연속적인 부반송파(subcarrier)를 포함한다.

[66] 도 1의 (b)는 타입 2 프레임 구조(frame structure type 2)를 나타낸다.

[67] 타입 2 무선 프레임은 각 153600*T_s=5ms의 길이의 2개의 하프 프레임(half frame)으로 구성된다. 각 하프 프레임은 30720*T_s=1ms 길이의 5개의 서브프레임으로 구성된다.

[68] TDD 시스템의 타입 2 프레임 구조에서 상향링크-하향링크 구성(uplink-downlink configuration)은 모든 서브프레임에 대하여 상향링크와 하향링크가 할당(또는 예약)되는지 나타내는 규칙이다.

[69] 표 1은 상향링크-하향링크 구성을 나타낸다.

[70] [표1]

Uplink-Downlink configu-ration	Downlink-to-Uplink Switch-point periodicity	Subframe number									
		0	1	2	3	4	5	6	7	8	9
0	5ms	D	S	U	U	U	D	S	U	U	U
1	5ms	D	S	U	U	D	D	S	U	U	D
2	5ms	D	S	U	D	D	D	S	U	D	D
3	10ms	D	S	U	U	U	D	D	D	D	D
4	10ms	D	S	U	U	D	D	D	D	D	D
5	10ms	D	S	U	D	D	D	D	D	D	D
6	5ms	D	S	U	U	U	D	S	U	U	D

[71] 표 1을 참조하면, 무선 프레임의 각 서브프레임 별로, 'D'는 하향링크 전송을 위한 서브프레임을 나타내고, 'U'는 상향링크 전송을 위한 서브프레임을 나타내며, 'S'는 DwPTS(Downlink Pilot Time Slot), 보호구간(GP: Guard Period), UpPTS(Uplink Pilot Time Slot) 3가지의 필드로 구성되는 스페셜 서브프레임(special subframe)을 나타낸다.

[72] DwPTS는 단말에서의 초기 셀 탐색, 동기화 또는 채널 추정에 사용된다. UpPTS는 기지국에서의 채널 추정과 단말의 상향링크 전송 동기를 맞추는 데 사용된다. GP는 상향링크와 하향링크 사이에 하향링크 신호의 다중경로

지연으로 인해 상향링크에서 생기는 간섭을 제거하기 위한 구간이다.

[73] 각 서브프레임 i는 각 T_slot=15360*T_s=0.5ms 길이의 슬롯 2i 및 슬롯 2i+1로 구성된다.

[74] 상향링크-하향링크 구성은 7가지로 구분될 수 있으며, 각 구성 별로 하향링크 서브프레임, 스페셜 서브프레임, 상향링크 서브프레임의 위치 및/또는 개수가 다르다.

[75] 하향링크에서 상향링크로 변경되는 시점 또는 상향링크에서 하향링크로 전환되는 시점을 전환 시점(switching point)이라 한다. 전환 시점의 주기성(Switch-point periodicity)은 상향링크 서브프레임과 하향링크 서브프레임이 전환되는 양상이 동일하게 반복되는 주기를 의미하며, 5ms 또는 10ms가 모두 지원된다. 5ms 하향링크-상향링크 전환 시점의 주기를 가지는 경우에는 스페셜 서브프레임(S)은 하프-프레임 마다 존재하고, 5ms 하향링크-상향링크 전환 시점의 주기를 가지는 경우에는 첫번째 하프-프레임에만 존재한다.

[76] 모든 구성에 있어서, 0번, 5번 서브프레임 및 DwPTS는 하향링크 전송만을 위한 구간이다. UpPTS 및 서브프레임 서브프레임에 바로 이어지는 서브프레임은 항상 상향링크 전송을 위한 구간이다.

[77] 이러한, 상향링크-하향링크 구성은 시스템 정보로써 기지국과 단말이 모두 알고 있을 수 있다. 기지국은 상향링크-하향링크 구성 정보가 바뀔 때마다 구성 정보의 인덱스만을 전송함으로써 무선 프레임의 상향링크-하향링크 할당상태의 변경을 단말에 알려줄 수 있다. 또한, 구성 정보는 일종의 하향링크 제어정보로서 다른 스케줄링 정보와 마찬가지로 PDCCH(Physical Downlink Control Channel)를 통해 전송될 수 있으며, 방송 정보로서 브로드캐스트 채널(broadcast channel)을 통해 셀 내의 모든 단말에 공통으로 전송될 수도 있다.

[78] 표 2는 스페셜 서브프레임의 구성(DwPTS/GP/UpPTS의 길이)을 나타낸다.

[79] [표2]

Special subframe configuration	Normal cyclic prefix in downlink			Extended cyclic prefix in downlink		
	DwPTS	UpPTS		DwPTS	UpPTS	
		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink		Normal cyclic prefix in uplink	Extended cyclic prefix in uplink
0	$6592 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$	$7680 \cdot T_s$	$2192 \cdot T_s$	$2560 \cdot T_s$
1	$19760 \cdot T_s$			$20480 \cdot T_s$		
2	$21952 \cdot T_s$			$23040 \cdot T_s$		
3	$24144 \cdot T_s$			$25600 \cdot T_s$		
4	$26336 \cdot T_s$			$7680 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$
5	$6592 \cdot T_s$	$4384 \cdot T_s$	$5120 \cdot T_s$	$20480 \cdot T_s$		
6	$19760 \cdot T_s$			$23040 \cdot T_s$		
7	$21952 \cdot T_s$			-	-	-
8	$24144 \cdot T_s$			-	-	-

[80] 도 1의 예시에 따른 무선 프레임의 구조는 하나의 예시에 불과하며, 무선 프레임에 포함되는 부 반송파의 수 또는 서브 프레임에 포함되는 슬롯의 수, 슬롯에 포함되는 OFDM 심볼의 수는 다양하게 변경될 수 있다.

[81] 도 2는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하나의 하향링크 슬롯에 대한 자원 그리드(resource grid)를 예시한 도면이다.

[82] 도 2를 참조하면, 하나의 하향링크 슬롯은 시간 영역에서 복수의 OFDM 심볼을 포함한다. 여기서, 하나의 하향링크 슬롯은 7개의 OFDM 심볼을 포함하고, 하나의 자원 블록은 주파수 영역에서 12개의 부 반송파를 포함하는 것을 예시적으로 기술하나, 이에 한정되는 것은 아니다.

[83] 자원 그리드 상에서 각 요소(element)를 자원 요소(resource element)하고, 하나의 자원 블록(RB: resource block)은 12×7 개의 자원 요소를 포함한다. 하향링크 슬롯에 포함되는 자원 블록들의 수 N^DL은 하향링크 전송 대역폭(bandwidth)에 종속한다.

[84] 상향링크 슬롯의 구조는 하향링크 슬롯의 구조와 동일할 수 있다.

[85] 도 3은 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 서브 프레임의 구조를 나타낸다.

[86] 도 3을 참조하면, 서브 프레임내의 첫번째 슬롯에서 앞의 최대 3개의 OFDM 심볼들이 제어 채널들이 할당되는 제어 영역(control region)이고, 나머지 OFDM 심볼들은 PDSCH(Physical Downlink Shared Channel)이 할당되는 데이터 영역(data region)이다. 3GPP LTE에서 사용되는 하향링크 제어 채널의 일례로 PCFICH(Physical Control Format Indicator Channel), PDCCH(Physical Downlink Control Channel), PHICH(Physical Hybrid-ARQ Indicator Channel) 등이 있다.

[87] PCFICH는 서브 프레임의 첫번째 OFDM 심볼에서 전송되고, 서브 프레임 내에 제어 채널들의 전송을 위하여 사용되는 OFDM 심볼들의 수(즉, 제어 영역의

크기)에 관한 정보를 나른다. PHICH는 상향 링크에 대한 응답 채널이고, HARQ(Hybrid Automatic Repeat Request)에 대한 ACK(Acknowledgement)/NACK(Not-Acknowledgement) 신호를 나른다. PDCCH를 통해 전송되는 제어 정보를 하향링크 제어정보(DCI: downlink control information)라고 한다. 하향링크 제어정보는 상향링크 자원 할당 정보, 하향링크 자원 할당 정보 또는 임의의 단말 그룹에 대한 상향링크 전송(Tx) 파워 제어 명령을 포함한다.

[88] PDCCH는 DL-SCH(Downlink Shared Channel)의 자원 할당 및 전송 포맷(이를 하향링크 그랜트라고도 한다.), UL-SCH(Uplink Shared Channel)의 자원 할당 정보(이를 상향링크 그랜트라고도 한다.), PCH(Paging Channel)에서의 페이징(paging) 정보, DL-SCH에서의 시스템 정보, PDSCH에서 전송되는 랜덤 액세스 응답(random access response)과 같은 상위 레이어(upper-layer) 제어 메시지에 대한 자원 할당, 임의의 단말 그룹 내 개별 단말들에 대한 전송 파워 제어 명령들의 집합, VoIP(Voice over IP)의 활성화 등을 나를 수 있다. 복수의 PDCCH들은 제어 영역 내에서 전송될 수 있으며, 단말은 복수의 PDCCH들을 모니터링할 수 있다. PDCCH는 하나 또는 복수의 연속적인 CCE(control channel elements)의 집합으로 구성된다. CCE는 무선 채널의 상태에 따른 부호화율(coding rate)을 PDCCH에 제공하기 위하여 사용되는 논리적 할당 단위이다. CCE는 복수의 자원 요소 그룹(resource element group)들에 대응된다. PDCCH의 포맷 및 사용 가능한 PDCCH의 비트 수는 CCE들의 수와 CCE들에 의해 제공되는 부호화율 간의 연관 관계에 따라 결정된다.

[89] 기지국은 단말에게 전송하려는 DCI에 따라 PDCCH 포맷을 결정하고, 제어 정보에 CRC(Cyclic Redundancy Check)를 붙인다. CRC에는 PDCCH의 소유자(owner)나 용도에 따라 고유한 식별자(이를 RNTI(Radio Network Temporary Identifier)라고 한다.)가 마스킹된다. 특정의 단말을 위한 PDCCH라면 단말의 고유한 식별자, 예를 들어 C-RNTI(Cell-RNTI)가 CRC에 마스킹될 수 있다. 또는 페이징 메시지를 위한 PDCCH라면 페이징 지시 식별자, 예를 들어 P-RNTI(Paging-RNTI)가 CRC에 마스킹될 수 있다. 시스템 정보, 더욱 구체적으로 시스템 정보 블록(SIB: system information block)를 위한 PDCCH라면 시스템 정보 식별자, SI-RNTI(system information RNTI)가 CRC에 마스킹될 수 있다. 단말의 랜덤 액세스 프리앰블의 전송에 대한 응답인 랜덤 액세스 응답을 지시하기 위하여, RA-RNTI(random access-RNTI)가 CRC에 마스킹될 수 있다.

[90] EPDCCH(enhanced PDCCH)는 단말 특정(UE-specific) 시그널링을 나른다. EPDCCH는 단말 특정하게 설정된 물리 자원 블록(PRB: physical resource block)에 위치한다. 다시 말해, 상술한 바와 같이 PDCCH는 서브 프레임내의 첫번째 슬롯에서 앞의 최대 3개의 OFDM 심볼들에서 전송될 수 있으나, EPDCCH는 PDCCH 이외의 자원 영역에서 전송될 수 있다. 서브프레임 내 EPDCCH가 시작되는 시점(즉, 심볼)은 상위 계층 시그널링(예를 들어, RRC 시그널링 등)을

통해 단말에 설정될 수 있다.

[91] EPDCCH는 DL-SCH와 관련된 전송 포맷, 자원 할당 및 HARQ 정보, UL-SCH와 관련된 전송 포맷, 자원 할당 및 HARQ 정보, SL-SCH(Sidelink Shared Channel) 및 PSCCH(Physical Sidelink Control Channel)과 관련된 자원 할당 정보 등을 나를 수 있다. 다중의 EPDCCH가 지원될 수 있으며, 단말은 EPCCH의 세트를 모니터링할 수 있다.

[92] EPDCCH는 하나 또는 그 이상의 연속된 진보된 CCE(ECCE: enhanced CCE)를 이용하여 전송될 수 있으며, 각 EPDCCH 포맷 별로 단일의 EPDCCH 당 ECCE의 개수가 정해질 수 있다.

[93] 각 ECCE는 복수의 자원 요소 그룹(EREG: enhanced resource element group)으로 구성될 수 있다. EREG는 ECCE의 RE에의 매핑을 정의하기 위하여 사용된다. PRB 쌍 별로 16개의 EREG가 존재한다. 각 PRB 쌍 내에서 DMRS를 나르는 RE를 제외하고, 모든 RE는 주파수가 증가하는 순서대로 그 다음 시간이 증가하는 순서대로 0 내지 15까지의 번호가 부여된다.

[94] 단말은 복수의 EPDCCH를 모니터링할 수 있다. 예를 들어, 단말이 EPDCCH 전송을 모니터링하는 하나의 PRB 쌍 내 하나 또는 두 개의 EPDCCH 세트가 설정될 수 있다.

[95] 서로 다른 개수의 ECCE가 병합됨으로써 EPCCH를 위한 서로 다른 부호화율(coding rate)이 실현될 수 있다. EPCCH는 지역적 전송(localized transmission) 또는 분산적 전송(distributed transmission)을 사용할 수 있으며, 이에 따라 PRB 내 RE에 ECCE의 매핑이 달라질 수 있다.

[96] 도 4는 본 발명이 적용될 수 있는 무선 통신 시스템에서 상향링크 서브 프레임의 구조를 나타낸다.

[97] 도 4를 참조하면, 상향링크 서브 프레임은 주파수 영역에서 제어 영역과 데이터 영역으로 나눌 수 있다. 제어 영역에는 상향링크 제어 정보를 나르는 PUCCH(Physical Uplink Control Channel)이 할당된다. 데이터 영역은 사용자 데이터를 나르는 PUSCH(Physical Uplink Shared Channel)이 할당된다. 단일 반송파 특성을 유지하기 위해 하나의 단말은 PUCCH와 PUSCH을 동시에 전송하지 않는다.

[98] 하나의 단말에 대한 PUCCH에는 서브 프레임 내에 자원 블록(RB: Resource Block) 쌍이 할당된다. RB 쌍에 속하는 RB들은 2개의 슬롯들의 각각에서 서로 다른 부 반송파를 차지한다. 이를 PUCCH에 할당된 RB 쌍은 슬롯 경계(slot boundary)에서 주파수 도약(frequency hopping)된다고 한다.

[99]

[100] **MIMO**(Multi-Input Multi-Output)

[101] MIMO 기술은 지금까지 일반적으로 한 개의 송신안테나와 한 개의 수신안테나를 사용했던 것에서 탈피하여, 다중 송신(Tx) 안테나와 다중 수신(Rx) 안테나를 사용한다. 다시 말해서, MIMO 기술은 무선 통신 시스템의 송신단 또는

수신단에서 다중 입출력 안테나를 사용하여 용량 증대 또는 성능 개성을 꾀하기 위한 기술이다. 이하에서는 'MIMO'를 '다중 입출력 안테나'라 칭하기로 한다.

[102] 더 구체적으로, 다중 입출력 안테나 기술은 하나의 완전한 메시지(total message)를 수신하기 위하여 한 개의 안테나 경로에 의존하지 않으며, 여러 개의 안테나를 통해 수신한 복수의 데이터 조각을 수집하여 완전한 데이터를 완성시킨다. 결과적으로, 다중 입출력 안테나 기술은 특정 시스템 범위 내에서 데이터 전송율을 증가시킬 수 있으며, 또한 특정 데이터 전송율을 통해 시스템 범위를 증가시킬 수 있다.

[103] 차세대 이동통신은 기존 이동통신에 비해 훨씬 높은 데이터 전송률을 요구하므로 효율적인 다중 입출력 안테나 기술이 반드시 필요할 것으로 예상된다. 이와 같은 상황에서 MIMO 통신 기술은 이동통신 단말과 중계기 등에 폭넓게 사용할 수 있는 차세대 이동통신 기술이며, 데이터 통신 확대 등으로 인해 한계 상황에 따라 다른 이동통신의 전송량 한계를 극복할 수 있는 기술로서 관심을 모으고 있다.

[104] 한편, 현재 연구되고 있는 다양한 전송효율 향상 기술 중 다중 입출력 안테나(MIMO) 기술은 추가적인 주파수 할당이나 전력증가 없이도 통신 용량 및 송수신 성능을 획기적으로 향상시킬 수 있는 방법으로서 현재 가장 큰 주목을 받고 있다.

[105] 도 5는 일반적인 다중 입출력 안테나(MIMO) 통신 시스템의 구성도이다.

[106] 도 5를 참조하면, 송신 안테나의 수를 N_T개로, 수신 안테나의 수를 N_R개로 동시에 늘리게 되면, 송신기나 수신기에서만 다수의 안테나를 사용하게 되는 경우와 달리 안테나 수에 비례하여 이론적인 채널 전송 용량이 증가하므로, 전송 레이트(transfer rate)를 향상시키고, 주파수 효율을 획기적으로 향상시킬 수 있다. 이 경우, 채널 전송 용량의 증가에 따른 전송 레이트는 하나의 안테나를 이용하는 경우의 최대 전송 레이트(R_o)에 다음과 같은 레이트 증가율(R_i)이 곱해진 만큼으로 이론적으로 증가할 수 있다.

[107] [수식1]

$$R_i = \min\left(N_T, N_R\right)$$

[108] 즉, 예를 들어, 4개의 송신 안테나와 4개의 수신 안테나를 이용하는 MIMO 통신 시스템에서는 단일 안테나 시스템에 비해 이론상 4배의 전송 레이트를 획득할 수 있다.

[109] 이와 같은 다중 입출력 안테나의 기술은 다양한 채널 경로를 통과한 심볼들을 이용하여 전송 신뢰도를 높이는 공간 다이버시티(spatial diversity) 방식과, 다수의 송신 안테나를 이용하여 다수의 데이터 심볼을 동시에 송신하여 전송률을 향상시키는 공간 멀티플렉싱(spatial multiplexing) 방식으로 나눌 수 있다. 또한 이러한 두 가지 방식을 적절히 결합하여 각각의 장점을 적절히 얻고자 하는 방식에 대한 연구도 최근 많이 연구되고 있는 분야이다.

[110] 각각의 방식에 대해 좀더 구체적으로 살펴보면 다음과 같다.

[111] 첫째로, 공간 다이버시티 방식의 경우에는 시공간 블록 부호 계열과, 다이버시티 이득과 부호화 이득을 동시에 이용하는 시공간 트렐리스(Trelis) 부호 계열 방식이 있다. 일반적으로 비트 오류율 개선 성능과 부호 생성 자유도는 트렐리스 부호 방식이 우수하지만, 연산 복잡도는 시공간 블록 부호가 간단하다. 이와 같은 공간 다이버서티 이득은 송신 안테나 수(N_T)와 수신 안테나 수(N_R)의 곱(N_T × N_R)에 해당되는 양을 얻을 수 있다.

[112] 둘째로, 공간 멀티플렉싱 기법은 각 송신 안테나에서 서로 다른 데이터 열을 송신하는 방법인데, 이때 수신기에서는 송신기로부터 동시에 전송된 데이터 사이에 상호 간섭이 발생하게 된다. 수신기에서는 이 간섭을 적절한 신호처리 기법을 이용하여 제거한 후 수신한다. 여기에 사용되는 잡음 제거 방식은 MLD(maximum likelihood detection) 수신기, ZF(zero-forcing) 수신기, MMSE(minimum mean square error) 수신기, D-BLAST (Diagonal-Bell Laboratories Layered Space-Time), V-BLAST(Vertical-Bell Laboratories Layered Space-Time) 등이 있으며, 특히 송신단에서 채널 정보를 알 수 있는 경우에는 SVD(singular value decomposition) 방식 등을 사용할 수 있다.

[113] 셋째로, 공간 다이버시티와 공간 멀티플렉싱의 결합된 기법을 들 수 있다. 공간 다이버시티 이득만을 얻을 경우 다이버시티 차수의 증가에 따른 성능개선 이득이 점차 포화되며, 공간 멀티플렉싱 이득만을 취하면 무선 채널에서 전송 신뢰도가 떨어진다. 이를 해결하면서 두 가지 이득을 모두 얻는 방식들이 연구되어 왔으며, 이 중 시공간 블록 부호 (Double-STTD), 시공간 BICM(STBICM) 등의 방식이 있다.

[114] 상술한 바와 같은 다중 입출력 안테나 시스템에 있어서의 통신 방법을 보다 구체적인 방법으로 설명하기 위해 이를 수학적으로 모델링하는 경우 다음과 같이 나타낼 수 있다.

[115] 먼저, 도 5에 도시된 바와 같이 N_T개의 송신 안테나와 N_R개의 수신 안테나가 존재하는 것을 가정한다.

[116] 먼저, 송신 신호에 대해 살펴보면, 이와 같이 N_T개의 송신 안테나가 있는 경우 최대 전송 가능한 정보는 N_T개 이므로, 이를 다음과 같은 벡터로 나타낼 수 있다.

[117] [수식2]

$$\mathbf{s} = \left[s_1, s_2, \cdots, s_{N_T}\right]^T$$

[118] 한편, 각각의 전송 정보 s_1, s_2, ..., s_N_T에 있어 전송 전력을 달리 할 수 있으며, 이때 각각의 전송 전력을 P_1, P_2, ..., P_N_T라 하면, 전송 전력이 조정된 전송 정보는 다음과 같은 벡터로 나타낼 수 있다.

[119] [수식3]

$$\hat{\mathbf{s}} = \left[\hat{s}_1, \hat{s}_2, \cdots, \hat{s}_{N_T}\right]^T = \left[P_1 s_1, P_2 s_2, \cdots, P_{N_T} s_{N_T}\right]^T$$

[120] 또한, 수학식 3의 전송 전력이 조정된 전송 정보를 전송 전력의 대각 행렬 P로 다음과 같이 나타낼 수 있다.

[121] [수식4]

$$\hat{\mathbf{s}} = \begin{bmatrix} P_1 & & & 0 \\ & P_2 & & \\ & & \ddots & \\ 0 & & & P_{N_T} \end{bmatrix} \begin{bmatrix} s_1 \\ s_2 \\ \vdots \\ s_{N_T} \end{bmatrix} = \mathbf{Ps}$$

[122] 한편, 수학식 4의 전송 전력이 조정된 정보 벡터는 그 후 가중치 행렬 W가 곱해져 실제 전송되는 N_T개의 전송 신호 x_1, x_2, ..., x_N_T를 구성한다. 여기서, 가중치 행렬은 전송 채널 상황 등에 따라 전송 정보를 각 안테나에 적절히 분배해 주는 역할을 수행한다. 이와 같은 전송 신호 x_1, x_2, ..., x_N_T를 벡터 x를 이용하여 다음과 같이 나타낼 수 있다.

[123] [수식5]

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_i \\ \vdots \\ x_{N_T} \end{bmatrix} = \begin{bmatrix} w_{11} & w_{12} & \cdots & w_{1N_T} \\ w_{21} & w_{22} & \cdots & w_{2N_T} \\ \vdots & & \ddots & \\ w_{i1} & w_{i2} & \cdots & w_{iN_T} \\ \vdots & & \ddots & \\ w_{N_T1} & w_{N_T2} & \cdots & w_{N_TN_T} \end{bmatrix} \begin{bmatrix} \hat{s}_1 \\ \hat{s}_2 \\ \vdots \\ \hat{s}_j \\ \vdots \\ \hat{s}_{N_T} \end{bmatrix} = \mathbf{W}\hat{\mathbf{s}} = \mathbf{WPs}$$

[124] 여기서, w_ij는 i번째 송신 안테나와 j번째 전송 정보간의 가중치를 나타내며, W는 이를 행렬로 나타낸 것이다. 이와 같은 행렬 W를 가중치 행렬(Weight Matrix) 또는 프리코딩 행렬(Precoding Matrix)라 부른다.

[125] 한편, 상술한 바와 같은 전송 신호(x)는 공간 다이버시티를 사용하는 경우와 공간 멀티플랙싱을 사용하는 경우로 나누어 생각해 볼 수 있다.

[126] 공간 멀티플랙싱을 사용하는 경우는 서로 다른 신호를 다중화하여 보내게 되므로, 정보 벡터 s의 원소들이 모두 다른 값을 가지게 되는 반면, 공간 다이버시티를 사용하게 되면 같은 신호를 여러 채널 경로를 통하여 보내게 되므로 정보 벡터 s의 원소들이 모두 같은 값을 갖게 된다.

[127] 물론, 공간 멀티플랙싱과 공간 다이버시티를 혼합하는 방법도 고려 가능하다. 즉, 예를 들어 3 개의 송신 안테나를 통하여 같은 신호를 공간 다이버시티를 이용하여 전송하고, 나머지는 각각 다른 신호를 공간 멀티플랙싱하여 보내는 경우도 고려할 수 있다.

[128] 다음으로, 수신신호는 N_R개의 수신 안테나가 있는 경우, 각 안테나의 수신신호 y_1, y_2, ..., y_N_R을 벡터 y로 다음과 같이 나타내기로 한다.

[129] [수식6]

$$\mathbf{y} = \left[y_1, y_2, \cdots, y_{N_R} \right]^{\mathrm{T}}$$

[130] 한편, 다중 입출력 안테나 통신 시스템에 있어서의 채널을 모델링하는 경우, 각각의 채널은 송수신 안테나 인덱스에 따라 구분할 수 있으며, 송신 안테나 j로부터 수신 안테나 i를 거치는 채널을 h_ij로 표시하기로 한다. 여기서, h_ij의 인덱스의 순서가 수신 안테나 인덱스가 먼저, 송신안테나의 인덱스가 나중임에 유의한다.

[131] 이러한 채널은 여러 개를 한데 묶어서 벡터 및 행렬 형태로도 표시 가능하다. 벡터 표시의 예를 들어 설명하면 다음과 같다.

[132] 도 6은 다수의 송신 안테나에서 하나의 수신 안테나로의 채널을 나타낸 도이다.

[133] 도 6에 도시된 바와 같이 총 N_T개의 송신 안테나로부터 수신안테나 i로 도착하는 채널은 다음과 같이 표현 가능하다.

[134] [수식7]

$$\mathbf{h}_i^T = \left[h_{i1}, h_{i2}, \cdots, h_{iN_T} \right]$$

[135] 또한, 상기 수학식 7과 같은 행렬 표현을 통해 N_T개의 송신 안테나로부터 N_R개의 수신 안테나를 거치는 채널을 모두 나타내는 경우 다음과 같이 나타낼 수 있다.

[136] [수식8]

$$\mathbf{H} = \begin{bmatrix} \mathbf{h}_1^{\mathrm{T}} \\ \mathbf{h}_2^{\mathrm{T}} \\ \vdots \\ \mathbf{h}_i^{\mathrm{T}} \\ \vdots \\ \mathbf{h}_{\mathrm{N_R}}^{\mathrm{T}} \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} & \cdots & h_{1N_T} \\ h_{21} & h_{22} & \cdots & h_{2N_T} \\ \vdots & & \ddots & \\ h_{i1} & h_{i2} & \cdots & h_{iN_T} \\ \vdots & & \ddots & \\ h_{N_R1} & h_{N_R2} & \cdots & h_{N_RN_T} \end{bmatrix}$$

[137] 한편, 실제 채널은 위와 같은 채널 행렬 H를 거친 후에 백색 잡음(AWGN: Additive White Gaussian Noise)가 더해지게 되므로, N_R개의 수신 안테나 각각에 더해지는 백색 잡음 n_1, n_2, ..., n_N_R을 백터로 표현하면 다음과 같다.

[138] [수식9]

$$\mathbf{n} = \left[n_1, n_2, \cdots, n_{N_R} \right]^{\mathrm{T}}$$

[139] 상술한 바와 같은 전송 신호, 수신 신호, 채널, 및 백색 잡음의 모델링을 통해 다중 입출력 안테나 통신 시스템에서의 각각은 다음과 같은 관계를 통해 나타낼 수 있다.

[140] [수식10]

$$\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_i \\ \vdots \\ y_{N_R} \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} & \cdots & h_{1N_T} \\ h_{21} & h_{22} & \cdots & h_{2N_T} \\ \vdots & & \ddots & \\ h_{i1} & h_{i2} & \cdots & h_{iN_T} \\ \vdots & & \ddots & \\ h_{N_R1} & h_{N_R2} & \cdots & h_{N_RN_T} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_j \\ \vdots \\ x_{N_T} \end{bmatrix} + \begin{bmatrix} n_1 \\ n_2 \\ \vdots \\ n_i \\ \vdots \\ n_{N_R} \end{bmatrix} = \mathbf{Hx} + \mathbf{n}$$

[141] 한편, 채널의 상태를 나타내는 채널 행렬 H의 행과 열의 수는 송수신 안테나 수에 의해서 결정된다. 채널 행렬 H는 앞서 살펴본 바와 같이 행의 수는 수신 안테나의 수 N_R과 같아지고, 열의 수는 송신 안테나의 수 N_T와 같아 지게 된다. 즉, 채널 행렬 H는 N_R×N_T 행렬이 된다.

[142] 일반적으로, 행렬의 랭크(rank)는 서로 독립인(independent) 행 또는 열의 개수 중에서 최소 개수로 정의된다. 따라서, 행렬의 랭크는 행 또는 열의 개수보다 클 수 없게 된다. 수식적으로 예를 들면, 채널 행렬 H의 랭크(rank(H))는 다음과 같이 제한된다.

[143] [수식11]

$$rank(\mathbf{H}) \le \min(N_T, N_R)$$

[144] 또한, 행렬을 고유치 분해(Eigen value decomposition)를 하였을 때, 랭크는 고유치(eigen value)들 중에서 0이 아닌 고유치들의 개수로 정의할 수 있다. 비슷한 방법으로, 랭크를 SVD(singular value decomposition) 했을 때 0이 아닌 특이값(singular value)들의 개수로 정의할 수 있다. 따라서, 채널 행렬에서 랭크의 물리적인 의미는 주어진 채널에서 서로 다른 정보를 보낼 수 있는 최대 수라고 할 수 있다.

[145] 본 명세서에 있어, MIMO 전송에 대한 '랭크(Rank)'는 특정 시점 및 특정 주파수 자원에서 독립적으로 신호를 전송할 수 있는 경로의 수를 나타내며, '레이어(layer)의 개수'는 각 경로를 통해 전송되는 신호 스트림의 개수를 나타낸다. 일반적으로 송신단은 신호 전송에 이용되는 랭크 수에 대응하는 개수의 레이어를 전송하기 때문에 특별한 언급이 없는 한 랭크는 레이어 개수와 동일한 의미를 가진다.

[146]

[147] <u>캐리어 병합(Carrier Aggregation)</u>

[148] 본 발명의 실시예들에서 고려하는 통신 환경은 멀티 캐리어(Multi-carrier) 지원 환경을 모두 포함한다. 즉, 본 발명에서 사용되는 멀티 캐리어 시스템 또는 캐리어 병합(CA: Carrier Aggregation) 시스템이라 함은 광대역을 지원하기 위해서, 목표로 하는 광대역을 구성할 때 목표 대역보다 작은 대역폭(bandwidth)을 가지는 1개 이상의 컴포넌트 캐리어(CC: Component

Carrier)를 병합(aggregation)하여 사용하는 시스템을 말한다.

[149] 본 발명에서 멀티 캐리어는 캐리어의 병합(또는, 반송파 집성)을 의미하며, 이때 캐리어의 병합은 인접한(contiguous) 캐리어 간의 병합뿐 아니라 비 인접한(non-contiguous) 캐리어 간의 병합을 모두 의미한다. 또한, 하향링크와 상향링크 간에 집성되는 컴포넌트 캐리어들의 수는 다르게 설정될 수 있다. 하향링크 컴포넌트 캐리어(이하, 'DL CC'라 한다.) 수와 상향링크 컴포넌트 캐리어(이하, 'UL CC'라 한다.) 수가 동일한 경우를 대칭적(symmetric) 집성이라고 하고, 그 수가 다른 경우를 비대칭적(asymmetric) 집성이라고 한다. 이와 같은 캐리어 병합은 반송파 집성, 대역폭 집성(bandwidth aggregation), 스펙트럼 집성(spectrum aggregation) 등과 같은 용어와 혼용되어 사용될 수 있다.

[150] 두 개 이상의 컴포넌트 캐리어가 결합되어 구성되는 캐리어 병합은 LTE-A 시스템에서는 100MHz 대역폭까지 지원하는 것을 목표로 한다. 목표 대역보다 작은 대역폭을 가지는 1개 이상의 캐리어를 결합할 때, 결합하는 캐리어의 대역폭은 기존 IMT 시스템과의 호환성(backward compatibility) 유지를 위해서 기존 시스템에서 사용하는 대역폭으로 제한할 수 있다. 예를 들어서 기존의 3GPP LTE 시스템에서는 {1.4, 3, 5, 10, 15, 20}MHz 대역폭을 지원하며, 3GPP LTE-advanced 시스템(즉, LTE-A)에서는 기존 시스템과의 호환을 위해 상기의 대역폭들만을 이용하여 20MHz보다 큰 대역폭을 지원하도록 할 수 있다. 또한, 본 발명에서 사용되는 캐리어 병합 시스템은 기존 시스템에서 사용하는 대역폭과 상관없이 새로운 대역폭을 정의하여 캐리어 병합을 지원하도록 할 수도 있다.

[151] LTE-A 시스템은 무선 자원을 관리하기 위해 셀(cell)의 개념을 사용한다.

[152] 상술한 캐리어 병합 환경은 다중 셀(multiple cells) 환경으로 일컬을 수 있다. 셀은 하향링크 자원(DL CC)과 상향링크 자원(UL CC) 한 쌍의 조합으로 정의되나, 상향링크 자원은 필수 요소는 아니다. 따라서, 셀은 하향링크 자원 단독, 또는 하향링크 자원과 상향링크 자원으로 구성될 수 있다. 특정 단말이 단 하나의 설정된 서빙 셀(configured serving cell)을 가지는 경우 1개의 DL CC와 1개의 UL CC를 가질 수 있으나, 특정 단말이 2개 이상의 설정된 서빙 셀을 가지는 경우에는 셀의 수만큼의 DL CC를 가지며 UL CC의 수는 그와 같거나 그보다 작을 수 있다.

[153] 또는, 그 반대로 DL CC와 UL CC가 구성될 수도 있다. 즉, 특정 단말이 다수의 설정된 서빙 셀을 가지는 경우 DL CC의 수보다 UL CC가 더 많은 캐리어 병합 환경도 지원될 수 있다. 즉, 캐리어 병합(carrier aggregation)은 각각 캐리어 주파수(셀의 중심 주파수)가 서로 다른 둘 이상의 셀들의 병합으로 이해될 수 있다. 여기서, 말하는 '셀(Cell)'은 일반적으로 사용되는 기지국이 커버하는 영역으로서의 '셀'과는 구분되어야 한다.

[154] LTE-A 시스템에서 사용되는 셀은 프라이머리 셀(PCell: Primary Cell) 및 세컨더리 셀(SCell: Secondary Cell)을 포함한다. P셀과 S셀은 서빙 셀(Serving

Cell)로 사용될 수 있다. RRC_CONNECTED 상태에 있지만 캐리어 병합이 설정되지 않았거나 캐리어 병합을 지원하지 않는 단말의 경우, P셀로만 구성된 서빙 셀이 단 하나 존재한다. 반면, RRC_CONNECTED 상태에 있고 캐리어 병합이 설정된 단말의 경우 하나 이상의 서빙 셀이 존재할 수 있으며, 전체 서빙 셀에는 P셀과 하나 이상의 S셀이 포함된다.

[155] 서빙 셀(P셀과 S셀)은 RRC 파라미터를 통해 설정될 수 있다. PhysCellId는 셀의 물리 계층 식별자로 0부터 503까지의 정수값을 가진다. SCellIndex는 S셀을 식별하기 위하여 사용되는 간략한(short) 식별자로 1부터 7까지의 정수값을 가진다. ServCellIndex는 서빙 셀(P셀 또는 S셀)을 식별하기 위하여 사용되는 간략한(short) 식별자로 0부터 7까지의 정수값을 가진다. 0값은 P셀에 적용되며, SCellIndex는 S셀에 적용하기 위하여 미리 부여된다. 즉, ServCellIndex에서 가장 작은 셀 ID (또는 셀 인덱스)을 가지는 셀이 P셀이 된다.

[156] P셀은 프라이머리 주파수(또는, primary CC) 상에서 동작하는 셀을 의미한다. 단말이 초기 연결 설정(initial connection establishment) 과정을 수행하거나 연결 재-설정 과정을 수행하는데 사용될 수 있으며, 핸드오버 과정에서 지시된 셀을 지칭할 수도 있다. 또한, P셀은 캐리어 병합 환경에서 설정된 서빙 셀 중 제어관련 통신의 중심이 되는 셀을 의미한다. 즉, 단말은 자신의 P셀에서만 PUCCH를 할당 받아 전송할 수 있으며, 시스템 정보를 획득하거나 모니터링 절차를 변경하는데 P셀만을 이용할 수 있다. E-UTRAN(Evolved Universal Terrestrial Radio Access)은 캐리어 병합 환경을 지원하는 단말에게 이동성 제어 정보(mobilityControlInfo)를 포함하는 상위 계층의 RRC 연결 재설정(RRCConnectionReconfigutaion) 메시지를 이용하여 핸드오버 절차를 위해 P셀만을 변경할 수도 있다.

[157] S셀은 세컨더리 주파수(또는, Secondary CC) 상에서 동작하는 셀을 의미할 수 있다. 특정 단말에 P셀은 하나만 할당되며, S셀은 하나 이상 할당될 수 있다. S셀은 RRC 연결이 설정이 이루어진 이후에 구성 가능하고 추가적인 무선 자원을 제공하는데 사용될 수 있다. 캐리어 병합 환경에서 설정된 서빙 셀 중에서 P셀을 제외한 나머지 셀들, 즉 S셀에는 PUCCH가 존재하지 않는다. E-UTRAN은 S셀을 캐리어 병합 환경을 지원하는 단말에게 추가할 때, RRC_CONNECTED 상태에 있는 관련된 셀의 동작과 관련된 모든 시스템 정보를 특정 시그널(dedicated signal)을 통해 제공할 수 있다. 시스템 정보의 변경은 관련된 S셀의 해제 및 추가에 의하여 제어될 수 있으며, 이 때 상위 계층의 RRC 연결 재설정 (RRCConnectionReconfigutaion) 메시지를 이용할 수 있다. E-UTRAN은 관련된 S셀 안에서 브로드캐스트하기 보다는 단말 별로 상이한 파라미터를 가지는 특정 시그널링(dedicated signaling) 할 수 있다.

[158] 초기 보안 활성화 과정이 시작된 이후에, E-UTRAN은 연결 설정 과정에서 초기에 구성되는 P셀에 부가하여 하나 이상의 S셀을 포함하는 네트워크를 구성할 수 있다. 캐리어 병합 환경에서 P셀 및 S셀은 각각의 컴포넌트

캐리어로서 동작할 수 있다. 이하의 실시 예에서는 프라이머리 컴포넌트 캐리어(PCC)는 P셀과 동일한 의미로 사용될 수 있으며, 세컨더리 컴포넌트 캐리어(SCC)는 S셀과 동일한 의미로 사용될 수 있다.

[159] 도 7은 본 발명이 적용될 수 있는 무선 통신 시스템에서 컴포넌트 캐리어 및 캐리어 병합의 일례를 나타낸다.

[160] 도 7의 (a)는 LTE 시스템에서 사용되는 단일 캐리어 구조를 나타낸다. 컴포넌트 캐리어에는 DL CC와 UL CC가 있다. 하나의 컴포넌트 캐리어는 20MHz의 주파수 범위를 가질 수 있다.

[161] 도 7의 (b)는 LTE_A 시스템에서 사용되는 캐리어 병합 구조를 나타낸다. 도 7의 (b)의 경우에 20MHz의 주파수 크기를 갖는 3 개의 컴포넌트 캐리어가 결합된 경우를 나타낸다. DL CC와 UL CC가 각각 3 개씩 있으나, DL CC와 UL CC의 개수에 제한이 있는 것은 아니다. 캐리어 병합의 경우 단말은 3개의 CC를 동시에 모니터링할 수 있고, 하향링크 신호/데이터를 수신할 수 있고 상향링크 신호/데이터를 송신할 수 있다.

[162] 만약, 특정 셀에서 N개의 DL CC가 관리되는 경우에는, 네트워크는 단말에 M (M≤N)개의 DL CC를 할당할 수 있다. 이때, 단말은 M 개의 제한된 DL CC 만을 모니터링하고 DL 신호를 수신할 수 있다. 또한, 네트워크는 L (L≤M≤N)개의 DL CC에 우선순위를 주어 주된 DL CC를 단말에 할당할 수 있으며, 이러한 경우 UE는 L 개의 DL CC는 반드시 모니터링해야 한다. 이러한 방식은 상향링크 전송에도 똑같이 적용될 수 있다.

[163] 하향링크 자원의 반송파 주파수(또는 DL CC)와 상향링크 자원의 반송파 주파수(또는, UL CC) 사이의 링키지(linkage)는 RRC 메시지와 같은 상위계층 메시지나 시스템 정보에 의해 지시될 수 있다. 예를 들어, SIB2(System Information Block Type2)에 의해서 정의되는 링키지에 의해서 DL 자원과 UL 자원의 조합이 구성될 수 있다. 구체적으로, 링키지는 UL 그랜트를 나르는 PDCCH가 전송되는 DL CC와 상기 UL 그랜트를 사용하는 UL CC간의 맵핑 관계를 의미할 수 있으며, HARQ를 위한 데이터가 전송되는 DL CC(또는 UL CC)와 HARQ ACK/NACK 신호가 전송되는 UL CC(또는 DL CC)간의 맵핑 관계를 의미할 수도 있다.

[164] 단말이 하나 이상의 S셀이 설정되면, 네트워크는 설정된 S셀(들)을 활성화(activate) 또는 비활성화(deactivate)할 수 있다. P셀은 항상 활성화된다. 네트워크는 활성/비활성(Activation/Deactivation) MAC 제어 요소(MAC control element)를 전송함으로써 S셀(들)을 활성화 또는 비활성화한다.

[165] 활성/비활성 MAC 제어 요소는 고정된 크기를 가지고, 7개의 C 필드(C-field)와 1개의 R 필드(R-field)를 포함하는 단일의 옥텟(octet)으로 구성된다. C 필드는 각 S셀 인덱스(SCellIndex) 별로 구성되고, S셀의 활성/비활성 상태를 지시한다. C 필드 값이 '1'로 셋팅되면 해당 S셀 인덱스를 가지는 S셀의 활성화되는 것을 지시하고, '0'으로 셋팅되면 해당 S셀 인덱스를 가지는 S셀의 비활성화되는 것을

지시한다.

[166] 또한, 단말은 설정된 S셀 별로 타이머(sCellDeactivationTimer)를 유지하고, 타이머가 만료될 때 관련된 S셀을 비활성화한다. 동일한 초기 타이머 값이 타이머(sCellDeactivationTimer)의 각 인스턴스(instance)에 적용되며, RRC 시그널링에 의해 설정된다. S셀(들)이 추가될 때 또는 핸드오버 이후, 초기 S셀(들)은 비활성화 상태이다.

[167] 단말은 각 TTI에서 각각의 설정된 S셀(들)에 대하여 아래와 같은 동작을 수행한다.

[168] - 단말이 특정 TTI(서브프레임 n)에서 S셀을 활성화하는 활성/비활성 MAC 제어 요소를 수신하면, 단말은 정해진 타이밍에 해당하는 TTI(서브프레임 n+8 또는 그 이후)에서 S셀을 활성화하고, 해당 S셀과 관련된 타이머를 (재)시작시킨다. 단말이 S셀을 활성화한다는 것은 단말이 S셀 상에서 SRS(Sounding Reference Signal) 전송, S셀을 위한 CQI(Channel Quality Indicator)/PMI(Precoding Matrix Indicator)/RI(Rank Indication)/PTI(Precoding Type Indicator) 보고, S셀 상에서 PDCCH 모니터링, S셀을 위한 PDCCH 모니터링과 같은 일반 S셀 동작을 적용한다는 것을 의미한다.

[169] - 단말이 특정 TTI(서브프레임 n)에서 S셀을 비활성화하는 활성/비활성 MAC 제어 요소를 수신하거나 또는 특정 TTI(서브프레임 n) 활성화된 S셀과 관련된 타이머가 만료되면, 단말은 정해진 타이밍에 해당하는 TTI(서브프레임 n+8 또는 그 이후)에서 S셀을 비활성화하고, 해당 S셀의 타이머를 중단하며, 해당 S셀과 관련된 모든 HARQ 버퍼를 비운다(flush).

[170] - 활성화된 S셀 상의 PDCCH가 상향링크 그랜트(uplink grant) 또는 하향링크 승인(downlink assignment)을 지시하거나, 또는 활성화된 S셀을 스케줄링하는 서빙 셀 상의 PDCCH가 활성화된 S셀을 위한 상향링크 그랜트(uplink grant) 또는 하향링크 승인(downlink assignment)을 지시하면, 단말은 해당 S셀과 관련된 타이머를 재시작한다.

[171] - S셀이 비활성화되면, 단말은 S셀 상에서 SRS를 전송하지 않고, S셀을 위한 CQI/PMI/RI/PTI를 보고하지 않으며, S셀 상에서 UL-SCH를 전송하지 않으며, S셀 상에서 PDCCH를 모니터하지 않는다.

[172]

[173] **랜덤 액세스 절차(Random Access Procedure)**

[174] 이하에서는 LTE/LTE-A 시스템에서 제공하는 랜덤 액세스 절차(random access procedure)에 대해 살펴본다.

[175] 랜덤 액세스 절차는 단말이 기지국과 상향링크 동기를 얻거나 상향링크 무선 자원을 할당 받기 위해 사용된다. 단말의 전원이 켜진 후, 단말은 초기 셀과의 하향링크 동기를 획득하고 시스템 정보를 수신한다. 시스템 정보로부터 사용 가능한 랜덤 액세스 프리앰블(random access preamble)의 집합과 랜덤 액세스 프리앰블의 전송에 사용되는 무선 자원에 관한 정보를 얻는다. 랜덤 액세스

프리앰블의 전송에 사용되는 무선 자원은 적어도 하나 이상의 서브프레임 인덱스와 주파수 영역 상의 인덱스의 조합으로 특정될 수 있다. 단말은 랜덤 액세스 프리앰블의 집합으로부터 임의로 선택한 랜덤 액세스 프리앰블을 전송하고, 상기 랜덤 액세스 프리앰블을 수신한 기지국은 상향링크 동기를 위한 타이밍 정렬(TA: timing alignment) 값을 랜덤 액세스 응답을 통해 단말로 보낸다. 이로써 단말은 상향링크 동기를 획득하는 것이다.

[176] 랜덤 액세스 절차는 FDD(frequency division duplex)와 TDD(time division duplex)에서 공통적인 절차이다. 랜덤 액세스 절차는 셀 사이즈에 무관하며, 캐리어 병합(CA: carrier aggregation)이 설정된 경우 서빙 셀(serving cell)의 개수와도 무관하다.

[177] 먼저, 단말이 랜덤 액세스 절차를 수행하는 경우로는 다음과 같은 경우가 있다.

[178] - 단말이 기지국과의 RRC 연결(RRC Connection)이 없어, RRC 아이들 상태에서 초기 접속 (initial access)을 수행하는 경우

[179] - RRC 연결 재-확립 절차(RRC connection re-establishment procedure)를 수행하는 경우

[180] - 단말이 핸드오버 과정에서, 타겟(target) 셀로 처음 접속하는 경우

[181] - 기지국의 명령에 의해 랜덤 액세스 절차가 요청되는 경우

[182] - RRC 연결 상태 중, 상향링크 시간 동기가 맞지 않은 상황에서(non-synchronized) 하향링크로 전송될 데이터가 발생하는 경우

[183] - RRC 연결 상태 중, 상향링크의 시간 동기가 맞지 않거나(non-synchronized), 무선자원을 요청하기 위해 사용되는 지정된 무선자원이 할당되지 않은 상황에서, 상향링크로 전송할 데이터가 발생하는 경우

[184] - RRC 연결 상태 중, 타이밍 어드밴스(timing advance)가 필요한 상황에서 단말의 위치 결정(positioning)을 수행하는 경우

[185] - 무선 연결 실패(radio link failure) 또는 핸드오버 실패(handover failure) 시 복구 과정을 수행하는 경우

[186] 3GPP Rel-10에서는 캐리어 병합을 지원하는 무선 접속 시스템에서 하나의 특정 셀(예를 들어, P셀)에 적용 가능한 TA(timing advance) 값을 복수의 셀에 공통으로 적용하는 것을 고려하였다. 다만, 단말이 서로 다른 주파수 밴드에 속한(즉, 주파수 상에서 크게 이격된) 복수의 셀들 혹은 전파(propagation) 특성이 다른 복수의 셀들을 병합할 수 있다. 또한 특정 셀의 경우 커버리지 확대 혹은 커버리지 홀의 제거를 위해 RRH(remote radio header)(즉, 리피터), 펨토 셀(femto cell) 혹은 피코 셀(pico cell) 등과 같은 스몰 셀(small cell) 또는 세컨더리 기지국(SeNB: secondary eNB)이 셀 내에 배치되는 상황에서 단말은 하나의 셀을 통해 기지국(즉, 매크로 기지국(macro eNB))과 통신을 수행하고, 다른 셀을 통해 세컨더리 기지국과 통신을 수행하는 경우 복수의 셀들이 서로 다른 전파 지연 특성을 가지게 될 수 있다. 이 경우, 하나의 TA 값을 복수의 셀들에 공통으로 적용하는 방식으로 사용하는 상향링크 전송을 수행할 경우 복수의 셀들 상에서

전송되는 상향링크 신호의 동기에 심각한 영향을 끼칠 수 있다. 따라서, 복수의 셀들이 병합된 CA 상황에서 복수의 TA를 가지는 것이 바람직할 수 있으며, 3GPP Rel-11에서는 다중 TA(multiple TA)를 지원하기 위하여 특정 셀 그룹 단위로 TA를 독립적으로 할당하는 것을 고려한다. 이를 TA 그룹(TAG: TA group)이라 하며, TAG는 하나 이상의 셀들을 포함할 수 있으며, TAG 내 포함된 하나 이상의 셀에는 동일한 TA가 공통적으로 적용될 수 있다. 이러한 다중 TA를 지원하기 위하여, MAC TA 명령 제어 요소(element)는 2 비트의 TAG 식별자(TAG ID)와 6 비트의 TA 명령 필드로 구성된다.

[187] 캐리어 병합이 설정된 단말은 P셀과 관련되어 앞서 설명한 랜덤 액세스 절차를 수행하는 경우가 발생되면 랜덤 액세스 절차를 수행하게 된다. P셀이 속한 TAG(즉, pTAG: primary TAG)의 경우, 기존과 동일하게 P셀을 기준으로 결정되는, 혹은 P셀에 수반되는 랜덤 액세스 절차를 통해 조정되는 TA를 pTAG 내 모든 셀(들)에 적용할 수 있다. 반면, S셀로만 구성되는 TAG(즉, sTAG: secondary TAG)의 경우, sTAG 내 특정 S셀을 기준으로 결정되는 TA는 해당 sTAG 내 모든 셀(들)에 적용할 수 있으며, 이 때 TA는 기지국에 의해 개시되 랜덤 액세스 절차에 의해 획득될 수 있다. 구체적으로, sTAG 내에서 S셀은 RACH(Random Access Channel) 자원으로 설정되고, 기지국은 TA를 결정하기 위하여 S셀에서 RACH 접속을 요청한다. 즉, 기지국은 P셀에서 전송되는 PDCCH 오더에 의해 S셀들 상에서 RACH 전송을 개시시킨다. S셀 프리앰블에 대한 응답 메시지는 RA-RNTI를 사용하여 P셀을 통해 전송된다. 단말은 랜덤 액세스를 성공적으로 마친 S셀을 기준으로 결정되는 TA는 해당 sTAG 내 모든 셀(들)에 적용할 수 있다. 이와 같이, 랜덤 액세스 절차는 S셀에서도 해당 S셀이 속한 sTAG의 타이밍 정렬(timing alignment)을 획득하기 위하여 S셀에서도 수행될 수 있다.

[188] LTE/LTE-A 시스템에서는 랜덤 액세스 프리앰블(random access preamble, RACH preamble)을 선택하는 과정에서, 특정한 집합 안에서 단말이 임의로 하나의 프리앰블을 선택하여 사용하는 경쟁 기반 랜덤 액세스 절차(contention based random access procedure)과 기지국이 특정 단말에게만 할당해준 랜덤 액세스 프리앰블을 사용하는 비 경쟁 기반 랜덤 액세스 절차(non-contention based random access procedure)을 모두 제공한다. 다만, 비 경쟁 기반 랜덤 액세스 절차는, 상술한 핸드오버 과정, 기지국의 명령에 의해 요청되는 경우, 단말 위치 결정(positioning) 및/또는 sTAG을 위한 타이밍 어드밴스 정렬에 한하여 사용될 수 있다. 랜덤 액세스 절차가 완료된 후에 일반적인 상향링크/하향링크 전송이 발생된다.

[189] 한편, 릴레이 노드(RN: relay node) 또한 경쟁 기반 랜덤 액세스 절차와 비 경쟁 기반 랜덤 액세스 절차를 모두 지원한다. 릴레이 노드가 랜덤 액세스 절차를 수행할 때, 그 시점에서 RN 서브프레임 구성(configuration)을 중단시킨다(suspend). 즉, 이는 일시적으로 RN 서브프레임 구성을 폐기하는

것으로 의미한다. 이후, 성공적으로 랜덤 액세스 절차가 완료되는 시점에서 RN 서브프레임 구성이 재개된다.

[190] 도 8은 본 발명이 적용될 수 있는 무선 통신 시스템에서 경쟁 기반 랜덤 액세스 절차를 설명하기 위한 도면이다.

[191] (1) 제1 메시지(Msg 1, message 1)

[192] 먼저, 단말은 시스템 정보(system information) 또는 핸드오버 명령(handover command)을 통해 지시된 랜덤 액세스 프리앰블의 집합에서 임의로(randomly) 하나의 랜덤 액세스 프리앰블(random access preamble, RACH preamble)을 선택하고, 상기 랜덤 액세스 프리앰블을 전송할 수 있는 PRACH(physical RACH) 자원을 선택하여 전송한다.

[193] 랜덤 액세스 프리앰블은 RACH 전송 채널에서 6비트로 전송되고, 6비트는 RACH 전송한 단말을 식별하기 위한 5비트의 임의 식별자(radom identity)와, 추가 정보를 나타내기 위한 1비트(예를 들어, 제3 메시지(Msg 3)의 크기를 지시)로 구성된다.

[194] 단말로부터 랜덤 액세스 프리앰블을 수신한 기지국은 프리앰블을 디코딩하고, RA-RNTI를 획득한다. 랜덤 액세스 프리앰블이 전송된 PRACH와 관련된 RA-RNTI는 해당 단말이 전송한 랜덤 액세스 프리앰블의 시간-주파수 자원에 따라 결정된다.

[195] (2) 제2 메시지(Msg 2, message 2)

[196] 기지국은 제1 메시지 상의 프리앰블을 통해서 획득한 RA-RNTI로 지시(address)되는 랜덤 액세스 응답(random access response)을 단말로 전송한다. 랜덤 액세스 응답에는 랜덤 액세스 프리앰블 구분자/식별자(RA preamble index/identifier), 상향링크 무선자원을 알려주는 상향링크 승인(UL grant), 임시 셀 식별자(TC-RNTI: Temporary C-RNTI) 그리고 시간 동기 값(TAC: time alignment command)들이 포함될 수 있다. TAC는 기지국이 단말에게 상향링크 시간 정렬(time alignment)을 유지하기 위해 보내는 시간 동기 값을 지시하는 정보이다. 단말은 상기 시간 동기 값을 이용하여, 상향링크 전송 타이밍을 갱신한다. 단말이 시간 동기를 갱신하면, 시간 동기 타이머(time alignment timer)를 개시 또는 재시작한다. UL grant는 후술하는 스케줄링 메시지(제3 메시지)의 전송에 사용되는 상향링크 자원 할당 및 TPC(transmit power command)를 포함한다. TPC는 스케줄링된 PUSCH를 위한 전송 파워의 결정에 사용된다.

[197] 단말은 랜덤 액세스 프리앰블을 전송 후에, 기지국이 시스템 정보 또는 핸드오버 명령을 통해 지시된 랜덤 액세스 응답 윈도우(random access response window) 내에서 자신의 랜덤 액세스 응답(random access response)의 수신을 시도하며, PRACH에 대응되는 RA-RNTI로 마스킹된 PDCCH를 검출하고, 검출된 PDCCH에 의해 지시되는 PDSCH를 수신하게 된다. 랜덤 액세스 응답 정보는 MAC PDU(MAC packet data unit)의 형식으로 전송될 수 있으며, 상기 MAC

PDU는 PDSCH을 통해 전달될 수 있다. PDCCH에는 상기 PDSCH를 수신해야 하는 단말의 정보와, 상기 PDSCH의 무선 자원의 주파수 그리고 시간 정보, 그리고 상기 PDSCH의 전송 형식 등이 포함되어 있는 것이 바람직하다. 상술한 바와 같이, 일단 단말이 자신에게 전송되는 PDCCH의 검출에 성공하면, 상기 PDCCH의 정보들에 따라 PDSCH로 전송되는 랜덤 액세스 응답을 적절히 수신할 수 있다.

[198] 랜덤 액세스 응답 윈도우는 프리앰블을 전송한 단말이 랜덤 액세스 응답 메시지를 수신하기 위해서 대기하는 최대 시구간을 의미한다. 랜덤 액세스 응답 윈도우는 프리앰블이 전송되는 마지막 서브프레임에서 3개의 서브프레임 이후의 서브프레임으로부터 시작하여 'ra-ResponseWindowSize'의 길이를 가진다. 즉, 단말은 프리앰블을 전송이 종료된 서브프레임으로부터 3개의 서브프레임 이후부터 확보한 랜덤 액세스 윈도우 동안 랜덤 액세스 응답을 수신하기 위해 대기한다. 단말은 시스템 정보(system information)을 통해 랜덤 액세스 윈도우 사이즈('ra-ResponseWindowsize') 파라미터 값을 획득할 수 있으며, 랜덤 액세스 윈도우 사이즈는 2부터 10 사이의 값으로 결정될 수 있다.

[199] 단말은 기지국에 전송하였던 랜덤 액세스 프리앰블과 동일한 랜덤 액세스 프리앰블 구분자/식별자를 가지는 랜덤 액세스 응답을 성공적으로 수신하면, 랜덤 액세스 응답의 모니터링을 중지한다. 반면, 랜덤 액세스 응답 윈도우가 종료될 때까지 랜덤 액세스 응답 메시지를 수신하지 못하거나, 기지국에 전송하였던 랜덤 액세스 프리앰블과 동일한 랜덤 액세스 프리앰블 구분자를 가지는 유효한 랜덤 액세스 응답을 수신하지 못한 경우 랜덤 액세스 응답의 수신은 실패하였다고 간주되고, 이후 단말은 프리앰블 재전송을 수행할 수 있다.

[200] 상술한 바와 같이 랜덤 액세스 응답에서 랜덤 액세스 프리앰블 구분자가 필요한 이유는, 하나의 랜덤 액세스 응답에는 하나 이상의 단말들을 위한 랜덤 액세스 응답 정보가 포함될 수 있기 때문에, 상기 UL grant, TC-RNTI 그리고 TAC가 어느 단말에게 유효한지를 알려주기 위는 것이 필요하기 때문이다.

[201] (3) 제3 메시지(Msg 3, message 3)

[202] 단말이 자신에게 유효한 랜덤 액세스 응답을 수신한 경우에는, 상기 랜덤 액세스 응답에 포함된 정보들을 각각 처리한다. 즉, 단말은 TAC을 적용시키고, TC-RNTI를 저장한다. 또한, UL grant를 이용하여, 단말의 버퍼에 저장된 데이터 또는 새롭게 생성된 데이터를 기지국으로 전송한다. 단말의 최초 접속의 경우, RRC 계층에서 생성되어 CCCH를 통해 전달된 RRC 연결 요청이 제3 메시지에 포함되어 전송될 수 있으며, RRC 연결 재확립 절차의 경우 RRC 계층에서 생성되어 CCCH를 통해 전달된 RRC 연결 재확립 요청이 제3 메시지에 포함되어 전송될 수 있다. 또한, NAS 접속 요청 메시지를 포함할 수도 있다.

[203] 제3 메시지는 단말의 식별자가 포함되어야 한다. 경쟁 기반 랜덤 액세스 절차에서는 기지국에서 어떠한 단말들이 상기 랜덤 액세스 절차를 수행하는지 판단할 수 없는데, 차후에 충돌 해결을 하기 위해서는 단말을 식별해야 하기

때문이다.

[204] 단말의 식별자를 포함시키는 방법으로는 두 가지 방법이 존재한다. 첫 번째 방법은 단말이 상기 랜덤 액세스 절차 이전에 이미 해당 셀에서 할당 받은 유효한 셀 식별자(C-RNTI)를 가지고 있었다면, 단말은 상기 UL grant에 대응하는 상향링크 전송 신호를 통해 자신의 셀 식별자를 전송한다. 반면에, 만약 랜덤 액세스 절차 이전에 유효한 셀 식별자를 할당 받지 못하였다면, 단말은 자신의 고유 식별자(예를 들면, S-TMSI 또는 임의 값(random number))를 포함하여 전송한다. 일반적으로 상기의 고유 식별자는 C-RNTI보다 길다. UL-SCH 상의 전송에서는 단말 특정 스크램블링이 사용된다. 다만, 단말이 아직 C-RNTI를 할당받지 못한 경우라면, 스크램블링은 C-RNTI에 기반할 수 없으며 대신 랜덤 액세스 응답에서 수신한 TC-RNTI가 사용된다. 단말은 상기 UL grant에 대응하는 데이터를 전송하였다면, 충돌 해결을 위한 타이머(contention resolution timer)를 개시한다.

[205] (4) 제4 메시지(Msg 4, message 4)

[206] 기지국은 단말로부터 제3 메시지를 통해 해당 단말의 C-RNTI를 수신한 경우 수신한 C-RNTI를 이용하여 단말에게 제4 메시지를 전송한다. 반면, 단말로부터 제3 메시지를 통해 상기 고유 식별자(즉, S-TMSI 또는 임의 값(random number))를 수신한 경우, 랜덤 액세스 응답에서 해당 단말에게 할당한 TC-RNTI를 이용하여 제4 메시지를 단말에게 전송한다. 여기서, 제4 메시지는 C-RNTI를 포함하는 RRC 연결 설정 메시지(RRC connection setup)가 해당될 수 있다.

[207] 단말은 랜덤 액세스 응답에 포함된 UL grant를 통해 자신의 식별자를 포함한 데이터를 전송한 이후, 충돌 해결을 위해 기지국의 지시를 기다린다. 즉, 특정 메시지를 수신하기 위해 PDCCH의 수신을 시도한다. 상기 PDCCH를 수신하는 방법에 있어서도 두 가지 방법이 존재한다. 앞에서 언급한 바와 같이 상기 UL grant에 대응하여 전송된 제3 메시지가 자신의 식별자가 C-RNTI인 경우, 자신의 C-RNTI를 이용하여 PDCCH의 수신을 시도하고, 상기 식별자가 고유 식별자(즉, S-TMSI 또는 임의 값(random number))인 경우에는, 랜덤 액세스 응답에 포함된 TC-RNTI를 이용하여 PDCCH의 수신을 시도한다. 그 후, 전자의 경우, 만약 상기 충돌 해결 타이머가 만료되기 전에 자신의 C-RNTI를 통해 PDCCH를 수신한 경우에, 단말은 정상적으로 랜덤 액세스 절차가 수행되었다고 판단하고, 랜덤 액세스 절차를 종료한다. 후자의 경우에는 상기 충돌 해결 타이머가 만료되기 전에 TC-RNTI를 통해 PDCCH를 수신하였다면, 상기 PDCCH가 지시하는 PDSCH이 전달하는 데이터를 확인한다. 만약 상기 데이터의 내용에 자신의 고유 식별자가 포함되어 있다면, 단말은 정상적으로 랜덤 액세스 절차가 수행되었다고 판단하고, 랜덤 액세스 절차를 종료한다. 제4 메시지를 통해 단말은 C-RNTI를 획득하고, 이후 단말과 네트워크는 C-RNTI를 이용하여 단말 특정 메시지(dedicated message)를 송수신하게 된다.

[208] 다음은 랜덤 액세스에서 충돌 해결을 위한 방법에 대하여 설명한다.

[209] 랜덤 액세스를 수행함에 있어서 충돌이 발생하는 이유는 기본적으로 랜덤 액세스 프리앰블의 수가 유한하기 때문이다. 즉, 기지국은 모든 단말들에게 단말 고유의 랜덤 액세스 프리앰블을 부여할 수 없기 때문에, 단말은 공통의 랜덤 액세스 프리앰블들 중에서 임의적으로 하나를 선택해서 전송하게 된다. 이에 따라 동일한 무선 자원(PRACH 자원)을 통해 둘 이상의 단말들이 같은 랜덤 액세스 프리앰블을 선택하여 전송하게 되는 경우가 발생하지만, 기지국에서는 하나의 단말에게서 전송되는 하나의 랜덤 액세스 프리앰블로 판단하게 된다. 이로 인해, 기지국은 랜덤 액세스 응답을 단말에게 전송하고 랜덤 액세스 응답은 하나의 단말이 수신할 것으로 예측한다. 하지만, 상술한 바와 같이 충돌이 발생할 수 있기 때문에, 둘 이상의 단말들이 하나의 랜덤 액세스 응답을 수신하게 되며, 이에 따라 단말마다 각각 랜덤 액세스 응답의 수신에 따른 동작을 수행하게 된다. 즉, 랜덤 액세스 응답에 포함된 하나의 UL Grant를 이용하여, 둘 이상의 단말들이 서로 다른 데이터를 동일한 무선자원에 전송하게 되는 문제점이 발생하게 된다. 이에 따라, 상기 데이터의 전송은 모두 실패할 수도 있고, 단말들의 위치 또는 전송파워에 따라 특정 단말의 데이터만을 기지국에서 수신할 수도 있다. 후자의 경우, 둘 이상의 단말들은 모두 자신의 데이터의 전송이 성공했다고 가정하기 때문에, 기지국은 경쟁에서 실패한 단말들에게 실패 사실에 대한 정보를 알려주어야 한다. 즉, 상기 경쟁의 실패 또는 성공에 대한 정보를 알려주는 것이 충돌 해결(contention resolution)라 한다.

[210] 충돌 해결 방법에는 두 가지 방법이 있는데 한 가지 방법은, 충돌 해결 타이머(contention resolution timer)를 이용하는 방법과, 다른 한가지 방법은 성공한 단말의 식별자를 단말들에게 전송하는 방법이다. 전자의 경우는, 단말이 랜덤 액세스 과정 전에 이미 고유의 C-RNTI를 가지고 있는 경우에 사용된다. 즉, 이미 C-RNTI를 가지고 있는 단말은 랜덤 액세스 응답에 따라 자신의 C-RNTI를 포함한 데이터를 기지국으로 전송하고, 충돌 해결 타이머를 작동한다. 그리고, 충돌 해결 타이머가 만료되기 전에, 자신의 C-RNTI에 의해 지시되는 PDCCH 정보가 수신되면, 단말은 자신이 경쟁에서 성공했다고 판단하고, 랜덤 액세스를 정상적으로 마치게 된다. 반대로, 만약 충돌 해결 타이머가 만료되기 전에, 자신의 C-RNTI에 의해 지시되는 PDCCH를 전송 받지 못한 경우는, 자신이 경쟁에서 실패했다고 판단하고, 랜덤 액세스 과정을 다시 수행하거나, 상위 계층으로 실패 사실을 통보할 수 있다. 충돌 해소 방법 중 후자의 경우, 즉 성공한 단말의 식별자를 전송하는 방법은, 단말이 랜덤 액세스 과정 전에 고유의 셀 식별자가 없는 경우에 사용된다. 즉, 단말 자신이 셀 식별자가 없는 경우, 랜덤 액세스 응답에 포함된 UL Grant 정보에 따라 데이터에 셀 식별자 보다 상위 식별자(S-TMSI 또는 random number)를 포함하여 전송하고, 단말은 충돌 해결 타이머를 작동시킨다. 충돌 해결 타이머가 만료되기 전에, 자신의 상위 식별자를 포함한 데이터가 DL-SCH로 전송된 경우, 단말은 랜덤 액세스 과정이 성공했다고 판단한다. 반면에, 충돌 해결 타이머가 만료되기 전에, 자신의 상위

식별자를 포함한 데이터를 DL-SCH로 전송 받지 못하는 경우에는, 단말은 랜덤 액세스 과정이 실패했다고 판단하게 되는 것이다.

[211] 한편, 비경쟁 기반 임의접속 과정에서의 동작은 도 8에 도시된 경쟁 기반 임의접속 과정과 달리 제1 메시지 전송 및 제2 메시지 전송만으로 임의접속 절차가 종료되게 된다. 다만, 제1 메시지로서 단말이 기지국에 임의접속 프리엠블을 전송하기 전에 단말은 기지국으로부터 임의접속 프리엠블을 할당받게 되며, 이 할당받은 임의접속 프리엠블을 기지국에 제1 메시지로서 전송하고, 기지국으로부터 임의접속 응답을 수신함으로써 임의접속 절차가 종료되게 된다.

[212]

[213] 참조 신호(RS: Reference Signal)

[214] 무선 통신 시스템에서 데이터는 무선 채널을 통해 전송되기 때문에, 신호는 전송 중에 왜곡될 수 있다. 수신단에서 왜곡된 신호를 정확하게 수신하기 위하여, 수신된 신호의 왜곡은 채널 정보를 이용하여 보정되어야 한다. 채널 정보를 검출하기 위하여 송신측과 수신측 모두 알고 있는 신호 전송 방법과 신호가 채널을 통해 전송될 때 왜곡된 정도를 이용하여 채널 정보를 검출하는 방법을 주로 이용한다. 상술한 신호를 파일럿 신호 또는 참조 신호(RS: reference signal)라고 한다.

[215] 또한 최근 대부분의 이동통신 시스템에서 패킷을 전송할 때, 지금까지 한 개의 송신안테나와 한 개의 수신안테나를 사용했던 것에서 탈피, 다중송신안테나와 다중수신안테나를 채택해 송수신 데이터 효율을 향상시킬 수 있는 방법을 사용한다. 다중 입출력 안테나를 이용하여 데이터를 송수신할 때, 신호를 정확하게 수신하기 위하여 송신 안테나와 수신 안테나 간의 채널 상태가 검출되어야 한다. 따라서 각 송신 안테나는 개별적인 참조 신호를 가져야 한다.

[216] 이동 통신 시스템에서 RS는 그 목적에 따라 크게 두 가지로 구분될 수 있다. 채널 정보 획득을 위한 목적의 RS와 데이터 복조를 위해 사용되는 RS가 있다. 전자는 UE가 하향 링크로의 채널 정보를 획득하는데 그 목적이 있으므로, 광대역으로 전송되어야 하고, 특정 서브 프레임에서 하향 링크 데이터를 수신하지 않는 UE라도 그 RS를 수신하고 측정할 수 있어야 한다. 또한 이는 핸드오버 등의 측정 등을 위해서도 사용된다. 후자는 기지국이 하향링크를 보낼 때 해당 리소스에 함께 보내는 RS로서, UE는 해당 RS를 수신함으로써 채널 추정을 할 수 있고, 따라서 데이터를 복조할 수 있게 된다. 이 RS는 데이터가 전송되는 영역에 전송되어야 한다.

[217] 하향 참조 신호는 셀 내 모든 단말이 공유하는 채널 상태에 대한 정보 획득 및 핸드오버 등의 측정 등을 위한 하나의 공통 참조 신호(CRS: common RS)와 특정 단말만을 위하여 데이터 복조를 위해 사용되는 전용 참조 신호(dedicated RS)가 있다. 이와 같은 참조 신호들을 이용하여 복조(demodulation)와 채널 측정(channel measurement)을 위한 정보를 제공할 수 있다. 즉, DRS는 데이터 복조용으로만

사용되며 CRS는 채널 정보 획득 및 데이터 복조의 두 가지 목적으로 다 사용된다.

[218] 수신 측(즉, 단말)은 CRS로부터 채널 상태를 측정하고, CQI(Channel Quality Indicator), PMI(Precoding Matrix Index) 및/또는 RI(Rank Indicator)와 같은 채널 품질과 관련된 지시자를 송신 측(즉, 기지국)으로 피드백한다. CRS는 셀 특정 기준신호(cell-specific RS)라고도 한다. 반면, 채널 상태 정보(CSI: Channel State Information)의 피드백과 관련된 참조 신호를 CSI-RS라고 정의할 수 있다.

[219] DRS는 PDSCH 상의 데이터 복조가 필요한 경우 자원 요소들을 통해 전송될 수 있다. 단말은 상위 계층을 통하여 DRS의 존재 여부를 수신할 수 있으며, 상응하는 PDSCH가 매핑되었을 때만 유효하다. DRS를 단말 특정 참조 신호(UE-specific RS) 또는 복조 참조 신호(DMRS: Demodulation RS)라고 할 수 있다.

[220] 도 9는 본 발명이 적용될 수 있는 무선 통신 시스템에서 하향링크 자원 블록 쌍에 매핑된 참조 신호 패턴을 예시한다.

[221] 도 9를 참조하면, 참조 신호가 매핑되는 단위로 하향링크 자원 블록 쌍은 시간 영역에서 하나의 서브 프레임 × 주파수 영역에서 12개의 부 반송파로 나타낼 수 있다. 즉, 시간 축(x축) 상에서 하나의 자원 블록 쌍은 일반 순환 전치(normal CP: normal Cyclic Prefix) 인 경우 14개의 OFDM 심볼의 길이를 가지고(도 9(a)의 경우), 확장 순환 전치(extended CP: extended Cyclic Prefix)인 경우 12개의 OFDM 심볼의 길이를 가진다(도 9(b)의 경우). 자원 블록 격자에서 '0', '1', '2' 및 '3'으로 기재된 자원 요소들(REs)은 각각 안테나 포트 인덱스 '0', '1', '2' 및 '3'의 CRS의 위치를 의미하며, 'D'로 기재된 자원 요소들은 DRS의 위치를 의미한다.

[222] 이하 CRS에 대하여 좀 더 상세하게 기술하면, CRS는 물리적 안테나의 채널을 추정하기 위해 사용되고, 셀 내에 위치한 모든 단말에 공통적으로 수신될 수 있는 참조 신호로써 전체 주파수 대역에 분포된다. 즉, 이 CRS는 cell-specific한 시그널로, 광대역에 대해서 매 서브 프레임마다 전송된다. 또한, CRS는 채널 품질 정보(CSI) 및 데이터 복조를 위해 이용될 수 있다.

[223] CRS는 전송 측(기지국)에서의 안테나 배열에 따라 다양한 포맷으로 정의된다. 3GPP LTE 시스템(예를 들어, 릴리즈-8)에서는 기지국의 전송 안테나 개수에 따라서 최대 4개의 안테나 포트에 대한 RS가 전송된다. 하향링크 신호 송신 측은 단일의 송신 안테나, 2개의 송신 안테나 및 4개의 송신 안테나와 같이 3 종류의 안테나 배열을 가진다. 예를 들어 기지국의 송신 안테나의 개수가 두 개일 경우, 0번과 1번 안테나 포트에 대한 CRS가 전송되고, 네 개인 경우 0~3 번 안테나 포트에 대한 CRS가 각각 전송된다. 기지국의 송신 안테나가 4개일 경우 한 RB에서의 CRS 패턴은 도 9와 같다.

[224] 기지국이 단일의 송신 안테나를 사용하는 경우, 단일 안테나 포트를 위한 참조 신호가 배열된다.

[225] 기지국이 2개의 송신 안테나를 사용하는 경우, 2개의 송신 안테나 포트를 위한

참조 신호는 시분할 다중화(TDM: Time Division Multiplexing) 및/또는 주파수 분할 다중화(FDM Frequency Division Multiplexing) 방식을 이용하여 배열된다. 즉, 2개의 안테나 포트를 위한 참조 신호는 각각이 구별되기 위해 서로 다른 시간 자원 및/또는 서로 다른 주파수 자원이 할당된다.

[226] 게다가, 기지국이 4개의 송신 안테나를 사용하는 경우, 4개의 송신 안테나 포트를 위한 참조 신호는 TDM 및/또는 FDM 방식을 이용하여 배열된다. 하향링크 신호의 수신 측(단말)에 의하여 측정된 채널 정보는 단일의 송신 안테나 전송, 송신 다이버시티, 폐쇄 루프 공간 다중화(closed-loop spatial multiplexing), 개방 루프 공간 다중화(open-loop spatial multiplexing) 또는 다중 사용자-다중 입출력 안테나(Multi-User MIMO)와 같은 전송 방식을 이용하여 전송된 데이터를 복조하기 위하여 사용될 수 있다.

[227] 다중 입출력 안테나가 지원되는 경우 참조 신호가 특정의 안테나 포트로부터 전송될 때, 상기 참조 신호는 참조 신호의 패턴에 따라 특정된 자원 요소들의 위치에 전송되며, 다른 안테나 포트를 위해 특정된 자원 요소들의 위치에 전송되지 않는다. 즉, 서로 다른 안테나 사이의 참조 신호는 서로 겹치지 않는다.

[228] 이하 DRS에 대하여 좀 더 상세하게 기술하면, DRS는 데이터를 복조하기 위하여 사용된다. 다중 입출력 안테나 전송에서 특정의 단말을 위해 사용되는 선행 부호화(precoding) 가중치는 단말이 참조 신호를 수신하였을 때 각 송신 안테나에서 전송된 전송 채널과 결합되어 상응하는 채널을 추정하기 위하여 변경 없이 사용된다.

[229] 3GPP LTE 시스템(예를 들어, 릴리즈-8)은 최대로 4개의 전송 안테나를 지원하고, 랭크 1 빔포밍(beamforming)을 위한 DRS가 정의된다. 랭크 1 빔포밍을 위한 DRS는 또한 안테나 포트 인덱스 5 를 위한 참조 신호를 나타낸다.

[230] LTE 시스템의 진화 발전된 형태의 LTE-A 시스템에서 기지국의 하향 링크로 최대 8개의 송신 안테나를 지원할 수 있도록 디자인되어야 한다. 따라서 최대 8개 송신 안테나에 대한 RS 역시 지원되어야 한다. LTE 시스템에서 하향 링크 RS는 최대 4개의 안테나 포트에 대한 RS만 정의되어 있으므로, LTE-A 시스템에서 기지국이 4개 이상 최대 8개의 하향 링크 송신 안테나를 가질 경우 이들 안테나 포트에 대한 RS가 추가적으로 정의되고 디자인되어야 한다. 최대 8개의 송신 안테나 포트에 대한 RS는 위에서 설명한 채널 측정을 위한 RS와 데이터 복조를 위한 RS 두 가지가 모두 디자인되어야 한다.

[231] LTE-A 시스템을 디자인 함에 있어서 중요한 고려 사항 중 하나는 하위 호환성(backward compatibility), 즉 LTE 단말이 LTE-A 시스템에서도 아무 무리 없이 잘 동작해야 하고, 시스템 또한 이를 지원해야 한다는 것이다. RS 전송 관점에서 보았을 때, LTE에서 정의되어 있는 CRS가 전 대역으로 매 서브 프레임마다 전송되는 시간-주파수 영역에서 추가적으로 최대 8개의 송신 안테나 포트에 대한 RS가 추가적으로 정의되어야 한다. LTE-A 시스템에서 기존 LTE의 CRS와 같은 방식으로 최대 8개의 송신 안테나에 대한 RS 패턴을 매 서브

프레임마다 전 대역에 추가하게 되면 RS 오버헤드가 지나치게 커지게 된다.

[232] 따라서 LTE-A 시스템에서 새로이 디자인되는 RS는 크게 두 가지 분류로 나누게 되는데, MCS, PMI 등의 선택을 위한 채널 측정 목적의 RS (CSI-RS: Channel State Information-RS, Channel State Indication-RS 등)와 8개의 전송 안테나로 전송되는 데이터 복조를 위한 RS(DM-RS: Data Demodulation-RS)이다.

[233] 채널 측정 목적의 CSI-RS는 기존의 CRS가 채널 측정, 핸드 오버 등의 측정 등의 목적과 동시에 데이터 복조를 위해 사용되는 것과 달리 채널 측정 위주의 목적을 위해서 디자인되는 특징이 있다. 물론 이 또한 핸드 오버 등의 측정 등의 목적으로도 사용될 수도 있다. CSI-RS가 채널 상태에 대한 정보를 얻는 목적으로만 전송되므로 CRS와 달리 매 서브 프레임마다 전송되지 않아도 된다. CSI-RS의 오버헤드를 줄이기 위하여 CSI-RS는 시간 축 상에서 간헐적으로 전송된다.

[234] 데이터 복조를 위해서 해당 시간-주파수 영역에서 스케줄링 된 UE에게 전용적(dedicated)으로 DM-RS가 전송된다. 즉, 특정 UE의 DM-RS는 해당 UE가 스케줄링 된 영역, 즉 데이터를 수신 받는 시간-주파수 영역에만 전송되는 것이다.

[235] LTE-A 시스템에서 eNB는 모든 안테나 포트에 대한 CSI-RS를 전송해야 한다. 최대 8개의 송신 안테나 포트에 대한 CSI-RS를 매 서브 프레임마다 전송하는 것은 오버헤드가 너무 큰 단점이 있으므로, CSI-RS는 매 서브 프레임마다 전송되지 않고 시간 축에서 간헐적으로 전송되어야 그 오버헤드를 줄일 수 있다. 즉, CSI-RS는 한 서브 프레임의 정수 배의 주기를 가지고 주기적으로 전송되거나 특정 전송 패턴으로 전송될 수 있다. 이 때 CSI-RS가 전송되는 주기나 패턴은 eNB가 설정할 수 있다.

[236] CSI-RS를 측정하기 위해서 UE는 반드시 자신이 속한 셀의 각각의 CSI-RS 안테나 포트에 대한 CSI-RS의 전송 서브 프레임 인덱스, 전송 서브 프레임 내에서 CSI-RS 자원 요소(RE) 시간-주파수 위치, 그리고 CSI-RS 시퀀스 등에 대한 정보를 알고 있어야 한다.

[237] LTE-A 시스템에 eNB는 CSI-RS를 최대 8개의 안테나 포트에 대해서 각각 전송해야 한다. 서로 다른 안테나 포트의 CSI-RS 전송을 위해 사용되는 자원은 서로 직교(orthogonal)해야 한다. 한 eNB가 서로 다른 안테나 포트에 대한 CSI-RS를 전송할 때 각각의 안테나 포트에 대한 CSI-RS를 서로 다른 RE에 맵핑함으로써 FDM/TDM방식으로 이들 자원을 orthogonal하게 할당할 수 있다. 또는 서로 다른 안테나 포트에 대한 CSI-RS를 서로 orthogonal한 코드에 맵핑시키는 CDM방식으로 전송할 수 있다.

[238] CSI-RS에 관한 정보를 eNB가 자기 셀 UE에게 알려줄 때, 먼저 각 안테나 포트에 대한 CSI-RS가 매핑되는 시간-주파수에 대한 정보를 알려줘야 한다. 구체적으로, CSI-RS가 전송되는 서브 프레임 번호들, 또는 CSI-RS가 전송되는 주기, CSI-RS가 전송되는 서브 프레임 오프셋이며, 특정 안테나의 CSI-RS RE가

전송되는 OFDM 심볼 번호, 주파수 간격(spacing), 주파수 축에서의 RE의 오프셋 또는 쉬프트 값 등이 있다.

[239] CSI-RS는 1개, 2개, 4개 또는 8개의 안테나 포트를 통해 전송된다. 이때, 사용되는 안테나 포트는 각각 p=15, p=15,16, p=15,...,18, p=15,...,22이다. CSI-RS는 서브캐리어 간격 Δf=15kHz에 대해서만 정의될 수 있다.

[240] (k',l')(여기서, k'는 자원 블록 내 부반송파 인덱스이고, l'는 슬롯 내 OFDM 심볼 인덱스를 나타낸다.) 및 n_s의 조건은 아래 표 4 또는 표 5와 같은 CSI-RS 설정(configuration)에 따라 결정된다.

[241] 표 3은 일반 CP에서 CSI-RS 구성으로부터 (k',l')의 매핑을 예시한다.

[242] [표3]

	CSI reference signal configuration	Number of CSI reference signals configured					
		1 or 2		4		8

[245] 표 3 및 표 4를 참조하면, CSI-RS의 전송에 있어서, 이종 네트워크(HetNet: heterogeneous network) 환경을 포함하여 멀티 셀 환경에서 셀간 간섭(ICI: inter-cell interference)을 줄이기 위하여 최대 32개(일반 CP 경우) 또는 최대 28개(확장 CP 경우)의 서로 다른 구성(configuration)이 정의된다.

[246] CSI-RS 구성은 셀 내의 안테나 포트의 개수 및 CP에 따라 서로 다르며, 인접한 셀은 최대한 서로 다른 구성을 가질 수 있다. 또한, CSI-RS 구성은 프레임 구조에 따라 FDD 프레임과 TDD 프레임에 모두 적용하는 경우와 TDD 프레임에만 적용하는 경우로 나눠질 수 있다.

[247] 표 3 및 표 4를 기반으로 CSI-RS 구성에 따라 (k',l') 및 n_s가 정해지고, 각 CSI-RS 안테나 포트가 CSI-RS 전송에 이용하는 시간-주파수 자원이 결정된다.

[248] 도 10은 본 발명이 적용될 수 있는 무선 통신 시스템에서 CSI-RS 구성을 예시하는 도면이다.

[249] 도 10(a)는 1개 또는 2개의 CSI-RS 안테나 포트들에 의한 CSI-RS 전송에 사용

가능한 20가지 CSI-RS 구성들을 나타낸 것이고, 도 10(b)는 4개의 CSI-RS 안테나 포트들에 의해 사용 가능한 10가지 CSI-RS 구성들을 나타낸 것이며, 도 10(c)는 8개의 CSI-RS 안테나 포트들에 의해 CSI-RS 전송에 사용 가능한 5가지 CSI-RS 구성들을 나타낸 것이다.

[250] 이와 같이, 각 CSI-RS 구성에 따라 CSI-RS가 전송되는 무선 자원(즉, RE 쌍)이 결정된다.

[251] 특정 셀에 대하여 CSI-RS 전송을 위해 1개 혹은 2개의 안테나 포트가 설정되면, 도 10(a)에 도시된 20가지 CSI-RS 구성들 중 설정된 CSI-RS 구성에 따른 무선 자원 상에서 CSI-RS가 전송된다.

[252] 마찬가지로, 특정 셀에 대하여 CSI-RS 전송을 위해 4개의 안테나 포트가 설정되면, 도 10(b)에 도시된 10가지 CSI-RS 구성들 중 설정된 CSI-RS 구성에 따른 무선 자원 상에서 CSI-RS가 전송된다. 또한, 특정 셀에 대하여 CSI-RS 전송을 위해 8개의 안테나 포트가 설정되면, 도 10(c)에 도시된 5가지 CSI-RS 구성들 중 설정된 CSI-RS 구성에 따른 무선 자원 상에서 CSI-RS가 전송된다.

[253] 2개의 안테나 포트 별(즉, {15,16}, {17,18}, {19,20}, {21,22})로 각각의 안테나 포트에 대한 CSI-RS는 동일한 무선 자원에 CDM되어 전송된다. 안테나 포트 15 및 16를 예를 들면, 안테나 포트 15 및 16에 대한 각각의 CSI-RS 복소 심볼은 동일하나, 서로 다른 직교 코드(예를 들어, 왈시 코드(walsh code)가 곱해져서 동일한 무선 자원에 매핑된다. 안테나 포트 15에 대한 CSI-RS의 복소 심볼에는 [1, 1]이 곱해지고, 안테나 포트 16에 대한 CSI-RS의 복소 심볼에는 [1 -1]이 곱해져서 동일한 무선 자원에 매핑된다. 이는 안테나 포트 {17,18}, {19,20}, {21,22}도 마찬가지이다.

[254] UE는 전송된 심볼에 곱해진 코드를 곱하여 특정 안테나 포트에 대한 CSI-RS를 검출할 수 있다. 즉, 안테나 포트 15에 대한 CSI-RS를 검출하기 위해서 곱해진 코드 [1 1]을 곱하고, 안테나 포트 16에 대한 CSI-RS를 검출하기 위해서 곱해진 코드 [1 -1]을 곱한다.

[255] 도 10(a) 내지 (c)를 참조하면, 동일한 CSI-RS 구성 인덱스에 해당하게 되면, 안테나 포트 수가 많은 CSI-RS 구성에 따른 무선 자원은 CSI-RS 안테나 포트 수가 적은 CSI-RS 구성에 따른 무선 자원을 포함한다. 예를 들어, CSI-RS 구성 0의 경우, 8개 안테나 포트 수에 대한 무선 자원은 4개 안테나 포트 수에 대한 무선 자원과 1 또는 2개의 안테나 포트 수에 대한 무선 자원을 모두 포함한다.

[256] 하나의 셀에서 복수의 CSI-RS 구성이 사용될 수 있다. 넌-제로 전력(NZP: non-zero power) CSI-RS는 0개 또는 1개 CSI-RS 구성만이 이용되고, 제로 전력(ZP: zero power) CSI-RS는 0개 또는 여러 개의 CSI-RS 구성이 이용될 수 있다.

[257] 상위 계층에 의해 설정되는 16 비트의 비트맵인 ZP CSI-RS(ZeroPowerCSI-RS)에서 1로 설정된 각 비트 별로, UE는 위의 표 3 및 표 4의 4개의 CSI-RS 열(column)에 해당하는 RE들에서(상위 계층에 의해 설정된

NZP CSI-RS를 가정하는 RE와 중복되는 경우를 제외) 제로 전송 전력을 가정한다. 최상위 비트(MSB: Most Significant Bit)는 가장 낮은 CSI-RS 구성 인덱스에 해당하고, 비트맵 내에서 그 다음의 비트는 순서대로 다음의 CSI-RS 구성 인덱스에 해당한다.

[258] CSI-RS는 위의 표 3 및 표 4에서 (n_s mod 2)의 조건을 만족하는 하향링크 슬롯 및 CSI-RS 서브프레임 구성을 만족하는 서브프레임에서만 전송된다.

[259] 프레임 구조 타입 2(TDD)의 경우, 스페셜 서브프레임, 동기 신호(SS), PBCH 또는 SIB 1(SystemInformationBlockType1) 메시지 전송과 충돌되는 서브프레임 또는 페이징 메시지 전송을 위해 설정된 서브프레임에서 CSI-RS는 전송되지 않는다.

[260] 또한, 안테나 포트 세트 S(S={15}, S={15,16}, S={17,18}, S={19,20} 또는 S={21,22}) 내 속하는 어떠한 안테나 포트에 대한 CSI-RS가 전송되는 RE는 PDSCH 또는 다른 안테나 포트의 CSI-RS 전송에 사용되지 않는다.

[261] CSI-RS 전송에 사용되는 시간-주파수 자원들은 데이터 전송에 사용될 수 없으므로, CSI-RS 오버헤드가 증가할수록 데이터 처리량(throughput)이 감소하게 된다. 이를 고려하여 CSI-RS는 매 서브프레임마다 전송되도록 구성되지 않고, 다수의 서브프레임에 해당하는 소정의 전송 주기마다 전송되도록 구성된다. 이 경우, 매 서브프레임마다 CSI-RS가 전송되는 경우에 비하여 CSI-RS 전송 오버헤드가 많이 낮아질 수 있다.

[262] CSI-RS 전송을 위한 서브프레임 주기(이하, 'CSI 전송 주기'로 지칭함)(T_CSI-RS) 및 서브프레임 오프셋(Δ_CSI-RS)은 아래 표 5과 같다.

[263] 표 5은 CSI-RS 서브프레임 구성을 예시한다.

[264] [표5]

CSI-RS-SubframeConfig I_{CSI-RS}	CSI-RS periodicity T_{CSI-RS} (subframes)	CSI-RS subframe offset Δ_{CSI-RS} (subframes)
0 - 4	5	I_{CSI-RS}
5 - 14	10	$I_{CSI\ RS}-5$
15 - 34	20	$I_{CSI-RS}-15$
35 - 74	40	$I_{CSI-RS}-35$
75 - 154	80	$I_{CSI-RS}-75$

[265] 표 5을 참조하면, CSI-RS 서브프레임 구성(I_CSI-RS)에 따라 CSI-RS 전송 주기(T_CSI-RS) 및 서브프레임 오프셋(Δ_CSI-RS)이 결정된다.

[266] 표 5의 CSI-RS 서브프레임 구성은 앞서 'SubframeConfig' 필드 및 'zeroTxPowerSubframeConfig' 필드 중 어느 하나로 설정될 수 있다. CSI-RS 서브프레임 구성은 NZP CSI-RS 및 ZP CSI-RS에 대하여 개별적으로(separately) 설정될 수 있다.

[267] CSI-RS를 포함하는 서브프레임은 아래 수학식 12를 만족한다.

[268] [수식12]

$$(10n_f + \lfloor n_s/2 \rfloor - \Delta_{CSI-RS}) \bmod T_{CSI-RS} = 0$$

[269] 수학식 12에서 T_CSI-RS는 CSI-RS 전송 주기, Δ_CSI-RS는 서브프레임 오프셋 값, n_f는 시스템 프레임 넘버, n_s는 슬롯 넘버를 의미한다.

[270] 서빙 셀에 대해 전송 모드 9(transmission mode 9)가 설정된 UE의 경우, UE는 하나의 CSI-RS 자원 구성이 설정될 수 있다. 서빙 셀에 대해 전송 모드 10(transmission mode 10)이 설정된 UE의 경우, UE는 하나 또는 그 이상의 CSI-RS 자원 구성(들)이 설정될 수 있다.

[271] 각 CSI-RS 자원 구성을 위한 아래와 같이 파라미터가 상위 계층 시그널링을 통해 설정된다.

[272] - 전송 모드 10이 설정된 경우, CSI-RS 자원 구성 식별자

[273] - CSI-RS 포트 개수

[274] - CSI-RS 구성 (표 3 및 표 4 참조)

[275] - CSI-RS 서브프레임 구성(I_CSI-RS) (표 5 참조)

[276] - 전송 모드 9가 설정된 경우, CSI 피드백을 위한 전송 파워(P_C)

[277] - 전송 모드 10이 설정된 경우, 각 CSI 프로세스에 대하여 CSI 피드백을 위한 전송 파워(P_C). CSI 프로세스에 대하여 CSI 서브프레임 세트들 C_CSI,0 및 C_CSI,1가 상위 계층에 의해 설정되면, P_C는 CSI 프로세스의 각 CSI 서브프레임 세트 별로 설정된다.

[278] - 임의 랜덤(pseudo-rnadom) 시퀀스 발생기 파라미터(n_ID)

[279] - 전송 모드 10이 설정된 경우, QCL(QuasiCo-Located) 타입 B UE 가정을 위한 QCL 스크램블링 식별자(qcl-ScramblingIdentity-r11), CRS 포트 카운트(crs-PortsCount-r11), MBSFN 서브프레임 설정 리스트(mbsfn-SubframeConfigList-r11) 파라미터를 포함하는 상위 계층 파라미터('qcl-CRS-Info-r11')

[280] UE가 도출한 CSI 피드백 값이 [-8, 15] dB 범위 내의 값을 가질 때, P_C는 CSI-RS EPRE에 대한 PDSCH EPRE의 비율로 가정된다. 여기서, PDSCH EPRE는 CRS EPRE에 대한 PDSCH EPRE의 비율이 ρ_A인 심볼에 해당한다.

[281] 서빙 셀의 동일한 서브프레임에서 CSI-RS와 PMCH이 함께 설정되지 않는다.

[282] 프레임 구조 타입 2에서 4개의 CRS 안테나 포트가 설정된 경우, UE는 일반 CP의 경우 [20-31] 세트(표 3 참조) 또는 확장 CP의 경우 [16-27] 세트(표 4 참조)에 속하는 CSI-RS 구성 인덱스가 설정되지 않는다.

[283] UE는 CSI-RS 자원 구성의 CSI-RS 안테나 포트가 지연 확산(delay spread), 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift), 평균 이득(average gain) 및 평균 지연(average delay)에 대하여 QCL 관계를 가진다고 가정할 수 있다.

[284] 전송 모드 10 그리고 QCL 타입 B가 설정된 UE는 CSI-RS 자원 구성에 해당하는

안테나 포트 0-3과 CSI-RS 자원 구성에 해당하는 안테나 포트 15-22가 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift)에 대하여 QCL 관계라고 가정할 수 있다.

[285] 전송 모드 10이 설정된 UE의 경우, 서빙 셀에 대하여 하나 또는 그 이상의 CSI-IM(Channel-State Information - Interference Measurement) 자원 구성이 설정될 수 있다.

[286] 상위 계층 시그널링을 통해 각 CSI-IM 자원 구성을 위한 아래와 같은 파라미터가 설정될 수 있다.

[287] - ZP CSI-RS 구성 (표 3 및 표 4 참조)

[288] - ZP CSI RS 서브프레임 구성(I_CSI-RS) (표 5 참조)

[289] CSI-IM 자원 구성은 설정된 ZP CSI-RS 자원 구성 중 어느 하나와 동일하다.

[290] 서빙 셀의 동일한 서브프레임 내 CSI-IM 자원과 PMCH가 동시에 설정되지 않는다.

[291] 전송 모드 1-9가 설정된 UE의 경우, 서빙 셀에 대하여 UE는 하나의 ZP CSI-RS 자원 구성이 설정될 수 있다. 전송 모드 10이 설정된 UE의 경우, 서빙 셀에 대하여 UE는 하나 또는 그 이상의 ZP CSI-RS 자원 구성이 설정될 수 있다.

[292] 상위 계층 시그널링을 통해 ZP CSI-RS 자원 구성을 위한 아래와 같은 파라미터가 설정될 수 있다.

[293] - ZP CSI-RS 구성 리스트 (표 3 및 표 4 참조)

[294] - ZP CSI-RS 서브프레임 구성(I_CSI-RS) (표 5 참조)

[295] 서빙 셀의 동일한 서브프레임에서 ZP CSI-RS와 PMCH가 동시에 설정되지 않는다.

[296]

[297] **셀 측정(Cell Measurement)/측정 보고(Measurement Report)**

[298] 단말의 이동성(mobility) 보장을 위한 여러 방법들(핸드오버, 랜덤 액세스, 셀 탐색 등) 중 하나 또는 그 여러 방법들을 위하여 UE는 셀 측정(cell measurement)한 결과를 기지국(혹은 네트워크)에 보고한다.

[299] 3GPP LTE/LTE-A 시스템에서 셀 특정 참조 신호(CRS)는 시간 축으로 각 서브프레임 내의 0, 4, 7, 11 번째 OFDM 심볼을 통해 전송되고, 이는 셀 측정(cell measurement)를 위해 기본적으로 사용된다. 즉, 단말은 서빙 셀(serving cell)과 이웃 셀(neighbor cell)로부터 각각 수신되는 CRS를 이용하여, 셀 측정을 수행한다.

[300] 셀 측정(cell measurement)은 서빙 셀 및 이웃 셀의 신호 세기 혹은 총 수신 전력 대비 신호 세기 등을 측정하는 참조 신호 수신 전력(RSRP: Reference signal receive power), 수신신호강도(RSSI: Received signal strength indicator), 참조신호수신품질(RSRQ: Reference signal received quality) 등의 RRM(Radio resource management) 측정과 서빙 셀과의 링크 품질을 측정하여 라디오 링크 실패(radio link failure) 여부를 평가할 수 있는 RLM(Radio Link Monitoring)

측정을 포함하는 개념이다.

[301] RSRP는 측정 주파수 대역 내에서 CRS가 전송되는 RE의 전력 분배의 선형 평균이다. RSRP 결정을 위해, 안테나 포트 '0'에 해당하는 CRS(R0)가 사용될 수 있다. 또한, RSRP 결정을 위해, 안테나 포트 '1'에 해당하는 CRS(R1)가 추가로 사용될 수도 있다. RSRP를 결정하기 위하여 UE에 의해 이용되는 측정 주파수 대역 및 측정 구간 내에서 이용하는 RE들의 수는 해당 측정 정확도 요구(accuracy requirements)가 만족되는 한도에서 UE가 결정할 수 있다. 또한, RE 당 전력은 순환 전치(CP)를 제외한 심볼의 나머지 부분 내에서 수신한 에너지로부터 결정될 수 있다.

[302] RSSI는 측정 대역 내에서 안테나 포트 '0'에 해당하는 RS를 포함하는 OFDM 심볼들에서 동일 채널(co-channel)의 서빙 셀(serving cell)과 넌-서빙 셀(non-serving cell), 인접 채널로부터의 간섭, 열 잡음(thermal noise) 등을 포함하는 해당 UE에 의해 모든 소스들로부터 감지된 총 수신 전력의 선형 평균으로 도출된다. 상위 계층 시그널링에 의하여 RSRQ 측정을 수행하기 위한 특정 서브프레임들이 지시되는 경우, RSSI는 지시된 서브프레임들 내의 모든 OFDM 심볼에 통해 측정된다.

[303] RSRQ는 N×RSRP/RSSI로 도출된다. 여기서, N은 RSSI 측정 대역폭의 RB 개수를 의미한다. 또한, 위의 식에서 분자 및 분모의 측정은 동일한 RB의 세트에서 구해질 수 있다.

[304] 기지국은 상위 계층 시그널링(예를 들어, RRC 연결 재구성(RRC Connection Reconfiguration) 메시지)을 통해 UE에게 측정(measurement)을 위한 설정 정보를 전달할 수 있다.

[305] RRC 연결 재구성 메시지는 무선 자원 구성 전용('radioResourceConfigDedicated') 정보 요소(IE: Information Element)와, 측정 설정('measConfig') IE를 포함한다.

[306] 'measConfig' IE는 UE에 의해 수행되어야 하는 측정을 특정하고, 측정 갭(measurement gap)의 구성 뿐만 아니라 인트라-주파수(intra-frequency) 이동성, 인터-주파수(inter-frequency) 이동성, 인터-RAT(inter-RAT) 이동성을 위한 설정 정보를 포함한다.

[307] 특히, 'measConfig' IE는 측정에서 제거될 측정 대상('measObject')의 리스트를 나타내는 'measObjectToRemoveList'와 새로이 추가되거나 수정될 리스트를 나타내는 'measObjectToAddModList'가 포함된다. 또한, 'measObject'에는 통신 기술에 따라 'MeasObjectCDMA2000', 'MeasObjctEUTRA', 'MeasObjectGERAN' 등이 포함된다.

[308] 'RadioResourceConfigDedicated' IE는 무선 베어러(Radio Bearer)를 설정/변경/해제(setup/modify/release) 하거나, MAC 메인 구성을 변경하거나, 반정적 스케줄링(SPS: Semi-Persistent Scheduling) 설정을 변경하거나 및 전용 물리적 설정(dedicated physical configuration)을 변경하기 위하여 사용된다.

[309] 'RadioResourceConfigDedicated' IE는 서빙 셀 측정을 위한 시간 영역 측정 자원 제한 패턴(time domain measurement resource restriction pattern)을 지시하는 'measSubframePattern-Serv' 필드를 포함한다. 또한, UE에 의해 측정될 이웃 셀을 지시하는 'measSubframeCellList' 와 이웃 셀 측정을 위한 시간 영역 측정 자원 제한 패턴을 지시하는 'measSubframePattern-Neigh'를 포함한다.

[310] 측정 셀(서빙 셀 및 이웃 셀 포함)을 위해 설정된 시간 영역 측정 자원 제한 패턴(time domain measurement resource restriction pattern)은 RSRQ 측정을 수행하기 위한 무선 프레임 당 적어도 하나의 서브프레임을 지시할 수 있다. 측정 셀을 위해 설정된 시간 영역 측정 자원 제한 패턴에 의하여 지시된 서브프레임 이외에서는 RSRQ 측정이 수행되지 않는다.

[311] 이와 같이, UE(예를 들어, 3GPP Rel-10)는 서빙 셀 측정을 위한 서브프레임 패턴('measSubframePattern-Serv') 및 이웃 셀 측정을 위한 서브프레임 패턴('measSubframePattern-Neigh')에 의해 설정된 구간에서만 RSRQ가 측정되어야 한다.

[312] 다만, RSRP는 이러한 패턴 내 측정이 제약되어 있지 않지만, 정확도 요구(accuracy requirement)를 위해서는 이러한 패턴 내에서만 측정되는 것이 바람직하다.

[313]

[314] <u>안테나 포트 간 QCL(quasi co-located)</u>

[315] QC/QCL(quasi co-located 혹은 quasi co-location)은 다음과 같이 정의될 수 있다.

[316] 두 개의 안테나 포트가 QC/QCL 관계에 있다(혹은 QC/QCL 되었다)고 하면, 하나의 안테나 포트를 통해 전달되는 신호의 광범위 특성(large-scale property)이 다른 하나의 안테나 포트를 통해 전달되는 신호로부터 암시(infer)될 수 있다고 단말이 가정할 수 있다. 여기서, 상기 광범위 특성은 지연 확산(Delay spread), 도플러 확산(Doppler spread), 주파수 쉬프트(Frequency shift), 평균 수신 파워(Average received power), 수신 타이밍(Received Timing) 중 하나 이상을 포함한다.

[317] 또한, 다음과 같이 정의될 수도 있다. 두 개의 안테나 포트가 QC/QCL 관계에 있다(혹은 QC/QCL 되었다)고 하면, 하나의 안테나 포트를 통해 일 심볼이 전달되는 채널의 광범위 특성(large-scale property)이 다른 하나의 안테나 포트를 통해 일 심볼이 전달되는 무선 채널로부터 암시(infer)될 수 있다고 단말이 가정할 수 있다. 여기서, 상기 광범위 특성은 지연 확산(delay spread), 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift), 평균 이득(average gain) 및 평균 지연(average delay) 중 하나 이상을 포함한다.

[318] 즉, 두 개의 안테나 포트들이 QC/QCL 관계에 있다(혹은 QC/QCL 되었다)고 함은, 하나의 안테나 포트로부터의 무선 채널의 광범위 특성이 나머지 하나의 안테나 포트로부터의 무선 채널의 광범위 특성과 같음을 의미한다. RS가 전송되는 복수의 안테나 포트를 고려하면, 서로 다른 두 종류의 RS가 전송되는

안테나 포트들이 QCL 관계에 있으면, 한 종류의 안테나 포트로부터의 무선 채널의 광범위 특성을 다른 한 종류의 안테나 포트로부터의 무선 채널의 광범위 특성으로 대체할 수 있을 것이다.

[319] 본 명세서에서 위 QC/QCL 관련 정의들을 구분하지 않는다. 즉, QC/QCL 개념은 위 정의들 중에 하나를 따를 수 있다. 혹은 유사한 다른 형태로, QC/QCL 가정이 성립하는 안테나 포트 간에는 마치 동일 위치(co-location)에서 전송하는 것처럼 가정할 수 있다는 형태 (예를 들어, 동일 전송 포인트(transmission point)에서 전송하는 안테나 포트라고 단말이 가정할 수 있다는 등)으로 QC/QCL 개념 정의가 변형될 수도 있으며, 본 발명의 사상은 이와 같은 유사 변형예들을 포함한다. 본 발명에서는 설명의 편의상 위 QC/QCL 관련 정의들을 혼용하여 사용한다.

[320] 상기 QC/QCL의 개념에 따라, 단말은 비-QC/QCL(Non-QC/QCL) 안테나 포트들에 대해서는 해당 안테나 포트들로부터의 무선 채널 간에 동일한 상기 광범위 특성을 가정할 수 없다. 즉, 이 경우 단말은 타이밍 획득 및 트랙킹(tracking), 주파수 오프셋 추정 및 보상, 지연 추정 및 도플러 추정 등에 대하여 각각의 설정된 비-QC/QCL 안테나 포트 별로 독립적인 프로세싱을 수행하여야 한다.

[321] QC/QCL을 가정할 수 있는 안테나 포트들간에 대해서, 단말은 다음과 같은 동작을 수행할 수 있다는 장점이 있다:

[322] - 지연 확산 및 도플러 확산에 대하여, 단말은 어떤 하나의 안테나 포트로부터의 무선 채널에 대한 전력-지연-프로파일(power-delay profile), 지연 확산 및 도플러 스펙트럼(Doppler spectrum), 도플러 확산 추정 결과를, 다른 안테나 포트로부터의 무선 채널에 대한 채널 추정 시 사용되는 위너 필터(Wiener filter) 등에 동일하게 적용할 수 있다.

[323] - 주파수 쉬프트(shift) 및 수신된 타이밍에 대하여, 단말은 어떤 하나의 안테나 포트에 대한 시간 및 주파수 동기화 수행한 후, 동일한 동기화를 다른 안테나 포트의 복조에 적용할 수 있다.

[324] - 평균 수신 전력에 대하여, 단말은 둘 이상의 안테나 포트들에 대하여 RSRP(Reference Signal Received Power) 측정을 평균할 수 있다.

[325] 예를 들어, 단말이 하향링크 데이터 채널 복조를 위한 DMRS 안테나 포트가 서빙 셀의 CRS 안테나 포트와 QC/QCL 되었다면, 단말은 해당 DMRS 안테나 포트를 통한 채널 추정 시 자신의 CRS 안테나 포트로부터 추정했던 무선 채널의 광범위 특성들(large-scale properties)을 동일하게 적용하여 DMRS 기반 하향링크 데이터 채널 수신 성능을 향상시킬 수 있다.

[326] 왜냐하면, CRS는 매 서브프레임 그리고 전체 대역에 걸쳐 상대적으로 높은 밀도(density)로 브로드캐스팅되는 참조 신호이므로, 광범위 특성에 관한 추정치는 CRS로부터 보다 안정적으로 획득이 가능하기 때문이다. 반면, DMRS는 특정 스케줄링된 RB에 대해서는 단말 특정하게 전송되며, 또한

PRG(precoding resource block group) 단위가 기지국이 전송에 사용하는 프리코딩 행렬(precoding matrix)가 변할 수 있으므로 단말에게 수신되는 유효 채널은 PRG 단위로 달라질 수 있어 다수의 PRG를 스케줄링 받은 경우라고 하더라도 넓은 대역에 걸쳐 DMRS를 무선 채널의 광범위 특성 추정용으로 사용 시에 성능 열화가 발생할 수 있다. 또한, CSI-RS도 그 전송 주기가 수~수십 ms가 될 수 있고, 자원 블록 당 평균적으로 안테나 포트 당 1 자원 요소의 낮은 밀도를 가지므로 CSI-RS도 마찬가지로 무선 채널의 광범위 특성 추정용으로 사용할 경우 성능 열화가 발생할 수 있다.

[327] 즉, 안테나 포트 간의 QC/QCL 가정을 함으로써 단말은 하향링크 참조 신호의 검출/수신, 채널 추정, 채널 상태 보고 등에 활용할 수 있다.

[328]

[329] <u>제한된 RLM 및 RRM/CSI 측정</u>

[330] 간섭 조정(Interference coordination)의 한 방법으로서, 공격 셀(aggressor cell)이 일부 물리 채널의 전송 파워(transmission power)/동작(activity)를 줄이는 (여기서, 전송 파워/동작을 줄이는 것은 제로 파워로 설정하는 동작까지 포함할 수 있음) 침묵 서브프레임(silent subframe)(또는, ABS(almost blank subframe)으로 지칭될 수 있음)을 사용하고, 희생 셀(victim cell)이 이를 고려하여 UE를 스케줄링하는 시간 도메인 셀 간 간섭 조정(scheduling하는 time domain inter-cell interference coordination)이 가능하다.

[331] 이 경우, 희생 셀(victim cell) UE의 입장에서는 간섭 레벨(interference level)이 서브프레임에 따라서 크게 변화할 수 있다.

[332] 이러한 상황에서 각 서브프레임에서의 보다 정확한 무선 링크 모니터링(RLM: radio link monitoring)이나 RSRP/RSRQ 등을 측정하는 무선 자원 관리(RRM: radio resource management) 동작을 수행하거나 링크 적응(link adaptation)을 위해서 채널 상태 정보(CSI: channel state information)를 측정하기 위해서, 상기 모니터링/측정은 균일한 간섭 특성을 지니는 서브프레임의 세트들로 제한되어야 한다. 3GPP LTE 시스템에서는 아래와 같이 제한된 RLM 및 RRM/CSI 측정을 정의한다.

[333] UE는 Pcell의 하향링크 무선 링크 품질(downlink link quality)을 감지하기 위하여 셀 특정 참조 신호(CRS)에 기반하여 하향링크 링크 품질을 모니터한다. 단말은 하향링크 무선 링크 품질을 추정하고, Pcell의 하향링크 무선 링크 품질을 모니터링하기 위하여 임계치 Q_out 및 Q_in와 추정치를 비교한다.

[334] 임계치 Q_out은 하향링크 무선 링크가 신뢰있게(reliably) 수신될 수 없는 레벨로 정의되고, 아래 표 6에서 명시된 전송 파라미터에 기반하여 PCFICH 에러를 고려한 가상의(hypothetical) PDCCH 전송의 10% 블록 에러율(BER: block error rate)에 해당한다.

[335] 임계치 Q_in는 하향링크 무선 링크 품질이 Q_out에서의 하향링크 무선 링크 품질 보다 현저하게 신뢰있게 수신될 수 있는 레벨로 정의되고, 아래 표 7에서

명시된 전송 파라미터에 기반하여 PCFICH 에러를 고려한 가상의(hypothetical) PDCCH 전송의 2% BER에 해당한다.

[336] 상위 계층 시그널링이 제한된 RLM을 위한 특정 서브프레임을 지시할 때, 무선 링크 품질이 모니터링된다.

[337] RLM 측정을 수행하기 위한 시간 도메인 측정 자원 제한 패턴이 상위 계층에 의해 설정될 때, 또한 측정되는 셀을 위해 설정된 시간 도메인 측정 자원 제한 패턴이 RLM 측정을 수행하기 위한 무선 프레임 당 적어도 하나의 서브프레임을 지시한다면, 일정한 요구 사항이 적용된다.

[338] CRS 지원(assistance) 정보가 제공되는 경우, CRS 지원 정보가 제공된 하나 또는 그 이상의 셀의 전송 안테나 포트(transmit antenna port)의 개수가 RLM이 수행되는 셀의 전송 안테나 포트의 개수와 상이할 때 상기 요구 사항이 만족될 수 있다.

[339] 만약, 단말이 CRS 지원 정보를 제공받지 않거나 CRS 지원 데이터가 전체 평가 기간 동안에 유효하지 않으면, CRS와 논-MBSFN(multicast broadcast single frequency network) 서브프레임 내에서 설정된 ABS의 충돌 하에 시간 도메인 측정 제한이 적용될 수 있다.

[340] 표 6은 동기가 맞지 않은 상태(out-of-sync)에 대한 PDCCH/PCFICH 전송 파라미터를 예시한다.

[341] [표6]

속성(Attribute)	값(Value)
DCI 포맷	1A
제어 OFDM 심볼의 수	2; 대역폭 ≥ 10 MHz 3; 3 MHz ≤ 대역폭 ≤ 10 MHz 4; 대역폭 = 1.4 MHz
병합 레벨(Aggregation level) (CCE)	4; 대역폭 = 1.4 MHz 8; 대역폭 ≥ 3 MHz
PDCCH RE 에너지 대 평균 RS RE 에너지의 비 (Ratio of PDCCH RE energy to average RS RE energy)	4 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 1 dB; Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우
PCFICH RE 에너지 대 평균 RS RE 에너지의 비 (Ratio of PCFICH RE energy to average RS RE energy)	4 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 1 dB: Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우

[342] 표 7은 동기가 맞는 상태(in-sync)에 대한 PDCCH/PCFICH 전송 파라미터를 예시한다.

[343] [표7]

속성(Attribute)	값(Value)
DCI 포맷	1C
제어 OFDM 심볼의 수	2; 대역폭 ≥ 10 MHz 3; 3 MHz ≤ 대역폭 ≤ 10 MHz 4; 대역폭 = 1.4 MHz
병합 레벨(Aggregation level) (CCE)	4
PDCCH RE 에너지와 평균 RS RE 에너지 간 비율 (Ratio of PDCCH RE energy to average RS RE energy)	0 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 -3 dB; Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우
PCFICH RE 에너지 대 평균 RS RE 에너지의 비 (Ratio of PCFICH RE energy to average RS RE energy)	4 dB; Pcell에 의한 CRS 전송을 위해 단일 안테나 포트가 사용되는 경우 1 dB; Pcell에 의한 CRS 전송을 위해 2개 또는 4개 안테나 포트가 사용되는 경우

[344] Pcell에 대한 하향링크 무선 링크 품질은 UE에 의해 상위 계층에 동기가 맞지 않은 상태(out-of-sync status)/동기가 맞는 상태(in-sync status)를 지시하기 위하여 모니터된다.

[345] 비-DRX(non-DRX) 모드 동작에서, UE의 물리 계층은 매 무선 프레임에서 임계치(Q_out 및 Q_in)를 고려하여 이전 시간 구간 동안 평가된 무선 링크 품질을 측정(assess)한다.

[346] 상위 계층 시그널링이 제한된 RLM을 위한 특정 서브프레임을 지시하면, 무선 링크 품질의 측정은 상위 계층 시그널링에서 지시되지 않는 이외 다른 서브프레임에서 수행되지 않는다.

[347] 무선 링크 품질이 임계치 Q_out 보다 불량하면, UE의 물리 계층은 무선 링크 품질이 측정된 무선 프레임 내에서 상위 계층에게 out-of-sync를 지시한다. 무선 링크 품질이 임계치 Q_in 보다 양호하면, UE의 물리 계층은 무선 링크 품질이 측정된 무선 프레임 내에서 상위 계층에게 in-sync를 지시한다.

[348]

[349] <u>매시브 MIMO(Massive MIMO)</u>

[350] LTE 릴리즈(Rel: release)-12 이후의 무선 통신 시스템에서는 능동 안테나 시스템(AAS: Active Antenna System)의 도입이 고려되고 있다.

[351] 신호의 위상 및 크기를 조정할 수 있는 증폭기와 안테나가 분리되어 있는 기존의 수동 안테나 시스템과 달리, AAS는 각각의 안테나가 증폭기와 같은 능동 소자를 포함하도록 구성된 시스템을 의미한다.

[352] AAS는 능동 안테나 사용에 따라 증폭기와 안테나를 연결하기 위한 별도의 케이블, 커넥터, 기타 하드웨어 등이 필요하지 않고, 따라서 에너지 및 운용 비용 측면에서 효율성이 높은 특징을 갖는다. 특히, AAS는 각 안테나 별 전자식 빔 제어(electronic beam control) 방식을 지원하기 때문에 빔 방향 및 빔 폭을 고려한

정교한 빔 패턴 형성 또는 3차원 빔 패턴을 형성하는 등의 진보된 MIMO 기술을 가능하게 한다.

[353] AAS 등의 진보된 안테나 시스템의 도입으로 다수의 입출력 안테나와 다차원 안테나 구조를 갖는 대규모 MIMO 구조 또한 고려되고 있다. 일례로, 기존의 일자 형 안테나 배열과 달리 2차원 안테나 배열을 형성할 경우, AAS의 능동 안테나에 의해 3차원 빔 패턴을 형성할 수 있다. 송신 안테나 관점에서 상기 3차원 빔 패턴을 활용할 경우, 빔의 수평 방향뿐만 아니라 수직 방향으로의 준-정적 또는 동적인 빔 형성을 수행할 수 있으며 일례로 수직 방향의 섹터 형성 등의 응용을 고려할 수 있다.

[354] 또한, 수신 안테나 관점에서는 대규모 수신 안테나를 활용하여 수신 빔을 형성할 때, 안테나 배열 이득(antenna array gain)에 따른 신호 전력 상승 효과를 기대할 수 있다. 따라서, 상향링크의 경우, 기지국이 다수의 안테나를 통해 단말로부터 전송되는 신호를 수신할 수 있으며, 이때 단말은 간섭 영향을 줄이기 위해 대규모 수신 안테나의 이득을 고려하여 자신의 송신 전력을 매우 낮게 설정할 수 있는 장점이 있다.

[355] 도 11은 본 발명이 적용될 수 있는 무선 통신 시스템에서 기지국 또는 단말이 AAS 기반의 3D(3-Dimension) 빔 형성이 가능한 다수의 송/수신 안테나를 갖고 있는 시스템을 예시한다.

[356] 도 11은 앞서 설명한 예를 도식화한 것으로서, 2차원 안테나 배열(즉, 2D-AAS)를 이용한 3D MIMO 시스템을 예시한다.

[357]

[358] <u>매시브 MIMO의 셀 커버리지(Cell coverage of massive MIMO)</u>

[359] 다중 안테나 시스템, 일례로서 N개의 전송 안테나를 갖는 시스템은 단일 안테나 시스템에 비교해서 전체 전송 전력을 동일하게 전송한다고 가정하면, 특정 지점에 수신 파워가 최대 N배 높도록 빔포밍(beamforming) 해줄 수 있다.

[360] 다중 안테나를 갖는 기지국에서도 CRS, PSS/SSS, PBCH 및 브로드캐스트(broadcast) 정보를 전달하는 채널은 기지국 커버리지 영역내의 모든 UE들이 수신할 수 있도록 특정 방향으로 beamforming을 해주지는 않는다.

[361] 이와 달리, 특정 UE에게 유니캐스트(unicast) 정보를 전달하는 채널인 PDSCH는 해당 UE의 위치 및 링크 상황에 맞추어 beamforming을 해주어 전송 효율을 높이도록 한다. 즉, PDSCH의 전송 데이터 스트림은 특정 방향으로 빔을 형성하기 위하여 프로코딩(precoding)되어 다중의 안테나 포트를 통해 전송된다. 그러므로 대표적으로 CRS와 PDSCH의 전송 전력이 동일한 경우에, 특정 UE에게 CRS의 평균 수신 전력과 비교해서 해당 UE를 향해 beamforming 된 프로코딩된(precoded) PDSCH의 수신 전력은 최대 N배까지 높을 수 있다.

[362] 현재까지 LTE Rel-11 시스템에서 최대 8개의 전송 안테나를 갖는 기지국을 고려하는데, 이는 CRS 평균 수신 전력에 비해서 precoded PDSCH 수신 전력이 8배 클 수 있음을 의미한다. 그러나, 향후에 매시브 MIMO 시스템의 도입으로

기지국의 전송 안테나가 100개 이상 되는 경우에 CRS와 precoded PDSCH의 수신 전력은 100배 이상 차이를 나타낼 수 있다. 결론적으로 massive MIMO 시스템의 도입으로 특정 기지국에서 전송하는 CRS의 커버리지 영역과 DM-RS 기반 PDSCH의 커버리지 영역이 일치하지 않게 된다.

[363] 특히, 이러한 현상은 인접한 두 개의 기지국의 전송 안테나 개수의 차이가 많을 때 크게 나타날 수 있다. 대표적으로 64개의 전송 안테나를 갖는 매크로 셀(macro cell)과 단일 전송 안테나를 갖는 마이크로 셀(micro cell)(예를 들어, 피코 셀(pico cell))이 인접하고 있는 경우를 예로 들 수 있다. Massive MIMO의 초기 배치(deployment) 과정에서 서빙받는(served) UE가 많은 macro cell부터 먼저 안테나 개수를 늘릴 것으로 기대하고 있기 때문에 macro cell, micro cell 그리고 pico cell이 혼재되어 있는 이종의 네트워크(heterogeneous network)의 경우에 인접한 기지국간에 전송 안테나의 개수가 크게 차이 나게 된다.

[364] 예를 들어, 단일 전송 안테나를 갖는 pico cell의 경우에 CRS와 PDSCH의 커버리지 영역이 일치하게 된다. 그러나 64개의 전송 안테나를 갖는 macro cell의 경우에 CRS의 커버리지 영역보다 PDSCH의 커버리지 영역이 더 크게 된다. 그러므로 macro cell과 pico cell의 경계에서 CRS의 수신 품질인 RSRP 또는 RSRQ에만 의존하여 초기접속 및 핸드오버를 결정하게 되면 PDSCH의 최대 품질을 제공해 줄 기지국을 서빙 셀(serving cell)로 선택할 수 없게 된다. 이에 대한 단순한 해결책으로 N개의 전송 안테나를 갖는 기지국의 PDSCH 수신 전력은 N배 클 것으로 가정할 수 있으나, 기지국이 가능한 모든 방향으로 beamforming을 다 해줄 수 없는 경우를 고려할 때 최적 해결책은 아니다.

[365]

[366] **RRM-RS**

[367] 본 특허에서는 프리코딩된 RS(precoded RS)를 전송하고 이에 대한 RRM 측정(measurement)를 수행하는 방법을 제안한다. 이하, 본 명세서에서는 이러한 목적의 precoded RS를 'RRM-RS'라고 명칭하도록 한다. RRM-RS는 다수개의 안테나 포트로 구성되어 있으며 각 안테나 포트 별로 beamforming을 다르게 설정하여 각 전송 빔(beam) 별로 UE가 RSRP를 측정할 수 있도록 한다. 일례로, 기지국에서 M개의 방향으로 beamforming이 가능한 경우에 M 포트(M-port)로 구성된 RRM-RS를 설정하도록 한다.

[368]

[369] **RRM-RS의 주기 및 다중화(multiplexing)**

[370] M-port RRM-RS는 동일 서브프레임에서 CDM되거나 또는 FDM/TDM으로 구분되어 전송될 수 있다. 즉, M-port RRM-RS의 각 안테나 포트 별 전송 신호는 동일 서브프레임에서 다른 전송 RE를 사용하여 전송되거나, 또는 동일 RE를 사용하여 전송되는 경우에 안테나 포트 간에 직교 스크램블링 코드(orthogonal scrambling code)를 사용하여 상호간에 간섭 없이 구분할 수 있도록 한다.

[371] 이와 달리 하나의 서브프레임에서 동시에 전송 가능한 RRM-RS의 안테나 포트

수를 K로 설정하고 (M/K)개의 서브프레임에 나누어 전송할 수 있다.

[372] 이 경우, RRM-RS의 설정 파라미터는 전체 안테나 포트의 개수 M과 하나의 서브프레임에서 동시 전송되는 안테나 포트 수 K를 포함한다. RRM-RS의 설정 파라미터로써 RRM-RS 전송 주기 P와 오프셋 O를 포함한다. 여기서, RRM-RS 전송 주기는 RRM-RS가 전송되는 서브프레임의 간격으로 정의한다. 예로써 P=10, O=5, M=64, K=32인 경우에 RRM-RS는 서브프레임 인덱스(SFI: subframe index)가 5, 15, 25, 35, ... 인 서브프레임에서 전송되며, SFI=5인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 전송되고, SFI=15인 서브프레임에서 안테나 포트 32에서 63의 RRM-RS가 전송되고, SFI=25인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 또다시 전송된다.

[373] 이와 달리 RRM-RS 전송 주기를 동일 안테나 port의 RS가 전송되는 서브프레임의 간격으로 정의하고, (M/K)개의 서브프레임에 RRM-RS의 안테나 포트들을 나누어 전송하는 방식에서 (M/K)개의 연속된 서브프레임에 나누어 전송하도록 한다. 예로써 P=20, O=5, M=64, K=32인 경우에 RRM-RS는 SFI가 5, 6, 25, 26, 45, 46, ...인 서브프레임에서 전송되며, SFI=5인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 전송되고, SFI=6인 서브프레임에서 안테나 포트 32에서 63의 RRM-RS가 전송되고, SFI=25인 서브프레임에서 안테나 포트 0에서 31의 RRM-RS가 또다시 전송된다.

[374]

[375] **RSRP** 측정 및 보고

[376] RRM-RS의 RSRP는 안테나 포트 별로 측정하여 보고하도록 한다. UE는 다수개의 RRM-RS를 설정 받을 수 있다.

[377] 각 셀에서 RRM-RS를 하나씩 전송하는 경우에, UE는 서빙 셀 및 인접 셀들이 전송하는 RRM-RS들의 설정을 지정 받을 수 있다. 하나의 셀이 다수개의 RRM-RS를 전송할 수도 있다. UE는 RRM-RS의 RSRP를 보고할 때 해당 RSRP가 몇 번째 RRM-RS의 몇 번째 안테나 포트의 RSRP 측정결과인지 함께 알려준다.

[378] RRM-RS의 RSRP를 계산하기 위하여 각 안테나 포트의 수신 신호 레벨의 평균을 취하는데, 평균을 취하는 시간 윈도우(window)를 기지국이 지정해 줄 수 있거나, 또는 미리 정해진 시간 (예를 들어, 200ms) 동안 RRM-RS의 각 안테나 포트 별 수신 신호 레벨의 평균을 취하여 RSRP를 얻도록 한다. 또는 각각의 시간 윈도우에서 얻은 평균 수신 파워를 다시 필터링하여 보고할 RSRP를 얻을 수 있다.

[379] 다수개의 RRM-RS를 설정 받은 UE는 각 RRM-RS의 각 안테나 포트별 RSRP를 측정한다. RRM-RS를 R개 설정 받고 r번째 RRM-RS의 안테나 포트 수가 M_r인 경우에, r번째 RRM-RS의 m번째 안테나 포트의 RSRP를 RSRP(r,m)로 정의한다. UE는 RSRP(r,m)을 정렬하고 그 중에서 강하게 수신되는 L개 안테나 포트의 RSRP를 선택하여 보고하도록 한다.

[380] 위 방식을 약간 변형하여 UE는 RSRP(r,m)을 정렬하고 그 중에서 가장 강하게

수신되는 안테나 port를 선택하고 선택된 안테나 포트의 RSRP, 즉 max(RSRP(r,m))와 대비하여 일정 차이 내로 들어오는 포트의 RSRP들로 보고를 한정시킨다. 즉, 다음과 같이 RSRP 비율(ratio) 또는 dB 스케일(scale) 표현에서 RSRP의 차이가 일정 임계치 보다 높은 최대 L개의 안테나 포트의 RSRP를 보고하도록 한다.

[381] [수식13]

```
RSRP(r,m) - max(RSRP(r,m)) > Threshold
```

[382] 다른 일례로, UE는 참조(reference) 안테나 포트를 지정 받을 수 있다. 참조 안테나 포트로써 해당 UE에게 설정된 프리코딩된(precoded) CSI-RS와 빔 방향이 유사한 서빙 셀이 전송하는 RRM-RS의 안테나 포트를 지정해 주는 것이 바람직하다. UE는 r_0번째 RRM-RS의 m_0번째 안테나 포트를 참조 안테나 포트로 지정 받은 경우에, 참조 안테나 포트의 RSRP에 비해 다른 안테나 포트의 RSRP가 일정 차이 내로 들어오는 경우에 보고하도록 한다. 즉 다음과 같이 RSRP 비율(ratio) 또는 dB 스케일(scale) 표현에서 RSRP의 차이가 일정 임계치를 넘는 경우에 보고하도록 한다.

[383] [수식14]

```
RSRP(r,m) - RSRP(r_0,m_0) > Threshold
```

[384] 도 12는 본 발명의 일 실시예에 따른 RRM-RS의 안테나 포트 별 RSRP를 예시한다.

[385] 도 12에서는 32 안테나 포트로 구성된 RRM-RS의 각 안테나 포트별 RSRP의 일 예시를 나타내고 있다.

[386] 최대 RSRP를 갖는 안테나 포트에 비교해서 5dB이내의 RSRP를 갖는 안테나 포트들의 RSRP를 보고하도록 설정된 경우, 도 12와 같이 안테나 포트 13이 최대 RSRP 40dB를 가지므로 RSRP가 35dB를 넘는 안테나 포트에 대해 보고하도록 한다. 즉, 안테나 포트 13을 포함하여 안테나 포트 24, 25, 26의 RSRP가 기지국에 보고된다.

[387]

[388] <u>안테나 포트 그룹핑(Antenna port grouping)</u>

[389] 안테나 포트 별로 빔 포밍을 다르게 설정할 수 있으므로, 이 경우 안테나 포트와 빔은 일대일 대응 관계를 갖는다.

[390] 그러므로 안테나 포트 인덱스 (i)는 빔 인덱스(beam index) (i)와 일대일로 매핑시킬 수 있다. (i)번째 빔과 (i+1)번째 빔의 방향이 서로 인접하도록 빔들을 인덱싱하는 경우, 앞서 도 12의 예시에서처럼 인접한 안테나 포트들간의 RSRP는 서로 유사한 특징을 보이게 된다. 이러한 유사도는 (i)번째 빔과 (i+c)번째 빔 사이에서도 나타나지만 c가 커질수록 유사도는 떨어진다. 몇 개의 연속된 인접 빔들 사이에서 높은 유사도가 나올지는, 빔의 간격 및 빔의 폭(width), 그리고 다중-경로(multipath)들의 분산(scattering) 정도에 따라서 좌우된다.

[391] RRM-RS에 기반한 RSRP 측정 결과를 보고 받은 기지국은 해당 UE의 대략적 위치를 파악하고 해당 지점으로 향하여 전송되는 프리코딩된(precoded) CSI-RS 설정을 UE에게 알려주어 UE가 CSI-RS를 측정하여 PDSCH 스케줄링을 위한 CSI(RI, PMI, CQI 등)를 피드백 할 수 있도록 한다. 또한, 다수의 셀에서 전송하는 RRM-RS들에 기반한 RSRP 측정 결과를 보고 받은 기지국은 RSRP 측정 결과에 기반하여 해당 UE를 어떤 셀로 핸드오버 시킬지 그리고 타겟 셀에서 어떤 프리코딩된(precoded) CSI-RS를 UE에게 설정해 줄지 결정한다. 즉, RRM-RS에 기반한 RSRP 측정 결과는 해당 UE에게 향후에 어떤 프리코딩된(precoded) CSI-RS를 설정해 줄지를 판단하는데 필요한 중요 정보를 기지국에 제공한다.

[392] 앞서 도 12의 예시와 같은 RSRP 측정 결과를 바탕으로 해당 UE에게 최대 4개의 데이터 스트림 전송이 가능하도록 하거나 또는 페이딩(fading)의 변화에 맞추어 빠르게 최상의 빔 스위칭(best beam switching)을 하기 위하여 4-포트 CSI-RS를 설정해주는 경우에, RSRP가 가장 큰 RRM-RS 포트 13, 24, 25, 26의 빔 방향과 동일한 4-포트 CSI-RS를 생성하여 설정해 주는 것이 최적일 것으로 예상된다. 하지만 CSI-RS가 UE 별로 최적화하여 생성하고 전송하기에는 오버헤드(overhead)가 너무 크다. 그러므로 동일 환경에 있는 많은 UE들이 CSI-RS를 공유하는 것이 CSI-RS 전송 오버헤드를 줄일 수 있는 방법이다. 이러한 목적을 달성하기 위하여 하나의 CSI-RS 설정내의 CSI-RS 안테나 포트들의 프리코딩은 인접 방향으로 전송되는 빔의 특징을 나타내도록 프리코딩되어야 한다. 즉, 다른 서빙 받는 UE(served UE)들을 고려하여 미리 RRM-RS 포트 12, 13, 14, 15의 빔 방향과 동일한 4-포트 CSI-RS1과 RRM-RS 포트 24, 25, 26, 27의 빔 방향과 동일한 4-포트 CSI-RS2가 미리 설정되어 있는 경우에, 해당 UE에게 어떤 CSI-RS를 설정해주는 것이 좋을지를 RRM-RS의 RSRP 보고를 통해 판단할 수 있어야 한다.

[393] 본 발명의 또 다른 실시예로서 안테나 포트 그룹(antenna port group)에 대해서 RSRP를 측정 보고하도록 한다. 제안 방식에서 안테나 포트들을 그룹핑하고 그룹에 속하는 안테나 포트의 RSRP들을 평균 취하여 해당 안테나 포트 그룹의 RSRP를 얻도록 한다. 그룹은 미리 정해져 있거나 또는 기지국이 정해서 알려 줄 수 있다. 또는 UE가 그룹핑 방식을 정하고 이를 보고 할 수 있다.

[394] 앞서 도 12의 예시에서처럼 32-포트로 구성된 RRM-RS의 경우에 4 포트 씩 그룹핑 될 수 있다. 각 그룹들간에 분리(disjoint)하여 8(=32/4)개의 그룹으로 그룹핑될 수 있다. 이 경우에 (i)번째 포트 그룹은 RRM-RS 포트 (4i), (4i+1), (4i+2), (4i+3)로 구성된다. (i)번째 포트 그룹의 RSRP는 안테나 포트 (4i), (4i+1), (4i+2), 그리고 (4i+3)의 RSRP의 평균으로 정의한다.

[395] 또 다른 실시예로서, 그룹간의 중첩을 허용하여 그룹핑할 수 있다. 32-포트로 구성된 RRM-RS을 4 포트씩 그룹핑하는 경우에 15개의 그룹으로 그룹핑하도록 한다. 이 경우에 (i)번째 포트 그룹은 RRM-RS 포트 (2i), (2i+1), (2i+2), (2i+3)로 구성된다. 제안 방식을 일반화하여 A 개의 포트씩 그룹핑하고, 인접 그룹간의

포트 간격을 B로 설정하면, (i)번째 포트 그룹은 RRM-RS 포트 (B*i), (B*i+1), ..., (B*i+A-1)로 구성된다. 파라미터 A와 B의 설정은 기지국이 UE에게 지정해 주거나, 또는 UE가 채널 환경 및 UE 능력(capability)을 고려하여 선정하여 보고할 수 있다.

[396] 제안 방식의 변형으로 UE는 보고할 안테나 포트 그룹을 선택하는 방식으로 RSRP보다 해당 안테나 포트 그룹으로 얻을 수 있는 능력(capability)을 고려할 수 있다. 이 경우에 UE는 안테나 포트 그룹내의 다수의 안테나로부터 다중-계층(multi-layer) 데이터 전송을 고려하여 능력을 계산하도록 한다.

[397]

[398] 안테나 포트 그룹핑 레벨(Antenna port grouping level)

[399] 제안 방식에서 크기가 다른 다수개의 그룹핑 방법을 사용할 수 있다. 즉, A1 포트씩 그룹핑하는 방법과 A2 포트씩 그룹핑하는 방법을 동시에 사용할 수 있다. 이하, A_i 포트씩 그룹핑하는 방법을 그룹핑 레벨(grouping level) i로 명칭하도록 한다.

[400] 도 13은 본 발명의 일 실시예에 따른 RRM-RS 안테나 포트 그룹핑 레벨을 예시한다.

[401] 도 13에서는 16 포트 RRM-RS를 4단계의 그룹핑 레벨을 적용하여 그룹핑하는 방식의 일례를 보여주고 있다. 예시에서 그룹핑 레벨 1은 1 포트씩 그룹핑하는 방법으로 그룹핑을 하지 않지 않는 방식을 나타낸다. 그리고 그룹핑 레벨 2, 3, 4는 각각 2 포트, 4 포트, 8 포트씩 그룹핑하고 있다. 그림의 예시에서는 동일 레벨의 안테나 포트 그룹들이 분히(disjoint)하여 설정된 경우를 나타내고 있다.

[402] 이러한 다중 그룹핑 방식에서 UE는 그룹핑 레벨 별로 RSRP를 보고한다. 즉 각 그룹핑 레벨 별로 RSRP가 높은 안테나 그룹을 선택하여 보고하도록 한다. 또는 레벨이 다른 안테나 그룹간에 RSRP를 비교하여 최상의(best) 그룹과 그룹 레벨을 보고할 수 있다. 레벨1이 다른 안테나 그룹간의 RSRP를 비교하기 위하여 각 레벨의 그룹 RSRP에 일정 오프셋만큼 보정하고 비교하도록 한다. RRM-RS를 R개 설정 받은 경우에, (r)번째 RRM-RS의 (l)번째 그룹핑 레벨의 (g)번째 안테나 포트 그룹의 RSRP를 GRSRP(r,l,g)로 정의하면, 다음과 같이 기지국으로부터 (r)번째 RRM-RS의 (l)번째 그룹핑 레벨을 위해 지정 받은 offset(r,l)만큼을 보정하여 Adj_GRSRP(r,l,g)를 계산하고 이를 비교하도록 한다.

[403] [수식15]

```
Adj_GRSRP(r,l,g) = GRSRP(r,l,g) + offset(r,l)
```

[404] 추가적으로, 그룹핑 레벨 별로 또는 전체 그룹핑 방식에서 최상의(best) L개의 포트 그룹 RSRP를 보고하는 방식에서 보고되는 최상의(best) L에 대한 잦은 변동을 줄이기 위해 히스테리시스 파라미터(Hysteresis parameter), Hy를 추가하여 RSRP를 보정할 수 있다.

[405] [수식16]

$$Adj_GRSRP(r,l,g) = GRSRP(r,l,g) + offset(r,l) \pm Hy$$

[406] 여기서, Hy는 해당 포트 그룹이 이전 보고에서 최상의(best) L GRSRP에 포함되는지 여부에 따라서 Hy를 더할지 뺄지 결정된다. 해당 포트 그룹이 이전 보고에서 최상의(best) L GRSRP에 포함되어 있는 경우에 Hy를 더하여 높은 Adj_RSRP를 갖도록 바이어스를 줘서 최상의(best) L Adj_GRSRP를 갖는 포트 그룹이 자주 바뀌는 것을 줄여 주도록 한다.

[407] 제안 방식으로 UE는 참조(reference) 안테나 포트 그룹을 지정 받을 수 있다. 기지국은 해당 UE에게 설정된 프리코딩된(precoded) CSI-RS와 빔 방향이 동일한 서빙 셀이 전송하는 RRM-RS의 안테나 포트 그룹을 참조 안테나 포트 그룹으로 지정해 주는 것이 바람직하다. UE는 그룹핑 레벨 별로 참조 안테나 포트 그룹을 지정 받을 수 있다. 또는 전체 그룹핑 레벨에서 하나의 참조 안테나 포트 그룹을 지정 받을 수 있다. UE는 r_0번째 RRM-RS의 l_0번째 그룹핑 레벨의 m_0번째 안테나 포트 그룹을 참조 안테나 포트 그룹으로 지정 받은 경우에, 참조 안테나 포트 그룹의 Adj_GRSRP에 비해 다른 안테나 포트 그룹의 Adj_GRSRP가 일정 임계츠를 넘는 경우에 보고하도록 한다. 즉 다음과 같이 Adj_GRSRP 비율(ratio) 또는 dB 스케일(scale) 표현에서 RSRP의 차이가 일정 임계치를 넘는 경우에 보고하도록 한다.

[408] [수식17]

$$Adj_GRSRP(r,l,g) - Adj_GRSRP(r_0, l_0, m_0) > Threshold$$

[409] 또는 제안 방식의 변형으로 참조 RSRP를 현재 설정되어 있는 CSI-RS를 통해 특정하여 CSI-RS 기반 RSRP에 비해 RRM-RS 기반 RSRP 결과를 비교하여 선택 보고하도록 한다.

[410]

[411] **3차원(3D: 3-Dimension)을 위한 RRM-RS**

[412] 앞서 본 발명에서 제안하는 방식은 빔(beam)의 방향성이 2차원 공간에서 3차원 공간으로 확장되는 경우에도 변형하여 적용 가능하다. 3차원 공간상에서 빔의 방향성은 상하각(수직각)과 좌우각(수평각)의 두 개의 각도의 의해 조절된다. 그러므로 인접 빔 여부를 파악하기 위하여 빔들을 두 개의 인덱스, 즉 수평 인덱스와 수직 인덱스로 인덱스하는 것이 효율적이다. 본 발명의 특징에 따라 빔 인덱스와 RRM-RS 포트 인덱스와 일대일 대응 관계를 갖기 위하여 RRM-RS 포트도 수평 인덱스와 수직 인덱스로 인덱싱되는 것이 바람직하다.

[413] 수직 방향으로 M_v개의 빔을 갖고 수평 방향으로 M_h개의 빔을 갖는 3D MIMO 시스템의 경우에 전체 (M_v×M_h)개의 빔이 가능하다. 본 발명에서는 (M_v×M_h)-포트 RRM-RS를 설정하고 각 안테나 포트에 수평 인덱스 j_h(j_h=0, ..., M_h-1)와 수직 인덱스 j_v(j_v=0, ..., M_v-1)를 부여하도록 한다. (M_v×M_h)-포트 RRM-RS의 자원 매핑을 고려하여 각 안테나 포트들은 일차원

인덱스 i(i=0, ..., M_v×M_h-1)와 이차원 인덱스 j_h와 j_v를 부여 받게 되는데, (i) = f(j_h, j_v)의 관계를 갖게 된다.

[414] 도 14는 본 발명의 일 실시예에 따른 이차원 인덱스로 배열된 RRM-RS의 안테나 포트와 안테나 포트 그룹을 예시하는 도면이다.

[415] 도 14를 참조하면, 각 안테나 포트들은 (j_h, j_v)로 인덱싱되어 있다. 본 발명에서 제안하는 방식을 적용하여 A_h×A_v 개의 포트씩 그룹핑하고, 인접 그룹간의 포트 간격을 B_h와 B_v로 설정하면, (i_h, i_v)번째 포트 그룹은 RRM-RS port (B_h×i_h+j_h, B_v×i_v+j_v), (j_h=0, ..., A_h-1), (j_v=0, ..., A_v-1)로 구성된다. 파라미터 A_h, A_v와 B_h, B_v의 설정은 기지국이 UE에게 지정해 주거나, 또는 UE가 채널 환경 및 UE 능력(capability)를 고려하여 선정하여 보고할 수 있다.

[416]

[417] **RRM**-RS과 CSI-RS의 차이점

[418] 기존 LTE/LTE-A 시스템에서는 CSI 보고의 목적으로 CSI-RS를 전송한다. UE는 CSI로써 RI, PMI, CQI 등을 보고한다. 이와 달리 본 발명에서 제안하는 RRM-RS는 안테나 포트 별로 RSRP를 측정하기 위해 사용된다. RRM-RS의 전송 자원을 새롭게 정의하기 보다는 기존의 CSI-RS가 설정 가능한 자원을 사용하는 것이 바람직하다. 이는 레가시(legacy) UE들의 전송 효율을 떨어뜨리지 않기 때문이다. 새로운 자원에 RRM-RS를 전송하는 경우에 레가시(legacy) UE들은 이를 인식하지 못하므로, RRM-RS이 전송되는 서브프레임에서 전송 효율이 떨어지거나 또는 스케줄링하지 못하게 된다. 그러므로 기존의 CSI-RS가 설정 가능한 자원을 사용하여 RRM-RS를 전송하는 방식은 레가시(legacy) UE에게 해당 자원을 포함하여 CSI-RS 설정을 해주어 해당 자원에 데이터 매핑이 되지 않음을 알려줄 수 있다.

[419] UE에게 CSI 보고를 위해 설정된 다수개의 CSI-RS에는 데이터 매핑이 이루어지지 않는다. 즉 CSI-RS가 매핑되는 RE를 제외하고 PDSCH를 매핑한다. 본 발명의 제안 방식에서 RRM-RS는 CSI-RS 마찬가지로 RRM-RS가 매핑되는 RE를 제외하고 PDSCH를 매핑하도록 할 수 있다. 그러나 변형된 방식으로 RRM-RS와 무관하게 PDSCH를 매핑하도록 할 수 있다. 이 경우에 UE는 동일 RE에서 RRM-RS와 PDSCH를 동시에 수신할 수 있어야 한다. 또는 기지국이 RRM-RS의 안전한 수신을 보장하기 위하여 해당 자원을 ZP-CSI-RS로 설정하여 PDSCH가 매핑되지 않도록 할 수 있다.

[420]

[421] **RRM**-RS의 QCL 설정

[422] 각 셀에서 RRM-RS를 전송하는 경우에, UE는 서빙 셀 및 인접 셀들이 전송하는 RRM-RS들의 설정을 지정 받을 수 있다. 이를 통하여 UE는 서빙 셀의 빔포밍(beamforming)에 따른 이득 및 인접 셀의 beamforming에 따른 이득을 측정하여 네트워크에 보고하고 핸드오버의 판단 기준으로 활용하도록 해준다.

RRM-RS는 전송 밀도(density)가 매우 낮게 설정되므로 신호의 트래킹(tracking) 목적으로 부족할 수 있다. 그러므로 밀도(density)가 높아 신뢰(reliable)있게 수신되는 신호 대표적으로 CRS를 트래킹(tracking)하고 RRM-RS의 검출하는데 트래킹(tracking) 결과를 활용하도록 한다. 즉, 서빙 셀과 인접 셀의 반송파 주파수를 발생하는 오실레이터의 오차에 의하여 서빙 셀의 CRS에 의해 트래킹(tracking)된 결과를 인접 셀에서 전송된 RRM-RS를 위해 사용하기에는 부적합하다. 그러므로 각각의 RRM-RS 별로 RRM-RS를 검출할 때 사용할 QCL(Quasi Co-Located)된 CRS (혹은 CSI-RS 등 특정 다른 RS)를 알려주도록 한다. UE는 QCL된 CRS (혹은 CSI-RS 등 특정 다른 RS)로부터 추정된 채널의 광범위 특성(large-scale) 특성을 RRM-RS의 검출에 사용한다. 여기서 채널의 광범위 특성(large-scale) 특성은 지연 확산(Delay spread), 도플러 확산(Doppler spread), 도플러 쉬프트(Doppler shift), 평균 이득(average gain), 그리고 평균 지연(average delay) 중에 하나 이상을 포함할 수 있다.

[423]

[424] **RSRQ로 확장**

[425] 본 발명의 제안 방식들은 RRM-RS의 각 안테나 포트 별로 RSRQ를 측정하는 방식으로 확장 적용될 수 있다. RSRQ는 RSRP와 RSSI의 비율로 정의된다. 그러므로 추가적으로 RSSI의 측정이 추가된다. RSSI의 측정 자원은 동일 반송파 주파수를 갖는, 즉 동일 컴포넌트 캐리어(component carrier)에 설정된 모든 RRM-RS들에 있어서 동일하게 설정될 수 있다. 이 경우에 동일 컴포넌트 캐리어 내의 RRM-RS들의 포트들 간의 비교는 RSRP을 사용하나 RSRQ를 사용하나 동일하다. 그러나 이종 동일 컴포넌트 캐리어 내의 RRM-RS들의 포트들간의 비교는 RSRP을 사용할지 RSRQ를 사용할지에 따라 달라진다. 그러므로 기지국은 UE에게 RRM-RS에 기반한 RRM 보고를 수행함에 있어서 RSRP을 사용할지 RSRQ를 사용할지를 지정해 주도록 한다.

[426] 이와 달리 각각의 RRM-RS들 개별적으로 RSSI 측정 자원을 따로 설정해 줄 수 있다. 이 경우에는 동일 컴포넌트 캐리어 내에서도 RRM-RS들의 포트들간의 비교는 RSRP을 사용할지 RSRQ를 사용할지에 따라 달라진다. 그러므로 기지국은 UE에게 RRM-RS에 기반한 RRM 보고를 수행함에 있어서 RSRP을 사용할지 RSRQ를 사용할지를 지정해 주도록 한다.

[427]

[428] **RRM-RS RSRP와 CRS RSRP의 연관성**

[429] 본 발명의 RRM-RS에 기반한 RSRP는 다중 안테나를 가지고 있는 기지국의 beamforming 이득을 서빙 셀 선택에 반영함을 목적으로 하고 있다. RRM-RS의 RSRP에 근거하여 특정 인접 셀의 beamforing이 가장 좋다고 판단되어도, 해당 셀에서 브로드캐스트하는 채널들, 즉 CRS 기반 복조(demodulation)를 하는 채널이 안정적으로 수신되지 않으면 해당 인접 셀로 UE를 핸드오버 시킬 수 없다. 그러므로 UE에게 특정 기지국에서 전송하는 RRM-RM와 CRS 모두 좋은

품질을 갖는지 보고 받고 이를 근거를 핸드오버 결정 및 빔 선택(beam selection을 수행해야 한다. 이를 위하여 UE는 설정 받은 i번째 RRM-RS의 j번째 안테나 포트 또는 포트그룹의 RSRP를 보고하면서 i번째 RRM-RS과 연결된 CRS의 RSRP를 같이 보고 하도록 한다. 여기서 RRM-RS와 연결된 CRS는 RRM-RS와 QCL된 CRS일 수 있다.

[430]

[431] 개선된 RRM 및 RLM 동작

[432] FD-MIMO가 사용될 때, 일반적인 셀 연관(conventional cell association) 방법으로 인하여 셀 경계(cell-edge) 사용자는 현저하게 성능 저하(degradation)가 유발될 수 있다. 또한, CRS/PDCCH의 수직 빔(vertical beam)의 폭(width)은, 폭이 좁은 수직 빔(narrow vertical beam)으로 인해 발생되는 CRS/PDCCH의 커버리지 홀(coverage hole) 때문에 성능 저하(degradation)가 유발되는 시스템의 수율(throughput)에 현저한 영향을 미칠 수 있다. 만약, FD-MIMO를 위해 CRS 가상화(virtualization)가 사용된다면, 시스템 성능 측면에서 특히, 셀 경계(cell edge) UE의 부적절한 셀 연관(cell association)을 야기시킬 수 있다. FD-MIMO 전송 방식은 일반적인 전송 방식에 비하여 더 높은 빔 이득으로 동작하기 때문에, UE는 해당 UE를 위한 PDSCH에 적용되는 최적인 수직 빔을 제공할 수 있는 셀에 어태치되어야 한다.

[433] 즉, FD-MIMO 동작에 있어서, UE는 해당 UE에 대한 PDSCH에 적용되는 최적의 수직 빔(best vertical beam)을 제공할 수 있는 셀에 어태치(attach)되어야 한다.

[434] UE가 셀에 미리 어태치(attach)되어 있는 상황에서는 CSI-RS(디스커버리 RS(DRS: Discovery RS)로서 이용되는 경우 DRS-CSI-RS) 기반 RRM 측정을 통해 이를 가능하게 할 수 있다. 더욱 구체적으로, (FD-MIMO를 지원하는) UE는 상술한 FD-MIMO 측면에서 최적의 셀(best cell)이 아니더라도 주로 RACH 절차를 포함하는 기존의 CRS 기반 셀 선택 절차에 따라 셀에 어태치된다. UE가 RRC-Connected 모드에 셋업되면, UE는 DRS 측정 타이밍 설정(DMTC: DRS measurement timing configuration), DRS-CSI-RS 설정 등을 포함하는 디스커버리 절차를 위하여 필요한 모든 상위 계층 시그널링이 설정될 필요가 있다. 이러한 설정에 따라, UE는 DMTC 내 설정된 주기(예를 들어, 40, 80 또는 160 ms)에 따라 주기적으로 DRS-CSI-RS를 측정한다.

[435] 특히, UE는 DRS-CSI-RS 기반 RRM 측정에 기반하여(예를 들어, FD-MIMO 사용 케이스에서 각각 서로 다른 수직 빔(vertical beam)이 적용되는 경우 등), 특수한 동작에 따라 CSI-RS 기반 RRM 보고를 수행할 수 있다. eNB에서 이러한 RRM 보고 결과를 취합하고, eNB가 해당 UE의 현재 서빙 셀이 FD-MIMO 모드에 의해 전송된 PDSCH에 적용되는 최적의 수직 빔을 UE에게 제공하지 않는다고 판단하면, UE는 eNB으로부터 다른 셀로 핸드오버하도록 지시 받을 수 있다. 다시 말해, 서빙 셀 이외 다른 셀로부터 전송되는 특정 DRS-CSI-RS에 기반하여

최적 RRM 결과가 도출되고, 보고될 수 있다.

[436] DRS와 같이 프리코딩된 CSI-RS는 FD-MIMO를 지원하는 UE를 위한 잠재적인 핸드오버 결정뿐만 아니라 최적의 수직 빔 선택을 포함하는 RRM을 위해 이용될 수 있다.

[437] 그러나, FD-MIMO를 더 효율적으로 지원하기 위하여, 순수하게 RRM 측정 목적의 RS를 설계하는 것이 고려될 수 있다.

[438] 현재 DRS-CSI-RS는 안테나 포트 15에서만 전송되기 때문에, 셀 별로 서로 다른 수직 빔 각각에 상응하는 개별적인 DRS-CSI-RS 설정이 단말에 설정되는 것이 필요하다. 다만, FD-MIMO를 지원하기 위한 RRM 목적을 고려하여, 자원 사용 효율을 높이기 위해 CSI-RS 설정 내 안테나 포트 간 CDM(예를 들어, 안테나 포트 15 및 16)이 여전히 적용되기 위하여, 동일 셀 내 서로 다른 수직 빔 방향에 각각 적용되는 다중의 CSI-RS 안테나 포트가 단일의 CSI-RS 설정 내 설정될 수 있다. 또한, 설정들과 관련된 DRS 시점(occasion) 등을 포함하여 디스커버리 절차를 위해 필요한 다른 설정 및 동작은 이러한 RRM 목적을 위해 생략될 수 있다.

[439] 따라서, FD-MIMO를 지원하기 위하여 RRM 목적을 위한 개별적인 RS가 요구된다.

[440] UE을 위한 PDSCH에 적용되는 최적의 수직 빔(best vertical beam)을 제공할 수 있는 셀에 적절히 연관(association)하는 중에 발생되는 상술한 지연(latency)을 고려하여, 그러한 지연을 감소시키는 방법 또한 UE이 최초 접속 단계(initial access stage)에서도 최적의 셀에 연관하는 방법이 요구된다.

[441] 더욱 구체적으로, 일반적인 셀 연관 동작(cell association behavior)에 따라, 최악의 경우에서 지연(worst-case latency)은 UE가 그러한 디스커버리 절차와 관련된 DMTC를 포함하는 RRC 시그널링을 수신하고, UE가 설정된 RRC 시그널링에 따라 장기(long-term) DRS-CSI-RS 측정 및 보고를 수행하고, UE가 FD-MIMO 측면에서 최적이 아닌 셀에 어태치되었음이 판명된 경우 또 다른 셀로 핸드오버하는 것일 수 있다.

[442] 이에 따라 UE가 아이들 모드(idle mode)일 때 최적의 셀(best cell)을 최초로 탐색할 수 있도록 FD-MIMO를 지원하는 UE를 위한 셀 선택/재선택 절차의 개선을 고려할 수 있다.

[443] 또한, FD-MIMO 전송에 의해 서비스받는 단말이 최적의 셀에 연관(association)하기 위한 측면에서 무선 링크 모니터링 동작에 대한 개선이 필요하다.

[444] 따라서, FD-MIMO를 지원하는 UE이 최적의 셀로 적절히 연관하는 중에 발생될 수 있는 잠재적인 지연을 감소시키는 방법이 요구된다.

[445]

[446] <u>RRM-RS 기반 셀 선택 방법</u>

[447] 상술한 RRM-RS 등과 같이 특정 방향 빔포밍된 RS 포트(beamformed RS ports)

또는, (서로 다른 TP(들)/셀(들)의 개수로 구성되는) 무정형 셀(amorphous cells) 환경에서의 서로 다른 RS 포트(different RS ports)에 기반하여 단말이 RRM 측정치(예를 들어, RSRP, RSRQ 등)들을 기지국에 보고함으로써 기지국의 단말 연관(association) 결정을 도울 수 있다.

[448] 여기서, 무정형 셀(amorphous cell)은 고정적인 셀 형태를 가지지 않고, 단말 중심으로 무정형하게 구성되는 셀을 의미한다. 즉, 고정적인 셀 형태 없이 밀집한 (스몰) 셀들 간의 협력을 통해 이동 단말에게 데이터를 전달함으로써 커버리지를 형성하게 된다. 따라서, 단말이 이동하면 이동한 위치의 셀이 고려가 되어 핸드오버를 최소화할 수 있다.

[449] 즉, 이러한 일련의 동작을 단말이 수행하기 위해서는 우선 종래의 랜덤 액세스 절차(즉, RACH(Random Access Channel) 절차) 등의 초기 접속(initial access) 과정을 통해 특정 셀에 접속을 하여야 하고, 단말은 RRC 연결(RRC-connected) 상태에서 상기 RRM-RS 관련 설정 정보 등 다양한 사전 정보를 RRC 시그널링에 의해 제공 받아야 한다. 그 후, 상기 설명된 다양한 RRM 보고 절차에 따라 기지국에 각종 RRM 측정치들을 보고하는 동작까지가 단말이 수행하게 된다. 그 후, 최적의 셀 선택/핸드오버(best cell selection/hand-over) 과정들은 기지국에서 수행/결정함으로써, 해당 단말을 필요 시에 핸드오버(hand-over)시키거나 최적의 전송 포인트(best TP(transmission point))를 결정하여 CSI-RS 설정 등에 반영하는 형태로 동작될 수 있다. 결국, 이러한 일련의 과정을 통해 단말의 최적의 서빙 셀(best serving-cell)이 초기 접속 과정에 의해 접속된 서빙 셀이 아닌 것으로 판명되는 경우, 불가피하게 핸드오버가 발생할 수 있다. 따라서, 만일 초기에 접속하자 마자 위와 같은 과정을 통해 다른 셀로 조기에 핸드오버되는 단말의 경우, 최적의 셀 연관(best cell association)에 있어서 불필요한 큰 지연(latency)이 발생한다는 한계가 있다.

[450] 또 다른 종래 기술의 활용의 한계점에 관한 예시로서, 릴리즈(Rel: release)-12 스몰 셀 향상(small-cell enhancement)에 따른 디스커버리 절차(discovery procedure)를 활용하여, 예를 들어 상기 RRM-RS의 역할을 하는 RS(예를 들어, 디스커버리 신호(discovery signal) 또는 디스커버리 참조 신호(DRS: discovery reference signal) 또는 DRS-CSI-RS)(이하, 편의상 DRS로 지칭함)가 설정되고, DRS 측정 타이밍 설정(DMTC: DRS measurement timing configuration)을 포함한 DRS 기반 측정 관련 제반 정보가 설정될 수 있다. 그리고, 이를 통해 상기 풀-차원-MIMO(FD-MIMO: full-dimension MIMO) 사용 케이스 또는 진보된 무정형 셀(amorphous cells) 환경에서의 최적의 UE 기준의 셀 선택(best UE-centric cell selection)에 활용할 수 있는 방법이 존재한다.

[451] DMTC는 상위 계층 메시지(예를 들어, RRC 메시지)를 통해 단말에 제공될 수 있다. DMTC는 DRS 전송 주기/오프셋, 측정 주파수 대역, 측정 구간(즉, 디스커버리 신호 시점(discovery signal occasion)), DRS 안테나 포트 정보 등을 포함할 수 있다.

[452] 보다 구체적으로 살펴보면, 스몰 셀 향상은 스몰 셀의 에너지 절감(saving) 및 인접 셀로의 간섭을 감소시키기 위하여 단말이 스몰 셀 커버리지 내 존재하는 경우에만 스몰 셀의 온 상태(on-state)를 유지하고, 그렇지 않으면 스몰 셀의 오프 상태(off-state)를 유지하는 스몰 셀 on/off 메커니즘을 지원한다. 이 경우, 단말에서 스몰 셀이 on/off-state를 판단할 수 있도록 디스커버리 절차(discovery procedure)가 필요하다. 이를 위해, on/off-state와 무관하게 스몰 셀은 항상 DRS를 전송(즉, 방송)한다. 즉, 스몰 셀이 off-state인 경우에도 일정 주기를 가지고 DRS를 방송한다. 일정 주기를 측정 주기(measurement period) 또는 DRS 측정 타이밍 설정(DMTC) 주기라고 지칭할 수 있으며, 일례로 40ms, 80ms, 160ms 등이 해당될 수 있다.

[453] 이때, 스몰 셀은 DRS를 방송하는 on-state를 일정 시간(예를 들어, 1개 내지 5개 서브프레임) 유지할 수 있다. 예를 들어, 측정 주기가 40ms인 경우, 6ms 동안 on-state를 유지하면서 DRS를 방송하고, 나머지 34ms 동안 off-state를 유지할 수 있다. 이처럼 DRS를 전송하는 구간을 측정 윈도우(measurement window) 또는 디스커버리 신호 시점(DRS occasion)라고 지칭할 수 있다. 즉, 디스커버리 신호 시점은 연속된 서브프레임의 구간(예를 들어, 1개(또는 2개) 내지 5개의 연속된 서브프레임 구간)으로 구성될 수 있으며, 하나의 디스커버리 신호 시점은 매 측정 주기(또는 DMTC 주기) 내에서 한 번씩 존재할 수 있다.

[454] 단말은 스몰 셀로부터 수신한 DRS를 기반으로 측정(measurement)를 수행하고, 기지국(또는 네트워크)에게 측정 보고(measurement report)를 전송한다. 이와 같이, 단말로 하여금 스몰 셀이 on/off-state인지 무관하게 항상 스몰셀에서 전송되는 DRS를 측정하여 기지국(또는 네트워크)에게 보고하도록 함으로써, 기지국(네트워크)은 해당 단말 주변에 가장 효율이 좋은 스몰 셀을 파악할 수 있다. 예를 들어, 기지국(네트워크)이 UE로부터 측정 결과를 보고 받은 결과, off-state인 스몰 셀이나 단말에서의 DRS 수신 파워가 큰 경우에 기지국은 해당 스몰 셀을 on-state로 전환시킬 수 있다.

[455] 그러나 이 경우도 마찬가지로, 우선 UE가 특정 서빙 셀에 종래 방식대로 어태치(attach)된 후 RRC-connected 상태에서 DMTC 등 스몰 셀 디스커버리 관련 설정 정보를 RRC 시그널링을 통해 수신한 후, (프리코딩된(precoded)) DRS들(각각이 별도의 FD-MIMO 빔 방향을 타겟하거나, 또는 서로 다른 무정형 셀을 구성하는 TP들로부터 전송됨)에 대한 다수개의 CSI-RS-RSRP 보고(즉, DRS 기반 RSRP 보고)를 수행하여야 하며, 이것들에 기반하여 기지국이 해당 단말이 CRS 기반 RSRP 관점에서는 최적(best)이 아니지만 FD-MIMO 또는 무정형 셀 관점에서 최적의 셀이 따로 있다면 해당 셀로 핸드오버 시켜야 한다. 결국, 이 방식도 마찬가지로, 최적의 셀(best cell)로 연관(association)되기까지 (예를 들어, RRC-connection → DMTC 관련 RRC 정보 수신 → 장기(long-term) DRS-CSI-RS 측정 및 보고 → 핸드오버 절차의 과정을 모두 거쳐야 하는 단말이 있을 수 있으므로) 지연이 크게 증가할 수 있다는 한계가 있다.

[456] 따라서, 본 발명에서는 상기 FD-MIMO 또는 무정형 셀(amorphous cell) 환경 등과 같이, 종래의 셀 특정(cell-specific)하게 전송되는 RS(예를 들어, CRS)와 다른 별도의 RS(예를 들어, RRM 측정을 위한 RS, 셀 선택/재선택을 위한 RS) 포트를 활용하여 특정 RRM 측정(예를 들어, RSRP, RSRQ 등)을 단말이 수행하는 방법 및/또는 RRM 측정치들을 기반으로 단말이 초기 접속 시 등의 RRC 아이들 모드(idle-mode)(예를 들어, RRC_IDLE) 상태에서도 자신이 설정 받을 최적의 전송 모드를 미리 고려하여 최적의 셀을 선택(selection) 또는 재선택(reselection)하는 방법 및/또는 선택된 최적의 셀로 초기 접속(initial access) 과정을 개시하는 방법을 제안한다. 또한, 단말은 본 발명에서 제안하는 방법들을 순차적으로 수행함으로써 단말의 초기 접속(initial access) 과정을 수행할 수 있다.

[457] 이하, 본 발명의 설명함에 있어서, RRM-RS는 앞서 설명한 바와 같이 FD-MIMO와 같이 날카로운 빔(sharp beam)을 통해 지역적으로 방향을 다르게 전송되는 RS, 지리적으로 분산되어 배치된 TP(또는 cell) 별로 서로 다른 안테나 포트를 통해 전송되는 RS, 그 외에도 셀 특정 참조 신호(CRS)와 다른 별도의 RRM 측정 및 보고를 위한 RS(예를 들어, CSI-RS, DRS 등)를 통칭한다.

[458]

[459] 1. 단말의 초기 셀 탐색 과정

[460] - 본 발명에 따른 초기 접속(initial access) 과정의 첫 번째 과정으로서 단말의 초기 셀 탐색 과정이 수행될 수 있다.

[461] 단말의 초기 셀 탐색(initial cell search) 과정에서, 단말은 종래와 동일하게 각 셀이 전송하는 1차 동기신호(PSS: Primary Synchronization Signal) 및 2차 동기신호(SSS: Secondary Synchronization Signal) 등의 특정 동기 신호를 검출함으로써 해당 셀이 사용하고 있는 물리 셀 식별자(PCI: physical (layer) cell-ID)를 획득할 수 있다.

[462] PSS와 SSS의 특정 시퀀스에 의하여 단말은 PCI를 획득할 수 있다. 즉, SS는 3개의 PSS와 168개의 SSS의 조합을 통해 총 504개의 고유한 PCI를 나타낼 수 있다.

[463] 다시 말해, 상기 PCI들은 각 PCI가 오직 하나의 PCI 그룹의 부분이 되도록 각 그룹이 3개의 고유한 식별자들을 포함하는 168개의 PCI 그룹들로 그룹핑된다. 따라서, 물리 계층 셀 식별자 N_ID^cell = 3N_ID^(1) + N_ID^(2)는 PCI 그룹을 나타내는 0부터 167까지의 범위 내 번호 N_ID^(1)와 상기 PCI 그룹 내 상기 PCI를 나타내는 0부터 2까지의 번호 N_ID^(2)에 의해 고유하게 정의된다.

[464] 단말은 PSS를 검출하여 특정 PCI 그룹 내 3개의 고유한 PCI 중 하나를 알 수 있고, SSS를 검출하여 상기 PCI에 연관된 168개의 PCI 그룹들 중 하나를 식별할 수 있다.

[465] 그리고, 단말은 검출된 해당 PCI를 사용하여, 전송되는 해당 셀의 CRS를 검출 시도함으로써, 셀 ID(cell-ID)의 검증(verification)을 수행할 수 있다.

[466]

[467] 2. 탐색된 셀에서 시스템 정보 획득 과정

[468] 단말은 셀이 전송하는 예를 들어, PBCH(Physical Broadcast Channel), PDSCH(Physical Downlink Shared Channel) 등을 읽어서 해당 채널 상에서 전달되는 각종 시스템 정보(system information)를 획득한다.

[469] 시스템 정보(system information)는 마스터 정보 블록(MIB: Master Information Block)과 복수의 시스템 정보 블록(SIB: System Information Block)으로 나뉠 수 있다. 이하, SIB 타입 x(SystemInformationBlockTypex)를 간단히 'SIB x'로 지칭한다.

[470] 단말은 네트워크에 의해 브로드캐스트되는 시스템 정보를 획득하기 위하여 시스템 정보 획득 절차를 이용한다. 시스템 정보 획득 절차는 RRC_IDLE 모드인 단말 및 RRC_CONNECTED 모드인 단말 모두에게 적용된다. 예를 들어, 셀 선택(예를 들어, 단말 전원이 켜질 때) 및 셀 재선택, 핸드오버 완료 후, 다른 무선 접속 기술(RAT: Radio Access Technology)에 진입할 때, 커버리지 밖에서 커버리지 내로 진입할 때, 시스템 정보가 변경되었다는 통지를 수신하였을 때, 최대 유효 지속 기간(maximum validity duration)을 경과하였을 때 등 단말은 시스템 정보 획득 절차를 개시할 수 있다.

[471] 먼저, 단말은 네트워크로부터 MIB를 수신한다. 이때, MIB는 물리 채널(physical channel) PBCH에서 전송된다. MIB는 시스템 프레임 번호(SFN: System Frame Number) mod 4 = 0 인 무선 프레임의 서브프레임 #0에서 스케줄되고, 해당 주기 내에서 다른 모든 무선 프레임의 서브프레임 #0에서 반복된다. 그리고, 무선 프레임의 서브프레임 #0의 두 번째 슬롯의 처음 4개의 OFDM 심볼 내에서 중심의 72 서브캐리어를 점유한다.

[472] 단말은 MIB로부터 수신한 파라미터를 사용하여 네트워크로부터 SIB 1을 수신한다. 그리고, 단말은 SIB 1으로부터 획득한 스케줄링 정보 리스트(schedulingInfoList)를 기반으로, 네트워크로부터 SIB 1 이외의 SIB x를 수신한다.

[473] SIB 1은 SFN mod 8 = 0 인 무선 프레임의 서브프레임 #5에서 스케줄되고, 80 ms 주기 내에서 SFN mod 2 = 0 인 다른 모든 무선 프레임의 서브프레임 #5에서 반복된다. 반면, SIB 1을 제외한 나머지 SIB는 동일한 전송 주기를 가지는 SIB 별로 시스템 정보(SI: System Information) 메시지에 매핑되어 전송된다.

[474] 모든 SIB는 물리 채널 PDSCH에서 전달된다. SIB을 위한 PDCCH는 SI-RNTI(system information-RNTI)에 의해 스크램블된 CRC가 부착된 DCI를 전달하고, PDCCH로부터 SIB를 전달하는 PDSCH가 식별된다.

[475] 단말은 PDCCH 상의 SI-RNTI를 디코딩함으로써 SI 메시지를 전달하는 PDSCH의 구체적인 시간/주파수 자원 영역 스케줄링 등을 획득할 수 있다. 하나의 SI-RNTI가 SIB 1뿐만 아니라 모든 SI 메시지를 어드레스하기 위하여 사용된다.

[476] 단말은 시스템 정보 획득 절차를 통해 획득한 시스템 정보를 이미 저장되어 있는 시스템 정보에 덮어쓸 수 있다(overwrite).

[477] 이하, 본 발명에서는 MIB 또는 특정 SIB X 등 시스템 정보에 다음과 같은 RRM-RS 설정 관련 정보 중 적어도 하나가 포함되어 단말에게 전송하는 방법을 제안한다. 이에 대하여 아래 도면을 참조하여 설명한다.

[478] 도 15는 본 발명의 일 실시예에 따른 RRM-RS 기반 셀 선택 방법을 예시하는 도면이다.

[479] 도 15를 참조하면, 기지국은 단말에게 RRM-RS 설정 정보를 포함하는 시스템 정보를 전송한다(S1501).

[480] 상술한 바와 같이 이하 RRM-RS는 설명의 편의상 부여된 명칭일 뿐, CSI-RS 등과 동일 혹은 유사한 포맷으로 설정될 수 있는 등 다양한 명칭/변형 형태로 정의될 수 있다.

[481] - PCI (및/또는 인접 셀(neighbor-cell) 리스트)를 수반한 RRM-RS 설정(RRM-RS configurations with PCI)

[482] 해당 셀에서 전송하는 RRM-RS 설정 정보뿐만 아니라 인접 셀들에서 전송하는 RRM-RS 설정 정보도 함께 시스템 정보로서 단말에게 제공될 수 있다. 즉, 특정 RRM-RS 설정(들)은 특정 PCI와 연동(또는 대응)되어 있고 이 연동 정보가 함께 제공될 수 있다. 이때, 하나의 PCI 당 하나 이상의 RRM-RS가 연동(또는 대응)될 수 있다.

[483] 여기서, 인접 셀(neighbor-cell) 리스트는 인접-셀의 PCI 리스트를 포함한다. 일례로, 인접 셀의 일례로 해당 셀 주변의 1-타이어(tier) 정도의 영역에 존재하는 eNB 위치(site)에 속하는 셀들이 대상이 될 수 있다.

[484] 이러한 RRM-RS 설정 정보를 통해, 단말은 시스템 정보를 읽음으로써 해당 셀이 전송하는 RRM-RS 안테나 포트 뿐만 아니라 주변의 셀들이 전송하는 RRM-RS 안테나 포트에 대한 정보도 함께 획득할 수 있으므로 인접 셀들을 포함하여 최상의 RRM 측정치를 찾는 과정에 도움이 될 수 있다.

[485] 또한, 단말은 이와 같이 제공된 상기 RRM-RS 별로 연동된 특정 PCI 정보를 통해, 해당 RRM-RS 포트와 해당 연동된 PCI로 생성되는 CRS 포트 간에 서로 QCL(quasi-co-location) 가정을 할 수 있다. 이때, QCL 가정이 가능한 무선 채널의 광범위 특성(large-scale properties)은 {도플러 쉬프트(Doppler shift), 도플러 확산(Doppler spread), 평균 지연(average delay), 지연 확산(delay spread), 평균 이득(average gain)} 중에 적어도 하나를 포함할 수 있다.

[486] 또는, 평균 이득(average gain)은 RS가 서로 다르므로 QCL 가정에서 제외하고, QCL 가정이 가능한 무선 채널의 광범위 특성(large-scale properties)은 {도플러 쉬프트(Doppler shift), 도플러 확산(Doppler spread), 평균 지연(average delay), 지연 확산(delay spread)} 중에 적어도 하나를 포함하도록 정의될 수 있다).

[487] 보다 특징적으로 QCL 가정이 가능한 무선 채널의 광범위 특성은 {도플러 쉬프트(Doppler shift), 도플러 확산(Doppler spread)}로만 제한되어, 단말이 해당

RRM-RS의 주파수 동기(frequency sync)를 해당 연동된 CRS를 통해 획득하도록 할 수 있다. 이 경우, 단말은 시간 동기(time sync)를 RRM-RS 자체적으로 획득할 수 있다고 간주할 수 있다.

[488] 또는, 오직 단말이 RRM-RS로 RRM 측정만을 수행한다고 정의되거나 또는 설정된다면, QCL 가정이 가능한 무선 채널의 광범위 특성은 {도플러 쉬프트(Doppler shift)}만 적용할 수도 있다.

[489] 또는, 단말이 시간 동기(time sync)를 획득하기 위하여 CRS의 도움을 받아야 하고, 또한 RRM-RS로 RRM 측정 목적만이 있다면, QCL 가정이 가능한 무선 채널의 광범위 특성은 {도플러 쉬프트(Doppler shift), 평균 지연(average delay)}을 포함할 수 있으며, RRM-RS의 복조에 CRS를 통해 획득된 동기를 적용할 수 있도록 한다.

[490] 앞서 RRM-RS의 QCL 가정에 관하여 설명된 문장에서, CRS 대신 "PSS 및/또는 SSS"가 대체되어 모든 문장 또는 일부 문장에 적용될 수도 있다. 다시 말해, RRM-RS 복조에 CRS로부터 획득된 주파수 및/또는 시간 동기를 적용할 수 있으며, 그리고/또는 (해당 PCI로 (함께) 연동된) PSS/SSS로부터 획득된 주파수 및/또는 시간 동기를 적용할 수도 있다. 즉, 해당 PCI로 연동된 상기 특정 {RRM-RS, CRS, PSS/SSS} 간에 전체 또는 일부에 대해 서로 QCL 가정이 성립함을 단말에게 설정하거나 사전에 정의될 수 있다.

[491] - RRM-RS 설정 당 RRM-RS 안테나 포트 수 정보, RRM-RS 안테나 포트 매핑 정보, 해당 RRM-RS 전송 주기/오프셋 관련 정보 및/또는 전송 (주파수/시간) 자원 관련 정보 등과 같은 단말이 해당 RRM-RS를 측정하기 위해 필요한 설정 정보들이 제공된다.

[492] 즉, 상술한 바와 같이, 하나의 PCI(즉, 셀) 당 하나 이상의 RRM-RS 설정이 연동(또는 대응)될 수 있으며, 하나의 RRM-RS 설정 당 해당 RRM-RS를 측정하기 위해 필요한 설정 정보들이 제공된다.

[493] 만일, 이러한 RRM-RS가 스몰 셀 디스커버리(discovery)에서의 DRS(또는 DRS-CSI-RS)를 재사용하는 형태 등으로 구성된다면, DMTC 등 DRS로서의 CSI-RS를 측정하기 위해 필요한 설정 정보도 해당 시스템 정보에 더 포함되어 전달될 수 있다.

[494] 위와 같은 형태로, 해당 RRM-RS 관련 설정 정보가 명시적인 시그널링(explicit signaling)될 수도 있지만, 앞서 설명한 "1. 단말의 초기 셀 탐색 과정"에서 검출된 해당 PCI에 연동되는 암묵적인 지시(implicit indication) 형태로 상술한 RRM-RS 관련 설정 정보 중 일부가 암묵적으로 제공되는 방식도 가능하다. 즉, 상기 시스템 정보는 RRM-RS 관련 설정 정보로서 PCI를 포함하지 않을 수 있으며, 단말은 시스템 정보에 포함된 RRM-RS 설정 정보를 초기 셀 탐색 과정에서 검출된 PCI와 연동(또는 대응)되는 RRM-RS 설정 정보로 판단(또는 간주)할 수 있다.

[495] 예를 들어, 상기 전송 (주파수/시간) 자원 관련 정보는 PCI에 따라 특정 참조

자원(reference resource) 위치가 사전에 고정적으로 정의되어 있을 수 있다. 물론, RRM-RS 안테나 포트 수 정보, RRM-RS 안테나 포트 매핑 정보, 해당 RRM-RS 전송 주기/오프셋 관련 정보 중 하나 이상도 해당 PCI에 따라 암묵적 매핑(즉, 고정)되어 있을 수도 있다.

[496] 그러나, RRM-RS 안테나 포트 수나 RRM-RS 전송 주기/오프셋 관련 정보는 상기 설명한 시스템 정보로서 개별적인 셀 별(즉, PCI 별)로 제공하는 것이 바람직할 수 있다. 이 경우, 예를 들어 32개의 안테나 포트 RRM-RS가 40ms 주기와 오프셋 5ms에 따라 전송된다는 설정 정보가 상기 시스템 정보로서 제공되었다면, 상기 "참조 자원(reference resource)" 위치는 특정 서브프레임 내에서의 특정 참조 RE 위치를 의미하는 형태로 사전에 정의될 수 있다. 즉, PCI에 의해 고정적으로 정의되어 있는 상기 참조 RE 위치를 시작점으로 하여 32개의 안테나 포트가 순차적으로 매핑되는 관계는 사전에 규칙이 정의될 수 있으며, 따라서 해당 참조 RE 위치로부터 32개의 안테나 포트에 대한 RS 매핑 위치가 모두 정해지게 된다. 이때, 만일 1-순환(cycle)의 RRM-RS 전송이 단일 서브프레임에서 모두 전송될 수 없고 다중 서브프레임에 걸쳐서 전송되는 형태라면, 그 중 첫 서브프레임에 상기 참조 RE 위치가 적용되는 것으로 정의될 수 있다.

[497] RRM-RS 설정 정보를 수신한 단말은 RRM-RS 설정 정보에 기초하여 RRM 측정을 수행하게 된다. 즉, 단말은 RRM-RS 설정 정보에 기초하여 RACH(즉, PRACH)를 전송하기 이전(즉, 랜덤 액세스 절차를 개시하기 전)에 다중 RRM-RS 포트에 대한 RRM 측정을 수행할 수 있다.

[498]

[499] 3. RRM-RS 등 기반 진보된(enhanced) RRM 측정의 수행에 따른 단말 관점에서의 선호 셀 결정

[500] 도 16은 본 발명의 일 실시예에 따른 RRM 측정 방법을 예시하는 도면이다.

[501] 도 16을 참조하면, 단말은 기지국으로부터 전송되는 셀 특정 참조 신호(CRS) 및/또는 RRM 참조 신호(RRM-RS)를 기반으로 RRM(예를 들어, RSRP, RSRQ 등)을 측정한다(S1601).

[502] 단말은 CRS 기반 RRM 측정값 및/또는 RRM-RS 기반 RRM 측정값을 기반으로 셀 선택한다(S1602).

[503] 단말은 초기 셀 탐색(initial cell search) 과정을 통해 탐색된 셀 또는 단말의 서빙 셀(또는 단말이 현재 캠핑(camping)하는 셀), 단말에 의해 탐색된 셀에 인접한 셀 또는 단말의 서빙 셀에 인접한 셀 중에서 CRS 기반 RRM 측정 값 및/또는 RRM-RS 기반 RRM 측정값을 기반으로 셀을 (재)선택한다. 이후, RRC_IDLE 단말의 경우 (재)선택된 셀로 초기 접속(initial access) 과정을 수행하거나 해당 셀에 캠핑(camping)한다. 또한, RRC_CONNECTED 단말의 경우 (재)선택된 셀로 핸드오버(handover) 과정을 수행할 수 있다.

[504] 보다 구체적으로 살펴보면, 앞서 설명된 RRM-RS 관련 설정 정보들을 토대로,

단말은 다중 RRM-RS 포트에 대한 별도의 RRM 측정을 수행한다. 상술한 바와 같이, 이러한 RRM 측정은 단일 타겟 셀에 국한된 것이 아닌 인접 후보 셀들이 전송하는 RRM-RS들도 포함하여 수행될 수 있다.

[505] 예를 들어, 단말은 셀 1(PCI 1) 및 셀 2(PCI 2)에서 전송하는 RRM-RS 세트 1 및 RRM-RS 세트 2에 대해 RRM-RS 기반 RRM 측정을 수행한 후, 각 세트 별로 최상의(best) RRM(예를 들어, RSRP, RSRQ 등) 측정치를 나타낸 RRM-RS 포트를 파악한다.

[506] 그리고, 단말은 이 중 가장 큰 RRM-RS 기반 RRM 값(즉, 최상의(best) 값)을 나타내는 RRM-RS를 전송한 셀로 초기 접속 (예를 들어, RACH 프리앰블(preamble) 전송에 의한 RACH 절차)를 개시할 수 있다. 즉, 단말은 해당 셀로 RACH 프리앰블을 송신함으로써 랜덤 액세스 절차(즉, RACH 절차)를 시작할 수 있다. 또는, RRC_IDLE 단말은 가장 큰 RRM-RS 기반 RRM 값(즉, 최상의(best) 값)을 나타내는 RRM-RS를 전송한 셀을 선택(selection)하거나 재선택(reselection)하여 해당 셀에서 캠핑(camping)할 수 있다. 또한, RRC_CONNECTED 단말은 가장 큰 RRM-RS 기반 RRM 값(즉, 최상의(best) 값)을 나타내는 RRM-RS를 전송한 셀로 핸드오버(handover)를 진행할 수 있다.

[507] RRC_IDLE 상태의 단말은 항상 적절한 품질의 셀을 선택하여 이 셀을 통해 서비스를 제공받기 위한 준비를 하고 있어야 한다. 예를 들어, 전원이 막 켜진 단말은 네트워크에 등록을 하기 위해 적절한 품질의 셀을 선택해야 한다. RRC_CONNECTED 상태에 있던 단말이 RRC_IDLE 상태에 진입하면, 상기 단말은 RRC_IDLE 상태에서 머무를 셀을 선택해야 한다. 이와 같이, 상기 단말이 RRC_IDLE 상태와 같은 서비스 대기 상태로 머물고 있기 위해서 어떤 조건을 만족하는 셀을 고르는 과정을 셀 선택(Cell Selection)이라고 한다.

[508] 그리고, 단말이 일단 셀 선택 과정을 통해 어떤 셀을 선택한 이후, 단말의 이동성 또는 무선 환경의 변화 등으로 단말과 기지국간의 신호의 세기나 품질이 바뀔 수 있다. 따라서 만약 선택한 셀의 품질이 저하되는 경우, 단말은 더 좋은 품질을 제공하는 다른 셀을 선택할 수 있다. 이렇게 셀을 다시 선택하는 경우, 일반적으로 현재 선택된 셀보다 더 좋은 신호 품질을 제공하는 셀을 선택한다. 이런 과정을 셀 재선택(Cell Reselection)이라고 한다.

[509] 이하, 설명의 편의를 위해 (초기 접속) 타겟 셀로 선택한다는 것은 단말이 RACH 절차를 개시하기 위한 셀을 선택하거나, 또는 RRC_IDLE 단말이 캠핑 셀(camping cell)을 선택 또는 재선택하거나, 또는 RRC_CONNECTED 단말이 핸드오버를 수행할 타겟 셀을 선택한다는 의미로 해석될 수 있다.

[510] 또는, 최상의(best) RRM-RS 기반 RRM 측정치를 보인 특정 RRM-RS를 전송한 셀로 RACH 프리앰블을 전송(즉, 랜덤 액세스 절차 개시)하는 방법 뿐만 아니라, RRM-RS 기반 RRM 측정치와 해당 셀이 전송하는 CRS 기반 RRM(CRS-based RRM) 측정 값도 함께 비교하여 최적의 초기 접속 타겟 셀을 결정하는 특정 함수(또는 규칙) 형태가 사전에 정의되거나 단말에 설정될 수 있다.

[511] 예를 들어, 최상의(best) RRM-RS 기반 RRM 측정치를 보인 특정 RRM-RS를 전송한 셀의 CRS 기반 RRM 측정값이, 다른 셀로부터의 CRS 기반 RRM 측정값(예를 들어, 가장 큰 CRS 기반 RRM 측정 값) 대비 임계값(즉, Y dB) 차이보다도 더 나쁜(작은) 경우에는 해당 셀은 타겟 셀이 될 수 없다는 등의 조건(또는 규칙)과 함께 특정 임계치 값 Y가 정의될 수도 있다. 이처럼 최상의(best) RRM-RS 기반 RRM 측정치를 보인 특정 RRM-RS를 전송한 셀이 타겟 셀에서 제외되는 경우, 단말은 그 다음으로 큰 큰 RRM-RS 기반 RRM 측정치를 가지는 셀을 선택할 수 있다. 이는 해당 셀의 기본적인 제어 채널(예를 들어, PDCCH) 전송에 대한 수신 품질이 지나치게 떨어질 경우 이 셀에 접속하는 것을 방지하기 위한 것이다.

[512] 또 다른 예시로는, 단말은 RRM-RS 기반 RRM(RRM-RS-based RRM) 측정치와 해당 셀이 전송하는 CRS 기반 RRM 측정치간에 특정 가중된 평균(weighted average)을 취하여 최적의(best) 타겟 셀을 결정할 수도 있다. 즉, 단말은 RRM-RS 기반 RRM 측정 값과 CRS 기반 RRM 측정 값의 가중 평균치가 가장 큰 셀을 타겟 셀로 선택할 수 있다.

[513] 이때, 가중된 평균(weighted average)에 관한 가중치(weights) 값은 사전에 정의될 수 있다. 또한, 가중치(weights) 값은 어느 정도 단말 구현의 범주로 허용하되 단말 테스트 시에 특정 테스트 벡터에 의해 성능에 대한 검증이 수행될 수 있다.

[514] 또 다른 예시로는, 각 검출된 셀 별로의 CRS 기반 RRM 측정치들을 크기 순서대로 나열했을 때, 예를 들어 가장 큰 측정치 값이 C1 (예를 들어, PCI 7에 대한)이고 그 다음 C2(예를 들어, PCI 9에 대한), C3(예를 들어, PCI 6에 대한), C4(예를 들어, PCI 5에 대한), ... 순서로 정렬되었을 때, C1-C4 > Y 로서 임계치 Y를 넘어가는 C4 이하의 RRM 측정치 값들은 타겟 셀 대상에서 제외할 수 있다. 즉, 가장 큰 CRS 기반 RRM 측정치와의 차이가 임계치 이하(또는 미만)인 셀을 타겟 셀 후보로 결정할 수 있다. 따라서, 위의 경우 C1, C2, C3의 CRS 기반 RRM 측정치에 해당하는 각 셀 (PCI 7, PCI 9, 또는 PCI 6를 가지는 셀)이 타겟 셀 후보로 고려될 수 있다. 그리고, 단말은 타겟 셀 후보 중에서 RRM-RS 기반 RRM 측정 값이 가장 큰 셀을 타겟 셀로 선택할 수 있다.

[515] 만약, 종래 동작에 따르면 단말은 C1값을 갖는 PCI 7 셀에 초기 접속을 개시하는 것이 바람직하다. 다만, 본 발명의 또 다른 실시예에 따르면 각 C1, C2, C3 값 각각에 대해 추가적으로 각 셀에서 전송하는 RRM-RS들 중에 최상의(best) RRM-RS 기반 RRM 측정치를 산출하여 추가 비교할 수 있다.

[516] 예를 들어, C1값을 나타낸 PCI 7 셀에서 전송하는 RRM-RS들 중에 최상의(best) RRM 측정치 값을 R1이라고 하고, C2값을 나타낸 PCI 9 셀에서 전송하는 RRM-RS들 중에 최상의(best) RRM 측정치 값을 R2이라고 하고, C3값을 나타낸 PCI 6 셀에서 전송하는 RRM-RS들 중에 최상의(best) RRM 측정치 값을 R3이라고 가정한다. 그리고, R2 = max{R1, R2, R3}라고 가정하고, 크기 순서로

정렬하자면 R2 > R3 > R1이었다고 가정한다.

[517] 이때, 결국 어떠한 셀에 초기 접속을 개시하도록 할 것인지에 관해 정형화된 규칙이 미리 정해지거나 단말에 설정될 수 있다.

[518] 이를 위해 사전에 상기 임계치 Y를 좀더 세분화 하여 0 < Y1 < Y2 < ... < Yn < Y 과 같은 형태로 세분화된 임계치가 사전에 정의되거나 단말에 설정될 수 있다. 예를 들어, 설명의 편의상 n=3으로 가정한다. 그러면, 0 < Y1 < Y2 < Y3 < Y 의 조건이 성립하는 세분화된 임계치 Y1, Y2, Y3가 미리 정의되거나 단말에 설정될 수 있다.

[519] 또한, 유사하게 상기 R1, R2, R3 값들에 대한 비교를 위해서도 사전에 0 < Z1 < Z2 < ... < Zm < Z 의 임계치 값들이 미리 정의되거나 단말에 설정될 수 있다. 예를 들어, 설명의 편의상 m=3으로 가정한다. 그러면, 0 < Z1 < Z2 < Z3 < Z 의 조건이 성립하는 세분화된 임계치 Z1, Z2, Z3가 미리 정의되거나 단말에 설정될 수 있다.

[520] 예를 들어 다음과 같은 형태의 규칙이 충족될 경우에만 상기 최상의(best) CRS 기반 RRM 측정치 C1을 나타낸 PCI7 셀이 아닌 다른 셀로 초기 접속을 개시할 수 있도록 하는 특정 명확한 동작이 정의될 수 있다.

[521] 이하, 상술한 규칙에 대하여 예시한다.

[522] (1) 특정 셀 i에 대한 Ci가 Y3 ≤ C1-Ci < Y 범위에 있는 경우, 해당 셀 i에 대한 Ri가 0 ≤ max_j{Rj} - Ri < Z1 인 경우에만 해당 셀 i를 초기 접속 타겟 셀로 선택할 수 있다.

[523] (2) 특정 셀 i에 대한 Ci가 Y2 ≤ C1-Ci < Y3 범위에 있는 경우, 해당 셀 i에 대한 Ri가 0 ≤ max_j{Rj} - Ri < Z2 인 경우에만 해당 셀 i를 초기 접속 타겟 셀로 선택할 수 있다.

[524] (3) 특정 셀 i에 대한 Ci가 Y1 ≤ C1-Ci < Y2 범위에 있는 경우, 해당 셀 i에 대한 Ri가 0 ≤ max_j{Rj} - Ri < Z3 인 경우에만 해당 셀 i를 초기 접속 타겟 셀로 선택할 수 있다.

[525] (4) 특정 셀 i에 대한 Ci가 0 ≤ C1-Ci < Y1 범위에 있는 경우, 해당 셀 i에 대한 Ri가 0 ≤ max_j{Rj} - Ri < Z 인 경우에만 해당 셀 i를 초기 접속 타겟 셀로 선택할 수 있다.

[526] 위의 수식을 살펴보면, 최상의 CRS 기반 RRM 측정값과 측정 대상 셀에 대한 CRS 기반 RRM 측정값의 차이와, 최상의 RRM-RS 기반 RRM 측정값과 측정 대상 셀의 최상의 RRM-RS 기반 측정값의 차이를 기반으로 초기 접속 타겟 셀이 선택될 수 있다. 다시 말해, 가장 큰 CRS 기반 RRM 측정 값과 특정 셀의 CRS 기반 RRM 측정 값의 차이가 상대적으로 크다면, 가장 큰 RRM-RS 기반 RRM 측정 값과 해당 특정 셀의 RRM-RS 기반 RRM 측정 값의 차이가 상대적으로 작은 경우에만 해당 특정 셀을 타겟 셀로 선택할 수 있다. 반대로, 가장 큰 CRS 기반 RRM 측정 값과 특정 셀의 CRS 기반 RRM 측정 값의 차이가 상대적으로 작다면, 가장 큰 RRM-RS 기반 RRM 측정 값과 해당 특정 셀의 RRM-RS 기반 RRM 측정 값의 차이가 상대적으로 크더라도 해당 특정 셀을 타겟 셀로 선택할

수 있다. 결국, 단말은 CRS 기반 RRM 측정 값과 RRM-RS 기반 RRM 측정 값 중 어느 하나라도 양호한 셀을 타겟 셀로 선택할 수 있다.

[527] 만일 상기 (1), (2), (3), (4) 조건들 중 다수가 충족되는 상황에서는, 그 중에서 가장 높은 Ri 값을 나타내는 셀을 초기 접속의 타겟 셀로 결정하여 RACH 프리앰블을 송신할 수 있다. 또한, RRC_IDLE 단말의 가장 높은 Ri 값을 나타내는 셀을 선택(selection)하거나 재선택(reselection)할 수 있다.

[528] 위 규칙은 하나의 예시에 불과하며, 본 발명이 이에 한정되는 것은 아니다. 즉, 이와 같이 CRS 기반 RRM 값(즉, C1, C2, C3,...)들과 RRM-RS 기반 RRM(즉, R1, R2, R3,...)들을 동시에 고려하여 초기 접속 타겟 셀을 결정하도록 하는 구체적인 조건 수식은 변형될 수 있다.

[529] 앞서 설명한 바와 같이, CRS 기반 RRM 측정치를 함께 고려하여 최적의(best) 타겟 셀을 정하지 않고, 오직 상기 RRM-RS 기반 RRM 측정치에 입각하여 최적의(best) 타겟 셀을 정하여 초기 접속을 개시하도록 하는 경우에는, 이후에 공통의 제어 채널(common control channel) 등 제어 채널의 경우 곧바로 단말 특정(UE-dedicated) 제어 채널 (예를 들어, EPDCCH)을 통해서만 제어가 이루어질 수 있는 시스템(예를 들어, CRS 및 PDCCH가 존재하지 않는 새로운 캐리어 타입(NCT: new-carrier type) 시스템)에서 활용될 수 있다.

[530] 이 경우, 상기 SIB X 등 시스템 정보에 (또는 RACH 절차 상의 초기에) EPDCCH 설정 관련 정보도 미리 단말들에게 알려 줄 수 있다. 예를 들어, 상기 시스템 정보를 통해 단말에게 분산 EPCCH(distributed EPDCCH) 관련 설정 정보만 우선 제공될 수 있다. 그 후에, 단말이 특정 RRM-RS가 최상의(best) RRM 측정치를 보이는 것으로 보고가 된다면, 이를 바탕으로 기지국이 해당 단말에게 보다 최적화된 지역 EPDCCH(localized EPDCCH) 관련 설정 정보를 제공하고 지역 EPDCCH(localized EPDCCH)에 의한 제어 정보가 전달되도록 할 수 있다.

[531]

[532] 4. RACH 절차 상에서의 추가 개선 동작

[533] 도 17은 본 발명의 일 실시예에 따른 랜덤 액세스 절차를 예시하는 도면이다.

[534] 이하, 설명의 편의를 위해 본 발명의 일 실시예에 따른 랜덤 액세스 절차는 앞서 도 8에 따른 랜덤 액세스 절차와 비교하여 차이가 있는 부분을 위주로 설명하며, 이하 설명되지 않은 내용은 앞서 도 8에 따른 랜덤 액세스 절차로 대체될 수 있다.

[535] 1) 1 단계 (단말의 RACH 프리앰블 송신)

[536] 단말은 RACH 프리앰블을 전송하는 타겟 셀은 앞서 설명한 "3. RRM-RS 등 기반 진보된(enhanced) RRM 측정의 수행에 따른 단말 관점에서의 선호 셀 결정"에서 설명한 방법들 중 적어도 어느 하나를 적용하여 결정하고, 해당 타겟 셀로 RACH 프리앰블(즉, 제1 메시지)을 송신한다(S1701).

[537] 이때, RRM 측정 값(예를 들어, RRM-RS 기반 RRM 측정 값 및/또는 CRS 기반 RRM 측정 값)을 RACH 절차 내에서 보고하는 단말은 그렇지 않은

레가시(legacy) 단말과 구분될 수 있도록, 레가시(legacy) 단말과 다른 RACH 프리앰블 집합에서 RACH 프리앰블을 선택할 수 있다. 이에 따라 기지국은 단말로부터 수신한 RACH 프리앰블이 속한 RACH 프리앰블 집합에 따라 해당 단말이 RACH 절차 내에서 RRM 측정 값을 보고하는 단말인지 여부를 판단할 수 있다. 이처럼 RACH 절차 내에서 RRM 측정 값을 보고하는 단말과 레가시(legacy) 단말이 서로 다른 RACH 프리앰블 집합을 이용하는 경우, 기지국은 시스템 정보에서 RACH 프리앰블 집합 정보를 전송할 수도 있다. 예를 들어, 앞서 도 15의 S1501 단계에서 RRM-RS 기반 RRM 측정을 수행한 단말 및/또는 레가시(legacy) 단말을 위한 RACH 프리앰블 집합 정보를 전송할 수 있다.

[538] 2) 2 단계 (기지국으로부터의 랜덤 액세스 응답(RAR: random access response) 수신)

[539] 기지국은 제2 메시지(message 2)(즉, RAR)를 통해 해당 단말이 전송한 RACH 프리앰블에 대한 응답을 전송한다(S1702).

[540] 현재 단계에서 기지국은 해당 단말이 상기 FD-MIMO 등을 지원할 수 있는 진보된(enhanced) 단말(즉, RRM-RS 기반 RRM 측정을 수행한 단말)에 대한 정보들을 알지 못하므로 레가시(legacy) 단말에 대한 동일한 형태의 제2 메시지(message 2) 응답을 제공할 수 있다.

[541] 또는, 상술한 바와 같이, RACH 절차 내에서 RRM 측정 값을 전송하는 단말과 레가시 단말이 서로 다른 RACH 프리앰블 집합에서 RACH 프리앰블을 선택하는 경우, RACH 절차 내에서 RRM 측정 값을 전송하는 단말과 레가시 단말에게 전송되는 제2 메시지는 서로 다른 포맷을 가질 수 있다. 예를 들어, 이와 같이 제2 메시지의 포맷이 구분되는 경우, RACH 절차 내에서 RRM 측정 값을 전송하는 단말에게 전송되는 제2 메시지에서만 후술하는 임계치 Z 값을 포함할 수 있다. 또한, 기지국은 RACH 절차 내에서 RRM 측정 값을 전송하는 단말에게는, 해당 단말이 후술하는 RRM 측정치를 포함하는 제3 메시지의 전송하는 점을 고려하여 시간/주파수 자원을 할당할 수 있다.

[542] 3 단계 (단말의 L2(layer 2)/L3(layer 3) 메시지 전송)

[543] 단말은 S1702 단계에서 기지국으로부터 수신한 RAR에 대한 응답으로 PUSCH를 통해 상향링크 메시지(즉, 제3 메시지(message 3))를 전송한다(S1703).

[544] 이때, S1702 단계에서 기지국으로부터 RAR을 통해 제공받은 (임시(temporal)) C-RNTI를 통해 PUSCH를 전송할 수 있다.

[545] 본 발명의 일 실시예에 따르면, 단말은 참조 신호 기반으로 측정된 RRM 측정치 값을 제3 메시지를 통해 기지국에 보고할 수 있다. 이때, RRM 측정 값은 앞서 설명한 RRM-RS 기반 측정치들이 해당되거나, 또는 CRS 기반 RRM 측정치들이 해당되거나, 또는 RRM-RS 기반 측정치와 CRS 기반 RRM 측정치가 모두 해당될 수도 있다.

[546] 예를 들어, 현재 제3 메시지(message 3)를 전송하는 타겟 셀이 전송하는

RRM-RS 설정들 및 모든 포트에 대한 RRM 측정치들을 모두 보고하도록 정의될 수 있다. 이를 통해 해당 셀은 이후 이 단말에게 적절한 CSI-RS 설정들을 할 때에 이 보고 정보에 기반하여 효과적으로 CSI-RS를 설정할 수 있다는 장점이 있다.

[547] 또는, 모든 RRM-RS 측정치들을 보고하는 것이 아니라, 최상의(best) RRM-RS 측정치 대비 Z dB 이내의 RRM-RS 측정치들을 보고하도록 정의될 수 있다.

[548] 이때, 임계치 Z 값은 사전에 고정적으로 정의되어 있거나, 앞서 S1702 단계의 RAR 메시지를 통해 기지국이 알려줄 수도 있다. 이 경우, 이 정보는 진보된 단말(enhanced UE)만 이해할 수 있는 정보로서 취급될 수 있다.

[549] 또한, 이와 같이 단말이 RRM-RS 측정치들을 보고할 때, 해당 RRM-RS를 전송하는 셀의 PCI를 함께 연동정보로서 보고할 수 있다.

[550] 이는 대상 셀 이외에도 인접 셀(neighbor cell)이 전송하고 있는 RRM-RS에 대한 RRM 측정값도 어느 수준 이상 높은 값을 보이고 있다면 (예를 들어, 임계치 Z' 이내), 해당 단말에게 가해지고 있는 인접 셀들로부터의 간섭 수준을 미리 파악할 수 있다는 장점이 있고 이를 통해 CSI 프로세스(CSI process) 관련 설정 등에 있어서 참고로 활용될 수 있다.

[551] 이와 같이 단말이 상기 RRM-RS 기반 RRM 측정치들 및/또는 CRS 기반 RRM 측정치 값들 자체를 기지국에 보고해주는 시점은 제3 메시지를 전송하는 단계(즉, S1703 단계)가 아니라 그 이후 다른 단계에서 보고될 수도 있다. 이 경우, 단말은 이후의 단계에서 상기 RRM-RS 기반 RRM 측정치들 및/또는 CRS 기반 RRM 측정치 값들을 보고한다는 것을 기지국에 알리기 위한 지시자(예를 들어, 1 비트 지시자)를 포함시켜 제3 메시지를 전송할 수도 있다.

[552] 예를 들어, 제4 메시지(message 4)를 단말이 기지국으로부터 수신한 후에 (그리고 제4 메시지에서 단말의 식별자를 포함함으로써 기지국이 충돌 해결을 확인(confirmation)을 해준 경우), 단말은 긍정 응답(positive ACKnowledgement)(즉, 'ACK')을 기지국에 전송하도록 종래 동작이 정의되어 있다. 이 시점과 연동되어 함께 상기 RRM-RS 기반 RRM 측정치들 및 CRS 기반 RRM 측정치 값들을 기지국에 보고하도록 전송 시점이 정의될 수 있다.

[553] 즉, 이러한 ACK을 보내는 시점이 서브프레임(SF: subframe) #n이라면, 단말이 상기 RRM-RS 기반 RRM 측정치들 및 CRS 기반 RRM 측정치 값들을 동일 SF #n에 전송하는 것으로 (예를 들어, PUSCH에 의해) 정의될 수 있다.

[554] 또는, 특정 SF 오프셋 k값이 사전에 정의되거나 기지국의 선행하는 메시지(예를 들어, 시스템 정보 또는 제2 메시지 등)를 통해 알려주는 경우 해당 k값을 적용하여 SF #n+k 시점에 상기 RRM-RS 기반 RRM 측정치들 및 CRS 기반 RRM 측정치 값들을 전송하는 것으로 미리 정의되거나 단말에 설정될 수 있다.

[555] 또는, 기지국으로부터 명시적인 트리거링(explicit triggering) (예를 들어, UL 그랜트(grant))에 따라 해당 시점에 전송하는 것으로 정의될 수도 있다. 다시 말해, 이 경우 모든 RACH 절차가 완료된 후 기지국으로부터 특정 UL 그랜트를 수신할 수 있고 (예를 들어, 해당 UL 그랜트 내에 특정 명시적(explicit) 또는

암묵적(implicit) 필드 지시가 포함되거나 별도의 RNTI로 마스킹(masking)되는 형태 등 특정 규약된 시그널링 형태를 따를 수 있음), 이와 같이 상기 RRM-RS 기반 RRM 측정치들 및 CRS 기반 RRM 측정치 값들을 기지국으로 전송하라는 특정 UL 그랜트를 수신한 시점(즉, UL 그랜트에 대한 응답으로)에 이 정보들을 기지국에 전송하도록 정의되거나 단말에 설정될 수 있다.

[556] Step 4 (기지국으로부터 충돌 해결 메시지(Contention resolution message) 수신)

[557] 기지국은 충돌 해결 메시지(즉, 제4 메시지)를 단말에게 전송할 수 있다. 이 단계 자체에 대해서는 도 8의 예시에 따른 방식을 그대로 사용할 수 있다.

[558] 또는, 본 발명의 또 다른 일 실시예에 따르면, 이 단계와 동시에 즉, 충돌 해결 메시지(즉, 제4 메시지) 내에서 기지국은 상기 제3 메시지(message 3) 단계에서의 RRM-RS 기반 RRM 보고 정보들을 고려하여 바로 해당 단말에게 전송 모드(transport mode) 설정 및 CSI 피드백 관련 설정 정보들을 제공할 수 있다.

[559] 이러한 과정을 통해, 본 발명에 따르면 단말의 정상적인 전송 모드 설정 및 CSI 피드백, 그리고 송/수신 동작을 위해 추가적인 핸드오버(hand-over)나 셀 재선택(cell re-selection) 과정 없이 빠르게 정상 동작 상태에 진입할 수 있도록 하는 장점이 있다.

[560] 앞서 본 발명에 대한 설명에 있어서, 설명의 편의상 FD-MIMO를 활용 사례를 위주로 설명을 하였으나, 상기 언급한 바와 같이 무정형 셀(amorphous cells) 환경에서의 다수의 RRM-RS 설정 (즉, 서로 다른 개수의 TP(들)들로 무정형 셀이 구성됨에 따라 서로 다른 개수의 TP(들)이 함께 각 RRM-RS를 전송하는 형태) 등 다양한 활용 사례에도 적용될 수 있음은 자명하다. 그 밖에도 종래의 셀 별로 단일 CRS 기반 RRM 측정치에 기반하여 초기 접속(initial access)을 위한 타겟 셀을 고려하는 방식이 아닌, 별도의 다른 RS(앞서 설명의 편의상 RRM-RS로 지칭하였음)들부터의 RRM 측정치에 기반하여 초기 접속(initial access)이 수행되도록 하는 또 다른 다양한 환경에서도 적용이 가능하다.

[561] 앞서 1. 내지 4.에서는 설명의 편의상 단말이 네트워크로의 초기 접속(initial access)하는 상황을 가정하여 설명하였으나, 반드시 1. 내지 4. 방법이 단말의 초기 접속(initial access) 과정에서만 순차적으로 적용될 필요는 없으며 각각의 방법이 독립적으로 수행될 수 있음은 물론이다.

[562] 앞서 2. 방법의 경우, 반드시 단말이 네트워크에 초기 접속 이전에 기지국으로부터 수신하는 시스템 정보로 한정될 필요는 없으며, 기지국으로부터 브로드캐스트되는 어떠한 시스템 정보를 통해서도 RRM-RS 설정 정보가 단말에게 제공될 수 있다.

[563] 또한, 앞서 3. 방법의 경우, 반드시 단말이 네트워크에 초기 접속 과정을 수행하기 전에 셀을 선택하는 경우로 한정될 필요는 없으며, 단말이 캠핑(camping)하는 셀을 (재)선택하거나 핸드오버(handover)하는 등 최적의 셀을 선택하기 위한 어떠한 상황에서든 이 방법이 적용될 수 있다.

[564] 또한, 앞서 4. 방법의 경우, 반드시 단말이 네트워크에 초기 접속하기 위한

RACH 절차로 한정될 필요는 없으며, 그 외에도 단말이 수행하는 어떠한 RACH 절차에서도 적용될 수 있다. 또한, 레가시(legacy) 단말에서도 CRS 기반 RRM 측정값을 기지국에 전송하기 위하여 4. 방법이 적용될 수 있다.

[565]

[566] 진보된 RLM(advanced RLM) 동작

[567] UE는 무선링크 상태 및 수신신호 품질에 대한 측정/보고/관리를 목적으로 상기 RRM 뿐만 아니라, 무선 링크 모니터링(RLM) 동작을 수행하여야 한다.

[568] RLM의 경우 구체적으로, UE는 주어진 시간 구간/주기(예를 들어, 특정 무선 프레임/서브프레임)에 대하여 참조 신호(예를 들어, CRS 등)를 기반으로 측정된 특정 시점(예를 들어, 서브프레임)에서 무선 링크 품질(예를 들어, 신호 대 잡음비(SNR: Signal-to-Noise Ratio) 또는 신호 대 간섭 및 잡음비(SINR: Signal-to-Interference plus Noise Ratio) 등)을 특정 임계치(즉, Q_out 및 Q_in)과 비교하고, 이를 토대로 무선 링크 상태(예를 들어, out-of sync 상태 또는 in-sync 상태)를 모니터링/평가할 수 있다.

[569] 이하, 본 발명의 설명에 있어서, 종래의 또는 통상적인 RLM 동작들을 통칭하여 편의상 "제1 RLM 동작(behaviors)"으로 지칭하기로 한다.

[570] UE 동작의 예를 들면, 제1 RLM 동작에 따라 UE는 자신이 접속해 있는 셀의 (CRS 기반의) 하향링크 링크 품질을 측정하고 이를 임계치 Q_out 및 Q_in와 비교하는 것을 포함하는 RLM 동작을 수행하게 된다. 만일, 해당 하향링크 무선 링크가 "신뢰있게 수신(reliably received)"되기 어렵다고 판정되는 경우(예를 들어, 3GPP TS 36.133에서 명시된 동작에 따라 무선 링크 품질이 임계치 Q_out 보다 불량한 경우)(또는 미리 정의된 횟수만큼 무선 링크 품질이 임계치 Q_out 보다 불량하다고 판단된 경우), UE는 특정 "무선 링크 실패(RLF: Radio Link Failure) 타이머(timer)" 관련 동작에 의해 무선 링크 실패(RLF)를 판정하기 위한 타이머를 가동시킨다. 그리고, UE는 해당 타이머가 만료(expire)되면 대상 셀과의 링크를 초기화하고, 새로운 셀을 탐색하는 등의 셀 (재)선택 과정을 수행할 수 있다. 만일, 상기 RLF 타이머가 만료되기 전에 다시 상기 Q_in 관련 조건을 충족하게 되면(즉, 무선 링크 품질이 임계치 Q_in 보다 양호한 경우)(또는 미리 정의된 횟수만큼 무선 링크 품질이 임계치 Q_in 보다 양호하다고 판단된 경우), UE는 해당 셀과의 링크를 유지할 수 있다. 이 경우 단말은 RLF 타이머를 중단할 수 있다.

[571] 이러한 동작이 상기 FD-MIMO 사용 케이스에 그대로 적용되는 상황을 고려하면, 단말이 상기 통상적인 (CRS 기반) RLM 동작에 따라 특정 셀에 대하여 무선 링크 품질이 매우 낮아져서 RLF를 판정하게 되는 상황이 발생할 경우라 하더라도, 만일 해당 단말에게 FD-MIMO 빔포밍이 적용되고 있는 PDSCH 그리고/또는 EPDCCH 전송의 무선 링크 품질이 여전히 안정적인 품질을 보이고 있다면, 해당 링크를 유지하도록 하는 것이 바람직할 수 있다.

[572] 즉, 이를 통해 통신 링크 단절 현상을 줄이고, 예를 들어 제어 채널은 FD-MIMO

빔포밍된 EPDCCH로부터 수신하고, 데이터 채널은 FD-MIMO 빔포밍된 PDSCH로부터 수신하는 동작을 유지함에 따른 성능 이득을 기대할 수 있다. 이는 FD-MIMO 전송 시 eNB단에서 많은 수의 안테나 요소를 활용하여 매우 높은 FD-MIMO 빔포밍 이득을 얻도록 할 수 있기 때문이다.

[573] 본 발명의 이하에서는 이러한 동작을 가능하게 하기 위해, 상기 "제1 RLM 동작"을 대체하여, 또는 상기 "제1 RLM 동작"에 추가하여 다음과 같은 요소들 중 적어도 하나를 포함하는 특정 "제2 RLM 동작"을 정의하거나 UE에 설정 UE에 설정(예를 들어, RRC 시그널링 등에 의해)하는 방법을 제안한다.

[574]

[575] (1) "제2 RLM 동작"은 상기 "제1 RLM 동작"에서 기반이 되는 CRS가 아닌, 별도의 특정 참조 신호(RS)를 기반으로 RLM 동작이 수행될 수 있다.

[576] 이러한 별도의 RS의 예시로는, 다음과 같은 RS 중 적어도 하나를 포함할 수 있다.

[577] 특정 CSI-RS(예를 들어, 단말에 설정된 가장 낮은 또는 가장 높은 CSI-RS 인덱스에 해당하는 CSI-RS)가 이용될 수 있다. 여기서, CSI-RS는 프리코딩된(pre-coded) CSI-RS일 수 있다.

[578] 또한, DRS-CSI-RS(즉, 디스커버리 참조 신호(DRS)로서 이용되는 CSI-RS)가 이용될 수 있다. 이때, 물리 셀 식별자(PCI 또는 PCID)는 상기 통상적인 "제1 RLM 동작"을 수행하는 대상이 되는 셀 ID일 수 있다. 즉, UE는 해당 PCI로 생성된 CRS를 기반으로 해당 셀에 대한 제1 RLM behaviors를 수행하고, 그리고/또는 해당 PCI에 연동된(또는 연관된) 특정 DRS-CSI-RS에 대하여 상기 제2 RLM 동작을 수행할 수 있다. 여기서, DRS-CSI-RS는 프리코딩된(pre-coded) DRS-CSI-RS일 수 있다.

[579] 또한, 앞서 설명한 별도의 RRM-RS가 이용될 수 있다. 여기서, 예를 들어, 이러한 RRM-RS는 상기 설명된 바와 같이 SIB 등 시스템 정보 관련 시그널링 메시지에 포함되어 단말의 초기 접속 시 그리고/또는 아이들 모드(idle mode)에서의 셀 (재)선택 관련 동작 시에 적용하도록 별도로 설정된 RRM-RS일 수 있다. 또 다른 일례로, RRM-RS는 앞서 설명한 바와 같이 FD-MIMO와 같이 날카로운 빔(sharp beam)을 통해 지역적으로 방향을 다르게 전송되는 RS에 해당될 수도 있으며 또는 서로 다른 셀 또는 전송 포인트(TP: Transmission Point)의 개수로 구성되는 무정형 셀(amorphous cell)에서 전송되는 RS에 해당될 수도 있다.

[580]

[581] (2) "제2 RLM 동작"과 관련하여, 제1 RLM 동작에 적용하는 RLF 판단을 위한 판정 조건(예를 들어, 전송 파라미터(앞서 표 6 및 표 7), out-of-sync/in-sync 판정을 위한 임계치 및/또는 RLF 타이머 등을 포함)과 별개의 독립적인 판정 조건들이 정의되거나 UE에 설정(예를 들어, RRC 시그널링 등에 의해)될 수 있다.

[582] 예를 들어, 제2 RLM 동작에 관한 DCI 포맷은 제1 RLM 동작에서의 DCI 1A (표 6 참조) 및 DCI 1C (표 7 참조)와 독립적인 특정 DCI 포맷으로 out-of-sync 및 in-sync를 각각 새롭게 정의하거나 UE에게 설정될 수 있다.

[583] 즉, UE는 제2 RLM 동작과 관련하여 사전에 정의되거나 UE에 설정된 DCI 포맷을 eNB로부터 수신할 때의 무선 링크 품질을 추정(또는 측정)하고, 추정(또는 측정)된 결과와 임계치(즉, Q'_out 및 Q'_in)를 비교하여 out-of-sync/in-sync 상태를 판단할 수 있다.

[584] 또한, 제2 RLM 동작에 관하여 정의/설정된 해당 DCI(예를 들어, out-of-sync 또는 in-sync에 대한)는 특정 EPDCCH 세트(예를 들어, 가장 낮은 또는 가장 높은 EPDCCH 세트)으로부터 전송되는 것을 UE가 가정하도록 정의되거나 UE에게 설정될 수 있다. 이는, 해당 특정 EPDCCH 세트로부터 전송되는 DCI가 FD-MIMO 빔포밍에 의해 전송되는 것(즉, FD-MIMO 빔포밍이 적용되는 것)을 고려하기 위함이다.

[585] - "제어 OFDM 심볼의 수(Number of control OFDM symbols)", "병합 레벨(CCE 또는 ECCE)", "(E)PDCCH RE 에너지 대 평균 RS RE 에너지의 비(Ratio of (E)PDCCH RE energy to average RS RE energy)" 등의 요소들 중 적어도 하나에 대해서도, out-of-sync 및 in-sync 각각에 대해 제1 RLM 동작에 적용하는 전송 파라미터와 독립적으로 (해당 EPDCCH 기반으로 계산될 수 있도록) 별도의 값들이 사전에 정의되거나 UE에게 설정될 수 있다.

[586] 이때, 예를 들어, 제2 RLM 동작에 적용되는 제어 OFDM 심볼의 수(Number of control OFDM symbols), (E)CCE 병합 레벨은 셀(또는 캐리어) 대역폭에 따라 상이하게 설정될 수 있다. 또한, (E)PDCCH RE 에너지 대 평균 RS RE 에너지의 비는 앞서 (1)에서 설명한 RS가 전송되는 안테나 포트의 개수에 따라 상이하게 설정될 수 있다.

[587] - 제1 RLM 동작과 별개로 제2 RLM 동작에서 RLF 관련 판정 조건에 사용되는 임계치가 독립적으로 정의되거나 UE에게 설정될 수 있다. 본 명세서에서는 설명의 편의상 이를 Q'_in 및 Q'_out으로 표기한다.

[588] - 임계치 Q'_out은 하향링크 무선 링크가 신뢰있게(reliably) 수신될 수 없는 레벨로 정의되고, 가상의(hypothetical) (E)PDCCH 전송(즉, EPDCCH 세트(예를 들어, 가장 낮은 EPDCCH 세트) 및 미리 정의된 관련 기준에 따른)의 X% 블록 에러율(BER)에 해당할 수 있다.

[589] - 임계치 Q'_in는 하향링크 무선 링크 품질이 Q'_out에서의 하향링크 무선 링크 품질 보다 현저하게 신뢰있게 수신될 수 있는 레벨로 정의되고, 가상의(hypothetical) (E)PDCCH 전송(즉, EPDCCH 세트(예를 들어, 가장 낮은 EPDCCH 세트) 및 미리 정의된 관련 기준에 따른)의 Y% BER에 해당할 수 있다.

[590]

[591] (3) 앞서 (1) 및/또는 (2)에서 설명한 "제2 RLM 동작"은 특정 상위 계층 신호(예를 들어, RRC 시그널링 등)에 의한 지시/설정에 따라, "제1 RLM 동작"을

대체하여 수행되도록 또는 병행하여 독립적인 조건에 따라 수행되도록 지시/설정될 수 있다.

[592] - 여기서, 특정 FD-MIMO 가능한(capable) UE(또는 보다 일반적으로, 본 발명에서 제안하는 제2 RLM 동작을 지원하는 UE 등)에게 상기 "제2 RLM 동작"은 항상 활성화될 수 있다. 즉, 특정 FD-MIMO 가능한(capable) UE의 경우 항상 제2 RLM 동작을 수행할 수 있다.

[593] 또는, 특정 FD-MIMO 가능한(capable) UE(또는 보다 일반적으로, 본 발명에서 제안하는 제2 RLM 동작을 지원하는 UE 등)라도 "제2 RLM 동작"이 항상 활성화되지는 않고, 해당 단말에게 FD-MIMO 관련 모드(또는 보다 일반적으로, 본 발명에서 제안하는 제2 RLM 동작을 지원하는 모드 등)가 설정된 경우에 "제2 RLM 동작"이 활성화될 수도 있다. 즉, 특정 FD-MIMO 가능한(capable) UE의 경우라도 항상 제2 RLM 동작을 수행하지 않고, FD-MIMO 관련 동작이 활성화(즉, FD-MIMO 관련 모드 설정)된 경우 제2 RLM 동작을 수행할 수 있다.

[594] 이 경우, 제1 RLM 동작을 대체하여 제2 RLM 동작을 수행하도록 정의 또는 UE에게 설정되거나, 제1 RLM 동작과 함께 제2 RLM 동작을 함께 병행하여 수행하도록 정의되거나 UE에게 설정될 수 있다.

[595] 후자와 같이, 제1 RLM 동작과 제2 RLM 동작의 병행하여 동작되는 경우, 제2 RLM 동작이 항상 별도의 동작 조건에 의해 제1 RLM 동작과 무관하게 동작될 수도 있다. 또는 제2 RLM 동작은 제1 RLM 동작에 종속되어, 제1 RLM 동작에 의해 특정 조건이 충족되는 경우, 여기에 연동되어 제2 RLM 동작의 동작 조건이 종속적으로 정의되거나 UE에게 설정될 수도 있다. 예를 들어, 후술하는 (4) 등의 실시예와 같이 제2 RLM 동작은 제1 RLM 동작에 종속되어 수행될 수 있다.

[596] 상술한, FD-MIMO 가능한(capable) UE는 UE가 네트워크에 초기 접속 시에 자신의 특정 능력 시그널링(즉, FD-MIMO 지원 가능한 능력)을 기지국에 전달할 수 있다. 이때, 이에 관한 특정 FD-MIMO 관련 능력 시그널링 포맷이 정의될 수 있다. 예를 들어, FD-MIMO 가능한(capable) UE(예를 들어, FD-MIMO 지원 가능한 능력을 시그널링한 UE)는 상기 제2 RLM 동작이 적용될 수 있다.

[597] 또는, 상기 제2 RLM 동작의 적용 가능 여부에 관한 능력 시그널링 형태로 세분화될 수도 있다. 즉, 특정 FD-MIMO 관련 능력 메시지는 제2 RLM 동작의 적용 가능 여부를 지시하는 정보를 포함할 수도 있다.

[598] 또한, 상기 RRM-RS 그리고/또는 연관된 최초 접속(initial access) 동작 방식에 관해서도 특정 능력 시그널링 형태로 유사하게 세분화될 수 있다. 즉, UE는 상술한 RRM-RS의 지원 가능 여부에 대한 능력 및/또는 이와 연관된 최초 접속(initial access) 동작 방식의 지원 가능 여부에 대한 능력 시그널링을 eNB에게 전송할 수 있다.

[599] - 만일, 상기 제2 RLM 동작이 제1 RLM 동작을 대체하는 형태로 정의되거나 UE에 설정된 경우라면, 이 UE의 RLF 판정 여부는 오직 상기 제2 RLM 동작 관련 판정 조건에 따라 정해진다. 즉, 앞서 (2)에서 설명한 제2 RLM 동작에 대한 판정

조건만으로 UE는 RLF를 판정할 수 있다.

[600] - 또한 만일, 상기 제2 RLM 동작이 제1 RLM 동작과 병행하여 둘 다 활성화되는 상태로 유지되는 형태로 정의되거나 UE에 설정된 경우라면, 이 UE의 RLF 판정 여부는 제1 RLM 동작과 제2 RLM 동작 관련 판정 조건을 모두 고려하여, 두 경우 모두에서 RLF 판정이 내려진 경우에만 해당 셀의 통신 링크를 끊을 수 있도록(즉, 해당 셀과의 링크를 초기화하도록) 정의되거나 UE에 설정될 수 있다.

[601] 또는, 제1 RLM 동작과 제2 RLM 동작 중 어느 하나라도 RLF 판정이 내려진 경우에는 해당 셀의 통신 링크를 끊을 수 있도록(즉, 해당 셀과의 링크를 초기화하도록) 정의되거나 UE에 설정될 수 있다. 그리고/또는, 제2(또는 제1) RLM 동작에 의해서 RLF 판정이 내려진 경우에는 제1(또는 제2) RLM 동작의 판정 결과와 무관하게 RLF 판정을 내리는 것으로 정해질 수도 있다. 즉, 제1 RLM 동작과 제2 RLM 동작 중 어느 하나가 RLF 판정에 있어서 다른 하나보다 높은 우선순위를 가질 수 있다.

[602]

[603] (4) 상술한 바와 같이 제2 RLM 동작은 제1 RLM 동작에 종속적으로 수행될 수 있다.

[604] 일례로, "제1 RLM 동작"에 의해 RLF 타이머가 작동 개시된 시점 t1으로부터 특정 오프셋 시간인 d1만큼의 시간(예를 들어, d1=0, 또는 d1은 특정 양수 값 등)이 지난 후부터, 상기 (1)에서 설명한 특정 RS에 대하여 "제2 RLM 동작"에 따른 RLF 판정 관련 동작이 개시될 수 있다.

[605] 또한, 상기 제1 RLM 동작에 의해 RLF 타이머가 작동 개시되고 만료되기 전까지, 상기 제2 RLM 동작에 의해 특정 Q'_in 조건이 충족하게 되는 경우(즉, 무선 링크 품질이 Q'_in 보다 양호한 경우), 해당 셀에 대해서는 RLF를 판정하지 않을 수 있다.

[606] 이러한 제안 동작에 의해, "제2 RLM 동작"은 오직 "제1 RLM 동작"의 RLF 타이머가 작동되는 시점과 연동된 특정 시간 구간 동안에만 활성화되는 것으로 제한함으로써, 단말의 불필요한 배터리 소모를 방지할 수 있다.

[607] 또한, UE가 새로운 셀을 (재)선택하여 정상적으로 (재)접속이 완료되기 까지(또는 (재)접속이 완료되어 해당 새로운 셀로부터 정상적인 "제1 RLM 동작"이 개시될 수 있는 상태가 되기까지)의 구간 동안에는, 반드시 이 UE에게는 해당 "제2 RLM 동작"과 연계된 특정 EPDCCH 세트(예를 들어, 가장 낮은 EPDCCH 세트)로부터의 DCI들을 통한 제어 시그널링만 수신이 가능한 것으로 정의되거나 설정될 수 있다. 그리고, EPDCCH에 의해 특정 PDSCH 수신 및 상향링크 송신 등의 동작이 지시될 수 있다.

[608] 또한, 새로운 셀을 (재)선택하여 정상적으로 (재)접속이 완료되기 까지(또는 (재)접속이 완료되어 해당 새로운 셀로부터 정상적인 "제1 RLM 동작"이 개시될 수 있는 상태가 되기까지)의 구간 동안에는 C-RNTI, SPS C-RNTI 등 특정 RNTI(들)로 마스킹된 DCI만 해당 EPDCCH 세트로부터 수신이 가능한 것으로

한정될 수도 있다. 즉, 이 경우 UE는 이러한 제한된 형태의 DCI들만 블라인드 검출(blind detection)을 시도하면 된다.

[609] 그리고/또는, UE는 이러한 상태에서 특정 정의되거나 UE에 설정된 동작 조건에 따라, 계속해서 새로운 셀 탐색 관련 동작을 수행해야 할 수 있다. 즉, 이와 같은 새로운 셀 탐색 관련 동작을 지속적으로 수행함과 동시에, 상기 "제2 RLM 동작"과 연계된 특정 EPDCCH 세트를 통한 특정 EPDCCH DCI(들)의 모니터링은 지속해야 한다. 이를 통해, FD-MIMO 빔포밍된 EPDCCH에 의해 스케줄링되는 FD-MIMO 빔포밍된 PDSCH는 (상기 "제1 RLM 동작"에 의해서는 RLF가 판정된 상태라 할지라도) 여전히 지속적으로 수행될 수 있도록 함으로써 통신 링크의 연결성을 크게 증대시킬 수 있다는 장점이 있다.

[610] 또 다른 일례로, "제1 RLM 동작"에 의한 RLF 판정 결과에 따라 "제2 RLM 동작"이 개시될 수도 있다.

[611] 예를 들어, "제1 RLM 동작"과 "제2 RLM 동작"의 판정 조건을 모두 고려하여, 두 경우 모두 RLF 판정이 내려진 경우에만 해당 셀의 통신 링크를 끊는(즉, 해당 셀과의 링크를 초기화) 경우를 가정한다. 이 경우, "제1 RLM 동작"에 의한 RLF 판정이 내려진 경우(즉, 무선 링크 품질이 임계치 Q_out 보다 불량하여 구동이 개시된 RLF 타이머가 만료된 경우)에만 "제2 RLM 동작"이 개시될 수도 있다. 반면, "제1 RLM 동작"에 의한 RLF 타이머가 작동 개시되었더라도 무선 링크 품질이 임계치 Q_in보다 양호한 경우에는 "제2 RLM 동작"이 개시되지 않을 수 있다.

[612] 또 다른 예로, "제1 RLM 동작"과 "제2 RLM 동작" 중 어느 하나라도 RLF 판정이 내려진 경우에는 해당 셀의 통신 링크를 끊을 수 있도록(즉, 해당 셀과의 링크를 초기화하도록) 정의되거나 UE에 설정된 경우를 가정한다. 또한, 제1 RLM 동작에 의해서 RLF 판정이 내려진 경우에는 제2 RLM 동작의 판정 결과와 무관하게 RLF 판정을 내리는 경우도 마찬가지이다. 이 경우, "제1 RLM 동작"에 의한 RLF 판정이 내려진 경우(즉, 무선 링크 품질이 임계치 Q_out 보다 불량하여 구동이 개시된 RLF 타이머가 만료된 경우)에는 해당 셀의 통신 링크를 끊게되며(즉, 해당 셀과의 링크를 초기화), "제2 RLM 동작"이 개시되지 않을 수 있다.

[613] 도 18은 본 발명의 일 실시예에 따른 무선 링크 모니터링을 위한 방법을 예시하는 도면이다.

[614] 도 18을 참조하면, UE는 CRS를 기반으로 셀(cell)에 대한 무선 링크 모니터링(이하, '제1 RLM')을 수행할 수 있다(S1801).

[615] UE는 CRS 이외 특정 참조 신호(RS)를 기반으로 셀(cell)에 대한 무선 링크 모니터링(이하, '제2 RLM')을 수행한다(S1802).

[616] 여기서, 특정 RS는 CRS 이외 앞서 (1)에서 설명한 RS를 의미할 수 있다. 예를 들어, (pre-coded) CSI-RS, (pre-coded) DRS-CSI-RS, 단말의 초기 접속 시 그리고/또는 아이들 모드(idle mode)에서의 셀 (재)선택 관련 동작 시에

적용하도록 별도로 설정된 RRM-RS, FD-MIMO와 같이 날카로운 빔(sharp beam)을 통해 지역적으로 방향을 다르게 전송되는 RS, 또는 서로 다른 셀 또는 전송 포인트(TP: Transmission Point)의 개수로 구성되는 무정형 셀(amorphous cell)에서 전송되는 RS가 해당될 수 있다.

[617] UE는 CRS 기반 제1 RLM 및 CRS 이외 참조 신호 기반 제2 RLM을 기반으로 또는 CRS 이외 참조 신호 기반 제2 RLM을 기반으로 셀에 대한 RLF를 판단한다(S1803).

[618] 여기서, S1803 단계에서 제2 RLM에 의해서만 해당 셀에 대한 RLF를 판단하는 경우, 앞서 S1801 단계는 수행되지 않을 수도 있다.

[619] 보다 구체적으로 살펴보면, UE는 해당 셀에 대한 하향링크 무선 링크 품질을 모니터링하고, 모니터링에 의한 측정치와 미리 정해진 임계치를 비교할 수 있다.

[620] 여기서, CRS 기반 제1 RLM의 경우, UE는 CRS 기반 모니터링에 의한 측정치를 Q_in 및 Q_out과 비교할 수 있다.

[621] 또한, CRS 이외 참조 신호 기반 제2 RLM의 경우, UE는 CRS 이외 참조 신호 기반 모니터링에 의한 측정치를 Q'_in 및 Q'_out과 비교할 수 있다. 이때, 상술한 바와 같이, Q'_in 및 Q'_out는 Q_in 및 Q_out와 독립적으로 미리 정의되거나, UE에게 설정될 수 있다.

[622] 여기서, 상술한 바와 같이, Q'_in 및 Q'_out은 각각 미리 정의된 전송 파라미터(즉, (E)PDCCH 전송 파라미터)를 이용한 가상의 (E)PDCCH 전송에 대한 BER에 해당할 수 있다. 즉, 가상의 (E)PDCCH 전송은 (E)PDCCH 전송 파라미터에 기반하여 전송된다고 가정되는 (E)PDCCH 전송을 의미한다. 이때, (E)PDCCH 전송 파라미터는 앞서 CRS 기반 제1 모니터링을 위한 전송 파라미터(즉, PDCCH/PCFICH 전송 파라미터)와 독립적으로 정의되거나 UE에게 설정될 수 있다.

[623] 그리고, UE는 모니터링에 의한 측정치와 미리 정해진 임계치를 비교한 결과에 기반하여 RLF 타이머를 구동시킬 수 있다. 그리고, RLF 타이머가 만료되면 상기 셀에 대한 RLF라고 결정할 수 있다.

[624] 예를 들어, CRS 기반 제1 RLM의 경우, 무선 링크 품질이 Q_out 보다 불량한 경우 out-of-sync 상태로 판단할 수 있으며, 무선 링크 품질이 Q_in 보다 양호한 경우 in-sync 상태로 판단할 수 있다. 이때, 무선 링크 품질이 Q_out 보다 불량한 경우(또는, 미리 정의된 횟수만큼 무선 링크 품질이 임계치 Q_out 보다 불량하다고 판단된 경우), UE는 제1 RLM에 대한 RLF 타이머를 구동시킬 수 있다. 그리고, 제1 RLM에 대한 RLF 타이머가 만료되면 상기 셀에 대한 RLF라고 결정할 수 있다. 이때, 제1 RLM에 대한 RLF 타이머 구동 중 무선 링크 품질이 Q_in 보다 양호한 경우(또는 미리 정의된 횟수만큼 무선 링크 품질이 임계치 Q_in 보다 양호하다고 판단된 경우), 제1 RLM에 대한 RLF 타이머를 중단시킬 수 있다.

[625] 또한, CRS 이외 참조 신호 기반 제2 RLM의 경우, 무선 링크 품질이 Q'_out 보다

불량한 경우 out-of-sync 상태로 판단할 수 있으며, 무선 링크 품질이 Q'_in 보다 양호한 경우 in-sync 상태로 판단할 수 있다. 이때, 무선 링크 품질이 Q'_out 보다 불량한 경우(또는, 미리 정의된 횟수만큼 무선 링크 품질이 임계치 Q'_out 보다 불량하다고 판단된 경우), UE는 제2 RLM에 대한 RLF 타이머를 구동시킬 수 있다. 그리고, 제2 RLM에 대한 RLF 타이머가 만료되면 상기 셀에 대한 RLF라고 결정할 수 있다. 이때, 제2 RLM에 대한 RLF 타이머 구동 중 무선 링크 품질이 Q'_in 보다 양호한 경우(또는 미리 정의된 횟수만큼 무선 링크 품질이 임계치 Q'_in 보다 양호하다고 판단된 경우), 제2 RLM에 대한 RLF 타이머를 중단시킬 수 있다.

[626] 상술한 바와 같이, UE는 제1 RLM 동작을 대체하여 제2 RLM 동작을 수행할 수도 있으나, 제1 RLM 동작과 함께 제2 RLM 동작을 수행할 수도 있다.

[627] 즉, 제1 RLM 동작을 대체하여 제2 RLM 동작을 수행하는 경우, UE는 제2 RLM 동작에 의해 해당 셀에 대한 RLF를 판단할 수 있다.

[628] 반면, 제1 RLM 동작과 함께 제2 RLM 동작을 수행하는 경우, UE는 제1 RLM 동작과 무관하게 제2 RLM 동작을 수행할 수도 있으나, 제1 RLM 동작에 의해 특정 조건이 만족되는 경우 제2 RLM 동작을 수행할 수도 있다.

[629] 예를 들어, 제1 RLM에 대한 RLF 타이머가 작동 개시된 시점으로부터 특정 오프셋 시간 이후부터 제2 RLM이 수행될 수 있다. 또는, 제1 RLM에 의해 해당 셀이 RLF라고 판단되면, 제2 RLM이 수행될 수도 있다.

[630] 이와 같이 제1 RLM 동작과 함께 제2 RLM 동작을 수행하는 경우, UE는 제1 RLM 동작 및 제2 RLM 동작에 의해 모두 해당 셀에 대한 RLF가 판정된 경우, 최종적으로 해당 셀에 대한 RLF라고 판단할 수 있다.

[631] 또는, 제1 RLM 동작과 함께 제2 RLM 동작을 수행하는 경우, UE는 제1 RLM 동작 또는 제2 RLM 동작에 의해 해당 셀에 대한 RLF가 판정된 경우, 최종적으로 해당 셀에 대한 RLF라고 판단할 수 있다. 이때, 제1 RLM 동작 및 제2 RLM 동작 중 어느 하나에 의해 RLF라고 판단된 경우, 이외 동작에 대한 판정 결과와 무관하게 최종적으로 해당 셀에 대한 RLF라고 판단할 수도 있다.

[632] 위와 같이, 제1 RLM 및/또는 제2 RLM에 의해 최종적으로 해당 셀에 대하여 RLF라고 판단된 경우, UE는 해당 셀과의 링크를 초기화하고, 새로운 셀을 탐색하는 등의 셀 (재)선택 과정을 수행할 수 있다.

[633]

[634] 앞서, 본 발명의 설명에 있어서, 설명의 편의상 FD-MIMO 사용 케이스를 위주로 설명하였으나, 앞서 설명한 바와 같이 무정형 셀(amorphous cells) 환경에서 다수의 RRM-RS 설정 (각 RRM-RS는 서로 다른 개수의 TP(들)/셀(들)이 함께 전송하는 형태) 등 다양한 사용 케이스에도 본 발명이 동일하게 적용될 수 있다. 즉, 앞서 통상적인 "제1 RLM 동작"과 상이하게 상기 앞서 본 발명에서 제안된 다양한 형태의 동작/적용 조건에 의해 별도의 "제2 RLM 동작"이 정의되거나 UE에게 설정될 수 있으며, 이에 따라 RLF 판정 조건 등이 상이하게

적용되도록 하는 형태로 일반화되어 확장 적용될 수 있음은 자명하다. 이러한 사용 케이스는 그 밖에도 다양하게 존재할 수 있으며, 본 발명의 제안 방식들은 특정 사용 케이스에 제한되지 않는다.

[635] 또한, 본 발명에서 "최초 접속(initial access) 관련 동작" 또는 "초기 접속 시에" 등의 표현은, 설명의 편의를 위한 것이고, 본 발명의 제안은 일반적으로 UE가 아이들 상태(예를 들어, RRC-connected 상태가 아닌 상태)에서 셀 선택/재선택을 수행할 때에 일반적으로 적용될 수 있는 것으로 이해되어야 한다. 즉, UE가 초기 턴-온(turn-on)되어 셀 선택을 해야 하는 상태 이외에도, 단말이 특정 셀에 접속된 후에라도 콜 드랍(call drop)이나, 휴지 기간 등의 여러 가지 이유로 아이들 상태에 있을 때, 지속적으로 최적의 셀을 탐색하고, 필요 시 다른 셀로 접속하여야 하므로 이러한 동작에 있어서도 일반적으로 적용될 수 있다.

[636] 구체적 예시로는, 이와 같이 단말이 아이들 상태에서 특정 셀에 접속하기 위해서는, 본 발명에서의 제안 방식이 우선 기존과 같이 CRS 기반으로 가장 평균 수신 파워가 강한 특정 셀의 시스템 정보를 획득하고 여기에 주변 인접 셀들의 상기 RRM-RS와 같은 목적의 RS 관련 정보가 제공되는 경우, 이에 따라 UE는 (아이들 상태에서) 인접 셀들의 RRM-RS 등을 함께 측정하여, 인접 셀이 (상기 "FD-MIMO" 관점에서) 더 최적의 셀(best cell)인 경우 해당 인접 셀로 (아이들 상태에서) 바로 셀-재선택(cell-reselection)을 수행 후 해당 인접 셀로 접속하는 방식이 적용될 수 있다.

[637]

[638] 본 발명이 적용될 수 있는 장치 일반

[639] 도 19는 본 발명의 일 실시예에 따른 무선 통신 장치의 블록 구성도를 예시한다.

[640] 도 19를 참조하면, 무선 통신 시스템은 기지국(1910)과 기지국(1910) 영역 내에 위치한 다수의 단말(1920)을 포함한다.

[641] 기지국(1910)은 프로세서(processor, 1911), 메모리(memory, 1912) 및 RF부(radio frequency unit, 1913)을 포함한다. 프로세서(1911)는 앞서 도 1 내지 도 18에서 제안된 기능, 과정 및/또는 방법을 구현한다. 무선 인터페이스 프로토콜의 계층들은 프로세서(1911)에 의해 구현될 수 있다. 메모리(1912)는 프로세서(1911)와 연결되어, 프로세서(1911)를 구동하기 위한 다양한 정보를 저장한다. RF부(1913)는 프로세서(1911)와 연결되어, 무선 신호를 송신 및/또는 수신한다.

[642] 단말(1920)은 프로세서(1921), 메모리(1922) 및 RF부(1923)을 포함한다. 프로세서(1921)는 앞서 도 1 내지 도 18에서 제안된 기능, 과정 및/또는 방법을 구현한다. 무선 인터페이스 프로토콜의 계층들은 프로세서(1921)에 의해 구현될 수 있다. 메모리(1922)는 프로세서(1921)와 연결되어, 프로세서(1921)를 구동하기 위한 다양한 정보를 저장한다. RF부(1923)는 프로세서(1921)와 연결되어, 무선 신호를 송신 및/또는 수신한다.

[643] 메모리(1912, 1922)는 프로세서(1911, 1921) 내부 또는 외부에 있을 수 있고, 잘

알려진 다양한 수단으로 프로세서(1911, 1921)와 연결될 수 있다. 또한, 기지국(1910) 및/또는 단말(1920)은 한 개의 안테나(single antenna) 또는 다중 안테나(multiple antenna)를 가질 수 있다.

[644] 이상에서 설명된 실시예들은 본 발명의 구성요소들과 특징들이 소정 형태로 결합된 것들이다. 각 구성요소 또는 특징은 별도의 명시적 언급이 없는 한 선택적인 것으로 고려되어야 한다. 각 구성요소 또는 특징은 다른 구성요소나 특징과 결합되지 않은 형태로 실시될 수 있다. 또한, 일부 구성요소들 및/또는 특징들을 결합하여 본 발명의 실시예를 구성하는 것도 가능하다. 본 발명의 실시예들에서 설명되는 동작들의 순서는 변경될 수 있다. 어느 실시예의 일부 구성이나 특징은 다른 실시예에 포함될 수 있고, 또는 다른 실시예의 대응하는 구성 또는 특징과 교체될 수 있다. 특허청구범위에서 명시적인 인용 관계가 있지 않은 청구항들을 결합하여 실시예를 구성하거나 출원 후의 보정에 의해 새로운 청구항으로 포함시킬 수 있음은 자명하다.

[645] 본 발명에 따른 실시예는 다양한 수단, 예를 들어, 하드웨어, 펌웨어(firmware), 소프트웨어 또는 그것들의 결합 등에 의해 구현될 수 있다. 하드웨어에 의한 구현의 경우, 본 발명의 일 실시예는 하나 또는 그 이상의 ASICs(application specific integrated circuits), DSPs(digital signal processors), DSPDs(digital signal processing devices), PLDs(programmable logic devices), FPGAs(field programmable gate arrays), 프로세서, 콘트롤러, 마이크로 콘트롤러, 마이크로 프로세서 등에 의해 구현될 수 있다.

[646] 펌웨어나 소프트웨어에 의한 구현의 경우, 본 발명의 일 실시예는 이상에서 설명된 기능 또는 동작들을 수행하는 모듈, 절차, 함수 등의 형태로 구현될 수 있다. 소프트웨어 코드는 메모리에 저장되어 프로세서에 의해 구동될 수 있다. 상기 메모리는 상기 프로세서 내부 또는 외부에 위치하여, 이미 공지된 다양한 수단에 의해 상기 프로세서와 데이터를 주고 받을 수 있다.

[647] 본 발명은 본 발명의 필수적 특징을 벗어나지 않는 범위에서 다른 특정한 형태로 구체화될 수 있음은 당업자에게 자명하다. 따라서, 상술한 상세한 설명은 모든 면에서 제한적으로 해석되어서는 아니 되고 예시적인 것으로 고려되어야 한다. 본 발명의 범위는 첨부된 청구항의 합리적 해석에 의해 결정되어야 하고, 본 발명의 등가적 범위 내에서의 모든 변경은 본 발명의 범위에 포함된다.

산업상 이용가능성

[648] 본 발명의 무선 통신 시스템에서 단말이 무선 링크 모니터링 방안은 3GPP LTE/LTE-A 시스템에 적용되는 예를 중심으로 설명하였으나, 3GPP LTE/LTE-A 시스템 이외에도 다양한 무선 통신 시스템에 적용하는 것이 가능하다.

청구범위

[청구항 1] 무선 통신 시스템에서 단말이 무선 링크 모니터링(RLM: radio link monitoring)을 수행하는 방법에 있어서,
셀 특정 참조 신호(CRS: cell-specific reference signal) 이외 참조 신호를 기반으로 셀에 대한 제2 RLM을 수행하는 단계; 및
상기 제2 RLM을 기반으로 상기 셀에 대한 무선 링크 실패(RLF: radio link failure)를 판단하는 단계를 포함하고,
상기 제2 RLM에 적용되는 RLF 판단을 위한 판단 조건은 CRS 기반 제1 RLM에 적용되는 RLF 판단을 위한 판단 조건과 상이한 무선 링크 모니터링 방법.

[청구항 2] 제1항에 있어서,
상기 CRS 기반으로 상기 제1 RLM을 수행하는 단계를 더 포함하고,
상기 셀에 대한 RLF는 상기 제1 RLM 및 상기 제2 RLM을 기반으로 판단되는 무선 링크 모니터링 방법.

[청구항 3] 제1항에 있어서,
상기 RLF 판단을 위한 판단 조건은 제어 채널 전송 파라미터, 비동기(out-of-sync)/동기(in-sync) 상태 판단을 위한 임계값 및 RLF 타이머 중 적어도 어느 하나를 포함하는 무선 링크 모니터링 방법.

[청구항 4] 제1항에 있어서,
상기 제2 RLM의 경우, 상기 제2 모니터링을 위한 하향링크 제어 정보(DCI: Downlink Control Information)가 소정의 진보된 물리 하향링크 제어 채널(EPDCCH: Enhanced Physical Downlink Control Channel) 세트로부터 전송된다고 가정되는 무선 링크 모니터링 방법.

[청구항 5] 제1항에 있어서,
상기 단말이 풀 차원 다중 입력 다중 출력(FD-MIMO: full dimension-Multi Input Multi Output) 지원 가능한 경우, 상기 제2 RLM이 수행되는 무선 링크 모니터링 방법.

[청구항 6] 제1항에 있어서,
상기 단말이 FD-MIMO 지원 가능하고 상기 단말이 FD-MIMO 모드가 활성화된 경우, 상기 제2 RLM이 수행되는 무선 링크 모니터링 방법.

[청구항 7] 제2항에 있어서,
상기 셀에 대한 RLF가 상기 제1 RLM 및 상기 제2 RLM을 기반으로 판단되는 경우,
상기 제1 RLM 및 상기 제2 RLM 중 적어도 어느 하나에 의해 상기 셀에 대한 RLF가 결정되면, 상기 셀에 대한 RLF가 결정되는 무선 링크 모니터링 방법.

[청구항 8] 제7항에 있어서,

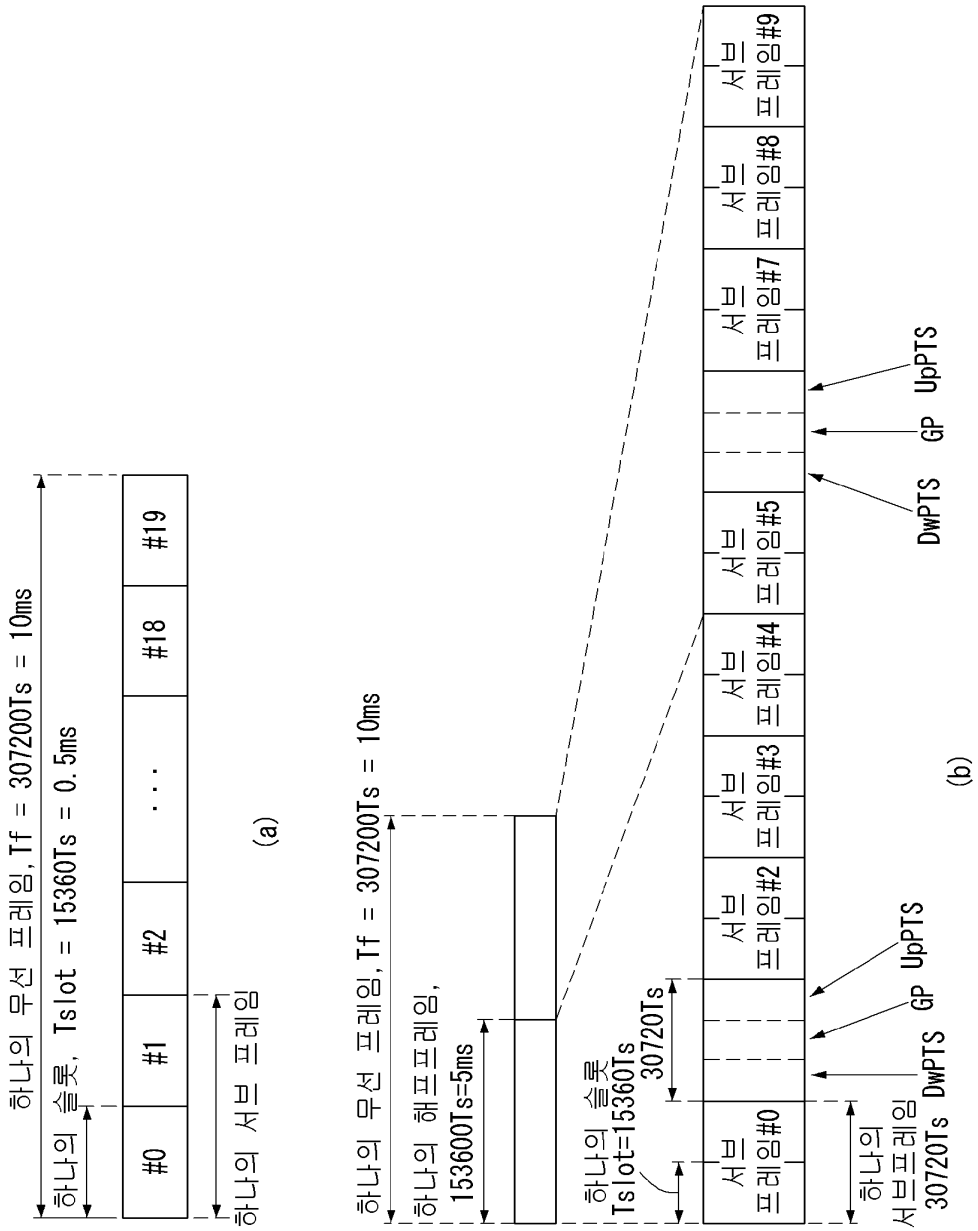
상기 제1 RLM 및 상기 제2 RLM 중 어느 하나가 상기 셀에 대한 RLF 판단에 있어서 높은 우선 순위를 가지는 무선 링크 모니터링 방법.

[청구항 9] 제2항에 있어서,
상기 셀에 대한 RLF가 상기 제1 RLM 및 상기 제2 RLM을 기반으로 판단되는 경우,
상기 제1 RLM 및 상기 제2 RLM 모두에 의해 상기 셀에 대한 RLF가 결정되면, 상기 셀에 대한 RLF가 결정되는 무선 링크 모니터링 방법.

[청구항 10] 제2항에 있어서,
상기 제2 RLM은 상기 제1 RLM에 의해 소정의 조건이 만족되는 경우 수행되는 무선 링크 모니터링 방법.

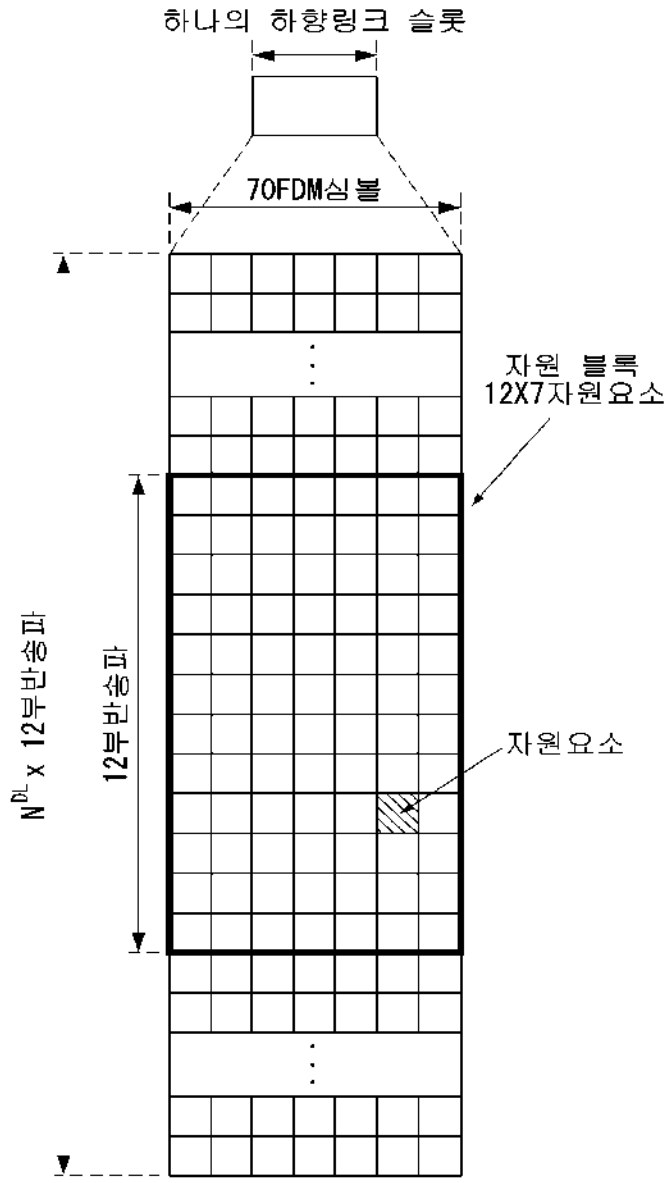
[청구항 11] 제10항에 있어서,
상기 제1 RLM에 의한 RLF 타이머가 가동된 시점으로부터 소정의 오프셋 시간 이후 상기 제2 RLM이 개시되는 무선 링크 모니터링 방법.

[청구항 12] 제11항에 있어서,
상기 제1 RLM에 의한 RLF 타이머가 가동된 시점으로부터 상기 단말에 의한 다른 셀의 선택(selection) 또는 재선택(reselection) 절차가 완료되기까지 구간 동안, 상기 제2 RLM과 연계된 EPDCCH 세트를 통해 DCI가 수신되고, 상기 DCI에 의해 스케줄링된 물리 하향링크 공유 채널(PDSCH: Physical Downlink Shared Channel)를 통해 하향링크 데이터가 수신되는 무선 링크 모니터링 방법.



[청구항 13] 제12항에 있어서,
미리 정해진 무선 네트워크 임시 식별자(RNTI: Radio Network Temporary Identifier)로 마스킹된 DCI만 상기 EPDCCH 세트를 통해 수신되는 무선 링크 모니터링 방법.

[청구항 14] 제1항에 있어서,
상기 CSI 이외 참조 신호는 채널 상태 정보 참조 신호(CSI-RS: Channel State Information-Reference Signal), 디스커버리 참조 신호(DRS: Discovery Reference Signal), 프리코딩된(precoded) 참조 신호 및 셀 (재)선택 관련 동작 시에 적용하도록 설정된 참조 서로 다른 셀 또는 전송 포인트(TP: Transmission Point)의 개수로 구성되는 무정형 셀(amorphous cell)에서 전송되는 참조 신호 중 어느 하나인 무선 링크 모니터링 방법.



[청구항 15] 무선 통신 시스템에서 무선 링크 모니터링(RLM: radio link monitoring)을 수행하는 단말에 있어서,
무선 신호를 송수신하기 위한 RF(Radio Frequency) 유닛; 및
상기 RF 유닛을 제어하는 프로세서를 포함하고,
상기 셀 특정 참조 신호(CRS: cell-specific reference signal) 이외 참조 신호를 기반으로 셀에 대한 제2 RLM을 수행하고,
상기 제2 RLM을 기반으로 상기 셀에 대한 무선 링크 실패(RLF: radio link

failure)를 판단하도록 구성되고,
상기 제2 RLM에 적용되는 RLF 판단을 위한 판단 조건은 CRS 기반 제1 RLM에 적용되는 RLF 판단을 위한 판단 조건과 상이한 단말.

(54) **Title**: ENHANCED PHYSICAL SIGNAL STRUCTURE FOR LTE V2V COMMUNICATIONS

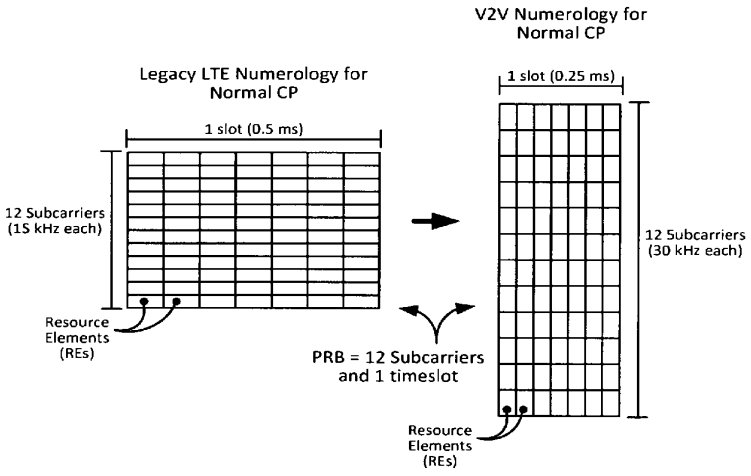

Fig. 4

(57) **Abstract**: A vehicle may wirelessly communicate with another vehicle via a physical channel (a vehicle-to-vehicle (V2V) channel) that is robust and reliable under high mobility propagation conditions. The physical channel may be created by modifying an existing long-term evolution (LTE) physical channel, such as an LTE sidelink (SL) channel. For instance, the V2V physical channel may be created by increasing, by a particular factor, the subcarrier spacing of legacy LTE channels (e.g., from 15 kilohertz (kHz) to 30 kHz). Additionally, a symbol duration and a fast Fourier transform (FFT) size for the V2V physical channel may each be reduced by the same factor. Doing so may enable the V2V physical channel to be implemented without significant modifications to other aspects of the LTE standard.

WO 2017/026983 A1

ENHANCED PHYSICAL SIGNAL STRUCTURE FOR LTE V2V COMMUNICATIONS

RELATED APPLICATIONS

The present application claims the benefit of U.S. Provisional Patent Application No. 62/203,301, which was filed on August 10, 2015, the contents of which are hereby incorporated by reference as though fully set forth herein.

BACKGROUND

The so-called "connected car concept" includes the idea that vehicles may be enabled to communicate wirelessly with one another. The 3GPP (3rd Generation Partnership Project) Long Term Evolution (LTE) communications standard has been proposed as the communication standard for implementing the connected car concept (also referred to as vehicle-to-vehicle (V2V) communications). V2V communications include one vehicle establishing a direct connection with one or multiple other vehicles.

Examples of such connections may include an LTE sidelink connection (also referred as direct connection, a proximity services (ProSe) connection, a device-to-device (D2D) connection, etc.). Once connected, vehicles may communicate a variety of information to each other, such as location information, velocity information, acceleration information, directional information, performance information, and more. Such information may be used to provide a variety of functionalities, such as preventing car accidents, determining driving conditions (e.g., traffic jams, icy roads, car accidents, etc.), determining optimal routes for driving from one location to another, etc.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments described herein will be readily understood by the following detailed description in conjunction with the accompanying drawings. To facilitate this description, like reference numerals may designate like structural elements. Embodiments are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings.

Fig. 1 is a diagram of an example environment in which systems and/or methods described herein may be implemented;

Fig. 2 is a diagram illustrating an example process for sending information to another vehicle;

Fig. 3 is a diagram illustrating an example process for receiving information from another vehicle;

Fig. 4 is a diagram of an example physical resource block (PRB) of a legacy long term evolution (LTE) numerology and an example PRB of a vehicle-to-vehicle (V2V) numerology, under normal cyclic prefix (CP) conditions;

Fig. 5 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under extended CP conditions;

Fig. 6 is a diagram of example PRB pairs of a legacy LTE numerology and example PRB pairs of a V2V numerology, under normal CP conditions;

Fig. 7 is a diagram of example PRB pairs of a legacy LTE numerology and PRB pairs of a V2V numerology, under extended CP conditions;

Figs. 8A-8D are diagrams of example PRBs according to one or more embodiments described herein;

Figs. 9A-9D are diagrams of example PRBs according to one or more embodiments described herein;

Fig. 10 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 30 kilohertz (kHz) subcarrier spacing;

Fig. 11 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 60 kHz subcarrier spacing;

Fig. 12 is a table representing an example of legacy LTE and V2V transmission multiplexing; and

Fig. 13 illustrates, for one embodiment, example components of an electronic device.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The following detailed description refers to the accompanying drawings. The same reference numbers in different drawings may identify the same or similar elements. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope of the present disclosure. Therefore, the following detailed description is not to be taken in a limiting sense, and the scope of embodiments defined by the appended claims and their equivalents.

As mentioned above, the 3GPP (3rd Generation Partnership Project) Long Term Evolution (LTE) communications standard has been proposed as the communication standard for vehicle-to-vehicle (V2V) communications. One reason behind the proposal is the reliability and high data rate capabilities of LTE technology. However, the current LTE standard includes

certain limitations when it comes to enabling vehicles to communicate with one another directly. For example, legacy LTE sidelink (SL) physical channels (also referred to as PC5 channels or device-to-device (D2D) channels) are considered to be used or enable V2V communications. At the same time, the legacy SL physical channels were designed with an assumption of substantially lower mobility conditions than the ones considered to be used for V2V communication (e.g., a scenario in which two vehicles are driving toward one another at 140 kilometers per hour (km/h) each). As a result, when subjected to wireless propagation in high mobility conditions (that may cause high Doppler fading and/or frequency shifts), legacy LTE physical channels may experience an unacceptably high block error rate (BLER) performance and/or use an unacceptably high signal-to-interference-noise ratio (SINR) to achieve reliable performance for V2V wireless communication.

Techniques described herein may be used to provide a physical channel (referred to herein as "V2V physical channel") of greater robustness and reliability when subjected to the high mobility conditions of V2V communications. For example, a V2V physical channel may have increased subcarrier spacing (e.g., 30 kilohertz (kHz) subcarriers) instead of the 15 kHz subcarrier spacing used in legacy LTE SL physical channels. The increased subcarrier spacing may improve physical channel robustness (particularly under high mobility wireless propagation effects) via a reduction of the impacts of frequency offset errors on the subcarriers orthogonality, reduced channel variations on the packet transmission duration, etc.

In some embodiments, the V2V physical channel may include additional alterations from current LTE SL physical channels. For example, the V2V physical channel may include a reduced symbol duration (e.g., a single-carrier frequency-division multiple access (SC-FDMA) symbol duration, etc.). The decrease in symbol duration may be proportional to the increased subcarrier spacing. For instance, if the subcarrier spacing of the V2V physical channel is twice as large as subcarrier spacing of a legacy LTE SL physical channel (e.g., 30 kHz instead of 15 kHz), the symbol duration for the V2V physical channel may be halved. Additionally, the decrease in symbol duration may be accompanied by a similar decrease (e.g., half) to a fast Fourier transform (FTT) size.

Additionally, since LTE air interfaces currently implement physical resource blocks (PRBs) as a fundamental unit of allocation for air interface resources, the techniques described herein may include one or more PRB formats for implementing the enhancements described above regarding modified subcarrier spacing and symbol duration of the V2V physical channels. For instance, a PRB of the V2V physical channel may

include time-domain changes, such as a change in the duration of each PRB and/or the number of slots per PRB. Similarly, a PRB of the V2V channel may include frequency-domain changes, such as the number of subcarriers per PRB, the PRB size in terms of frequency, etc. PRB formats may be discussed herein in terms of numerologies (e.g., legacy LTE numerologies and V2V numerologies), which may include a representation of subcarriers, slot durations, and resource elements (REs) of a PRB or PRB pair.

In some embodiments, the techniques described herein may be implemented within the context of cyclic prefixing (CP). For example, in the 3GPP LTE communication standard, CP may include copying a portion of one symbol (e.g., an end portion of the symbol) and adding the copied portion to a beginning portion of the symbol, such that the symbol begins and ends with the same portion. Doing so may, for example, reduce inter-symbol interference.

Fig. 1 is a diagram of an example environment 100 in which systems and/or methods described herein may be implemented. Environment 100 may include one or more vehicles with vehicle-to-X (V2X) devices 110, user equipment devices (UEs) 120, and network 130.

V2X device 110 may include a computing and communication device installed in a vehicle, such as a car, a truck, a sports utility vehicle (SUV), etc. V2X device 110 may be capable of gathering, processing, and communicating information regarding the vehicle in which V2X device 110 is installed. Examples of such information may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, etc. In some embodiments, V2X device 110 may be capable over gathering, processing, and communicating other types of information, such as information relating to a driver or passenger of the vehicle. V2X device 110 may be an example of user equipment device (UE) or another type of end terminal.

As shown, V2X device 110 may be capable of communicating with one or more networks or devices, such as UE 120, the V2X device of another vehicle, network 130, etc. In some embodiments, V2X device 110 may do so by establishing a connection that is based on a particular communications standard, such as the 3GPP LTE communication standard. For instance, V2X device 110 may establish a vehicle-to-pedestrian (V2P) connection with UE 120, which may include a D2D connection, an LTE SL connection, or other type of direct connection. V2X device 110 may also, or alternatively, establish a vehicle-to-infrastructure/network (V2I) connection with network 130. The V2I connection may include a standard connection with a base station (e.g., an evolved Node B (eNB)), a wireless access point (AP), or another device capable of enabling V2X device 110 to communicate with network 130.

As such, the "X" in "V2X device," may represent an ability of V2X device 110 to communicate with one or more types of devices (e.g., other V2X devices, UEs 120, a base station, a network access point (AP), etc.).

Additionally, or alternatively, V2X device 110 may establish a V2V connection with the V2X device of another vehicle. The V2V connection may include a D2D connection, an LTE SL connection, or other type of direct connection between UEs (e.g., a connection that does not, for example, include network 130). In some embodiments, V2X device 110 may be capable of communicating with other V2X devices using one or more of the techniques described herein. For example, V2X device 110 may be capable of using a V2V physical channel that ensure improved robustness and reliability when subjected to the high mobility conditions of V2V communications. The V2V physical channel may, for example, include greater subcarrier spacing and reduced symbol durations to, for example, improve demodulation performance including BLER reduction but still operating within the framework of an established communications standard (such as the 3GPP LTE communications standard).

UE 120 may include a portable computing and communication device, such as a personal digital assistant (PDA), a smart phone, a cellular phone, a laptop computer with connectivity to a cellular wireless network, a tablet computer, etc. UE 120 may also include non-portable computing devices, such as a desktop computer, a consumer or business appliance, or other devices that have the ability to connect to network 130. UE 120 may also include a computing and communication device that may be worn by a user (also referred to as wearable devices) as a watch, a fitness band, a necklace, glasses, an eyeglass, a ring, a belt, a headset, or another type of wearable device. As shown, UE 120 may establish a direct connection (e.g., a D2D connection) with V2X device 110. Additionally, UE 120 may communicate with V2X device 110 regarding the vehicle of V2X device 110, a driver or passenger of the vehicle, a user of UE 120, a location of the vehicle with respect to the user of UE 120, etc.

Network 130 may include one or more wired and/or wireless networks. For example, network 130 may include an LTE network. In some embodiments, network 130 may include one or more additional networks, such as a cellular network (e.g., a second generation (2G) network, a third generation (3G) network, a fourth generation (4G) network, a fifth generation (5G) network, a global system for mobile (GSM) network, a code division multiple access (CDMA) network, an evolution-data optimized (EVDO) network, or the like), a public land mobile network (PLMN), and/or another network. Additionally, or alternatively, network 150 may include a local area network (LAN), a wireless LAN (WLAN), a wide area network (WAN), a metropolitan network (MAN), the Public Switched Telephone Network (PSTN), an

ad hoc network, a managed IP network, a virtual private network (VPN), an intranet, the Internet, a fiber optic-based network, and/or a combination of these or other types of networks.

The quantity of devices and/or networks, illustrated in Fig. 1, is provided for explanatory purposes only. In practice, there may be additional devices and/or networks; fewer devices and/or networks; different devices and/or networks; or differently arranged devices and/or networks than illustrated in Fig. 1. Alternatively, or additionally, one or more of the devices of environment 100 may perform one or more functions described as being performed by another one or more of the devices of system 100. Furthermore, while "direct" connections are shown in Fig. 1, these connections should be interpreted as logical communication pathways, and in practice, one or more intervening devices (e.g., routers, gateways, modems, switches, hubs, etc.) may be present.

Additionally, while some of the techniques described herein may involve V2V communications as an example, the techniques described herein may be applied to various scenarios and/or other types of communications. For example, techniques described herein may be applicable to time division duplexing (TDD) or frequency division duplexing (FDD) communications. In some embodiments, techniques described herein may be applied to all of downlink (DL), uplink (UL), and sidelink (SL) communications, while other embodiments may only apply the techniques described herein to DL or UL or SL communications. Additionally, while the techniques described herein may be described within the context of the 3GPP LTE communications standard, the techniques may also be applied to other communication standards. Additionally, while examples provided herein may include enabling vehicles to communicate with one another more reliably, the techniques described herein may be applied to other scenarios as well (such as another system or device that may experience significant Doppler fading conditions when attempting to communicate wirelessly).

Fig. 2 is a diagram illustrating an example process 200 for sending information to another vehicle. Process 200 may be particularly appropriate for devices capable of wireless communications that may be subjected to high mobility propagation conditions (e.g., wireless propagation in high mobility conditions characterized by high Doppler fading and/or frequency shifts that may jeopardize the integrity or reliability of the wireless communications). Process 200 may be implemented by, for example, V2X device 110. Additionally, process 200 provides an example of how a V2V physical channel may be used; however, it should be noted that the V2V physical channel, as described herein, may

be used in additional and alternative ways, which may include fewer, additional, and/or alternative operations than the operations described below with reference to Fig. 2.

As shown, process 200 may include identifying a physical channel that is appropriate for communicating with another vehicle (block 210). For example, in some embodiments, V2X device 110 may be capable of using multiple physical channels for communicating with another vehicle. As described above, examples of such channels may include an LTE SL physical channel, a V2V physical channel (as described herein), etc. In some embodiments, V2X device 110 may identify the appropriate physical channel based on one or more factors.

Examples of such factors may include whether the physical channel will likely be subjected to high mobility propagation conditions. For instance, if the vehicle of the V2X device 110 and/or the other vehicle are traveling at a high speed, V2X device 110 may determine that communications between the vehicles are likely to be subjected to such conditions. As such, a V2V physical channel (as opposed to, for example, a legacy LTE SL channel) may be appropriate for communicating with the other vehicle.

Another example of a factor that may be considered by V2X device 110 may include the communication capabilities of the other vehicle. For example, V2X device 110 may determine the types of physical channels that the other vehicle is capable of using and select the most appropriate physical channel from on the physical channels that the other vehicle is capable of using. In some embodiments, determining the communication capabilities of the other vehicle may include determining what type of communications device is being implemented by the other vehicle (e.g., a V2X device or another type of communications device).

Additional examples of factors that may be used to identify an appropriate physical channel may include physical channel availability (e.g., whether V2X device is already using one or more physical channels), a measure of importance regarding the information (or type of information) that is to be sent to the other vehicle (e.g., less important information may be allocated with less reliable physical channels), a measure of importance of other information that is to communicated to a different vehicle, etc. In yet another example, V2X device may implement one or more rules for prioritizing which type of physical channel (e.g., an LTE SL channel, a V2V physical channel, etc.) should be implemented in light of one or more of the factors described above.

Process 200 may include generating information to communicate to the vehicle (block 220). For example, V2X device 110 may generate the information that is to be

transmitted to the other vehicle. Examples of such information may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, information relating to a driver or passenger of the vehicle, etc.

Process 200 may include processing the information based on the physical channel identified for communicating with the other vehicle (block 230). For example, V2X device 110 may arrange the information in accordance with a particular PRB format, which may be particular to the type of physical channel identified as the suitable for communicating with the other vehicle. For instance, if the identified physical channel corresponds to a currently available physical channel (such as an LTE LS physical channel), the information may be allocated to accommodate a format where a PRB includes 12 subcarriers (also referred to herein as frequency REs) with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. However, if the identified physical channel corresponds to a V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time. Additional examples of PRB formats are discussed below with reference to Figs. 4-9.

Process 200 may include using the physical channel to communicate information to vehicle (block 240). For example, V2X device 110 may use the physical channel identified as being appropriate for communicating with the vehicle to transmit the information to the vehicle. As described above, the physical channel may include a legacy channel (such as an LTE SL channel) or a V2V physical channel, and the information may be formatted in accordance with a format (e.g., a PRB format) that is particular to the physical channel used to transmit the information.

Fig. 3 is a diagram illustrating an example process 300 for receiving information from another vehicle. Process 300 may be particularly appropriate for devices capable of wireless communications that may be subjected to high mobility conditions (e.g., that may cause high Doppler fading and/or frequency shifts) during V2V communications. Process 300 may be implemented by, for example, V2X device 110.

As shown, process 300 may include receiving information from another vehicle via a physical channel (block 310). For example, V2X device 110 may be capable of using physical channels for communicating with another vehicle. As described above, examples

of such channels may include an LTE SL channel, a V2V physical channel, etc. The information sent and received between vehicles may include vehicle performance information, vehicle location information, vehicle usage information, vehicle status information, vehicle diagnostic information, information relating to a driver or passenger of the vehicle, etc.

Process 300 may include determining a physical channel type corresponding to the physical channel (block 320). For example, V2X device 110 may identify the type of physical channel (e.g., an LTE SL channel, a V2V channel, etc.) used to receive the information. In some embodiments, V2X device 110 may determine the manner in which the information is arranged in the physical channel based on the physical channel type may include. For example, if the physical channel corresponds to an LTE SL physical channel, the information may be formatted into PRBs that include 12 subcarriers with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. In another example, if the physical channel corresponds to a V2V physical channel, the information may be formatted into PRBs that include 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for a V2V physical channel, the information may be allocated to accommodate a format where a PRB includes 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time. Additional examples of PRB formats are discussed below with reference to Figs. 4-9.

Process 300 may include interpreting the information based on the physical channel type of the physical channel (block 330). For example, V2X device 110 may interpret the information, received from another vehicle, based on a type of physical channel used to communicate the information. For instance, if the physical channel corresponds to an LTE LS physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 15 kHz subcarrier spacing and 1 slot of 0.5 ms duration in time. By contrast, if the physical channel corresponds to a V2V physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 30 kHz subcarrier spacing and 1 slot of 0.25 ms duration in time. Alternatively, for V2V physical channel, the information may be interpreted based on the assumption that the information was formatted into PRBs that include 12 subcarriers with 60 kHz subcarrier spacing and 1 slot of 0.125 ms duration in time.

Fig. 4 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under normal CP conditions. The legacy LTE numerology may correspond to a legacy LTE physical channel (e.g., an LTE SL channel), while the V2V

numerology may correspond to a V2V physical channel. A numerology, as discussed herein, may include parameters and characteristics of a physical channel (e.g., a legacy LTE SL channel or a V2V physical channel).

Such parameters and characteristics may include a bandwidth supported by the physical channel, a number of subcarriers per channel, a subcarrier spacing, a fast Fourier transform (FFT) size, a symbol duration, a slot duration, a subframe duration. Additional examples of numerological parameters and characteristics may include a direct, or indirect, description of a PRB and/or PRB pair of the physical channel, such as a number of subcarriers per PRB, a PRB duration (e.g., a number of slots per PRB), a number of resource elements (REs) per PRB, a number of symbols per PRB, etc.

Additionally, in the 3GPP LTE communication standard, CP may include copying a small portion of one symbol (e.g., an end portion of the symbol) and adding the copied portion to a beginning portion of the symbol, such that the symbol begins and ends with the same portion. Normal CP (as depicted in Figs. 4 and 6) may be implemented for wireless communications over shorter distances, while extended CP (as depicted in Figs. 5 and 7) may be implemented for wireless communications over longer distances. As such, normal CP may include a PRB of more symbols (or REs) per slot in time domain (e.g., 7), while extended CP may include a PRB of fewer symbols (or REs) per slot in time domain (e.g., 6).

As shown in Fig. 4, a PRB of the legacy LTE numerology for normal CP may include 12 subcarriers with 15 kHz subcarrier spacing, a slot of 0.5 ms in time domain comprising 7 consecutive symbols, and 84 REs in total. By contrast, the PRB of the V2V numerology for normal CP may include 12 subcarriers with 30 kHz subcarrier spacing, 1 slot of 0.25 ms in the time domain, comprising 7 consecutive symbols, and 84 REs in total. As such, each subcarrier of a V2V physical channel PRB may have twice as much subcarrier spacing as the subcarriers of the legacy LTE channel PRB; however, the duration of the slot of the V2V physical channel may be half the duration of the slot of the legacy LTE physical channel. As mentioned above, the decrease in slot duration may be accompanied by a similar decrease (e.g., a factor of 2, 4, etc.) to the FTT size associated with the V2V physical channel. Doing so may help ensure that the sampling time and/or sampling frequency of the V2V physical channel remains the same as the sampling time and sampling frequency of the legacy LTE channel.

For example, sampling time, as described herein, may include the basic time unit for the corresponding physical channel. For instance, in the 3GPP LTE communication standard, sampling time may be represented by "Ts" and may be equal to 1/(subcarrier spacing x FFT

size) (e.g., 1/(1500Hz x 2048)). By contrast, sampling frequency, as described herein, may include the basic frequency unit for a particular physical channel. For example, in the 3GPP LTE communication standard, sampling frequency may be represented by "Fs" and may be equal to subcarrier spacing (e.g., 15 kHz) multiplied by the number of FFT time samples (e.g., 2048).

As described above, a V2V channel may have increased subcarrier spacing (e.g., 30 kHz or 60 kHz instead of 15 kHz) but still be implemented within the LTE framework since decreasing symbol duration and FFT size proportionally may help ensure that sampling frequency and sampling time for the V2V channel are the same as the sampling frequency and sampling time of legacy LTE channels (e.g., an LTE SL channel). For example, since sampling time is equal to the inverse of subcarrier spacing multiplied by the corresponding FFT size, increasing the subcarrier spacing by a factor of two (e.g., from 15 kHz to 30 kHz) or four (e.g., from 15 kHz to 60 kHz) does not change the sampling time so long as the FFT size is reduced by the same factor (e.g., from 2048 to 1024 for factor of two or from 2048 to 512 for factor of four). The same can be said for sampling frequency since sampling frequency may be equal to subcarrier spacing multiplied by the corresponding FFT size. As such, the arrow depicted in Fig. 4 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels (which may be more robust and reliable in high mobility conditions (e.g., that may cause high Doppler fading and/or frequency shifts)) without affecting other aspects of the LTE communications standard.

For example, in some embodiments, the duration for a single subframe of a V2V channel may be set to 0.5 ms, such that the subframe may include 2 slots at 0.25 ms each. In such an implementation, relatively few (if any) modifications to the 3GPP LTE communication standard may implement the V2V channel since, for example, legacy LTE channels also include 2 slots per subframe. In other embodiments, the duration for a single subframe of the V2V channel may be set to 1.0 ms (for example), which may result in a subframe including 4 slots at 0.25 ms each. In such embodiments, certain modifications to the 3GPP LTE communications standard may be beneficial, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

Fig. 5 is a diagram of an example PRB of a legacy LTE numerology and an example PRB of a V2V numerology, under extended CP conditions. The legacy LTE numerology may correspond to a legacy LTE channel (e.g., an LTE SL channel), while the V2V numerology may correspond to a V2V channel. As shown, a PRB of the legacy LTE numerology for extended CP may include 12 subcarriers of 15 kHz each, a slot of 0.5 ms, and 72 REs (6 symbols or (REs)

per slot). By contrast, the PRB of the V2V numerology for normal CP may include 12 subcarriers of 30 kHz each, 1 slot of 0.25 ms, and 84 REs. As such, each subcarrier of a V2V channel PRB may include twice as much bandwidth as the subcarriers of the legacy LTE channel PRB; however, the slot of the V2V channel PRB may be half the duration of the slot of the legacy LTE channel PRB. As mentioned above, the decrease in slot duration may be accompanied by a similar decrease (e.g., a factor of 2, 4, etc.) to the FTT size associated with the V2V channel. The sampling frequency of the V2V channel may remain the same as the sampling frequency of the legacy LTE channel. As such, the arrow depicted in Fig. 5 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels (which may be more robust and reliable in high mobility conditions) without affecting other aspects of the LTE communications standard.

Fig. 6 is a diagram of example PRB pairs of a legacy LTE numerology and example PRB pairs of a V2V numerology, under normal CP conditions. As shown, the legacy LTE numerology and the V2V numerology may each include 4 PRBs, PRB 6.1 through PRB 6.4 and PRB 6.5 through 6.8, respectively. Each PRB of the legacy LTE numerology, and each PRB of the V2V numerology, may be similar to the corresponding PRBs discussed above with reference to Fig. 4. Additionally, the PRBs of Fig. 6 may corresponds to normal CP conditions since the PRB format includes 7 symbols (or REs) for each slot.

In the legacy LTE numerology, the PRB pairs may be differentiated from one another in the frequency domain, such that PRB 6.1 and PRB 6.2 include one pair (e.g., a 1st PRB pair) and PRB 6.3 and PRB 6.4 are another pair (e.g., a 2nd PRB pair). By contrast, in V2V numerology, the PRB pairs may be differentiated from one another in the time domain, such that PRB 6.5 and PRB 6.6 include one pair (e.g., a 1st PRB pair) and PRB 6.7 and PRB 6.8 are another pair (e.g., a 2nd PRB pair). Similar to the arrows in Fig. 4 and Fig. 5, the arrow depicted in Fig. 6 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels affecting other aspects of the LTE communications standard.

Fig. 7 is a diagram of example PRB pairs of a legacy LTE numerology and PRB pairs of a V2V numerology, under extended CP conditions. As shown, the legacy LTE numerology and the V2V numerology may each include 4 PRBs, PRB 7.1 through PRB 7.4 and PRB 7.5 through 7.8, respectively. Each PRB of the legacy LTE numerology, and each PRB of the V2V numerology, may be similar to the corresponding PRBs discussed above with reference to Fig. 5. Additionally, the PRBs of Fig. 7 may correspond to extended CP conditions since the PRB format includes 6 symbols (or REs) for each slot.

In the legacy LTE numerology, the PRB pairs may be differentiated from one another in the frequency domain, such that PRB 7.1 and PRB 7.2 include one pair (e.g., a 1st PRB pair) and PRB 6.3 and PRB 6.4 are another pair (e.g., a 2nd PRB pair). By contrast, in V2V numerology, the PRB pairs may be differentiated from one another in the time domain, such that PRB 7.5 and PRB 7.6 include one pair (e.g., a 1st PRB pair) and PRB 7.7 and PRB 7.8 are another pair (e.g., a 2nd PRB pair). Similar to the arrow in Fig. 6, the arrow depicted in Fig. 7 may represent that the techniques described herein may enable legacy LTE channels to be modified (or replaced) by V2V channels affecting other aspects of the LTE communications standard.

Figs. 8A-8D are diagrams of example PRBs according to one or more embodiments described herein. Additionally, the PRBs of Figs. 8A-8D may corresponds to normal CP conditions since each PRB includes 7 symbols per slot in time domain. The example PRB of Fig. 8A may correspond to the V2V channel PRB described above with reference to Fig. 4. The example PRBs of Fig. 8B may include a PRB pair (PRB 8.1 and PRB 8.2), similar to the V2V channel PRB pairs described above with reference to Fig. 5. Fig. 8C may include an example PRB that is similar to the PRB of Fig. 8A, except that the example PRB of Fig. 8C includes only 6 subcarriers (also, "REs in frequency" or "Frequency REs") of 30 kHz each. Similarly, Fig. 8D may include an example PRB pair (PRB 8.3 and PRB 8.4) that is similar to the PRB pair of Fig. 9B, except that the example PRBs of Fig. 8D include only 6 subcarriers with 30 kHz subcarrier spacing. In some embodiments, reducing the number of subcarriers per V2V channel may increase the number of transmission channels that may be used for V2V communications, which may in turn increase V2V system capacity (e.g., in a location with a high number of vehicles, such as a traffic jam on a freeway or major intersection).

Figs. 9A-9D are diagrams of example PRBs according to one or more embodiments described herein. Additionally, the PRBs of Figs. 9A-9D may correspond to extended CP conditions since each PRB includes 6 symbols per slot. The example PRB of Fig. 9A may correspond to the V2V channel PRB described above with reference to Fig. 5. The example PRBs of Fig. 9B may include a PRB pair (PRB 9.1 and PRB 9.2), similar to the V2V channel PRB pairs described above with reference to Fig. 5. Fig. 9C may include an example PRB that is similar to the PRB of Fig. 9A, except that the example PRB of Fig. 9C includes only 6 subcarriers (also, "REs in frequency" or "Frequency REs") of 30 kHz each. Similarly, Fig. 9D may include an example PRB pair (PRB 9.3 and PRB 9.4) that is similar to the PRB pair of Fig. 9B, except that the example PRBs of Fig. 9D include only 6 (instead of 12) subcarriers of 30 kHz each. As described above with reference to Figs. 8A-8D, in some embodiments, reducing

the number of subcarriers per V2V channel may increase the number of transmission channels that may be used for V2V communications, which may in turn increase the level of V2V system capacity (e.g., in a location with a high number of vehicles, such as a traffic jam on a freeway or major intersection).

Fig. 10 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 30 kHz subcarrier spacing. As shown, the table of Fig. 10 includes a Channel Characteristics column, a Legacy LTE Channel Numerology column, and a V2V Channel numerology column. Fig. 10 provides a non-limiting example of differences and similarities that may exists between a legacy LTE channel and a V2V channel.

For example, a legacy LTE channel may include a subcarrier spacing of 15 kHz, while a V2V channel may include a subcarrier spacing of 30 kHz. Both channels may support the same bandwidths; however, the channels may only support some of the same FTT sizes. For instance, only the legacy LTE channel may use FTT sizes of 1536 and 2048, and the V2V channel may use FTT sizes of 64 and 768. As such, the FFT size for the legacy LTE channel may include a lower limit of 128 for the 1.4 MHz bandwidth and an upper limit of 2048 for 20 MHz bandwidth, while the FFT size for the V2V channel (with 30 kHz subcarrier spacing), may include a lower limit of 64 for 1.4 MHz bandwidth and an upper limit of 1024 for the 20 MHz bandwidth. As described above, this is due to reducing the FTT sizes for the V2V channel by the same factor (e.g., "2") that was used to increase the subcarrier spacing of the V2V channel. The following table may represent a logical relationship between different BWs, legacy LTE FFT sizes, and V2V channel FFT sizes (when the subcarrier spacing for the V2V channel is 30 kHz).

Bandwidth (BW)	Nominal FFT Size	
	Legacy LTE Channel	V2V Channel with 30 kHz
1.4 MHz	128	64
3 MHz	256	128
5 MHz	512	256
10 MHz	1024	512
15 MHz	1536	768
20 MHz	2048	1024

Since the same factor was used to increase and decrease the subcarrier spacing and FFT size (respectively), both channels may have the same sampling time (Ts) of 32.55 nanoseconds

(ns) because sampling time may be calculated by taking the inverse of the product of the subcarrier spacing and the FFT size (e.g., Ts = 1/(subcarrier spacing x FFT size). In some embodiments, for similar reasons, both channels may also have the same sampling frequency (Fs) (e.g., Fs = subcarrier spacing x FFT size). As mentioned above, maintaining the same sampling time and sampling frequency as the legacy LTE channel may help ensure that the V2V channel can be implemented in an LTE environment without having to make significant adjustments to other aspects of the 3GPP LTE communication standard.

Similar to the change in FFT size, the symbol durations for the V2V channel may also be reduced by the same factor (e.g., "2") that was used to increase the subcarrier spacing of the V2V channel. As shown in Figs. 6-7, this may enable PRBs and PRB pairs to be formatted in a manner that enables the V2V channel to reduce the slot duration by half (e.g., from 0.5 ms to 0.25 ms) and output PRBs at the same rate as the legacy LTE channel, even though the subcarrier spacing for the V2V channel was doubled. Similar to maintaining the same sampling time and sampling frequency, maintaining a similar output rate as the legacy LTE channel, may help reduce the impact of the V2V channel on other aspects of the 3GPP LTE communication standard.

Additionally, the single subframe duration for the legacy LTE channel may be 1.0 ms, whereas the single subframe duration for the V2V channel may be 0.5 or 1.0 ms. A single subframe duration of 0.5 ms may enable the V2V channel to have two slots per subframe since the slot duration for the V2V channel was reduced to 0.25 ms. Additionally, since a PRB duration may be 0.25 ms (which corresponds to 1 slot), a 0.5 ms subframe may consist of one PRB pair (i.e., two 0.25 ms PRBs). In other words, the V2V channel may have a subframe-to-PRB-pair ratio of 1:1 when the subframe duration of the V2V channel is 0.5 ms, which may reduce the impact of the V2V channel on the 3GPP LTE communication standard since, for example, the legacy LTE channel also has a subframe-to-PRB-pair ratio of 1:1.

By contrast, a single subframe duration of 1.0 ms may enable the V2V channel to have four slots per subframe since the slot duration for the V2V channel was reduced to 0.25 ms. As such, the subframe may include four slots. In other words, a subframe duration of 1.0 ms, as opposed to the 0.5 ms subframe scenario above, may give rise to a relative increase in the amount of information that may be communicated in one subframe. As a result, implementing a 1.0 ms subframe may additional modifications to the 3GPP LTE communication standard, including changes to the design of physical channels, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

As shown in Fig. 10, whether the legacy LTE channel and the V2V channel have the same number of subcarriers per PRB may depend on the scenario or embodiment. For example, both channels may have 12 subcarriers for each PRB. Additionally, or alternatively, the V2V channel may have 6 subcarriers per PRB. In some embodiments, while allocating 6 subcarriers (instead of 12) to each PRB may decrease the rate at which a channel may transmit data, doing so may also increase the number of V2V channels that are available for V2X devices 110 to communicate with other V2X devices, UEs, etc. As such, allocating 6 subcarriers to each V2V channel may be beneficial in scenarios where V2V channels might not benefit from a high data rate connections and/or a vehicle with a V2X device is in a traffic jam, rush hour traffic, or in another situation involving a lot of V2X devices 110, UEs 110, etc., that within range of one another.

Fig. 11 is a table of example characteristics of a legacy LTE numerology and a V2V numerology with 60 kHz subcarrier spacing. As shown, the table of Fig. 11 includes a Channel Characteristics column, a Legacy LTE Channel Numerology column, and a V2V Channel numerology column. Fig. 11 provides a non-limiting example of differences and similarities that may exists between a legacy LTE channel and a V2V channel.

For example, a legacy LTE channel may include a subcarrier spacing of 15 kHz, while a V2V channel may include a subcarrier spacing of 60 kHz. Both channels may support the same bandwidths; however, the channels may only support some of the same FTT sizes. For instance, only the legacy LTE channel may support FTT sizes of 1024, 1536, and 2048, and only the V2V channel may support an FTT size of 32, 64, and 384. As such, the FFT size for the legacy LTE channel may include a lower limit of 128 and an upper limit of 2048, while the FFT size for the V2V channel (with 60 kHz subcarrier spacing), may include a lower limit of 32 kHz and an upper limit of 512 kHz. This may be due to reducing the FTT sizes for the V2V channel by the same factor (e.g., "4") that was used to increase the subcarrier spacing of the V2V channel. The following table may represent a logical relationship between different BWs, legacy LTE FFT sizes, and V2V channel FFT sizes (when the subcarrier spacing for the V2V channel is 30 kHz).

Bandwidth (BW)	Nominal FFT Size	
	Legacy LTE Channel	V2V Channel with 60 kHz
1.5 MHz	128	32
3 MHz	256	64
5 MHz	512	128
10 MHz	1024	256

15 MHz	1536	384
20 MHz	2048	512

Since the same factor was used to increase and decrease the subcarrier spacing and FFT size (respectively), both channels may have the same sampling time (Ts) of 32.55 nanoseconds (ns) because sampling time may be calculated by taking the inverse of the product of the subcarrier spacing and the FFT size (e.g., Ts = 1/(subcarrier spacing x FFT size). In some embodiments, for similar reasons, both channels may also have the same sampling frequency (Fs) (e.g., Fs = subcarrier spacing x FFT size). As mentioned above, maintaining the same sampling time and sampling frequency as the legacy LTE channel may help ensure that the V2V channel can be implemented in an LTE environment without having to make significant adjustments to other aspects of the 3GPP LTE communication standard.

Similar to the change in FFT size, the symbol durations for the V2V channel may also be reduced by the same factor (e.g., "4") that was used to increase the subcarrier spacing of the V2V channel. This may enable PRBs and PRB pairs to be formatted in a manner that enables the V2V channel to reduce the slot duration by one-fourth (e.g., from 1.0 ms to 0.125 ms) and output PRBs at the same rate as the legacy LTE channel, even though the subcarrier spacing for the V2V channel was quadrupled. Similar to maintaining the same sampling time and sampling frequency, maintaining a similar output rate as the legacy LTE channel, may help reduce the impact of the V2V channel on other aspects of the 3GPP LTE communication standard.

Additionally, the single subframe duration for the legacy LTE channel may be 1.0 ms, whereas the single subframe duration for the V2V channel may be 0.25 or 1.0 ms. A single subframe duration of 0.25 ms may enable the V2V channel to have two slots per subframe since the slot duration for the V2V channel was reduced to 0.125 ms. Additionally, since a PRB duration may be 0.125 ms (which corresponds to 1 slot), a 0.25 ms subframe may consist of one PRB pair (i.e., two 0.125 ms PRBs). In other words, the V2V channel may have a subframe-to-PRB-pair ratio of 1:1 when the subframe duration of the V2V channel is 0.25 ms, which may reduce the impact of the V2V channel on the 3GPP LTE communication standard since, for example, the legacy LTE channel also has a subframe-to-PRB-pair ratio of 1:1.

By contrast, a single subframe duration of 1.0 ms may enable the V2V channel to have eight slots per subframe since the slot duration for the V2V channel was reduced to 0.125 ms. As such, the subframe may include eight slots. In other words, a subframe duration of 1.0 ms, as opposed to the 0.25 ms subframe scenario above, may give rise to a relative increase in the amount of information that may be communicated in one subframe. As a result, implementing a

1.0 ms subframe may additional modifications to the 3GPP LTE communication standard, including changes to the design of physical channels, such as modifications to the size of transport blocks, the transport block sizes (TBS) tables, etc.

As shown in Fig. 11, whether the legacy LTE channel and the V2V channel have the same number of subcarriers per PRB may depend on the scenario or embodiment. For example, both channels may have 12 subcarriers for each PRB. Additionally, or alternatively, the V2V channel may have 3 or 6 subcarriers per PRB. In some embodiments, while allocating 3 or 6 subcarriers (instead of 12) to each PRB may decrease the rate at which a channel may transmit data, doing so may also increase the number of V2V channels that are available for V2X devices 110 to communicate with other V2X devices, UEs, etc. As such, allocating 3 or 6 subcarriers to each V2V channel may be beneficial in scenarios where V2V channels might not benefit from high data rate connections and/or a vehicle with a V2X device is in a traffic jam, rush hour traffic, or in another situation involving a lot of V2X devices 110, UEs 110, etc., that within range of one another.

Fig. 12 is a table representing an example of legacy LTE and V2V transmission multiplexing. As shown, Fig. 12 may include a vertical axis representing frequency and a horizontal axis representing time. V2V devices 110, UEs 110, etc., may support both legacy and V2V PHY numerologies (e.g. for cellular and V2V operation). Time domain multiplexing of legacy and V2V transmissions at one UE 110 may be used for these purposes. To facilitate efficient use of resources the minimum granularity for time domain multiplexing may be a multiple of legacy subframe granularity (e.g., 1.0 ms).

In one example, subframes for legacy LTE and V2V operation may be semi-statically, higher-layer configured, by an eNB (e.g., via radio resource control (RRC) protocol), on a per V2V device basis (or V2V device group basis). Semi-statically may include, for example, physical channels that are predefined by the eNB and assigned to a particular V2V device 210 or UE in a given scenario. In another example, subframes for legacy LTE and V2V operation may be dynamically assigned. In yet another example, subframes for legacy LTE and V2V operation may be specified by a communications standard (such as the 3GPP LTE communication standard).

A V2V transmissions (e.g., transmissions with a V2V numerology) may take place in either TDD or FDD modes. In the latter case, the transmissions may be configured in either a DL or a UL spectrum and can be configured independently (e.g., V2V transmissions on a UL spectrum may not impose use of V2V numerology in a DL spectrum in the same time resources).

In some embodiments, V2V device 110, UE 110, etc., may implement an autonomous selection capability for the numerology for the V2V transmissions (e.g., either a legacy LTE numerology or a V2V numerology) based on one or more instructions, conditions, or other criteria. As such, a V2V receiver (or another type of communication component) may either be informed on the type of the transmission in advance or may dynamically detect the transmission type. In embodiments where the transmission type is dynamically detected, a receiver (or another component of V2V device 110) may attempt to receive information under different hypothesis simultaneously (e.g., attempt to receive a signal under both a 15 kHz subcarrier spacing assumption and a 30 kHz subcarrier spacing assumptions)

As used herein, the term "circuitry" or "processing circuitry" may refer to, be part of, or include an Application Specific Integrated Circuit (ASIC), an electronic circuit, a processor (shared, dedicated, or group), and/or memory (shared, dedicated, or group) that execute one or more software or firmware programs, a combinational logic circuit, and/or other suitable hardware components that provide the described functionality. In some embodiments, the circuitry may be implemented in, or functions associated with the circuitry may be implemented by, one or more software or firmware modules. In some embodiments, circuitry may include logic, at least partially operable in hardware.

Embodiments described herein may be implemented into a system using any suitably configured hardware and/or software. Fig. 13 illustrates, for one embodiment, example components of an electronic device 1300. In embodiments, the electronic device 1300 may be a UE, an eNB, a WLAN AP, or some other appropriate electronic device. In some embodiments, the electronic device 1300 may include application circuitry 1302, baseband circuitry 1304, Radio Frequency (RF) circuitry 1306, front-end module (FEM) circuitry 1308 and one or more antennas 1360, coupled together at least as shown.

The application circuitry 1302 may include one or more application processors. For example, the application circuitry 1302 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The processor(s) may include any combination of general-purpose processors and dedicated processors (e.g., graphics processors, application processors, etc.). The processors may be coupled with and/or may include memory/storage, such as storage medium 1303, and may be configured to execute instructions stored in the memory/storage to enable various applications and/or operating systems to run on the system. In some implementations, storage medium 1303 may include a non-transitory computer-readable medium. Application circuitry 1302 may, in some embodiments, connect to or include one or more sensors, such as environmental sensors, cameras, etc.

Baseband circuitry 1304 may include circuitry such as, but not limited to, one or more single-core or multi-core processors. The baseband circuitry 1304 may include one or more baseband processors and/or control logic to process baseband signals received from a receive signal path of the RF circuitry 1306 and to generate baseband signals for a transmit signal path of the RF circuitry 1306. Baseband processing circuitry 1304 may interface with the application circuitry 1302 for generation and processing of the baseband signals and for controlling operations of the RF circuitry 1306. For example, in some embodiments, the baseband circuitry 1304 may include a second generation (2G) baseband processor 1304a, third generation (3G) baseband processor 1304b, fourth generation (4G) baseband processor 1304c, and/or other baseband processor(s) 1304d for other existing generations, generations in development or to be developed in the future (e.g., fifth generation (5G), 6G, etc.). The baseband circuitry 1304 (e.g., one or more of baseband processors 1304a-d) may handle various radio control functions that enable communication with one or more radio networks via the RF circuitry 1306. The radio control functions may include, but are not limited to, signal modulation/demodulation, encoding/decoding, radio frequency shifting, etc. In some implementations, baseband circuitry 1304 may be associated with storage medium 1303 or with another storage medium.

In some embodiments, modulation/demodulation circuitry of the baseband circuitry 1304 may include FFT, precoding, and/or constellation mapping/demapping functionality. In some embodiments, encoding/decoding circuitry of the baseband circuitry 1304 may include convolution, tail-biting convolution, turbo, Viterbi, and/or Low Density Parity Check (LDPC) encoder/decoder functionality. Embodiments of modulation/demodulation and encoder/decoder functionality are not limited to these examples and may include other suitable functionality in other embodiments. In some embodiments, the baseband circuitry 1304 may include elements of a protocol stack such as, for example, elements of an evolved universal terrestrial radio access network (E-UTRAN) protocol including, for example, physical (PHY), MAC, radio link control (RLC), packet data convergence protocol (PDCP), and/or radio resource control (RRC) elements. A central processing unit (CPU) 1304e of the baseband circuitry 1304 may be configured to run elements of the protocol stack for signaling of the PHY, MAC, RLC, PDCP and/or RRC layers. In some embodiments, the baseband circuitry may include one or more audio digital signal processor(s) (DSP) 1304f. The audio DSP(s) 1304f may be include elements for compression/decompression and echo cancellation and may include other suitable processing elements in other embodiments.

The baseband circuitry 1304 may further include memory/storage 1304g. The memory/storage 1304g may be used to load and store data and/or instructions for operations

performed by the processors of the baseband circuitry 1304. Memory/storage for one embodiment may include any combination of suitable volatile memory and/or non-volatile memory. The memory/storage 1304g may include any combination of various levels of memory/storage including, but not limited to, read-only memory (ROM) having embedded software instructions (e.g., firmware), random access memory (e.g., dynamic random access memory (DRAM)), cache, buffers, etc. The memory/storage 1304g may be shared among the various processors or dedicated to particular processors.

Components of the baseband circuitry may be suitably combined in a single chip, a single chipset, or disposed on a same circuit board in some embodiments. In some embodiments, some or all of the constituent components of the baseband circuitry 1304 and the application circuitry 1302 may be implemented together such as, for example, on a system on a chip (SOC).

In some embodiments, the baseband circuitry 1304 may provide for communication compatible with one or more radio technologies. For example, in some embodiments, the baseband circuitry 1304 may support communication with an E-UTRAN and/or other wireless metropolitan area networks (WMAN), a WLAN, a wireless personal area network (WPAN). Embodiments in which the baseband circuitry 1304 is configured to support radio communications of more than one wireless protocol may be referred to as multi-mode baseband circuitry.

RF circuitry 1306 may enable communication with wireless networks using modulated electromagnetic radiation through a non-solid medium. In various embodiments, the RF circuitry 1306 may include switches, filters, amplifiers, etc. to facilitate the communication with the wireless network. RF circuitry 1306 may include a receive signal path which may include circuitry to down-convert RF signals received from the FEM circuitry 1308 and provide baseband signals to the baseband circuitry 1304. RF circuitry 1306 may also include a transmit signal path which may include circuitry to up-convert baseband signals provided by the baseband circuitry 1304 and provide RF output signals to the FEM circuitry 1308 for transmission.

In some embodiments, the RF circuitry 1306 may include a receive signal path and a transmit signal path. The receive signal path of the RF circuitry 1306 may include mixer circuitry 1306a, amplifier circuitry 1306b and filter circuitry 1306c. The transmit signal path of the RF circuitry 1306 may include filter circuitry 1306c and mixer circuitry 1306a. RF circuitry 1306 may also include synthesizer circuitry 1306d for synthesizing a frequency for use by the mixer circuitry 1306a of the receive signal path and the transmit signal path. In some

embodiments, the mixer circuitry 1306a of the receive signal path may be configured to down-convert RF signals received from the FEM circuitry 1308 based on the synthesized frequency provided by synthesizer circuitry 1306d. The amplifier circuitry 1306b may be configured to amplify the down-converted signals and the filter circuitry 1306c may be a low-pass filter (LPF) or band-pass filter (BPF) configured to remove unwanted signals from the down-converted signals to generate output baseband signals.

Output baseband signals may be provided to the baseband circuitry 1304 for further processing. In some embodiments, the output baseband signals may be zero-frequency baseband signals. In some embodiments, mixer circuitry 1306a of the receive signal path may comprise passive mixers, although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 1306a of the transmit signal path may be configured to up-convert input baseband signals based on the synthesized frequency provided by the synthesizer circuitry 1306d to generate RF output signals for the FEM circuitry 1308. The baseband signals may be provided by the baseband circuitry 1304 and may be filtered by filter circuitry 1306c. The filter circuitry 1306c may include a low-pass filter (LPF), although the scope of the embodiments is not limited in this respect.

In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may include two or more mixers and may be arranged for quadrature downconversion and/or upconversion respectively. In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may include two or more mixers and may be arranged for image rejection (e.g., Hartley image rejection). In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a may be arranged for direct downconversion and/or direct upconversion, respectively. In some embodiments, the mixer circuitry 1306a of the receive signal path and the mixer circuitry 1306a of the transmit signal path may be configured for super-heterodyne operation.

In some embodiments, the output baseband signals and the input baseband signals may be analog baseband signals, although the scope of the embodiments is not limited in this respect. In some alternate embodiments, the output baseband signals and the input baseband signals may be digital baseband signals. In these alternate embodiments, the RF circuitry 1306 may include analog-to-digital converter (ADC) and digital-to-analog converter (DAC) circuitry and the baseband circuitry 1304 may include a digital baseband interface to communicate with the RF circuitry 1306.

In some dual-mode embodiments, a separate radio IC circuitry may be provided for processing signals for each spectrum, although the scope of the embodiments is not limited in this respect.

In some embodiments, the synthesizer circuitry 1306d may be a fractional-N synthesizer or a fractional N/N+6 synthesizer, although the scope of the embodiments is not limited in this respect as other types of frequency synthesizers may be suitable. For example, synthesizer circuitry 1306d may be a delta-sigma synthesizer, a frequency multiplier, or a synthesizer comprising a phase-locked loop with a frequency divider.

The synthesizer circuitry 1306d may be configured to synthesize an output frequency for use by the mixer circuitry 1306a of the RF circuitry 1306 based on a frequency input and a divider control input. In some embodiments, the synthesizer circuitry 1306d may be a fractional N/N+6 synthesizer.

In some embodiments, frequency input may be provided by a voltage controlled oscillator (VCO. Divider control input may be provided by either the baseband circuitry 1304 or the applications processor 1302 depending on the desired output frequency. In some embodiments, a divider control input (e.g., N) may be determined from a look-up table based on a channel indicated by the applications processor 1302.

Synthesizer circuitry 1306d of the RF circuitry 1306 may include a divider, a delay-locked loop (DLL), a multiplexer and a phase accumulator. In some embodiments, the divider may be a dual modulus divider (DMD) and the phase accumulator may be a digital phase accumulator (DPA). In some embodiments, the DMD may be configured to divide the input signal by either N or N+6 (e.g., based on a carry out) to provide a fractional division ratio. In some example embodiments, the DLL may include a set of cascaded, tunable, delay elements, a phase detector, a charge pump and a D-type flip-flop. In these embodiments, the delay elements may be configured to break a VCO period up into Nd equal packets of phase, where Nd is the number of delay elements in the delay line. In this way, the DLL provides negative feedback to help ensure that the total delay through the delay line is one VCO cycle.

In some embodiments, synthesizer circuitry 1306d may be configured to generate a carrier frequency as the output frequency, while in other embodiments, the output frequency may be a multiple of the carrier frequency (e.g., twice the carrier frequency, four times the carrier frequency) and used in conjunction with quadrature generator and divider circuitry to generate multiple signals at the carrier frequency with multiple different phases with respect to each other. In some embodiments, the output frequency may be a LO frequency (fLO). In some embodiments, the RF circuitry 1306 may include an IQ/polar converter.

FEM circuitry 1308 may include a receive signal path which may include circuitry configured to operate on RF signals received from one or more antennas 1360, amplify the received signals and provide the amplified versions of the received signals to the RF circuitry 1306 for further processing. FEM circuitry 1308 may also include a transmit signal path which may include circuitry configured to amplify signals for transmission provided by the RF circuitry 1306 for transmission by one or more of the one or more antennas 1360.

In some embodiments, the FEM circuitry 1308 may include a TX/RX switch to switch between transmit mode and receive mode operation. The FEM circuitry may include a receive signal path and a transmit signal path. The receive signal path of the FEM circuitry may include a low-noise amplifier (LNA) to amplify received RF signals and provide the amplified received RF signals as an output (e.g., to the RF circuitry 1306). The transmit signal path of the FEM circuitry 1308 may include a power amplifier (PA) to amplify input RF signals (e.g., provided by RF circuitry 1306), and one or more filters to generate RF signals for subsequent transmission (e.g., by one or more of the one or more antennas 1360.

In some embodiments, the electronic device 1300 may include additional elements such as, for example, memory/storage, display, camera, sensors, and/or input/output (I/O) interface. In some embodiments, the electronic device of Fig. 13 may be configured to perform one or more methods, processes, and/or techniques such as those described herein.

A number of examples, relating to embodiments of the techniques described above, will next be given.

In a first example, a communication device may comprise: a radio frequency (RF) circuitry to communicate with other communication devices via a physical channel; and baseband circuitry to cause the RF circuitry to communicate with another communication device via the physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 2, the subject matter of example 1, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 3, the subject matter of example 1, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6

subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 4, the subject matter of example 1, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In example 5, the subject matter of example 1, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: a vehicle-to-vehicle (V2V) communication, a vehicular-to-infrastructure (V2I) communication, or a vehicular-to-pedestrian (V2P) communication.

In example 6, the subject matter of example 1, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an long-term evolution (LTE) sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In a seventh example, an apparatus for a wireless communication device may comprise: a radio (RF) circuitry to communicate with other communication devices via a physical channel; and a baseband circuitry to: use a physical channel, from a plurality of physical channel types, that is appropriate for communicating with the other wireless communication devices, the plurality of physical channel types including: a long-term evolution (LTE) physical channel, and a V2V physical channel that includes: a bandwidth that is at least as large as a bandwidth of the LTE physical channel; a subcarrier spacing that is greater, by a preselected factor, than a subcarrier spacing corresponding to the LTE physical channel, a fast Fourier transform (FFT) size that is less, by the preselected factor, than an FFT size corresponding to the LTE physical channel, a symbol duration that is less, by the preselected factor, than a symbol duration corresponding to the LTE physical channel, and a sampling frequency that is equal to a sampling frequency of the LTE physical channel, and a sampling time that is equal to a sampling time of the LTE physical channel; and communicate with the other wireless communication devices via the V2V physical channel.

In example 8, the subject matter of example 7, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an LTE sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In example 9, the subject matter of example 7, or any of the examples herein, may further include wherein the V2V physical channel includes physical resource blocks (PRBs) that

each include a number of subcarriers that is less than, or equal to, a number of subcarriers of the PRBs of the LTE physical channel.

In example 10, the subject matter of example 7, or any of the examples herein, may further include wherein: the subcarrier spacing for the V2V physical channel is 30 or 60 kilohertz (kHz); and the subcarrier spacing for the LTE physical channel is 15 kHz.

In example 11, the subject matter of example 7, or any of the examples herein, may further include wherein, for normal cyclic prefix (CP) conditions and extended CP conditions, a number of resource elements (REs) and a number of single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols per a physical resource block (PRB) of the V2V physical channel is equal to the number of REs and a number of SC-FDMA or OFDM symbols per PRB of the LTE physical channel.

In example 12, the subject matter of example 7, or any of the examples herein, may further include wherein application circuitry is to: communicate with a user equipment device (UE) of a vehicle via a vehicle-to-vehicle (V2V) connection, communicate with a UE of a user via a vehicle-to-pedestrian (V2P) connection, or communicate with a wireless telecommunications network via a vehicle-to-infrastructure (V2I) connection.

In example 13, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry uses the type of physical channel that is appropriate for communicating with the other wireless communication device based on at least one of: a likelihood of communications, between the wireless communication device and the other wireless communication device being subjected to high mobility conditions, whether the other wireless communication device is capable of communicating via the LTE physical channel or the V2V physical channel, an availability, of the LTE physical channel or the V2V physical channel, for communicating with the other wireless communication device, a measure of importance regarding information that will be communicated to the other wireless communication device, or a preselected priority for communicating via the LTE physical channel or the V2V physical channel.

In example 14, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry is configured, by via an eNB, to use the V2V physical channel or the LTE physical channel.

In example 15, the subject matter of example 7, or any of the examples herein, may further include wherein the baseband circuitry uses time-division multiplexing of the V2V physical channel and the LTE physical channel to communicate in different subframes.

In example 16, the subject matter of example 7, or any of the examples herein, may further include wherein subframes for the V2V physical channel and the LTE physical channel are semi-statically configured by an eNB.

In a seventeenth example, a wireless communication device as in the first or seventh examples, wherein a physical resource block (PRB), corresponding to the vehicle-to-vehicle (V2V) physical channel, includes: 7 consecutive single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols in time domain under normal cyclic prefix (CP) conditions, and 6 consecutive SC-FDMA or OFDM symbols in time domain under extended CP conditions.

In example 18, the subject matter of example 17, or any of the examples herein, may further include a subframe, corresponding to the V2V physical channel, includes two slots, a physical resource block (PRB), corresponding to the V2V physical channel, contains one slot; and a subframe duration, corresponding to the V2V physical channel, is equal to at least one of: 0.5 milliseconds (ms) and a slot duration is 0.25 ms when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz); or 0.25 milliseconds (ms) and a slot duration is 0.125 ms when subcarrier spacing for the V2V physical channel is 60 kilohertz (kHz).

In example 19, the subject matter of example 17, or any of the examples herein, may further include a subframe duration, corresponding to the vehicle-to-vehicle (V2V) physical channel, is equal to 1.0 ms, and the subframe, corresponding to the V2V physical channel, includes four slots with 0.25 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains two slots when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz), or the subframe, corresponding to the V2V physical channel, includes eight slots with 0.125 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains four slots when subcarrier spacing for the V2V physical channel is 60 kHz.

In a twentieth example, a computer readable medium may contain program instructions for causing one or more processors to: communicate with other communication devices via a physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 21, the subject matter of example 20, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 22, the subject matter of example 20, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 23, the subject matter of example 20, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: a vehicle-to-vehicle (V2V) communication, a vehicular-to-infrastructure (V2I) communication, or a vehicular-to-pedestrian (V2P) communication.

In example 24, the subject matter of example 20, or any of the examples herein, may further include wherein the physical channel corresponds to at least one of: an LTE sidelink (SL) physical channels, an LTE downlink (DL) physical channels, or an LTE uplink (UL) physical channels.

In example 25, the subject matter of example 20, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In a twenty-sixth example, a communication device may comprise: a means for communicating with other communication devices via a physical channel; and a means for causing the means for communicating to communicate with another communication device via the physical channel, the physical channel including: a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform, a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

In example 27, the subject matter of example 26, or any of the examples herein, may further include wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

In example 28, the subject matter of example 26, or any of the examples herein, may further include wherein a PRB, corresponding to the physical channel, includes 6

subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

In example 29, the subject matter of example 26, or any of the examples herein, may further include wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

In the preceding specification, various embodiments have been described with reference to the accompanying drawings. It will, however, be evident that various modifications and changes may be made thereto, and additional embodiments may be implemented, without departing from the broader scope as set forth in the claims that follow. The specification and drawings are accordingly to be regarded in an illustrative rather than restrictive sense.

For example, while series of signals and/or operations have been described with regard to Figs. 3-4, the order of the signals and/or operations may be modified in other embodiments. Further, non-dependent signals may be performed in parallel.

It will be apparent that example aspects, as described above, may be implemented in many different forms of software, firmware, and hardware in the embodiments illustrated in the figures. The actual software code or specialized control hardware used to implement these aspects should not be construed as limiting. Thus, the operation and behavior of the aspects were described without reference to the specific software code--it being understood that software and control hardware could be designed to implement the aspects based on the description herein.

Further, certain portions may be implemented as "logic" that performs one or more functions. This logic may include hardware, such as an application-specific integrated circuit ("ASIC") or a field programmable gate array ("FPGA"), or a combination of hardware and software.

Even though particular combinations of features are recited in the claims and/or disclosed in the specification, these combinations are not intended to be limiting. In fact, many of these features may be combined in ways not specifically recited in the claims and/or disclosed in the specification.

No element, act, or instruction used in the present application should be construed as critical or essential unless explicitly described as such. An instance of the use of the term "and," as used herein, does not necessarily preclude the interpretation that the phrase "and/or" was intended in that instance. Similarly, an instance of the use of the term "or," as used herein, does not necessarily preclude the interpretation that the phrase "and/or" was intended in that instance. Also, as used herein, the article "a" is intended to include one or more items, and may be used

interchangeably with the phrase "one or more." Where only one item is intended, the terms "one," "single," "only," or similar language is used.

WHAT IS CLAIMED IS:

1. A communication device, comprising:

a radio frequency (RF) circuitry to communicate with other communication devices via a physical channel; and

baseband circuitry to cause the RF circuitry to communicate with another communication device via the physical channel, the physical channel including:

a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform,

a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and

a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

2. The communication device of claim 1, wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

3. The communication device of claim 1, wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

4. The communication device of claim 1, wherein two PRBs form a PRB pair, of the physical channel, that corresponds to two consecutive PRBs in a time-domain.

5. The communication device of claim 1, wherein the physical channel corresponds to at least one of:

a vehicle-to-vehicle (V2V) communication,

a vehicular-to-infrastructure (V2I) communication, or

a vehicular-to-pedestrian (V2P) communication.

6. The communication device of claim 1, wherein the physical channel corresponds to at least one of:

an long-term evolution (LTE) sidelink (SL) physical channel,

an LTE downlink (DL) physical channel, or

an LTE uplink (UL) physical channel.

7. An apparatus for a wireless communication device, comprising:

a radio (RF) circuitry to communicate with other communication devices via a physical channel; and

a baseband circuitry to:

use a physical channel, from a plurality of physical channel types, that is appropriate for communicating with the other wireless communication devices, the plurality of physical channel types including:

a long-term evolution (LTE) physical channel, and

a V2V physical channel that includes:

a bandwidth that is at least as large as a bandwidth of the LTE physical channel;

a subcarrier spacing that is greater, by a preselected factor, than a subcarrier spacing corresponding to the LTE physical channel,

a fast Fourier transform (FFT) size that is less, by the preselected factor, than an FFT size corresponding to the LTE physical channel,

a symbol duration that is less, by the preselected factor, than a symbol duration corresponding to the LTE physical channel, and

a sampling frequency that is equal to a sampling frequency of the LTE physical channel, and

a sampling time that is equal to a sampling time of the LTE physical channel; and

communicate with the other wireless communication devices via the V2V physical channel.

8. The apparatus of claim 7, wherein the LTE physical channel and the V2V physical channel correspond to at least one of:

long-term evolution (LTE) sidelink (SL) physical channels,

LTE downlink (DL) physical channels, or

LTE uplink (UL) physical channels.

9. The apparatus of claim 7, wherein the V2V physical channel includes physical resource blocks (PRBs) that each include a number of subcarriers that is less than, or equal to, a number of subcarriers of the PRBs of the LTE physical channel.

10. The apparatus of claim 7, wherein:
the subcarrier spacing for the V2V physical channel is 30 or 60 kilohertz (kHz); and
the subcarrier spacing for the LTE physical channel is 15 kHz.

11. The apparatus of claim 7, wherein, for normal cyclic prefix (CP) conditions and extended CP conditions, a number of resource elements (REs) and a number of single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols per a physical resource block (PRB) of the V2V physical channel is equal to the number of REs and a number of SC-FDMA or OFDM symbols per PRB of the LTE physical channel.

12. The apparatus of claim 7, wherein application circuitry is to:
communicate with a user equipment device (UE) of a vehicle via a vehicle-to-vehicle (V2V) connection,
communicate with a UE of a user via a vehicle-to-pedestrian (V2P) connection, or
communicate with a wireless telecommunications network via a vehicle-to-infrastructure (V2I) connection.

13. The apparatus of claim 7, wherein the baseband circuitry uses the type of physical channel that is appropriate for communicating with the other wireless communication device based on at least one of:
a likelihood of communications, between the wireless communication device and the other wireless communication device being subjected to high mobility conditions,
whether the other wireless communication device is capable of communicating via the LTE physical channel or the V2V physical channel,
an availability, of the LTE physical channel or the V2V physical channel, for communicating with the other wireless communication device,
a measure of importance regarding information that will be communicated to the other wireless communication device, or

a preselected priority for communicating via the LTE physical channel or the V2V physical channel.

14. The apparatus of claim 7, wherein the baseband circuitry is configured, by via an eNB, to use the V2V physical channel or the LTE physical channel.

15. The apparatus of claim 7, wherein the baseband circuitry uses time-division multiplexing of the V2V physical channel and the LTE physical channel to communicate in different subframes.

16. The apparatus of either of claims 15, wherein subframes for the V2V physical channel and the LTE physical channel are semi-statically configured by an eNB.

17. A wireless communication device as in claims 1 or 7, wherein a physical resource block (PRB), corresponding to the vehicle-to-vehicle (V2V) physical channel, includes:

7 consecutive single-carrier frequency-division multiple access (SC-FDMA) or orthogonal frequency division multiplexing (OFDM) symbols in time domain under normal cyclic prefix (CP) conditions, and

6 consecutive SC-FDMA or OFDM symbols in time domain under extended CP conditions.

18. The wireless communication device of claim 17, wherein:

a subframe, corresponding to the V2V physical channel, includes two slots,

a physical resource block (PRB), corresponding to the V2V physical channel, contains one slot; and

a subframe duration, corresponding to the V2V physical channel, is equal to at least one of:

0.5 milliseconds (ms) and a slot duration is 0.25 ms when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz); or

0.25 milliseconds (ms) and a slot duration is 0.125 ms when subcarrier spacing for the V2V physical channel is 60 kilohertz (kHz).

19. The wireless communication device of claim 17, wherein:

a subframe duration, corresponding to the vehicle-to-vehicle (V2V) physical

channel, is equal to 1.0 ms, and

the subframe, corresponding to the V2V physical channel, includes four slots with 0.25 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains two slots when subcarrier spacing for the V2V physical channel is 30 kilohertz (kHz), or

the subframe, corresponding to the V2V physical channel, includes eight slots with 0.125 ms duration and a physical resource block (PRB), corresponding to the V2V physical channel, contains four slots when subcarrier spacing for the V2V physical channel is 60 kHz.

20. A computer readable medium containing program instructions for causing one or more processors to:

communicate with other communication devices via a physical channel, the physical channel including:

a single-carrier frequency-division multiple access (SC-FDMA) symbol duration (SC-FDMA) or an orthogonal frequency division multiplexing (OFDM) waveform,

a subcarrier spacing of at least 30 kilohertz (kHz) in a frequency domain, and

a symbol duration of 0.042 milliseconds (ms) or less in a time domain.

21. The computer readable medium of claim 20, wherein a physical resource block (PRB), corresponding to a signal of the physical channel, includes 12 subcarriers in a frequency domain with 30 kHz or with 60 kHz subcarrier spacing.

22. The computer readable medium of claim 20, wherein a PRB, corresponding to the physical channel, includes 6 subcarriers in frequency domain with 30 kHz subcarrier spacing or 3 subcarriers with 60 kHz subcarrier spacing.

23. The computer readable medium of claim 20, wherein the physical channel corresponds to at least one of:

a vehicle-to-vehicle (V2V) communication,

a vehicular-to-infrastructure (V2I) communication, or

a vehicular-to-pedestrian (V2P) communication.

24. The computer readable medium of claim 20, wherein the physical channel corresponds to at least one of:

an long-term evolution (LTE) sidelink (SL) physical channel,

an LTE downlink (DL) physical channel, or

an LTE uplink (UL) physical channel.

25. The computer readable medium of claim 20, wherein a PRB pair, of the physical channel, corresponds to two consecutive PRBs in a time-domain.

(54) Title: RANDOM ACCESS PROCESS IN NEW RADIO

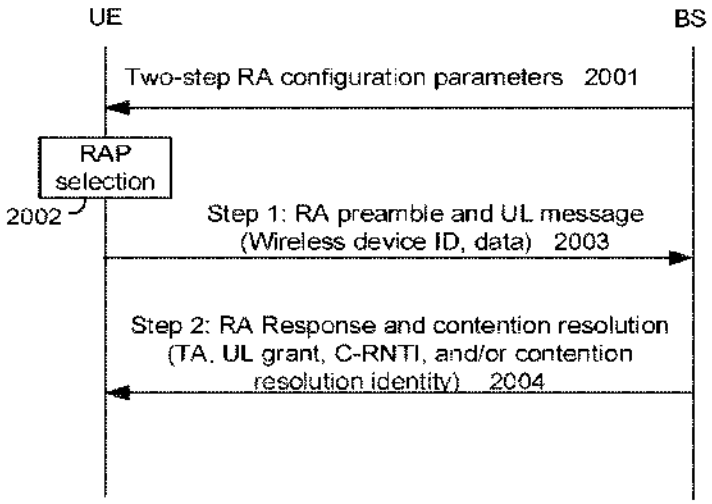

FIG. 20

(57) Abstract: Systems, apparatuses, and methods are described for wireless communications. Random access procedures may include various types of procedures, such as four-step or two-step random access procedures. One or more indicators may be included in one or more messages for a handover to indicate a type of a random access procedure. Additionally or alternatively, one or more indicators for transmission power may be used to determine a random access procedure.

RANDOM ACCESS PROCESS IN NEW RADIO

CROSS-REFERENCE TO RELATED APPLICATIONS

[01] This application claims the benefit of U.S. Provisional Application No. 62/475,028, titled "Random Access Process in New Radio" and filed on March 22, 2017, U.S. Provisional Application No. 62/475,033, titled "Handover Random Access" and filed on March 22, 2017, U.S. Provisional Application No. 62/475,039, titled "RAR in New Radio" and filed on March 22, 2017, U.S. Provisional Application No. 62/475,045, titled "2-Stage RACH in New Radio" and filed on March 22, 2017, and U.S. Provisional Application No. 62/475,537, titled "Power Control For 2-Step RACH, filed March 23, 2017, each of the above of which is hereby incorporated by reference in its entirety.

BACKGROUND

[02] In wireless communications, such as between a wireless device and a base station, a four-step random access (RA) procedure may be performed. A first step may include a random access preamble (RAP) transmission. A second step may include a random access response (RAR) transmission. A third step may include scheduled transmissions of one or more transport blocks (TBs). And, a fourth step may include contention resolution. While different RA procedures may be performed, difficulties may arise in determining and/or indicating a particular RA procedure among a plurality of RA procedures.

[03] In wireless communications, such as between a wireless device and a base station, an RA procedure may be performed to initiate the communications. A wireless device may handover from a source base station to a target base station, e.g., if the wireless device moves from a location in a first cell served by the source base station to a location in a second cell served by the target base station. The source base station and the target base station may perform different RA procedures to initiate communications with wireless devices. Difficulties may arise in determining a type of RA procedure to perform when a handover occurs.

[04] In wireless communications, such as between a wireless device and a base station, a random access procedure may be performed to initiate the communications. As a wireless device travels further from a base station, and as transmissions may comprise

more overlapping signals, the wireless device may require increasingly more power for communication transmissions to be successful. A wireless device may additionally have a maximum amount of power at which the wireless device may be allowed to transmit. Difficulties may arise for transmissions that may require more than a maximum amount of power to be successful.

SUMMARY

[05] The following summary presents a simplified summary of certain features. The summary is not an extensive overview and is not intended to identify key or critical elements.

[06] Systems, apparatuses, and methods are described for performing and indicating various RA procedures. RA procedures may comprise different steps. For example, a two-step RA procedure or a four-step RA procedure may be performed. A type of RA procedure may be indicated by one or more indicators. Such indicators may be used, for example, to indicate random access successes, random access failures, random access response size information, various steps for random access procedures, and/or other information about one or more RA procedures. One or more timers may be used to determine, e.g., whether an RA procedure fails (such as a failure of a 2-step RA procedure) and/or whether a different RA procedure should be performed (such as a fallback to a 4-step RA procedure).

[07] Systems, apparatuses, and methods are described for determining a type of RA procedure to perform when a handover occurs. RA procedures may comprise different steps. For example, a two-step RA procedure or a four-step RA procedure may be performed. The type of RA procedure may be identified by one or more indicators. The one or more indicators may be included in messages sent to or from devices involved in a handover, such as a wireless device, a source base station, a target base station, and/or one or more core network devices.

[08] Systems, apparatuses, and methods are described for performing and identifying various RA procedures. RA procedures may comprise different steps. For example, a four-step RA procedure or a two-step RA procedure, comprising overlapping signals, may be performed. The type of RA procedure may be determined based on, e.g., power demands for transmissions and a power threshold. The type of RA procedure may be indicated by one or more indicators in one or more messages. The one or more indicators may correspond with transmission power levels associated with random access procedure parameters.

[09] These and other features and advantages are described in greater detail below.

BRIEF DESCRIPTION OF THE DRAWINGS

[10] Some features are shown by way of example, and not by limitation, in the accompanying drawings. In the drawings, like numerals reference similar elements.

[11] FIG. 1 shows example sets of orthogonal frequency division multiplexing (OFDM) subcarriers.

[12] FIG. 2 shows example transmission time and reception time for two carriers in a carrier group.

[13] FIG. 3 shows example OFDM radio resources.

[14] FIG. 4 shows hardware elements of a base station and a wireless device.

[15] FIG. 5A, FIG. 5B, FIG. 5C and FIG. 5D show examples for uplink and downlink signal transmission.

[16] FIG. 6 shows an example protocol structure with multi-connectivity.

[17] FIG. 7 shows an example protocol structure with carrier aggregation (CA) and dual connectivity (DC).

[18] FIG. 8 shows example timing advance group (TAG) configurations.

[19] FIG. 9 shows example message flow in a random access process in a secondary TAG.

[20] FIG. 10A and FIG. 10B show examples for interfaces between a 5G core network and base stations.

[21] FIG. 11A, FIG. 11B, FIG. 11C, FIG. 11D, FIG. 11E, and FIG. 11F show examples for architectures of tight interworking between 5G RAN and long term evolution (LTE) radio access network (RAN).

[22] FIG. 12A, FIG. 12B, and FIG. 12C show examples for radio protocol structures of tight interworking bearers.

[23] FIG. 13A and FIG.13B show examples for gNodeB (gNB) deployment scenarios.

[24] FIG. 14 functional split option examples of a centralized gNB deployment scenario.

[25] FIG. 15 shows examples of contention-based and contention free random access procedures.

[26] FIG. 16 shows an example of a random access preamble selection procedure.

[27] FIG. 17 shows an example media access control (MAC) packet data unit (PDU) format of an example of MAC PDU comprising a MAC header and MAC random access responses (RARs) for a four-step RA procedure.

[28] FIG. 18 shows an example of shows an example of an uplink resource for a transmission in a first step of a two-step RA procedure.

[29] FIG. 19 shows an example MAC RAR format of an example of MAC RAR comprising a timing advance command, Uplink (UL) Grant, and Temporary Cell-Radio Network Temporary Identifier for a four-step RA procedure.

[30] FIG. 20 shows an example of a two-step RA procedure.

[31] FIG. 21 shows an example of contention resolution for a two-step RA procedure.

[32] FIG. 22 shows an example of a two-step RA procedure of an example failure of UL transmission for n times.

[33] FIG. 23 shows example RARs with a fixed size 8 bytes for example RAR formats for two-step RA procedures and for a four-step RA procedure.

[34] FIG. 24 shows an example RAR with a fixed size 12 bytes for example RAR formats for two-step and four-step RA procedures.

[35] FIG. 25 shows an example for hybrid automatic repeat request (HARQ) retransmission, such as when a cell detects a random access preamble identifier but fails to decode data.

[36] FIG. 26 shows an example of a two-step RA procedure failure as the number of HARQ retransmission reaches a threshold.

[37] FIG. 27 shows an example of a two-step RA procedure when a base station decodes a RAP and UL data and responds with an RAR to a wireless device.

[38] FIG. 28 shows an example of a handover of a wireless device from a source base station to a target base station.

[39] FIG. 29 shows an example of a handover of a wireless device from a source base station to a target base station that is facilitated by a core network entity.

[40] FIG. 30 shows an example of handover procedures for a wireless device.

[41] FIG. 31 shows an example of handover procedures for a source base station.

[42] FIG. 32 shows an example of handover procedures for a target base station.

[43] FIG. 33 shows an example of handover procedures for a core network device.

[44] FIG. 34 shows an example of handover procedures with different types of RA procedures for a wireless device.

[45] FIG. 35 shows an example network with a base station, a first wireless device, and a second wireless device.

[46] FIG. 36 shows an example of a process for determining whether to initiate a two-step or four-step random access procedure.

[47] FIG. 37 shows an example of a process for determining whether to drop data transmissions

[48] FIG. 38 shows an example of a process for determining whether to adjust transmission power for preamble and/or data transmissions.

[49] FIG. 39 shows an example of a process for recalculating transmission power for preamble and/or data transmissions, adjusting transmission power for data transmissions, and/or determining whether to perform a four-step random access procedure based on the transmission power for the data transmissions.

DETAILED DESCRIPTION

[50] The accompanying drawings, which form a part hereof, show examples of the disclosure. It is to be understood that the examples shown in the drawings and/or discussed herein are non-exclusive and that there are other examples of how the disclosure may be practiced.

[51] Examples may enable operation of carrier aggregation and may be employed in the technical field of multicarrier communication systems. Examples may relate to signal timing in a multicarrier communication systems.

[52] The following Acronyms are used throughout the present disclosure:

3GPP	3rd Generation Partnership Project
5G	5th generation wireless systems
5GC	5G Core Network
ACK	Acknowledgement
AMF	Access and Mobility Management Function
ASIC	application-specific integrated circuit
BPSK	binary phase shift keying
CA	carrier aggregation
CC	component carrier
CDMA	code division multiple access
CP	cyclic prefix
CPLD	complex programmable logic devices
CSI	channel state information
CSS	common search space
CU	central unit
DC	dual connectivity
DCI	downlink control information
DFTS-OFDM	discrete fourier transform spreading OFDM
DL	downlink
DU	distributed unit
eLTE	enhanced LTE
eMBB	enhanced mobile broadband
eNB	evolved Node B
EPC	evolved packet core
E-UTRAN	evolved-universal terrestrial radio access network
FDD	frequency division multiplexing
FPGA	field programmable gate arrays
Fs-C	Fs-control plane
Fs-U	Fs-user plane
gNB	next generation node B

HARQ	hybrid automatic repeat request
HDL	hardware description languages
ID	identifier
IE	information element
LTE	long term evolution
MAC	media access control
MCG	master cell group
MeNB	master evolved node B
MIB	master information block
MME	mobility management entity
mMTC	massive machine type communications
NACK	Negative Acknowledgement
NAS	non-access stratum
NG CP	next generation control plane core
NGC	next generation core
NG-C	NG-control plane
NG-U	NG-user plane
NR MAC	new radio MAC
NR PDCP	new radio PDCP
NR PHY	new radio physical
NR RLC	new radio RLC
NR RRC	new radio RRC
NR	new radio
NR	new radio
NSSAI	network slice selection assistance information
OFDM	orthogonal frequency division multiplexing
PCC	primary component carrier
PCell	primary cell
PDCCH	physical downlink control channel
PDCP	packet data convergence protocol
PDU	packet data unit
PHICH	physical HARQ indicator channel
PHY	physical
PLMN	public land mobile network
PSCell	primary secondary cell

pTAG	primary timing advance group
PUCCH	physical uplink control channel
PUSCH	physical uplink shared channel
QAM	quadrature amplitude modulation
QPSK	quadrature phase shift keying
RA	random access
RACH	random access channel
RAN	radio access network
RAP	random access preamble
RAPID / RAP ID	random access preamble identifier
RAR	random access response
RB	resource blocks
RBG	resource block groups
RLC	radio link control
RRC	radio resource control
RRM	radio resource management
RV	redundancy version
SCC	secondary component carrier
SCell	secondary cell
SCG	secondary cell group
SC-OFDM	single carrier-OFDM
SDU	service data unit
SeNB	secondary evolved node B
SFN	system frame number
S-GW	serving gateway
SIB	system information block
SC-OFDM	single carrier orthogonal frequency division multiplexing
SRB	signaling radio bearer
sTAG(s)	secondary timing advance group(s)
TA	timing advance
TAG	timing advance group
TAI	tracking area identifier
TAT	time alignment timer
TDD	time division duplexing
TDMA	time division multiple access

TTI	transmission time interval
TB	transport block
UE	user equipment
UL	uplink
UPGW	user plane gateway
URLLC	ultra-reliable low-latency communications
VHDL	VHSIC hardware description language
Xn-C	Xn-control plane
Xn-U	Xn-user plane
Xx-C	Xx-control plane
Xx-U	Xx-user plane

[53] Examples may be implemented using various physical layer modulation and transmission mechanisms. Example transmission mechanisms may include, but are not limited to: CDMA, OFDM, TDMA, Wavelet technologies, and/or the like. Hybrid transmission mechanisms such as TDMA/CDMA, and OFDM/CDMA may also be employed. Various modulation schemes may be applied for signal transmission in the physical layer. Examples of modulation schemes include, but are not limited to: phase, amplitude, code, a combination of these, and/or the like. An example radio transmission method may implement QAM using BPSK, QPSK, 16-QAM, 64-QAM, 256-QAM, and/or the like. Physical radio transmission may be enhanced by dynamically or semi-dynamically changing the modulation and coding scheme depending on transmission requirements and radio conditions.

[54] FIG. 1 shows example sets of OFDM subcarriers. As shown in this example, arrow(s) in the diagram may depict a subcarrier in a multicarrier OFDM system. The OFDM system may use technology such as OFDM technology, DFTS-OFDM, SC-OFDM technology, or the like. For example, arrow 101 shows a subcarrier transmitting information symbols. FIG. 1 is shown as an example, and a typical multicarrier OFDM system may include more subcarriers in a carrier. For example, the number of subcarriers in a carrier may be in the range of 10 to 10,000 subcarriers. FIG. 1 shows two guard bands 106 and 107 in a transmission band. As shown in FIG. 1, guard band 106 is between subcarriers 103 and subcarriers 104. The example set of subcarriers A 102 includes subcarriers 103 and subcarriers 104. FIG. 1 also shows an example set of subcarriers B 105. As shown, there is no guard band between any two subcarriers in the example set of subcarriers B

105. Carriers in a multicarrier OFDM communication system may be contiguous carriers, non-contiguous carriers, or a combination of both contiguous and non-contiguous carriers.

[55] FIG. 2 shows an example with transmission time and reception time for two carriers. A multicarrier OFDM communication system may include one or more carriers, for example, ranging from 1 to 10 carriers. Carrier A 204 and carrier B 205 may have the same or different timing structures. Although FIG. 2 shows two synchronized carriers, carrier A 204 and carrier B 205 may or may not be synchronized with each other. Different radio frame structures may be supported for FDD and TDD duplex mechanisms. FIG. 2 shows an example FDD frame timing. Downlink and uplink transmissions may be organized into radio frames 201. In this example, radio frame duration is 10 milliseconds (msec). Other frame durations, for example, in the range of 1 to 100 msec may also be supported. In this example, each 10 msec radio frame 201 may be divided into ten equally sized subframes 202. Other subframe durations such as including 0.5 msec, 1 msec, 2 msec, and 5 msec may also be supported. Subframe(s) may consist of two or more slots (e.g., slots 206 and 207). For the example of FDD, 10 subframes may be available for downlink transmission and 10 subframes may be available for uplink transmissions in each 10 msec interval. Uplink and downlink transmissions may be separated in the frequency domain. A slot may be 7 or 14 OFDM symbols for the same subcarrier spacing of up to 60kHz with normal CP. A slot may be 14 OFDM symbols for the same subcarrier spacing higher than 60kHz with normal CP. A slot may contain all downlink, all uplink, or a downlink part and an uplink part, and/or alike. Slot aggregation may be supported, e.g., data transmission may be scheduled to span one or multiple slots. In an example, a mini-slot may start at an OFDM symbol in a subframe. A mini-slot may have a duration of one or more OFDM symbols. Slot(s) may include a plurality of OFDM symbols 203. The number of OFDM symbols 203 in a slot 206 may depend on the cyclic prefix length and subcarrier spacing.

[56] FIG. 3 shows an example of OFDM radio resources. The resource grid structure in time 304 and frequency 305 is shown in FIG. 3. The quantity of downlink subcarriers or RBs may depend, at least in part, on the downlink transmission bandwidth 306 configured in the cell. The smallest radio resource unit may be called a resource element (e.g., 301). Resource elements may be grouped into resource blocks (e.g., 302). Resource blocks may be grouped into larger radio resources called Resource Block Groups (RBG) (e.g., 303). The transmitted signal in slot 206 may be described by one or several resource

grids of a plurality of subcarriers and a plurality of OFDM symbols. Resource blocks may be used to describe the mapping of certain physical channels to resource elements. Other pre-defined groupings of physical resource elements may be implemented in the system depending on the radio technology. For example, 24 subcarriers may be grouped as a radio block for a duration of 5 msec. A resource block may correspond to one slot in the time domain and 180 kHz in the frequency domain (for 15 kHz subcarrier bandwidth and 12 subcarriers).

[57] Multiple numerologies may be supported. A numerology may be derived by scaling a basic subcarrier spacing by an integer N. Scalable numerology may allow at least from 15kHz to 480kHz subcarrier spacing. The numerology with 15 kHz and scaled numerology with different subcarrier spacing with the same CP overhead may align at a symbol boundary every 1 msec in a NR carrier.

[58] FIG. 4 shows hardware elements of a base station 401 and a wireless device 406. A communication network 400 may include at least one base station 401 and at least one wireless device 406. The base station 401 may include at least one communication interface 402, one or more processors 403, and at least one set of program code instructions 405 stored in non-transitory memory 404 and executable by the one or more processors 403. The wireless device 406 may include at least one communication interface 407, one or more processors 408, and at least one set of program code instructions 410 stored in non-transitory memory 409 and executable by the one or more processors 408. A communication interface 402 in the base station 401 may be configured to engage in communication with a communication interface 407 in the wireless device 406, such as via a communication path that includes at least one wireless link 411. The wireless link 411 may be a bi-directional link. The communication interface 407 in the wireless device 406 may also be configured to engage in communication with the communication interface 402 in the base station 401. The base station 401 and the wireless device 406 may be configured to send and receive data over the wireless link 411 using multiple frequency carriers. Base stations, wireless devices, and other communication devices may include structure and operations of transceiver(s). A transceiver is a device that includes both a transmitter and receiver. Transceivers may be employed in devices such as wireless devices, base stations, relay nodes, and/or the like. Examples for radio technology implemented in the communication interfaces 402, 407 and the wireless link 411 are shown in FIG. 1, FIG. 2, FIG. 3, FIG. 5, and associated text. The communication network 400 may comprise any number and/or type of devices,

such as, for example, wireless devices, mobile devices, handsets, tablets, laptops, internet of things (IoT) devices, hotspots, cellular repeaters, computing devices, and/or, more generally, user equipment (e.g., UE). Although one or more of the above types of devices may be referenced herein (e.g., UE, wireless device, etc.), it should be understood that any device herein may comprise any one or more of the above types of devices or similar devices. The communication network 400, and any other network referenced herein, may comprise an LTE network, a 5G network, or any other network for wireless communications. Apparatuses, systems, and/or methods described herein may generally be described as implemented on one or more devices (e.g., wireless device, base station, eNB, gNB, computing device, etc.), in one or more networks, but it will be understood that one or more features and steps may be implemented on any device and/or in any network. As an example, any reference to a base station may comprise an eNB, a gNB, a computing device, or any other device, and any reference to a wireless device may comprise a UE, a handset, a mobile device, a computing device or any other device.

[59] The communications network 400 may comprise Radio Access Network (RAN) architecture. The RAN architecture may comprise one or more RAN nodes that may be a next generation Node B (gNB) (e.g., 401) providing New Radio (NR) user plane and control plane protocol terminations towards a first wireless device (*e.g.* 406). A RAN node may be a next generation evolved Node B (ng-eNB), providing Evolved UMTS Terrestrial Radio Access (E-UTRA) user plane and control plane protocol terminations towards a second wireless device. The first wireless device may communicate with a gNB over a Uu interface. The second wireless device may communicate with a ng-eNB over a Uu interface. Base station 401 may comprise at least one of a gNB, ng-eNB, and or the like.

[60] A gNB or an ng-eNB may host functions such as: radio resource management and scheduling, IP header compression, encryption and integrity protection of data, selection of Access and Mobility Management Function (AMF) at User Equipment (UE) attachment, routing of user plane and control plane data, connection setup and release, scheduling and transmission of paging messages (originated from the AMF), scheduling and transmission of system broadcast information (originated from the AMF or Operation and Maintenance (O&M)), measurement and measurement reporting configuration, transport level packet marking in the uplink, session management, support of network slicing, Quality of Service (QoS) flow management and mapping to data radio bearers,

support of UEs in RRC_INACTIVE state, distribution function for Non-Access Stratum (NAS) messages, RAN sharing, and dual connectivity or tight interworking between NR and E-UTRA.

[61] One or more gNBs and/or one or more ng-eNBs may be interconnected with each other by means of Xn interface. A gNB or an ng-eNB may be connected by means of NG interfaces to 5G Core Network (5GC). 5GC may comprise one or more AMF/User Plan Function (UPF) functions. A gNB or an ng-eNB may be connected to a UPF by means of an NG-User plane (NG-U) interface. The NG-U interface may provide delivery (*e.g.* non-guaranteed delivery) of user plane Protocol Data Units (PDUs) between a RAN node and the UPF. A gNB or an ng-eNB may be connected to an AMF by means of an NG-Control plane (NG-C) interface. The NG-C interface may provide functions such as NG interface management, UE context management, UE mobility management, transport of NAS messages, paging, PDU session management, configuration transfer or warning message transmission.

[62] A UPF may host functions such as anchor point for intra-/inter-Radio Access Technology (RAT) mobility (when applicable), external PDU session point of interconnect to data network, packet routing and forwarding, packet inspection and user plane part of policy rule enforcement, traffic usage reporting, uplink classifier to support routing traffic flows to a data network, branching point to support multi-homed PDU session, QoS handling for user plane, *e.g.* packet filtering, gating, Uplink (UL)/Downlink (DL) rate enforcement, uplink traffic verification (*e.g.* Service Data Flow (SDF) to QoS flow mapping), downlink packet buffering and/or downlink data notification triggering.

[63] An AMF may host functions such as NAS signaling termination, NAS signaling security, Access Stratum (AS) security control, inter Core Network (CN) node signaling for mobility between 3rd Generation Partnership Project (3GPP) access networks, idle mode UE reachability (*e.g.*, control and execution of paging retransmission), registration area management, support of intra-system and inter-system mobility, access authentication, access authorization including check of roaming rights, mobility management control (subscription and policies), support of network slicing and/or Session Management Function (SMF) selection

[64] An interface may be a hardware interface, a firmware interface, a software interface, and/or a combination thereof. The hardware interface may include connectors, wires,

electronic devices such as drivers, amplifiers, and/or the like. A software interface may include code stored in a memory device to implement protocol(s), protocol layers, communication drivers, device drivers, combinations thereof, and/or the like. A firmware interface may include a combination of embedded hardware and code stored in and/or in communication with a memory device to implement connections, electronic device operations, protocol(s), protocol layers, communication drivers, device drivers, hardware operations, combinations thereof, and/or the like.

[65] The term configured may relate to the capacity of a device whether the device is in an operational or a non-operational state. Configured may also refer to specific settings in a device that effect the operational characteristics of the device whether the device is in an operational or a non-operational state. In other words, the hardware, software, firmware, registers, memory values, and/or the like may be "configured" within a device, whether the device is in an operational or a nonoperational state, to provide the device with specific characteristics. Terms such as "a control message to cause in a device" may mean that a control message has parameters that may be used to configure specific characteristics in the device, whether the device is in an operational or a non-operational state.

[66] A 5G network may include a multitude of base stations, providing a user plane NR PDCP/NR RLC/NR MAC/NR PHY and control plane (NR RRC) protocol terminations towards the wireless device. The base station(s) may be interconnected with other base station(s) (e.g., employing an Xn interface). The base stations may also be connected employing, for example, an NG interface to an NGC. FIG. 10A and FIG. 10B show examples for interfaces between a 5G core network (e.g., NGC) and base stations (e.g., gNB and eLTE eNB). For example, the base stations may be interconnected to the NGC control plane (e.g., NG CP) employing the NG-C interface and to the NGC user plane (e.g., UPGW) employing the NG-U interface. The NG interface may support a many-to-many relation between 5G core networks and base stations.

[67] A base station may include many sectors, for example: 1, 2, 3, 4, or 6 sectors. A base station may include many cells, for example, ranging from 1 to 50 cells or more. A cell may be categorized, for example, as a primary cell or secondary cell. At RRC connection establishment/re-establishment/handover, one serving cell may provide the NAS (non-access stratum) mobility information (e.g., TAI), and at RRC connection re-establishment/handover, one serving cell may provide the security input. This cell may

be referred to as the Primary Cell (PCell). In the downlink, the carrier corresponding to the PCell may be the Downlink Primary Component Carrier (DL PCC), while in the uplink, it may be the Uplink Primary Component Carrier (UL PCC). Depending on wireless device capabilities, Secondary Cells (SCells) may be configured to form together with the PCell a set of serving cells. In the downlink, the carrier corresponding to an SCell may be a Downlink Secondary Component Carrier (DL SCC), while in the uplink, it may be an Uplink Secondary Component Carrier (UL SCC). An SCell may or may not have an uplink carrier.

[68] A cell, comprising a downlink carrier and optionally an uplink carrier, may be assigned a physical cell ID and a cell index. A carrier (downlink or uplink) may belong to only one cell. The cell ID or cell index may also identify the downlink carrier or uplink carrier of the cell (depending on the context it is used). The cell ID may be equally referred to a carrier ID, and cell index may be referred to carrier index. In implementation, the physical cell ID or cell index may be assigned to a cell. A cell ID may be determined using a synchronization signal transmitted on a downlink carrier. A cell index may be determined using RRC messages. For example, reference to a first physical cell ID for a first downlink carrier may indicate that the first physical cell ID is for a cell comprising the first downlink carrier. The same concept may apply to, for example, carrier activation. Reference to a first carrier that is activated may indicate that the cell comprising the first carrier is activated.

[69] Examples may be configured to operate as needed. The disclosed mechanisms may be performed when certain criteria are met, for example, in a wireless device, a base station, a radio environment, a network, a combination of the above, and/or the like. Example criteria may be based, at least in part, on for example, traffic load, initial system set up, packet sizes, traffic characteristics, a combination of the above, and/or the like. When the one or more criteria are met, various examples may be applied. Therefore, it may be possible to implement examples that selectively implement disclosed protocols.

[70] A base station may communicate with a mix of wireless devices. Wireless devices may support multiple technologies, and/or multiple releases of the same technology. Wireless devices may have some specific capability(ies) depending on its wireless device category and/or capability(ies). A base station may comprise multiple sectors. Reference to a base station communicating with a plurality of wireless devices may indicate that a subset of the total wireless devices in a coverage area. A plurality of wireless devices of a given

LTE or 5G release, with a given capability and in a given sector of the base station, may be used. The plurality of wireless devices may refer to a selected plurality of wireless devices, and/or a subset of total wireless devices in a coverage area which perform according to disclosed methods, and/or the like. There may be a plurality of wireless devices in a coverage area that may not comply with the disclosed methods, for example, because those wireless devices perform based on older releases of LTE or 5G technology.

[71] A base station may transmit (e.g., to a wireless device) one or more messages (*e.g.* RRC messages) that may comprise a plurality of configuration parameters for one or more cells. One or more cells may comprise at least one primary cell and at least one secondary cell. In an example, an RRC message may be broadcasted or unicasted to the wireless device. In an example, configuration parameters may comprise common parameters and dedicated parameters.

[72] Services and/or functions of an RRC sublayer may comprise at least one of: broadcast of system information related to AS and NAS; paging initiated by 5GC and/or NG-RAN; establishment, maintenance, and/or release of an RRC connection between a wireless device and NG-RAN, which may comprise at least one of addition, modification and release of carrier aggregation; or addition, modification, and/or release of dual connectivity in NR or between E-UTRA and NR. Services and/or functions of an RRC sublayer may further comprise at least one of security functions comprising key management; establishment, configuration, maintenance, and/or release of Signaling Radio Bearers (SRBs) and/or Data Radio Bearers (DRBs); mobility functions which may comprise at least one of a handover (*e.g.* intra NR mobility or inter-RAT mobility) and a context transfer; or a wireless device cell selection and reselection and control of cell selection and reselection. Services and/or functions of an RRC sublayer may further comprise at least one of QoS management functions; a wireless device measurement configuration/reporting; detection of and/or recovery from radio link failure; or NAS message transfer to/from a core network entity (*e.g.* AMF, Mobility Management Entity (MME)) from/to the wireless device.

[73] An RRC sublayer may support an RRC_Idle state, an RRC_Inactive state and/or an RRC_Connected state for a wireless device. In an RRC_Idle state, a wireless device may perform at least one of: Public Land Mobile Network (PLMN) selection; receiving broadcasted system information; cell selection/re-selection; monitoring/receiving a paging for mobile terminated data initiated by 5GC; paging for mobile terminated data

area managed by 5GC; or DRX for CN paging configured via NAS. In an RRC_Inactive state, a wireless device may perform at least one of: receiving broadcasted system information; cell selection/re-selection; monitoring/receiving a RAN/CN paging initiated by NG-RAN/5GC; RAN-based notification area (RNA) managed by NG-RAN; or DRX for RAN/CN paging configured by NG-RAN/NAS. In an RRC_Idle state of a wireless device, a base station (*e.g.* NG-RAN) may keep a 5GC-NG-RAN connection (both C/U-planes) for the wireless device; and/or store a UE AS context for the wireless device. In an RRC_Connected state of a wireless device, a base station (*e.g.* NG-RAN) may perform at least one of: establishment of 5GC-NG-RAN connection (both C/U-planes) for the wireless device; storing a UE AS context for the wireless device; transmit/receive of unicast data to/from the wireless device; or network-controlled mobility based on measurement results received from the wireless device. In an RRC_Connected state of a wireless device, an NG-RAN may know a cell that the wireless device belongs to.

[74] System information (SI) may be divided into minimum SI and other SI. The minimum SI may be periodically broadcast. The minimum SI may comprise basic information required for initial access and information for acquiring any other SI broadcast periodically or provisioned on-demand, i.e. scheduling information. The other SI may either be broadcast, or be provisioned in a dedicated manner, either triggered by a network or upon request from a wireless device. A minimum SI may be transmitted via two different downlink channels using different messages (*e.g. MasterInformationBlock* and *SystemInformationBlockType1*). The other SI may be transmitted via *SystemInformationBlockType2*. For a wireless device in an RRC_Connected state, dedicated RRC signaling may be employed for the request and delivery of the other SI. For the wireless device in the RRC_Idle state and/or the RRC_Inactive state, the request may trigger a random-access procedure.

[75] A wireless device may report its radio access capability information which may be static. A base station may request what capabilities for a wireless device to report based on band information. When allowed by a network, a temporary capability restriction request may be sent by the wireless device to signal the limited availability of some capabilities (*e.g.* due to hardware sharing, interference or overheating) to the base station. The base station may confirm or reject the request. The temporary capability restriction may be transparent to 5GC (*e.g.*, static capabilities may be stored in 5GC).

[76] When CA is configured, a wireless device may have an RRC connection with a network. At RRC connection establishment/re-establishment/handover procedure, one serving cell may provide NAS mobility information, and at RRC connection re-establishment/handover, one serving cell may provide a security input. This cell may be referred to as the PCell. Depending on the capabilities of the wireless device, SCells may be configured to form together with the PCell a set of serving cells. The configured set of serving cells for the wireless device may comprise one PCell and one or more SCells.

[77] The reconfiguration, addition and removal of SCells may be performed by RRC. At intra-NR handover, RRC may also add, remove, or reconfigure SCells for usage with the target PCell. When adding a new SCell, dedicated RRC signaling may be employed to send all required system information of the SCell. While in connected mode, wireless devices may not need to acquire broadcasted system information directly from the SCells.

[78] The purpose of an RRC connection reconfiguration procedure may be to modify an RRC connection, (*e.g.* to establish, modify and/or release RBs, to perform handover, to setup, modify, and/or release measurements, to add, modify, and/or release SCells and cell groups). As part of the RRC connection reconfiguration procedure, NAS dedicated information may be transferred from the network to the wireless device. The *RRCConnectionReconfiguration* message may be a command to modify an RRC connection. It may convey information for measurement configuration, mobility control, radio resource configuration (*e.g.* RBs, MAC main configuration and physical channel configuration) comprising any associated dedicated NAS information and security configuration. If the received RRC Connection Reconfiguration message includes the *sCellToReleaseList*, the wireless device may perform an SCell release. If the received RRC Connection Reconfiguration message includes the *sCellToAddModList*, the wireless device may perform SCell additions or modification.

[79] An RRC connection establishment (or reestablishment, resume) procedure may be to establish (or reestablish, resume) an RRC connection. an RRC connection establishment procedure may comprise SRB1 establishment. The RRC connection establishment procedure may be used to transfer the initial NAS dedicated information message from a wireless device to E-UTRAN. The *RRCConnectionReestablishment* message may be used to re-establish SRB1.

[80] A measurement report procedure may be to transfer measurement results from a wireless device to NG-RAN. The wireless device may initiate a measurement report procedure after successful security activation. A measurement report message may be employed to transmit measurement results.

[81] FIG. 5A, FIG. 5B, FIG. 5C, and FIG. 5D show examples for uplink and downlink signal transmission. FIG. 5A shows an example for an uplink physical channel. The baseband signal representing the physical uplink shared channel may be processed according to the following processes, which may be performed by structures described below. While these structures and corresponding functions are shown as examples, it is anticipated that other structures and/or functions may be implemented in various examples. The structures and corresponding functions may comprise, e.g., one or more scrambling devices 501A and 501B configured to perform scrambling of coded bits in each of the codewords to be transmitted on a physical channel; one or more modulation mappers 502A and 502B configured to perform modulation of scrambled bits to generate complex-valued symbols; a layer mapper 503 configured to perform mapping of the complex-valued modulation symbols onto one or several transmission layers; one or more transform precoders 504A and 504B to generate complex-valued symbols; a precoding device 505 configured to perform precoding of the complex-valued symbols; one or more resource element mappers 506A and 506B configured to perform mapping of precoded complex-valued symbols to resource elements; one or more signal generators 507A and 507B configured to perform the generation of a complex-valued time-domain DFTS-OFDM/SC-FDMA signal for each antenna port; and/or the like.

[82] Example modulation and up-conversion to the carrier frequency of the complex-valued DFTS-OFDM/SC-FDMA baseband signal for each antenna port and/or the complex-valued physical random access channel (PRACH) baseband signal is shown in FIG. 5B. For example, the baseband signal, represented as $s_l(t)$, may be split, by a signal splitter 510, into real and imaginary components, $\mathrm{Re}\{s_l(t)\}$ and $\mathrm{Im}\{s_l(t)\}$, respectively. The real component may be modulated by a modulator 511A, and the imaginary component may be modulated by a modulator 511B. The output signal of the modulator 511A and the output signal of the modulator 511B may be mixed by a mixer 512. The output signal of the mixer 512 may be input to a filtering device 513, and filtering may be employed by the filtering device 513 prior to transmission.

[83] An example structure for downlink transmissions is shown in FIG. 5C. The baseband signal representing a downlink physical channel may be processed by the following processes, which may be performed by structures described below. While these structures and corresponding functions are shown as examples, it is anticipated that other structures and/or functions may be implemented in various examples. The structures and corresponding functions may comprise, e.g., one or more scrambling devices 531A and 531B configured to perform scrambling of coded bits in each of the codewords to be transmitted on a physical channel; one or more modulation mappers 532A and 532B configured to perform modulation of scrambled bits to generate complex-valued modulation symbols; a layer mapper 533 configured to perform mapping of the complex-valued modulation symbols onto one or several transmission layers; a precoding device 534 configured to perform precoding of the complex-valued modulation symbols on each layer for transmission on the antenna ports; one or more resource element mappers 535A and 535B configured to perform mapping of complex-valued modulation symbols for each antenna port to resource elements; one or more OFDM signal generators 536A and 536B configured to perform the generation of complex-valued time-domain OFDM signal for each antenna port; and/or the like.

[84] Example modulation and up-conversion to the carrier frequency of the complex-valued OFDM baseband signal for each antenna port is shown in FIG. 5D. For example, the baseband signal, represented as $s_l^{(p)}(t)$, may be split, by a signal splitter 520, into real and imaginary components, $\mathrm{Re}\{s_l^{(p)}(t)\}$ and $\mathrm{Im}\{s_l^{(p)}(t)\}$, respectively. The real component may be modulated by a modulator 521A, and the imaginary component may be modulated by a modulator 521B. The output signal of the modulator 521A and the output signal of the modulator 521B may be mixed by a mixer 522. The output signal of the mixer 522 may be input to a filtering device 523, and filtering may be employed by the filtering device 523 prior to transmission.

[85] FIG. 6 and FIG. 7 show examples for protocol structures with CA and multi-connectivity. In FIG. 6, NR may support multi-connectivity operation, whereby a multiple receiver/transmitter (RX/TX) UE in RRC_CONNECTED may be configured to utilize radio resources provided by multiple schedulers located in multiple gNBs connected via a non-ideal or ideal backhaul over the Xn interface. gNBs involved in multi-connectivity for a certain UE may assume two different roles: a gNB may either act as a master gNB (e.g., 600) or as a secondary gNB (e.g., 610 or 620). In multi-connectivity, a UE may be connected to one master gNB (e.g., 600) and one or more secondary gNBs (e.g., 610

and/or 620). Any one or more of the Master gNB 600 and/or the secondary gNBs 610 and 620 may be a Next Generation (NG) NodeB. The master gNB 600 may comprise protocol layers NR MAC 601, NR RLC 602 and 603, and NR PDCP 604 and 605. The secondary gNB may comprise protocol layers NR MAC 611, NR RLC 612 and 613, and NR PDCP 614. The secondary gNB may comprise protocol layers NR MAC 621, NR RLC 622 and 623, and NR PDCP 624. The master gNB 600 may communicate via an interface 606 and/or via an interface 607, the secondary gNB 610 may communicate via an interface 615, and the secondary gNB 620 may communicate via an interface 625. The master gNB 600 may also communicate with the secondary gNB 610 and the secondary gNB 621 via interfaces 608 and 609, respectively, which may include Xn interfaces. For example, the master gNB 600 may communicate via the interface 608, at layer NR PDCP 605, with the secondary gNB 610 at layer NR RLC 612. The master gNB 600 may communicate via the interface 609, at layer NR PDCP 605, with the secondary gNB 620 at layer NR RLC 622.

[86] FIG. 7 shows an example structure for the UE side MAC entities, e.g., if a Master Cell Group (MCG) and a Secondary Cell Group (SCG) are configured. Media Broadcast Multicast Service (MBMS) reception may be included but is not shown in this figure for simplicity.

[87] In multi-connectivity, the radio protocol architecture that a particular bearer uses may depend on how the bearer is set up. As an example, three alternatives may exist, an MCG bearer, an SCG bearer, and a split bearer, such as shown in FIG. 6. NR RRC may be located in a master gNB and SRBs may be configured as a MCG bearer type and may use the radio resources of the master gNB. Multi-connectivity may have at least one bearer configured to use radio resources provided by the secondary gNB. Multi-connectivity may or may not be configured or implemented.

[88] In the case of multi-connectivity, the UE may be configured with multiple NR MAC entities: e.g., one NR MAC entity for a master gNB, and other NR MAC entities for secondary gNBs. In multi-connectivity, the configured set of serving cells for a UE may comprise two subsets: e.g., the Master Cell Group (MCG) containing the serving cells of the master gNB, and the Secondary Cell Groups (SCGs) containing the serving cells of the secondary gNBs.

[89] For an SCG, one or more of the following may be applied. At least one cell in the SCG may have a configured UL component carrier (CC) and one of the UL CCs, e.g., named PSCell (or PCell of SCG, or sometimes called PCell), may be configured with PUCCH resources. If the SCG is configured, there may be at least one SCG bearer or one split bearer. If a physical layer problem or a random access problem on a PSCell occurs or is detected, if the maximum number of NR RLC retransmissions has been reached associated with the SCG, or if an access problem on a PSCell during a SCG addition or a SCG change occurs or is detected, then an RRC connection re-establishment procedure may not be triggered, UL transmissions towards cells of the SCG may be stopped, a master gNB may be informed by the UE of a SCG failure type, and for a split bearer the DL data transfer over the master gNB may be maintained. The NR RLC Acknowledge Mode (AM) bearer may be configured for the split bearer. Like the PCell, a PSCell may not be de-activated. The PSCell may be changed with an SCG change (e.g., with a security key change and a RACH procedure). A direct bearer type may change between a split bearer and an SCG bearer, or a simultaneous configuration of an SCG and a split bearer may or may not be supported.

[90] With respect to the interaction between a master gNB and secondary gNBs for multi-connectivity, one or more of the following principles may be applied. The master gNB may maintain the RRM measurement configuration of the UE, and the master gNB may, (e.g., based on received measurement reports, and/or based on traffic conditions and/or bearer types), decide to ask a secondary gNB to provide additional resources (e.g., serving cells) for a UE. If a request from the master gNB is received, a secondary gNB may create a container that may result in the configuration of additional serving cells for the UE (or the secondary gNB decide that it has no resource available to do so). For UE capability coordination, the master gNB may provide some or all of the Active Set (AS) configuration and the UE capabilities to the secondary gNB. The master gNB and the secondary gNB may exchange information about a UE configuration, such as by employing NR RRC containers (e.g., inter-node messages) carried in Xn messages. The secondary gNB may initiate a reconfiguration of its existing serving cells (e.g., PUCCH towards the secondary gNB). The secondary gNB may decide which cell is the PSCell within the SCG. The master gNB may or may not change the content of the NR RRC configuration provided by the secondary gNB. In the case of an SCG addition and an SCG SCell addition, the master gNB may provide the latest measurement results for the SCG cell(s). Both a master gNB and a secondary gNBs may know the system frame

number (SFN) and subframe offset of each other by operations, administration, and maintenance (OAM) (e.g., for the purpose of discontinuous reception (DRX) alignment and identification of a measurement gap). In an example, when adding a new SCG SCell, dedicated NR RRC signaling may be used for sending required system information of the cell for CA, except, e.g., for the SFN acquired from an MIB of the PSCell of an SCG.

[91] FIG. 7 shows an example of dual-connectivity (DC) for two MAC entities at a UE side. A first MAC entity may comprise a lower layer of an MCG 700, an upper layer of an MCG 718, and one or more intermediate layers of an MCG 719. The lower layer of the MCG 700 may comprise, e.g., a paging channel (PCH) 701, a broadcast channel (BCH) 702, a downlink shared channel (DL-SCH) 703, an uplink shared channel (UL-SCH) 704, and a random access channel (RACH) 705. The one or more intermediate layers of the MCG 719 may comprise, e.g., one or more hybrid automatic repeat request (HARQ) processes 706, one or more random access control processes 707, multiplexing and/or de-multiplexing processes 709, logical channel prioritization on the uplink processes 710, and a control processes 708 providing control for the above processes in the one or more intermediate layers of the MCG 719. The upper layer of the MCG 718 may comprise, e.g., a paging control channel (PCCH) 711, a broadcast control channel (BCCH) 712, a common control channel (CCCH) 713, a dedicated control channel (DCCH) 714, a dedicated traffic channel (DTCH) 715, and a MAC control 716.

[92] A second MAC entity may comprise a lower layer of an SCG 720, an upper layer of an SCG 738, and one or more intermediate layers of an SCG 739. The lower layer of the SCG 720 may comprise, e.g., a BCH 722, a DL-SCH 723, an UL-SCH 724, and a RACH 725. The one or more intermediate layers of the SCG 739 may comprise, e.g., one or more HARQ processes 726, one or more random access control processes 727, multiplexing and/or de-multiplexing processes 729, logical channel prioritization on the uplink processes 730, and a control processes 728 providing control for the above processes in the one or more intermediate layers of the SCG 739. The upper layer of the SCG 738 may comprise, e.g., a BCCH 732, a DCCH 714, a DTCH 735, and a MAC control 736.

[93] Serving cells may be grouped in a TA group (TAG). Serving cells in one TAG may use the same timing reference. For a given TAG, user equipment (UE) may use at least one downlink carrier as a timing reference. For a given TAG, a UE may synchronize uplink

subframe and frame transmission timing of uplink carriers belonging to the same TAG. In an example, serving cells having an uplink to which the same TA applies may correspond to serving cells hosted by the same receiver. A UE supporting multiple TAs may support two or more TA groups. One TA group may contain the PCell and may be called a primary TAG (pTAG). In a multiple TAG configuration, at least one TA group may not contain the PCell and may be called a secondary TAG (sTAG). In an example, carriers within the same TA group may use the same TA value and/or the same timing reference. When DC is configured, cells belonging to a cell group (e.g., MCG or SCG) may be grouped into multiple TAGs including a pTAG and one or more sTAGs.

[94] FIG. 8 shows example TAG configurations. In Example 1, a pTAG comprises a PCell, and an sTAG comprises an SCell1. In Example 2, a pTAG comprises a PCell and an SCell1, and an sTAG comprises an SCell2 and an SCell3. In Example 3, a pTAG comprises a PCell and an SCell1, and an sTAG1 comprises an SCell2 and an SCell3, and an sTAG2 comprises a SCell4. Up to four TAGs may be supported in a cell group (MCG or SCG), and other example TAG configurations may also be provided. In various examples, structures and operations are described for use with a pTAG and an sTAG. Some of the examples may be applied to configurations with multiple sTAGs.

[95] In an example, an eNB may initiate an RA procedure, via a PDCCH order, for an activated SCell. The PDCCH order may be sent on a scheduling cell of this SCell. When cross carrier scheduling is configured for a cell, the scheduling cell may be different than the cell that is employed for preamble transmission, and the PDCCH order may include an SCell index. At least a non-contention based RA procedure may be supported for SCell(s) assigned to sTAG(s).

[96] FIG. 9 shows an example of random access processes, and a corresponding message flow, in a secondary TAG. A base station, such as an eNB, may transmit an activation command 900 to a wireless device, such as a UE. The activation command 900 may be transmitted to activate an SCell. The base station may also transmit a PDDCH order 901 to the wireless device, which may be transmitted after the activation command 900. The wireless device may begin to perform a RACH process for the SCell, which may be initiated after receiving the PDDCH order 901. The RACH process may include the wireless device transmitting to the base station a preamble 902 (e.g., Msg1), such as a random access preamble (RAP). The preamble 902 may be transmitted in response to the PDCCH order 901. The wireless device may transmit the preamble 902 via an SCell

belonging to an sTAG. In an example, preamble transmission for SCells may be controlled by a network using PDCCH format 1A. The base station may send a random access response (RAR) 903 (e.g., Msg2 message) to the wireless device. The RAR 903 may be in response to the preamble 902 transmission via the SCell. The RAR 903 may be addressed to a random access radio network temporary identifier (RA-RNTI) in a PCell common search space (CSS). If the wireless device receives the RAR 903, the RACH process may conclude. The RACH process may conclude after or in response to the wireless device receiving the RAR 903 from the base station. After the RACH process, the wireless device may transmit an uplink transmission 904. The uplink transmission 904 may comprise uplink packets transmitted via the same SCell used for the preamble 902 transmission.

[97] Initial timing alignment for communications between the wireless device and the base station may be achieved through a random access procedure, such as described above regarding FIG. 9. The random access procedure may involve a wireless device, such as a UE, transmitting a random access preamble and a base station, such as an eNB, responding with an initial TA command NTA (amount of timing advance) within a random access response window. The start of the random access preamble may be aligned with the start of a corresponding uplink subframe at the UE assuming NTA=0. The eNB may estimate the uplink timing from the random access preamble transmitted by the UE. The TA command may be derived by the eNB based on the estimation of the difference between the desired UL timing and the actual UL timing. The UE may determine the initial uplink transmission timing relative to the corresponding downlink of the sTAG on which the preamble is transmitted.

[98] The mapping of a serving cell to a TAG may be configured by a serving eNB with RRC signaling. The mechanism for TAG configuration and reconfiguration may be based on RRC signaling. If an eNB performs an SCell addition configuration, the related TAG configuration may be configured for the SCell. An eNB may modify the TAG configuration of an SCell by removing (e.g., releasing) the SCell and adding (e.g., configuring) a new SCell (with the same physical cell ID and frequency) with an updated TAG ID. The new SCell with the updated TAG ID may initially be inactive subsequent to being assigned the updated TAG ID. The eNB may activate the updated new SCell and start scheduling packets on the activated SCell. In some examples, it may not be possible to change the TAG associated with an SCell, but rather, the SCell may need to be removed and a new SCell may need to be added with another TAG. For example, if

there is a need to move an SCell from an sTAG to a pTAG, at least one RRC message, such as at least one RRC reconfiguration message, may be sent to the UE. The at least one RRC message may be sent to the UE to reconfigure TAG configurations, e.g., by releasing the SCell and then configuring the SCell as a part of the pTAG. If, e.g., an SCell is added or configured without a TAG index, the SCell may be explicitly assigned to the pTAG. The PCell may not change its TA group and may be a member of the pTAG.

[99] In LTE Release-10 and Release-11 CA, a PUCCH transmission is only transmitted on a PCell (e.g., a PSCell) to an eNB. In LTE-Release 12 and earlier, a UE may transmit PUCCH information on one cell (e.g., a PCell or a PSCell) to a given eNB. As the number of CA capable UEs increase, and as the number of aggregated carriers increase, the number of PUCCHs and the PUCCH payload size may increase. Accommodating the PUCCH transmissions on the PCell may lead to a high PUCCH load on the PCell. A PUCCH on an SCell may be introduced to offload the PUCCH resource from the PCell. More than one PUCCH may be configured. For example, a PUCCH on a PCell may be configured and another PUCCH on an SCell may be configured. One, two, or more cells may be configured with PUCCH resources for transmitting CSI, acknowledgment (ACK), and/or non-acknowledgment (NACK) to a base station. Cells may be grouped into multiple PUCCH groups, and one or more cell within a group may be configured with a PUCCH. In some examples, one SCell may belong to one PUCCH group. SCells with a configured PUCCH transmitted to a base station may be called a PUCCH SCell, and a cell group with a common PUCCH resource transmitted to the same base station may be called a PUCCH group.

[100] A MAC entity may have a configurable timer, e.g., timeAlignmentTimer, per TAG. The timeAlignmentTimer may be used to control how long the MAC entity considers the serving cells belonging to the associated TAG to be uplink time aligned. If a Timing Advance Command MAC control element is received, the MAC entity may apply the Timing Advance Command for the indicated TAG; and/or the MAC entity may start or restart the timeAlignmentTimer associated with a TAG that may be indicated by the Timing Advance Command MAC control element. If a Timing Advance Command is received in a Random Access Response message for a serving cell belonging to a TAG, the MAC entity may apply the Timing Advance Command for this TAG and/or start or restart the timeAlignmentTimer associated with this TAG. Additionally or alternatively, if the Random Access Preamble is not selected by the MAC entity, the MAC entity may

apply the Timing Advance Command for this TAG and/or start or restart the timeAlignmentTimer associated with this TAG. If the timeAlignmentTimer associated with this TAG is not running, the Timing Advance Command for this TAG may be applied, and the timeAlignmentTimer associated with this TAG may be started. If the contention resolution is not successful, a timeAlignmentTimer associated with this TAG may be stopped. If the contention resolution is successful, the MAC entity may ignore the received Timing Advance Command. The MAC entity may determine whether the contention resolution is successful or whether the contention resolution is not successful.

[101] FIG. 10A and FIG. 10B show examples for interfaces between a 5G core network (e.g., NGC) and base stations (e.g., gNB and eLTE eNB). For example, in FIG. 10A, a base station, such as a gNB 1020, may be interconnected to an NGC 1010 control plane employing an NG-C interface. The base station, e.g., the gNB 1020, may also be interconnected to an NGC 1010 user plane (e.g., UPGW) employing an NG-U interface. As another example, in FIG. 10B, a base station, such as an eLTE eNB 1040, may be interconnected to an NGC 1030 control plane employing an NG-C interface. The base station, e.g., the eLTE eNB 1040, may also be interconnected to an NGC 1030 user plane (e.g., UPGW) employing an NG-U interface. An NG interface may support a many-to-many relation between 5G core networks and base stations.

[102] FIG. 11A, FIG. 11B, FIG. 11C, FIG. 11D, FIG. 11E, and FIG. 11F are examples for architectures of tight interworking between a 5G RAN and an LTE RAN. The tight interworking may enable a multiple receiver/transmitter (RX/TX) UE in an RRC_CONNECTED state to be configured to utilize radio resources provided by two schedulers located in two base stations (e.g., an eLTE eNB and a gNB). The two base stations may be connected via a non-ideal or ideal backhaul over the Xx interface between an LTE eNB and a gNB, or over the Xn interface between an eLTE eNB and a gNB. Base stations involved in tight interworking for a certain UE may assume different roles. For example, a base station may act as a master base station or a base station may act as a secondary base station. In tight interworking, a UE may be connected to both a master base station and a secondary base station. Mechanisms implemented in tight interworking may be extended to cover more than two base stations.

[103] In FIG. 11A and FIG. 11B, a master base station may be an LTE eNB 1102A or an LTE eNB 1102B, which may be connected to EPC nodes 1101A or 1101B, respectively. This connection to EPC nodes may be, e.g., to an MME via the S1-C interface and/or to an S-

GW via the S1-U interface. A secondary base station may be a gNB 1103A or a gNB 1103B, either or both of which may be a non-standalone node having a control plane connection via an Xx-C interface to an LTE eNB (e.g., the LTE eNB 1102A or the LTE eNB 1102B). In the tight interworking architecture of FIG. 11A, a user plane for a gNB (e.g., the gNB 1103A) may be connected to an S-GW (e.g., the EPC 1101A) through an LTE eNB (e.g., the LTE eNB 1102A), via an Xx-U interface between the LTE eNB and the gNB, and via an S1-U interface between the LTE eNB and the S-GW. In the architecture of FIG. 11B, a user plane for a gNB (e.g., the gNB 1103B) may be connected directly to an S-GW (e.g., the EPC 1101B) via an S1-U interface between the gNB and the S-GW.

[104] In FIG. 11C and FIG. 11D, a master base station may be a gNB 1103C or a gNB 1103D, which may be connected to NGC nodes 1101C or 1101D, respectively. This connection to NGC nodes may be, e.g., to a control plane core node via the NG-C interface and/or to a user plane core node via the NG-U interface. A secondary base station may be an eLTE eNB 1102C or an eLTE eNB 1102D, either or both of which may be a non-standalone node having a control plane connection via an Xn-C interface to a gNB (e.g., the gNB 1103C or the gNB 1103D). In the tight interworking architecture of FIG. 11C, a user plane for an eLTE eNB (e.g., the eLTE eNB 1102C) may be connected to a user plane core node (e.g., the NGC 1101C) through a gNB (e.g., the gNB 1103C), via an Xn-U interface between the eLTE eNB and the gNB, and via an NG-U interface between the gNB and the user plane core node. In the architecture of FIG. 11D, a user plane for an eLTE eNB (e.g., the eLTE eNB 1102D) may be connected directly to a user plane core node (e.g., the NGC 1101D) via an NG-U interface between the eLTE eNB and the user plane core node.

[105] In FIG. 11E and FIG. 11F, a master base station may be an eLTE eNB 1102E or an eLTE eNB 1102F, which may be connected to NGC nodes 1101E or 1101F, respectively. This connection to NGC nodes may be, e.g., to a control plane core node via the NG-C interface and/or to a user plane core node via the NG-U interface. A secondary base station may be a gNB 1103E or a gNB 1103F, either or both of which may be a non-standalone node having a control plane connection via an Xn-C interface to an eLTE eNB (e.g., the eLTE eNB 1102E or the eLTE eNB 1102F). In the tight interworking architecture of FIG. 11E, a user plane for a gNB (e.g., the gNB 1103E) may be connected to a user plane core node (e.g., the NGC 1101E) through an eLTE eNB (e.g., the eLTE eNB 1102E), via an Xn-U interface between the eLTE eNB and the gNB, and via an NG-

U interface between the eLTE eNB and the user plane core node. In the architecture of FIG. 11F, a user plane for a gNB (e.g., the gNB 1103F) may be connected directly to a user plane core node (e.g., the NGC 1101F) via an NG-U interface between the gNB and the user plane core node.

[106] FIG. 12A, FIG. 12B, and FIG. 12C are examples for radio protocol structures of tight interworking bearers.

[107] In FIG. 12A, an LTE eNB 1201A may be an S1 master base station, and a gNB 1210A may be an S1 secondary base station. An example for a radio protocol architecture for a split bearer and an SCG bearer is shown. The LTE eNB 1201A may be connected to an EPC with a non-standalone gNB 1210A, via an Xx interface between the PDCP 1206A and an NR RLC 1212A. The LTE eNB 1201A may include protocol layers MAC 1202A, RLC 1203A and RLC 1204A, and PDCP 1205A and PDCP 1206A. An MCG bearer type may interface with the PDCP 1205A, and a split bearer type may interface with the PDCP 1206A. The gNB 1210A may include protocol layers NR MAC 1211A, NR RLC 1212A and NR RLC 1213A, and NR PDCP 1214A. An SCG bearer type may interface with the NR PDCP 1214A.

[108] In FIG. 12B, a gNB 1201B may be an NG master base station, and an eLTE eNB 1210B may be an NG secondary base station. An example for a radio protocol architecture for a split bearer and an SCG bearer is shown. The gNB 1201B may be connected to an NGC with a non-standalone eLTE eNB 1210B, via an Xn interface between the NR PDCP 1206B and an RLC 1212B. The gNB 1201B may include protocol layers NR MAC 1202B, NR RLC 1203B and NR RLC 1204B, and NR PDCP 1205B and NR PDCP 1206B. An MCG bearer type may interface with the NR PDCP 1205B, and a split bearer type may interface with the NR PDCP 1206B. The eLTE eNB 1210B may include protocol layers MAC 1211B, RLC 1212B and RLC 1213B, and PDCP 1214B. An SCG bearer type may interface with the PDCP 1214B.

[109] In FIG. 12C, an eLTE eNB 1201C may be an NG master base station, and a gNB 1210C may be an NG secondary base station. An example for a radio protocol architecture for a split bearer and an SCG bearer is shown. The eLTE eNB 1201C may be connected to an NGC with a non-standalone gNB 1210C, via an Xn interface between the PDCP 1206C and an NR RLC 1212C. The eLTE eNB 1201C may include protocol layers MAC 1202C, RLC 1203C and RLC 1204C, and PDCP 1205C and PDCP 1206C. An MCG

bearer type may interface with the PDCP 1205C, and a split bearer type may interface with the PDCP 1206C. The gNB 1210C may include protocol layers NR MAC 1211C, NR RLC 1212C and NR RLC 1213C, and NR PDCP 1214C. An SCG bearer type may interface with the NR PDCP 1214C.

[110] In a 5G network, the radio protocol architecture that a particular bearer uses may depend on how the bearer is setup. At least three alternatives may exist, e.g., an MCG bearer, an SCG bearer, and a split bearer, such as shown in FIG. 12A, FIG. 12B, and FIG. 12C. The NR RRC may be located in a master base station, and the SRBs may be configured as an MCG bearer type and may use the radio resources of the master base station. Tight interworking may have at least one bearer configured to use radio resources provided by the secondary base station. Tight interworking may or may not be configured or implemented.

[111] In the case of tight interworking, the UE may be configured with two MAC entities: e.g., one MAC entity for a master base station, and one MAC entity for a secondary base station. In tight interworking, the configured set of serving cells for a UE may comprise of two subsets: e.g., the Master Cell Group (MCG) containing the serving cells of the master base station, and the Secondary Cell Group (SCG) containing the serving cells of the secondary base station.

[112] For an SCG, one or more of the following may be applied. At least one cell in the SCG may have a configured UL CC and one of them, e.g., a PSCell (or the PCell of the SCG, which may also be called a PCell), is configured with PUCCH resources. If the SCG is configured, there may be at least one SCG bearer or one split bearer. If one or more of a physical layer problem or a random access problem is detected on a PSCell, if the maximum number of (NR) RLC retransmissions associated with the SCG has been reached, and/or if an access problem on a PSCell during an SCG addition or during an SCG change is detected, then: an RRC connection re-establishment procedure may not be triggered, UL transmissions towards cells of the SCG may be stopped, a master base station may be informed by the UE of a SCG failure type, and/or for a split bearer the DL data transfer over the master base station may be maintained. The RLC AM bearer may be configured for the split bearer. Like the PCell, a PSCell may not be de-activated. A PSCell may be changed with an SCG change, e.g., with security key change and a RACH procedure. A direct bearer type change, between a split bearer and an SCG bearer, may

not be supported. Simultaneous configuration of an SCG and a split bearer may not be supported.

[113] With respect to the interaction between a master base station and a secondary base station, one or more of the following principles may be applied. The master base station may maintain the RRM measurement configuration of the UE. The master base station may determine to ask a secondary base station to provide additional resources (e.g., serving cells) for a UE. This determination may be based on, e.g., received measurement reports, traffic conditions, and/or bearer types. If a request from the master base station is received, a secondary base station may create a container that may result in the configuration of additional serving cells for the UE, or the secondary base station may determine that it has no resource available to do so. The master base station may provide at least part of the AS configuration and the UE capabilities to the secondary base station, e.g., for UE capability coordination. The master base station and the secondary base station may exchange information about a UE configuration such as by using RRC containers (e.g., inter-node messages) carried in Xn or Xx messages. The secondary base station may initiate a reconfiguration of its existing serving cells (e.g., PUCCH towards the secondary base station). The secondary base station may determine which cell is the PSCell within the SCG. The master base station may not change the content of the RRC configuration provided by the secondary base station. If an SCG is added and/or an SCG SCell is added, the master base station may provide the latest measurement results for the SCG cell(s). Either or both of a master base station and a secondary base station may know the SFN and subframe offset of each other by OAM, (e.g., for the purpose of DRX alignment and identification of a measurement gap). If a new SCG SCell is added, dedicated RRC signaling may be used for sending required system information of the cell, such as for CA, except, e.g., for the SFN acquired from an MIB of the PSCell of an SCG.

[114] FIG. 13A and FIG.13B show examples for gNB deployment scenarios. A core 1301 and a core 1310, in FIG. 13A and FIG. 13B, respectively, may interface with other nodes via RAN-CN interfaces. In a non-centralized deployment scenario in FIG. 13A, the full protocol stack (e.g., NR RRC, NR PDCP, NR RLC, NR MAC, and NR PHY) may be supported at one node, such as a gNB 1302, a gNB 1303, and/or an eLTE eNB or LTE eNB 1304. These nodes (e.g., the gNB 1302, the gNB 1303, and the eLTE eNB or LTE eNB 1304) may interface with one of more of each other via a respective inter-BS interface. In the centralized deployment scenario in FIG. 13B, upper layers of a gNB

may be located in a Central Unit (CU) 1311, and lower layers of the gNB may be located in Distributed Units (DU) 1312, 1313, and 1314. The CU-DU interface (e.g., Fs interface) connecting CU 1311 and DUs 1312, 1312, and 1314 may be ideal or non-ideal. The Fs-C may provide a control plane connection over the Fs interface, and the Fs-U may provide a user plane connection over the Fs interface. In the centralized deployment, different functional split options between the CU 1311 and the DUs 1312, 1313, and 1314 may be possible by locating different protocol layers (e.g., RAN functions) in the CU 1311 and in the DU 1312, 1313, and 1314. The functional split may support flexibility to move the RAN functions between the CU 1311 and the DUs 1312, 1313, and 1314 depending on service requirements and/or network environments. The functional split option may change during operation after the Fs interface setup procedure, or the functional split option may change only in the Fs setup procedure (e.g., the functional split option may be static during operation after Fs setup procedure).

[115] FIG. 14 shows examples for different functional split options of a centralized gNB deployment scenario. Element numerals that are followed by "A" or "B" designations in FIG. 14 may represent the same elements in different traffic flows, e.g., either receiving data (e.g., data 1402A) or sending data (e.g., 1402B). In the split option example 1, an NR RRC 1401 may be in a CU, and an NR PDCP 1403, an NR RLC (e.g., comprising a High NR RLC 1404 and/or a Low NR RLC 1405), an NR MAC (e.g., comprising a High NR MAC 1406 and/or a Low NR MAC 1407), an NR PHY (e.g., comprising a High NR PHY 1408 and/or a LOW NR PHY 1409), and an RF 1410 may be in a DU. In the split option example 2, the NR RRC 1401 and the NR PDCP 1403 may be in a CU, and the NR RLC, the NR MAC, the NR PHY, and the RF 1410 may be in a DU. In the split option example 3, the NR RRC 1401, the NR PDCP 1403, and a partial function of the NR RLC (e.g., the High NR RLC 1404) may be in a CU, and the other partial function of the NR RLC (e.g., the Low NR RLC 1405), the NR MAC, the NR PHY, and the RF 1410 may be in a DU. In the split option example 4, the NR RRC 1401, the NR PDCP 1403, and the NR RLC may be in a CU, and the NR MAC, the NR PHY, and the RF 1410 may be in a DU. In the split option example 5, the NR RRC 1401, the NR PDCP 1403, the NR RLC, and a partial function of the NR MAC (e.g., the High NR MAC 1406) may be in a CU, and the other partial function of the NR MAC (e.g., the Low NR MAC 1407), the NR PHY, and the RF 1410 may be in a DU. In the split option example 6, the NR RRC 1401, the NR PDCP 1403, the NR RLC, and the NR MAC may be in CU, and the NR PHY and the RF 1410 may be in a DU. In the split option example 7, the NR RRC

1401, the NR PDCP 1403, the NR RLC, the NR MAC, and a partial function of the NR PHY (e.g., the High NR PHY 1408) may be in a CU, and the other partial function of the NR PHY (e.g., the Low NR PHY 1409) and the RF 1410 may be in a DU. In the split option example 8, the NR RRC 1401, the NR PDCP 1403, the NR RLC, the NR MAC, and the NR PHY may be in a CU, and the RF 1410 may be in a DU.

[116] The functional split may be configured per CU, per DU, per UE, per bearer, per slice, and/or with other granularities. In a per CU split, a CU may have a fixed split, and DUs may be configured to match the split option of the CU. In a per DU split, each DU may be configured with a different split, and a CU may provide different split options for different DUs. In a per UE split, a gNB (e.g., a CU and a DU) may provide different split options for different UEs. In a per bearer split, different split options may be utilized for different bearer types. In a per slice splice, different split options may be applied for different slices.

[117] A new radio access network (new RAN) may support different network slices, which may allow differentiated treatment customized to support different service requirements with end to end scope. The new RAN may provide a differentiated handling of traffic for different network slices that may be pre-configured, and the new RAN may allow a single RAN node to support multiple slices. The new RAN may support selection of a RAN part for a given network slice, e.g., by one or more slice ID(s) or NSSAI(s) provided by a UE or provided by an NGC (e.g., an NG CP). The slice ID(s) or NSSAI(s) may identify one or more of pre-configured network slices in a PLMN. For an initial attach, a UE may provide a slice ID and/or an NSSAI, and a RAN node (e.g., a gNB) may use the slice ID or the NSSAI for routing an initial NAS signaling to an NGC control plane function (e.g., an NG CP). If a UE does not provide any slice ID or NSSAI, a RAN node may send a NAS signaling to a default NGC control plane function. For subsequent accesses, the UE may provide a temporary ID for a slice identification, which may be assigned by the NGC control plane function, to enable a RAN node to route the NAS message to a relevant NGC control plane function. The new RAN may support resource isolation between slices. When the RAN resource isolation is implemented, shortage of shared resources in one slice does not cause a break in a service level agreement for another slice.

[118] The amount of data traffic carried over networks is expected to increase for many years to come. The number of users/devices is increasing and each user/device accesses an

increasing number and variety of services, e.g., video delivery, large files, and images. This requires not only high capacity in the network, but also provisioning very high data rates to meet customers' expectations on interactivity and responsiveness. More spectrum may be required for network operators to meet the increasing demand. Considering user expectations of high data rates along with seamless mobility, it is beneficial that more spectrum be made available for deploying macro cells as well as small cells for communication systems.

[119] Striving to meet the market demands, there has been increasing interest from operators in deploying some complementary access utilizing unlicensed spectrum to meet the traffic growth. This is exemplified by the large number of operator-deployed Wi-Fi networks and the 3GPP standardization of LTE/WLAN interworking solutions. This interest indicates that unlicensed spectrum, when present, may be an effective complement to licensed spectrum for network operators, e.g., to help address the traffic explosion in some scenarios, such as hotspot areas. Licensed Assisted Access (LAA) offers an alternative for operators to make use of unlicensed spectrum while managing one radio network, offering new possibilities for optimizing the network's efficiency.

[120] Listen-before-talk (clear channel assessment) may be implemented for transmission in an LAA cell. In a listen-before-talk (LBT) procedure, equipment may apply a clear channel assessment (CCA) check before using the channel. For example, the CCA may utilize at least energy detection to determine the presence or absence of other signals on a channel in order to determine if a channel is occupied or clear, respectively. For example, European and Japanese regulations mandate the usage of LBT in the unlicensed bands. Apart from regulatory requirements, carrier sensing via LBT may be one way for fair sharing of the unlicensed spectrum.

[121] Discontinuous transmission on an unlicensed carrier with limited maximum transmission duration may be enabled. Some of these functions may be supported by one or more signals to be transmitted from the beginning of a discontinuous LAA downlink transmission. Channel reservation may be enabled by the transmission of signals, by an LAA node, after gaining channel access, e.g., via a successful LBT operation, so that other nodes that receive the transmitted signal with energy above a certain threshold sense the channel to be occupied. Functions that may need to be supported by one or more signals for LAA operation with discontinuous downlink transmission may include one or more of the following: detection of the LAA downlink transmission (including cell

identification) by UEs, time synchronization of UEs, and frequency synchronization of UEs.

[122] DL LAA design may employ subframe boundary alignment according to LTE-A carrier aggregation timing relationships across serving cells aggregated by CA. This may not indicate that the eNB transmissions may start only at the subframe boundary. LAA may support transmitting PDSCH when not all OFDM symbols are available for transmission in a subframe according to LBT. Delivery of necessary control information for the PDSCH may also be supported.

[123] LBT procedures may be employed for fair and friendly coexistence of LAA with other operators and technologies operating in unlicensed spectrum. LBT procedures on a node attempting to transmit on a carrier in unlicensed spectrum may require the node to perform a clear channel assessment to determine if the channel is free for use. An LBT procedure may involve at least energy detection to determine if the channel is being used. For example, regulatory requirements in some regions, e.g., in Europe, specify an energy detection threshold such that if a node receives energy greater than this threshold, the node assumes that the channel is not free. While nodes may follow such regulatory requirements, a node may optionally use a lower threshold for energy detection than that specified by regulatory requirements. In an example, LAA may employ a mechanism to adaptively change the energy detection threshold, e.g., LAA may employ a mechanism to adaptively lower the energy detection threshold from an upper bound. Adaptation mechanism may not preclude static or semi-static setting of the threshold. A Category 4 LBT mechanism or other type of LBT mechanisms may be implemented.

[124] Various example LBT mechanisms may be implemented. For some signals, in some implementation scenarios, in some situations, and/or in some frequencies, no LBT procedure may performed by the transmitting entity. For example, Category 2 (e.g., LBT without random back-off) may be implemented. The duration of time that the channel is sensed to be idle before the transmitting entity transmits may be deterministic. For example, Category 3 (e.g., LBT with random back-off with a contention window of fixed size) may be implemented. The LBT procedure may have the following procedure as one of its components. The transmitting entity may draw a random number N within a contention window. The size of the contention window may be specified by the minimum and maximum value of N. The size of the contention window may be fixed. The random number N may be employed in the LBT procedure to determine the duration

of time that the channel is sensed to be idle before the transmitting entity transmits on the channel. In an example, Category 4 (e.g., LBT with random back-off with a contention window of variable size) may be implemented. The transmitting entity may draw a random number N within a contention window. The size of contention window may be specified by the minimum and maximum value of N. The transmitting entity may vary the size of the contention window when drawing the random number N. The random number N may be used in the LBT procedure to determine the duration of time that the channel is sensed to be idle before the transmitting entity transmits on the channel.

[125] LAA may employ uplink LBT at the UE. The UL LBT scheme may be different from the DL LBT scheme, e.g., by using different LBT mechanisms or parameters. These differences in schemes may be due to the LAA UL being based on scheduled access, which may affect a UE's channel contention opportunities. Other considerations motivating a different UL LBT scheme may include, but are not limited to, multiplexing of multiple UEs in a single subframe.

[126] A DL transmission burst may be a continuous transmission from a DL transmitting node, e.g., with no transmission immediately before or after from the same node on the same CC. An UL transmission burst from a UE perspective may be a continuous transmission from a UE, e.g., with no transmission immediately before or after from the same UE on the same CC. A UL transmission burst may be defined from a UE perspective or from an eNB perspective. If an eNB is operating DL and UL LAA over the same unlicensed carrier, DL transmission burst(s) and UL transmission burst(s) on LAA may be scheduled in a TDM manner over the same unlicensed carrier. An instant in time may be part of a DL transmission burst or part of an UL transmission burst.

[127] Random access (RA) procedures may be used to establish communications between a wireless device and a base station in a cell. A four-step RA procedure may include, e.g., a first step comprising a wireless device sending, to a base station, a request to establish communications with the base station. A second step may include, e.g., the base station sending, to the wireless device, a response indicating that the wireless device may send additional information for establishing the requested communications. A third step may include, e.g., the wireless device sending, to the base station, the additional information for establishing the requested communications. A fourth step may include, e.g., the base station sending, to the wireless device, information confirming the establishing of the requested communications. A four-step RA procedure may have an associated latency,

e.g., which may be a minimum of fourteen transmission time intervals (TTI). As an example, 3GPP TR 38.804 v14.0.0 indicates a minimum latency of fourteen TTIs comprising, e.g., 3 TTIs after a message from step 1 of a four-step RA procedure, 1 TTI for a message from step 2 of a four-step RA procedure, 5 TTIs after the message from step 2, 1 TTI for a message from step 3 of a four-step RA procedure, 3 TTIs after the message from step 3, and 1 TTI for a message from step 4 of a four-step procedure (e.g., 3 + 1 + 5 + 1 + 3 + 1 = 14). Reducing the number of steps in an RA procedure may reduce latency. By using parallel transmissions, a four-step RA procedure may be reduced to a two-step RA procedure. A two-step RA procedure may have an associated latency, e.g., which may be a minimum of four TTIs and which may be less than an associated latency for a four-step RA procedure. As an example, 3GPP TR 38.804 v14.0.0 indicates a minimum latency of four TTIs comprising, e.g., 3 TTIs after a message from step 1 of a two-step RA procedure and 1 TTI for a message from step 2 of a two-step RA procedure.

[128] FIG. 15 shows examples of (a) a contention-based four-step RA procedure, (b) a contention free three-step RA procedure, (c) descriptions of a contention-based four-step RA procedure, and (d) a contention free two-step RA procedure. A four-step RA procedure may comprise a RAP transmission in a first step, an RAR transmission in a second step, a scheduled transmission of one or more transport blocks (TBs) in a third step, and contention resolution in a fourth step.

[129] In step 1501, a base station may transmit four-step RA configuration parameters to a wireless device (e.g., a UE). The base station may generate and transmit RA configuration parameters periodically, e.g., based on a timer. The base station may broadcast RA configuration parameters in one or more messages. The wireless device may perform a RAP selection process at step 1502, e.g., after receiving the four-step RA configuration parameters. In a contention-based RA procedure, such as shown in part (a) of FIG. 15, the RA configuration parameters may comprise a root sequence that may be used by the wireless device to generate a RAP. The RAP may be randomly selected by the wireless device, among various RAP candidates generated by the root sequence, during the RAP selection process. The wireless device may perform the RAP selection using, e.g., the procedure described below regarding FIG. 16, and/or one or more RAP selections procedures described herein.

[130] During a first step of the RA procedure, at step 1503, a wireless device may transmit a RAP, e.g., using a configured RA preamble format with a single particular transmission (Tx) beam. A random access channel (RACH) resource may be defined as a time-frequency resource to transmit a RAP. Broadcast system information may indicate whether wireless device should transmit one preamble, or multiple or repeated preambles, within a subset of RACH resources.

[131] In the second step of the four-step RA procedure, at step 1504, a base station may transmit a random access response (RAR) to the wireless device. The base station may transmit the RAR in response to an RAP that the wireless device may transmit. A wireless device may monitor the physical-layer downlink control channel for RARs identified by the RA-RNTI in an RA response window. The RA response window may start at a subframe that contains the end of an RAP transmission, plus three subframes, and the RA response window may have the length *ra-ResponseWindowSize*. A wireless device may determine the RA-RNTI associated with the PRACH in which the wireless device transmits an RAP by the following operation:

$$\text{RA-RNTI} = 1 + t_id + 10 * f_id$$

[132] where t_id is the index of the first subframe of the specified PRACH ($0 \leq t_id < 10$), and f_id is the index of the specified PRACH within that subframe, in ascending order of frequency domain ($0 \leq f_id < 6$). Different types of UEs, e.g., narrow band-Internet of Things (NB-IoT), bandwidth limited (BL)-UE, and/or UE-Extended Coverage (UE-EC), may use different formulas or operations for determining RA-RNTI. A base station may configure an association between a DL signal or channel, a subset of RACH resources, and/or a subset of RAP indexes. Such an association may be for determining the DL transmission in the second step of the RA procedure, at step 1504 of FIG. 15. Based on the DL measurement and the corresponding association, a wireless device may select the subset of RACH resources and/or the subset of RAP indexes.

[133] In the third step of the four-step RA procedure (e.g., step 1505 in FIG. 15), a wireless device may adjust an UL time alignment by using the TA value corresponding to the TA command in the received RAR in the second step (e.g., step 1504 in FIG. 15). A wireless device may transmit one or more TBs to a base station using the UL resources assigned in the UL grant in the received RAR. One or more TBs that a wireless device may transmit in the third step (e.g., step 1505 in FIG. 15) may comprise RRC signaling, such

as an RRC connection request, an RRC connection Re-establishment request, or an RRC connection resume request. The one or more TBs may also comprise a wireless device identity, e.g., which may be used as part of the contention-resolution mechanism in the fourth step (e.g., step 1506 in FIG. 15).

[134] The fourth step in the four-step RA procedure (e.g., step 1506 in FIG. 15) may comprise a DL message for contention resolution. Based on the second step (e.g., step 1504 in FIG. 15), one or more wireless devices may perform simultaneous RA attempts using the same RAP in the first step (e.g., step 1503 in FIG. 15), and/or receive the same RAR with the same TC-RNTI in the second step (e.g., step 1504 in FIG. 15). The contention resolution in the fourth step may be to ensure that a wireless device does not incorrectly use another wireless device identity. The contention resolution mechanism may be based on either a C-RNTI on a PDCCH, or a UE Contention Resolution Identity on a DL-SCH, e.g., depending on whether or not a wireless device has a C-RNTI. If a wireless device has a C-RNTI, e.g., if the wireless device detects the C-RNTI on the PDCCH, the wireless device may determine the success of RA procedure. If the wireless device does not have a C-RNTI (e.g., if a C-RNTI is not pre-assigned), the wireless device may monitor a DL-SCH associated with a TC-RNTI, e.g., that a base station may transmit in an RAR of the second step. In the fourth step (e.g., step 1506 in FIG. 15), the wireless device may compare the identity in the data transmitted by the base station on the DL-SCH with the identity that the wireless device transmits in the third step (e.g., step 1505 in FIG. 15). If the wireless determines that two identities are the same or satisfy a threshold similarity, the wireless device may determine that the RA procedure is successful. If the wireless device determines that the RA is successful, the wireless device may promote the TC-RNTI to the C-RNTI. A TC-RNTI may be an identifier initially assigned to a wireless device when the wireless device first attempts to access a base station. A TC-RNTI may be used for a wireless device in an idle state. After access is allowed by the base station, a C-RNTI may be used for identifying the wireless device. A C-RNTI may be used for a wireless device in an inactive or an active state.

[135] The fourth step in the four-step RA procedure (e.g., step 1506 in FIG. 15) may allow HARQ retransmission. A wireless device may start a *mac-ContentionResolutionTimer* when the wireless device transmits one or more TBs to a base station in the third step (e.g., step 1505 in FIG. 15). The wireless may restart the *mac-ContentionResolutionTimer* at each HARQ retransmission. When a wireless device receives data on the DL resources identified by C-RNTI or TC-RNTI in the fourth step

(e.g., step 1506 in FIG. 15), the wireless device may stop the *mac-ContentionResolutionTimer*. If the wireless device does not detect the contention resolution identity that matches the identity transmitted by the wireless device in the third step (e.g., step 1505 in FIG. 15), the wireless device may determine that the RA procedure has failed and the wireless device may discard the TC-RNTI. Additionally or alternatively, if the *mac-ContentionResolutionTimer* expires, the wireless device may determine that the RA procedure has failed and the wireless device may discard the TC-RNTI. If the wireless device determines that the contention resolution has failed, the wireless device may flush the HARQ buffer used for transmission of the MAC PDU and the wireless device may restart the four-step RA procedure from the first step (e.g., step 1503 in FIG. 15). The wireless device may delay subsequent RAP transmission, e.g., by a backoff time. The backoff time may be randomly selected, e.g., according to a uniform distribution between 0 and the backoff parameter value corresponding to the BI in the MAC PDU for RAR.

[136] In a four-step RA procedure, the usage of the first two steps may be, e.g., to obtain a UL time alignment for a wireless device and/or to obtain an uplink grant. The UL time alignment may not be necessary in one or more scenarios. For example, in small cells, or for stationary wireless devices, the process for acquiring the UL time alignment may not be necessary if either a TA equal to zero may be sufficient (e.g., for small cells), or if a stored TA value from the last RA may be able to serve for the current RA (e.g., a stationary wireless device). If a wireless device is in an RRC connected state, e.g., with a valid TA value and no resource configured for UL transmission, the UL time alignment may not be necessary when the wireless device attempts to obtain an UL grant.

[137] Part (b) of FIG. 15 shows a three-step contention free RA procedure. A base station may transmit RA configuration parameters to a wireless device, e.g., a UE, in step 1510. In a contention-free RA procedure, such as shown in part (b) of FIG. 15, the configuration parameters may indicate to the wireless device what preamble to send to the base station and when to send the preamble. The base station may also transmit a control command to the wireless device at step 1511. The control command may comprise, e.g., downlink control information. In a first step of the RA procedure, the wireless device may transmit a random access preamble transmission to the base station at step 1512. The RAP transmission may be based on the RA configuration parameters and the control command. In a second step of the RA procedure, the base station may transmit to the wireless device a random access response at step 1513. In a third step of the RA

procedure, the wireless device may transmit scheduled transmissions at step 1514. The scheduled transmissions may be based on the RAR. The contention free RA procedure may end with the third step. Thereafter, the base station may transmit a downlink transmission to the wireless device at step 1515. This downlink transmission may comprise, e.g., an acknowledgement (ACK) indication, a non-acknowledgement (NACK) indication, data, or other information. Contention-free RA procedures such as described above may have reduced latency compared with contention-based RA procedures. Contention-based RA procedures may involve collisions, such as when more than one wireless device is attempting to communicate with the same base station at the same time.

[138] Part (c) of FIG. 15 shows an example of common language descriptions that may facilitate an understanding of some of the messaging involved in the contention-based four-step RA procedure described above regarding part (a) of FIG. 15. In step 1 of the RA procedure, a wireless device may send a communication to a base station similar to a request such as, "Hello, can I camp on?" (step 1520). If the base station can accommodate the wireless device request, the base station may respond to the wireless device with a message similar to an instruction such as "Send your info & data here" (step 1521). Based on the base station's response, the wireless device may send a message similar to a response such as "Here you are" (step 1522). Based on the information received by the base station, the base station may respond with a message similar to a grant such as "You are now in" (step 1523).

[139] Part (d) of FIG. 15 shows an example of a two-step contention free random access procedure of a wireless device. At step 1530, the wireless device may receive RA configuration parameters from a base station (e.g., from a handover source base station, and/or from a handover target base station via the handover source base station). The RA configuration parameters may comprise one or more parameters indicating a type of a random access process. The type of the random access process may indicate a two-step random access process. At step 1531, the wireless device may transmit an RA preamble and one or more transport blocks as a first step of the procedure, e.g., overlapping in time with each other. In response to the RA preamble and/or the one or more transport blocks, at step 1532, the wireless device may receive an RA response from a base station (e.g., a handover target base station).

[140] FIG. 16 shows an example of a RAP selection procedure for preamble groups that may be used as the RAP selection process at step 1502 of FIG. 15. A base station may broadcast the RAP grouping information, along with one or more thresholds, in system information. At step 1601, a wireless device may select a preamble group comprising preambles. Two or more RAP groups may be indicated by broadcast system information, and one or more of the RAP groups may be optional. At step 1602, the wireless device may select a RAP group among a plurality of RAP groups, based on, e.g., a size of data that the wireless may have to transmit, a measured pathloss, and/or other information. At step 1603, the wireless device may generate a RAP from the selected RAP group. If a base station configures two groups, e.g., in a four-step RA procedure, a wireless device may use the pathloss and a size of the message transmitted by the wireless device in the third step of the RA procedure, to determine from which group the wireless device selects an RAP. A base station may use a group type to which a RAP belongs as an indication of the message size in the third step and/or the radio conditions at a wireless device. The process may end at step 1603.

[141] FIG. 17 shows an example of a MAC PDU comprising a MAC header and MAC RARs. A four-step RA procedure may use the arrangement shown in FIG. 17. A two-step RA procedure may also use the arrangement shown in FIG. 17. Additionally or alternatively, a two-step RA procedure may use a variation of the arrangement shown in FIG. 17, e.g., with additional or fewer fields, and/or with longer or shorter fields. If an RAR comprises a RAPID corresponding to a RAP that a wireless device transmits, the wireless device may process the data in the RAR. The data in the RAR may comprise, e.g., one or more of a timing advance (TA) command, a UL grant, and/or a Temporary C-RNTI (TC-RNTI). The MAC header may comprise subheaders, such as an E/T/R/R/BI subheader (described further below) and up to n number of E/T/RAPID subheaders (described further below). The E/T/R/R/BI subheader may comprise an octet of bits comprising 1 bit each of E, T, R, and R, and four bits of BI. Each of n E/T/RAPID subheaders may comprise an octet comprising 1 bit each of E and T, and 6 bits of an RAPID.

[142] FIG. 18 shows an example of an uplink resource 1801 that may be used, e.g., for a transmission of a random access preamble and data in a first step of a two-step RA procedure. A transmission may comprise a random access preamble 1803, e.g., via a physical random access channel (PRACH), and data 1802. The data 1802 may comprise one or more transport blocks, an identifier of a wireless device, and/or other information. The data may be included in, e.g., an RRC connection request. The RRC connection

request may comprise one or more of, e.g., the data 1802, an identifier of a wireless device, an indication of a type of data (e.g., emergency, high priority access, standard access, signaling, etc.), and/or other information. The RAP 1803 may comprise a preamble sequence, e.g., bits arranged in octets 1804. A guard time and/or a cyclic prefix may be inserted, e.g., at either end of the preamble sequence. Additionally or alternatively, a guard band may be inserted above the preamble sequence and/or below the preamble sequence.

[143] FIG. 19 shows examples of MAC RAR formats comprising a TA command, a UL Grant, and a TC-RNTI for a four-step RA procedure. Part (a) shows an example MAC RAR format, part (b) shows an example MAC RAR for a PRACH enhanced coverage level 2 or level 3, and part (c) shows an example MAC RAR for NB-IoT UEs.

[144] In FIG. 19 part (a), a first octet comprises 1 bit of R, and 7 bits of the TA command. The second octet comprises an additional 4 bits of the TA command as well as 4 bits of the UL grant. The third and fourth octet each comprise 8 additional bits of the UL grant. And, the fifth and sixth octet each comprise 8 bits of the TC-RNTI. In FIG. 19 part (b), the MAC RAR for PRACH enhanced coverage level 2 or level 3 comprises a MAC RAR similar to the MAC RAR example in FIG. 19 part (a), except that in part (b) the UL grant comprises 8 bits in the third octet and the TC-RNTI is included in the fourth and fifth octets. In FIG. 19 part (c), a MAC RAR example for NB-IoT UEs comprises a MAC RAR similar to the MAC RAR in FIG. 19 part (a), except that the fourth octet in part (c) comprises 3 bits of the UL grant and 5 bits of R. As shown in FIG. 19 parts (a), (b), and (c), a MAC RAR may comprise one or more reserved bits (R bits). One or more of the R bits in the MAC RAR may indicate whether a RA procedure is a 2-step RA procedure or a 4-step RA procedure.

[145] FIG. 20 shows a two-step RA procedure that may comprise an uplink (UL) transmission of an RAP and data, followed by a downlink (DL) transmission of an RAR and contention resolution information. A two-step RA procedure may reduce RA latency compared with a four-step RA process, e.g., by integrating a process to obtain a timing advance (TA) value with a data transmission. In the UL transmission of a two-step RA procedure at step 2003, a wireless device may transmit, via a cell and to a base station, a RAP for UL time alignment and/or an UL message. The UL message may comprise, e.g., an UL grant, a wireless device ID, one or more TBs, a C-RNTI, and/or other information. In the DL transmission at step 2004, a base station may transmit an RAR

and contention resolution information. The DL transmission may identify an assignment of dedicated resources for the wireless to transmit data, e.g., which may include an assignment of one or more transport blocks. The DL transmission may be in response to the UL transmission. The RAR may comprise an acknowledgement of a reception of the one or more transport blocks, and/or an indication of a successful decoding of the one or more transport blocks. The contention resolution may comprise, e.g., TA information, an UL grant, a C-RNTI, and/or a contention resolution identity.

[146] In the UL transmission of a two-step RA procedure, a wireless device, may transmit, via a cell and to a base station, an RAP in parallel with one or more TBs. The wireless device may acquire one or more configuration parameters for the UL transmission before the wireless device starts a two-step RA procedure, e.g., at step 2001. In a contention-based RA procedure such as shown in FIG. 20, the one or more configuration parameters may comprise a root sequence that may be used by the wireless device to generate an RAP. The wireless device may determine an RAP at step 2002. An RAP selection by the wireless device may be based on the RA configuration parameters received at step 2001, e.g., comprising one or more RAP selections procedures described herein. The wireless device may use the root sequence to generate one or more candidate preambles, and the wireless device may randomly select one of the candidate preambles as the RAP. The one or more candidate preambles may be organized into groups that may indicate an amount of data for transmission. For example a first group may comprise RAPs indicated for small data transmissions, and a second group may comprise RAPs indicated for larger data transmissions. By transmitting an RAP from a specific group of RAPs, the wireless device may be able to indicate a size of data it may have for transmission. The wireless device may transmit the RAP via a RACH resource. The wireless device may transmit the one or more TBs via an UL resource associated with the RAP. The UL transmissions may occur, e.g., in the same subframe, in consecutive subframes, or in the same burst. A two-step RA procedure may be on a contention basis. The contention may occur for the RAP and/or data transmission.

[147] In the UL transmission, the RAP may be used to adjust UL time alignment for a cell and/or to aid in channel estimation for one or more TBs. A portion of the UL transmission for one or more TBs may comprise, e.g., a wireless device ID, a C-RNTI, a service request such as buffer state reporting (e.g., a buffer status report) (BSR), one or more user data packets, and/or other information. A wireless device in an RRC connected state may use a C-RNTI as an identifier of the wireless device (e.g., a wireless

device ID). A wireless device in an RRC inactive state may use a C-RNTI (if available), a resume ID, or a short MAC-ID as an identifier of the wireless device. A wireless device in an RRC idle state may use a C-RNTI (if available), a resume ID, a short MAC-ID, an IMSI (International Mobile Subscriber Identifier), a T-IMSI (Temporary-IMSI), and/or a random number as an identifier of the wireless device.

[148] The UL transmission may comprise one or more TBs that may be transmitted using a two-step RA procedure different ways. User data packet(s) may be multiplexed in the first step of a two-step RA procedure. A base station may configure one or more resources reserved for the UL transmission that may be indicated to a wireless device before the UL transmission. If the wireless device transmits one or more TBs in the first step of the two-step RA procedure, a base station may transmit in a DL transmission an RAR that may comprise a contention resolution message and/or an acknowledgement/non-acknowledgement message of the UL data transmission. The DL transmission may be in response to the UL transmission. A wireless device may transmit one or more TBs after the reception of an RAR. The wireless device may transmit an indicator, such as buffer state reporting, in the UL transmission. The indicator may indicate to a base station an amount of data the wireless device may attempt to transmit. The base station may assign a UL grant based on the indicator. The base station may transmit the UL grant to the wireless device via an RAR. If UL data transmission, based on the UL grant via an RAR, occurs after the reception of RAR, the UL data transmission may occur on a contention-based channel. The UL data transmission may occur after a wireless device receives the RAR, e.g., in a subframe x+5, or x+n, where x is a subframe in which the RAR is received by the wireless device and n is any whole number greater than zero.

[149] A wireless device may provide, to a base station, an indication of a required UL grant size. The wireless device may provide this indication, e.g., by determining a RAP selection (e.g., at step 2002), as opposed to transmitting a BSR, e.g., comprising one or more RAP selections procedures described herein. A base station may partition RAPs available to the base station into one or more RAP groups such that each partition may indicate a particular UL grant size. A wireless device may indicate a request, to a base station, of a small or large grant by selecting a RAP from a designated group. The base station may determine the requested grant size based on a RAP that the base station receives. A base station may configure an association between RAP groups and a UL

grant size. The base station may broadcast one or more parameters via system information to indicate the association between RAP groups and a UL grant size.

[150] A wireless device may provide, to a base station, an indication of a required UL grant size by transmitting an RAP on a partitioned radio resource. A base station may partition radio resources used for RAP transmission into one or more groups such that one or more resources in a group carrying an RAP may indicate a UL grant size that a wireless device may request. The base station may determine the requested grant size based on a RAP received by the base station via resources in a group. When a high granularity is required, a base station may configure a large number of radio resources for the RAP transmission. A base station may configure an association between radio resource groups and a UL grant size. The base station may broadcast one or more parameters via system information to indicate the association between radio resource groups and a UL grant size.

[151] In the second step of the two-step RA procedure (e.g., step 2004), a base station may transmit an RAR to a wireless device. The base station may transmit the RAR in response to receiving the RAP and data from the wireless device. The RAR may comprise TA information, a contention resolution identity, a UL grant, and/or a C-RNTI. A MAC PDU may comprise one or more of an RAR MAC subheader and a corresponding RAR. The TA may be used by the wireless device for a two-step RA procedure, e.g., when a TA timer has expired.

[152] A base station may or may not transmit the contention resolution identity to a wireless device. If a wireless device transmits a C-RNTI (e.g., as a wireless device ID) in a UL transmission, the wireless device may complete contention resolution based on a C-RNTI in an RAR. If a wireless device transmits a shared RNTI, that may be monitored by more than one wireless device as a wireless device ID in a UL transmission, the wireless device may complete contention resolution based on a contention resolution identity in an RAR. Other identifiers for a wireless device, such as a random number, resume ID, T-IMSI, and/or IMSI may be used to complete the contention resolution.

[153] The UL grant may be for a wireless device that may have subsequent UL data to transmit. BSR may be transmitted by a wireless device in the UL transmission. A base station may use the BSR for determining a UL grant.

[154] A wireless device may not have a C-RNTI, such as a wireless device in an RRC inactive state. If a two-step RA procedure is used for state transition from inactive to connected, a base station may assign a C-RNTI to a wireless device that lacks a C-RNTI.

[155] A wireless device may acquire one or more two-step RA configuration parameters (e.g., in step 2001 of FIG. 20) from one or more messages broadcast and/or unicast by a cell. A base station may broadcast or multicast, via a cell, one or more two-step RA configuration parameters comprised in one or more system information blocks. The base station may transmit configuration parameters to a wireless device via dedicated resource(s) and signaling, such as via a unicast to a wireless device in an RRC connected state.

[156] A base station may configure or restrict the usage of the two-step RA procedure to one or more case-based procedures, services, or radio conditions. If a cell is small such that there may be no need for a TA, a base station in the cell may use broadcast signaling to configure all wireless devices under its coverage to use a two-step RA procedure. A wireless device may acquire the configuration, via one or more system information blocks, and/or via L1 control signaling used to initiate a two-step RA procedure for downlink data arrival.

[157] If a base station has macro coverage, a wireless device having a stored and/or persisted TA value, e.g., a stationary or near stationary wireless device such as a sensor-type wireless device, may perform a two-step RA procedure. A base station having macro coverage may use dedicated signaling to configure a two-step RA procedure with one or more wireless devices having stored and/or persisted TA values under the coverage.

[158] A wireless device in an RRC connected state may perform a two-step RA procedure, e.g., when performing a network initiated handover, and/or when the wireless device requires or requests a UL grant within a required delay and there are no physical-layer uplink control channel resources available to transmit a scheduling request. A wireless device in an RRC inactive state may perform a two-step RA procedure, e.g., for a small data transmission while remaining in the inactive state or for resuming a connection. A wireless device may initiate a two-step RA procedure, for example, for initial access such as establishing a radio link, re-establishment of a radio link, handover, establishment of UL synchronization, and/or a scheduling request when there is no UL grant.

[159] Determining a type of RA procedure may comprise determining whether to do a 2-step or a 4-step RA procedure. An indicator may be provided in a MAC PDU subheader. Such an indicator may be included in a RAP identifier (RAPID), such as shown in FIG. 17. A RAPID may identify a specific RAP, where up to 2^n unique RAPs are possible for an n-bit wide RAPID. Multiple wireless devices may transmit their own RAPs to a base station. A base station may receive RAPs from a plurality of wireless devices. Each RAPID may indicate one of the plurality of RAPs transmitted to a base station. A wireless device may determine a RAP. This determination may be performed by the wireless device using a random process. The wireless device may transmit the RAP. If a base station detects the RAP from the wireless device, the base station may use bits in a RAPID field to identify that RAP. The base station may transmit the RAPID in a MAC subheader within a MAC header of a MAC PDU, such as shown in FIG. 17. The wireless device that transmits the RAP may receive a MAC PDU comprising the RAPID in a MAC subheader. The wireless device may determine, based on the RAPID, that the RAP was successfully received by the base station.

[160] The number of n bits in a RAPID may be 6 bits, such as in the RAPID shown in FIG. 17, or any number of bits greater or smaller than 6. The base station may determine an estimate of a number of wireless devices supported in a cell. The base station may also determine, based on the estimated number of wireless devices in a cell, a total number of RAPs that may be used for the cell. The base station may also determine, based on the number of RAPs that may be used for the cell, the number of bits to be used in the RAPID for identifying a RAP. The base station may reduce the number of bits used in the RAPID for identifying unique RAPs, which in turn, may allow one or more bits of the RAPID shown in FIG. 17, to be used for other information, such as a type of RA procedure to be used. Using fewer than n bits for identifying RAPs, may allow use of one or more unused RAPID bits as an indicator for other information such as whether a random access procedure uses a 2-step procedure or a 4-step procedure. The indication of whether a RA procedure is 2-steps or 4-steps may be in the form of a single bit, where "0" indicates one of the two possible RA procedures, such as a 2-step procedure, and "1" indicates the other, such as a 4-step procedure. Additionally or alternatively, more than one bit of a RAPID may be used, e.g., 2 or 3 bits, to indicate additional information, such as information specific to one or more steps in a RA procedure.

[161] One or more bits of the E and/or T fields, such as in a MAC subheader comprising a RAPID shown in FIG. 17, may be used as an indication of a type of RA procedure, such

as a 2-step RA procedure or a 4-step RA procedure. The E field may be an extension field. A MAC subheader with an E field set to 1 may indicate the presence of a backoff indicator (BI) in the subheader and the presence of an additional MAC subheader. A MAC subheader with an E field set to 0 may indicate the presence of a RAPID in the subheader. The T field may be an indication of a presence of additional MAC subheaders. A MAC subheader with a T field set to 1 may indicate the presence of an additional MAC subheader, and a MAC subheader with a T field set to 0 may indicate that the MAC subheader is the last MAC subheader in the MAC header. One or more of these E and/or T fields may be used to indicate a type of RA procedure, such as a 2-step RA procedure or a 4-step RA procedure.

[162] A wireless device may perform a method for determining whether to perform a 2-step RA procedure or a 4-step RA procedure. The wireless device may transmit, to a base station, a RAP comprising a RAP identifier (e.g., RAPID / RAP ID) and one or more transport blocks. Additionally or alternatively, the wireless device may transmit, to a base station, one or more preambles in parallel with one or more transport blocks. Any of the above transmissions by the wireless device may be based on a determination, by the wireless device, that the type of the RA procedure is a two-step RA procedure. The wireless device may receive, from the base station, a MAC PDU comprising one or more MAC subheaders and one or more MAC RARs, such as shown in FIG. 17. This transmission by base station may be based on the first transmission by the wireless device. Each of the RARs may be associated with one of the one or more MAC subheaders. The wireless device may determine, based on a first field in a particular MAC subheader of the one or more MAC subheaders, a type of an RA procedure. Additionally or alternatively, based on the type of RA procedure (e.g., based on the first field in the particular MAC subheader), the wireless device may determine a size of an RAR that is associated with the particular MAC subheader comprising the field (e.g., a first MAC subheader, a second MAC subheader, etc.). The type of RA procedure may be, e.g., either a 2-step RA procedure or a 4-step RA procedure. Additionally or alternatively, the RA procedure may be a 3-step RA procedure, or some other number of steps. This particular MAC subheader may comprise a second field comprising the first field and/or one or more bits of an RAP identifier (e.g., a RAPID / RAP ID). This particular MAC subheader may also comprise an extension field, a type field, and/or a reserved bit. The wireless device may determine, based on a comparison of the field in the particular MAC subheader with the RAPID of the RAP transmitted by the wireless

device, whether the RAP in the first transmission by the wireless device is successfully received by the base station. The wireless device may determine the type of RA procedure (e.g., a two-step RA procedure) based on whether an initial attempt of the particular RA procedure is successful. If the wireless device determines that the first attempt at the RA procedure is not successful, the wireless device may retransmit the first transmission and/or the wireless device may determine to perform a four-step RA procedure, such as shown in FIG. 15 part (a) and described above. The wireless device may determine whether a random process has completed. This determining whether a random access has completed may be based on, e.g., the first MAC subheader comprising a random access preamble identifier of the one or more preambles, and/or a second field in the first RAR that indicates that the one or more transport blocks have been successfully received by the base station. Additionally or alternatively, the determining that the random access procedure has completed may be based on the type of the random access procedure of the first RAR being a two-step random access procedure. The wireless device may transmit, based on a second field in the first RAR that indicates that at least one of the one or more transport blocks have not been successfully received by the base station, one or more messages using a four-step random access procedure. The wireless device may receive, from a base station, one or more messages comprising configuration parameters of a two-step random access procedure and/or configuration parameters of a four-step random access procedure. The wireless device may receive, from the base station, an RAR that may comprise an uplink grant. The wireless device may retransmit, in response to a field of the RAR (e.g., a first field, a second field, etc.) indicating that one or more transport blocks have not been successfully received by the base station, the one or more transport blocks. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[163] A base station may perform a method for determining whether to perform a two-step RA procedure or a four-step RA procedure. The base station may receive, from a wireless device, an RAP. The base station may also receive, in this first transmission from the wireless device, one or more transport blocks. The base station may determine, based on the RAP, a type of RA procedure. The type of RA procedure may be, e.g., either a two-step RA procedure or a four-step RA procedure. Additionally or alternatively, the RA procedure may be a 3-step RA procedure, or some other number of steps. The base

station may transmit, to the wireless device and based on the RAP, a MAC PDU comprising one or more MAC subheaders and one or more MAC RARs, such as shown in FIG. 17. A particular MAC subheader may comprise a field indicating the type of the RA procedure. This particular MAC subheader may comprise one or more bits of an RAP identifier (e.g., a RAPID / RAP ID). This particular subheader may also comprise an extension field, a type field, and/or a reserved bit. Each of the one or more RARs may be associated with one of the one or more MAC subheaders. The RAR may comprise the same size or one of a plurality of different sizes. An indication of the type of the RA procedure may be based on a RAPID in the RAP. Additionally or alternatively, an indication of the type of the RA procedure may be based on one or more of the extension field, the type field, and/or a reserved bit. A base station may perform any combination of one or more of the above steps. A wireless device, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[164] A base station may determine a first MAC PDU for a two-step RA procedure comprising RARs only for two-step RA procedures, and a base station may determine a second and different MAC PDU for a 4-step RA procedure comprising RARs only for 4-step RA procedures, wherein each RAR in a MAC PDU is for the same type of RA procedure. The base station may provide an indicator as to which type of RA procedure the MAC PDU corresponds. Such an indicator may be included in any location of the MAC PDU, e.g., within a MAC header or within MAC RARs (e.g., within an R field comprising reserved bits). By including the indicator in the MAC header, a wireless device may be able to determine the type of RA procedure, as well as the size of the MAC RARs, prior to receiving or decoding the MAC RARs of the MAC PDU.

[165] A base station may multiplex different type of RA responses (RARs) into one MAC PDU. A wireless device may require or request resources for both two-step RA and four-step RA procedures, and these resources for difference types of RA procedures may be independent of each other. A base station may require or request to use additional resources to accommodate a MAC PDU for 2-step RA procedures that may be different from a MAC PDU for 4-step procedures. If a base station multiplexes two types of RARs (e.g., RARs for 2-step RA procedures and RARs for 4-step RA procedures) into one MAC PDU, the base station may only be able to assign common RACH resources, where a UE can transmit a 2-step RAP or a 4-step RAP. Resources in the uplink and the downlink may be conserved by identifying an RA type without allocating separate resources for different MAC PDUs. If a base station multiplexes two types of RARs in

the same MAC PDU, e.g., if the length of a two-step RAR may be different than the length of a four-step RAR, one or more indicators may be required to indicate one or more RAR boundaries in the same MAC PDU.

[166] A base station may determine a type of RA procedure, such as a two-step RA procedure or a four-step RA procedure, for communications with one or more wireless devices. A base station may monitor RACH resources to determine whether one or more RAPs are received. If a RAP is received, the base station may determine a type of RA procedure for the RAP, such as a two-step RA procedure or a four-step RA procedure. The base station may determine, based on the type of the RA procedure for the RAP, a corresponding type of RA procedure for communications with the wireless device that transmitted the RAP. The base station may make the above determinations for a plurality of RAPs, and each of the plurality of RAPs may be associated with one of a plurality of wireless devices. The base station may multiplex a plurality of MAC PDUs. Each of the MAC PDUs may comprise a one or more MAC subheaders. At least one of the one or more MAC subheaders may comprise an indication of a type of an RA procedure, such as a two-step RA procedure or a four-step RA procedure. The base station may transmit the multiplexed plurality of MAC PDUs. One or more of the plurality of wireless devices may receive the multiplexed MAC PDUs and determine whether to perform one or more steps of an RA procedure with the base station. The one or more of the plurality of wireless devices may determine, based on one or more indications in a MAC subheader of at least one of the MAC PDUs, a type of the RA procedure for communications with the base station.

[167] A base station and/or a wireless device may determine whether an attempt for an RA procedure is successful. If an attempt for an RA procedure is successful, the base station and the wireless device may communicate using the type of RA procedure of the successful attempt. If the attempt for an RA procedure is not successful, the base station and/or the wireless device may make another attempt for an RA procedure of the same type as the prior attempt. If one or more attempts (e.g., up to a threshold number) for an RA procedure of a particular type of RA procedure (e.g., a two-step RA procedure) are not successful, the base station and/or the wireless device may attempt an RA procedure of a different type (e.g., a four-step RA procedure). A base station may perform any combination of one or more of the above steps. A wireless device, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[168] A two-step RA procedure may be attempted by a wireless device. The wireless device may transmit, to a base station, an RAP in parallel with data. The data may be an uplink message that may comprise, e.g., an identifier of the wireless device and other data such as one or more transport blocks. A base station may receive the transmission from the wireless device and the base station may decode one or more transport blocks received from the wireless device. The base station may transmit, to the wireless device, a random access response (RAR). The base station may include the RAR in a MAC PDU. The base station may also include one or more additional RARs in the MAC PDU. The base station may multiplex the MAC PDU with other MAC PDUs. The base station may transmit the multiplexed MAC PDUs. The base station may include in the RAR, which may be responsive to the first transmission of the wireless device, one or more indications of whether the one or more transport blocks were successfully received by the base station. The one or more indications may be included in one or more R fields of one or more reserved bits of the RAR. Examples of R fields are shown, e.g., as "R" in FIG. 19 parts (a), (b), and (c). The wireless device may receive the multiplexed MAC PDUs. The wireless device may demultiplex the multiplexed MAC PDUs. The wireless device may determine, based on a RAPID or other indication in a MAC subheader of a MAC PDU, that a particular RAR associated with that MAC subheader is intended for the wireless device. For example, if a RAPID in a MAC subheader of a MAC PDU corresponds to an RAP that a wireless device transmitted to a base station, the wireless device may determine that a particular RAR associated with that MAC subheader comprising the RAPID is intended for the wireless device. The RAPID or other indication in the MAC subheader may include an indication of the identifier of the wireless device that was previously included in the uplink message of the transmission by the wireless device. The wireless device may determine, based on the indication in the RAR associated with the MAC subheader, whether the one or more transport blocks were successfully received by the base station. As described above, the indication may comprise one or more bits in one or more R fields in the RAR. R fields may comprise remainder bits of an octet comprising fields designated for other purposes, and these remainder bits may be reserved for future use or for one or more indications such as described above. An indication whether one or more transport blocks were successfully received by the base station may comprise a single bit. The indication may also comprise one or more additional bits to provide additional information to the wireless device. The additional information provided by one or more additional bits may comprise, e.g., a

redundancy version for a retransmission of one or more transport blocks by the wireless device.

[169] A wireless device may perform a method for determining whether a 2-step RA procedure is successful. A wireless device may receive, from a base station, one or more messages comprising configuration parameters for a RACH of a cell. The configuration parameters may comprise one or more RA parameters. The wireless device may transmit, to the base station, an RAP in parallel with: one or more first TBs with a first redundancy version (RV) associated with a HARQ process. This first transmission by the wireless device may be based on the one or more RA parameters. The one or more first TBs may comprise an identifier associated with the wireless device (e.g., UE ID). The wireless device may receive, from the base station, an RAR MAC PDU comprising, e.g., a preamble identifier (e.g., RAPID), an uplink grant, a field indicating whether the one or more first TBs are successfully received by a base station, and/or an RNTI. The RNTI may comprise, e.g., one or more of a C-RNTI or a TC-RNTI. The uplink grant may comprise an indication of uplink resources. The field indicating whether the one or more first TBs are successfully received by the base station may comprise: one or more of the identifier associated with the wireless device or a C-RNTI, if the one or more first TBs are received successfully by the base station; or one or more of a fixed value or a TC-RNTI, if the one or more first TBs are not received successfully by the base station. One or more transport blocks may be considered successfully received by the base station if the base station is able to decode information contained in the one or more transport blocks. Additionally or alternatively, the RAR MAC PDU may comprise at least one MAC subheader that comprises one or more of a TC-RNTI or an indication of a decoding failure. The wireless device may transmit, to the base station, one or more first TBs with a second RV associated with the HARQ process, wherein the second RV may be the same as /or different from the first RV. The wireless device may receive, from the base station, a downlink packet comprising the identifier associated with the wireless device, if the one or more first TBs with the first RV or the second RV are received successfully by the base station. The wireless device may receive, from the base station, an indication of a NACK, if TBs are not received successfully. The wireless device may transmit, based on the indication of the NACK, a HARQ comprising retransmitted TBs with another RV different from the prior first and second RVs. The wireless device may receive, from the base station, an indication of an ACK, if TBs are successfully received. If the one or more first TBs are not received successfully by the base station, the wireless

device may determine that the RA procedure has failed and/or the wireless device may fall back to a four-step RA procedure, such as described above regarding FIG. 15 part (a). A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[170] A base station may perform a method for determining whether a two-step RA procedure is successful. A base station may transmit, to a wireless device, one or more messages comprising configuration parameters for a RACH of a cell. The configuration parameters may comprise one or more RA parameters. The base station may receive, from the wireless device, an RAP in parallel with: one or more first TBs with a first redundancy version (RV) associated with a HARQ process. This first transmission by the wireless device may be based on the one or more RA parameters. The one or more first TBs may comprise an identifier associated with the wireless device (e.g., UE ID). The base station may transmit, to the wireless device, an RAR MAC PDU comprising, e.g., a preamble identifier (e.g., RAPID), an uplink grant, a field indicating whether the one or more first TBs are received successfully, and/or an RNTI. The RNTI may comprise, e.g., one or more of a C-RNTI or a TC-RNTI. The uplink grant may comprise an indication of uplink resources. The field indicating whether the one or more first TBs are received successfully may comprise: one or more of the identifier associated with the wireless device or a C-RNTI, if the one or more first TBs are received successfully by the base station; or one or more of a fixed value or a TC-RNTI, if the one or more first TBs are not received successfully by the base station. One or more transport blocks may be considered successfully received by the base station if the base station is able to decode information contained in the one or more transport blocks. Additionally or alternatively, the RAR MAC PDU may comprise at least one MAC subheader that comprises one or more of a TC-RNTI or an indication of a decoding failure. The base station may receive, from the wireless device, one or more first TBs with a second RV associated with the HARQ process, wherein the second RV may be the same as or different from the first RV. The base station may transmit, to the wireless device, a downlink packet comprising the identifier associated with the wireless device, if the one or more first TBs with the first RV or the second RV are received successfully by the base station. The base station may transmit, to the wireless device, an indication of a NACK, if TBs are not received successfully. The base station may receive, based on the indication of the NACK, a HARQ comprising retransmitted TBs with another RV different from the prior first and

second RVs. The base station may transmit, to the wireless device, an indication of an ACK, if TBs are successfully received. If the one or more first TBs are not received successfully by the base station, the base station may determine that the RA procedure has failed and/or that a four-step RA procedure, such as described above regarding FIG. 15 part (a), should be attempted. The base station may transmit, to the wireless device, an indication that the RA procedure has failed and/or an indication to fall back to a four-step RA procedure. A base station may perform any combination of one or more of the above steps. A wireless device, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[171] Because a two-step RA procedure may reduce latency of UL data transfer compared with a four-step RA procedure, two-step RA procedures may be advantageous for UL data transfer such as UL data arrival for a wireless device in an RRC connected state or UL data arrival for a wireless device in an RRC inactive state. If a wireless device is in an RRC connected state, using two-step RA procedure may improve the latency of receiving an uplink grant for UL data arrival. The two-step RA procedure may be used, e.g., if a TA timer expires or a physical-layer uplink control channel resource for the SR is not configured for a wireless device. If a wireless device is in an RRC inactive state, the wireless device may transmit a UL data arrival using a two-step RA procedure without a state transition to the RRC connected state.

[172] If a base station configures four-step and two-step RA procedures, the base station may use separate preamble signature groups and/or separate time-frequency resources for each of four-step and two-step RA preamble transmissions. Using separate preamble signature groups and/or separate time-frequency resources for different types of RA procedures may help the base station determine whether a wireless device attempts to initiate a two-step RA procedure or a four-step RA procedure. A base station may broadcast and/or unicast one or more configuration parameters that indicate separate preamble signature groups, and/or that use separate time-frequency resources, for four-step and two-step RA preamble transmissions.

[173] One or more RAP groups may be configured for a two-step RA procedure via broadcast system information. If a base station configures one or more groups in the two-step RA procedure, a wireless device may use a size of the message transmitted by the wireless device in the third step, and/or the pathloss, to determine for which group the wireless device selects an RAP. A base station may use a group type to which an RAP belongs as

an indication of the message size in the third step and/or as an indication of the radio conditions at a wireless device. A base station may broadcast the RAP grouping information along with one or more thresholds on system information.

[174] A process for generating a RAP may be predetermined, or may be determined, e.g., using two-step RA configuration parameters. A type of sequence for RAP generation, e.g., a Zadoff-Chu sequence, the number of samples in a sequence, a sub-carrier spacing for a RAP transmission, and a format of a RAP transmission in a subframe (e.g., guard time/frequency, cyclic prefix length for a RAP transmission, and/or a resource block size allocated for an RAP and data transmission) may be predetermined. A cell may broadcast one or more parameters, such as a root sequence index and cyclic shift interval (e.g., rootSequenceindex, highspeedflag, and/or zeroCorrelationZoneConfig in LTE), required for a wireless device to generate a set of RAPs.

[175] The resources used for a RAP and data transmission may be pre-determined or indicated by RA configuration parameters. A table or other form of memory may indicate possible pairs of system frame number (SFN) and subframe number. A wireless device may attempt the first step of a two-step RA procedure, e.g., transmission of an RAP and data, based on such a table. A base station may broadcast one or more pairs of SFN and subframe used in the cell for the RAP and data transmission of a two-step RA procedure. A frequency offset with which a wireless device transmits an RAP and data within a subframe may be configured by two-step RA configuration parameters. A resource via which a data part is transmitted during the UL transmission may be pre-determined or configured by two-step RA configuration parameters. Such a resource may be associated with a selected RAP ID, such that a wireless devices that select different RAPs transmit data via different resources in the UL transmission.

[176] One or more wireless devices may perform the first step of a two-step RA procedure using the same cell in the same subframe. The cell may respond to one or more wireless devices' UL transmissions by multiplexing one or more RARs into a single MAC PDU as shown in FIG. 17. FIG. 17 is an example MAC PDU format. Other fields may be added, e.g., to the subheader and/or to the RARs. A MAC PDU may comprise a MAC header and MAC RARs. The MAC header may comprise one or more MAC subheaders, at least one of which may comprise a BI. Other MAC subheaders may comprise a RAPID that may indicate an index number of one of available RAPs in a cell. Each MAC RAR may comprise a wireless device ID, a C-RNTI, a TA command, an UL grant,

and/or other parameters. A wireless device may identify an RAR corresponding to the wireless device in a MAC PDU by first identifying a subheader having a RAPID that matches the RAP that the wireless device transmitted during the UL transmission. The wireless device may decode an RAR that is paired with the identified subheader.

[177] The MAC PDU may comprise a subheader that may comprise a bit string, e.g., including a special bit string comprising zeros, that may be pre-defined to indicate the failure of RAP detection but success of data decoding at a cell. The bit string may be indicated by a field of the RAPID or by a dedicated field for the bit string in the subheader. An RAR that is a pair of the subheader having the special bit string may include the wireless device ID (and/or other IDs) that a wireless device transmits in the UL transmission. The wireless device may decode the RAR having a corresponding subheader that has the special bit string, to determine whether the RAR is intended for the wireless device. The MAC subheader may comprise a field that may be a RAP identifier associated with the RAP if the RAP is detected. If the RAP is not detected, the field may comprise a pre-defined format. Additionally or alternatively, a second field in the MAC PDU subheader may indicate that a RAP is not detected.

[178] An RAR response timer may be configured using two-step RA configuration parameters. A wireless device may reset and/or start the RAR response timer in response to the wireless device transmitting a UL RAP and data transmission. The wireless device may monitor a downlink channel for an RAR on a cell until the RAR response timer is expired. A base station may transmit a MAC PDU that comprises one or more RARs, one or multiple times, in a DL transmission before the RAR response timer expires. The presence of an RAR may be indicated via a specific channel (e.g., a PDCCH in LTE) using an identity (e.g., RA-RNTI in LTE) created based on UL transmission time (e.g., as a combination of SFN and/or subframe number) and/or frequency offset. A wireless device may stop an RAR response timer when at least one of the following conditions are satisfied: the wireless device detects a MAC PDU that comprises a RAPID matching the RAP that the wireless device transmitted (and/or satisfying a threshold of similarity), the wireless device determines an RAR has a wireless device ID that the wireless device transmitted, and/or the RAR response timer is expired.

[179] A wireless device may monitor RARs for unique identifiers associated with the wireless device to determine whether information transmitted by the base station is intended for the wireless device. A base station may assign a unique identifier to each wireless device

of a plurality of wireless devices in a cell. The unique identifier may be associated with a radio network temporary identifier (RNTI). For a particular cell, the RNTI may be a cell radio network temporary identifier (C-RNTI). A wireless device may have a plurality of RNTIs associated with it, each of which may be for a different purpose. A wireless device may monitor resources in a time and frequency resource map by identifying a C-RNTI corresponding to the wireless device. If a base station transmits information in these resources, the information may be scrambled by the unique identifier of the wireless device, e.g., C-RNTI, to which the information is intended. If the wireless device receives a transmission from a base station, the wireless device may attempt to decode packets with the unique identifier assigned to the wireless device by the base station. The wireless device may determine, using its unique identifier, whether there is any data for the particular wireless device. The wireless device may monitor one or more channels, such as downlink control channels, with its unique identifier, e.g., at least one of RNTI assigned to the wireless device, to determine whether information is intended for that particular wireless device. If the wireless device uses its unique identifier to attempt to decode information but is not successful, then the wireless device may determine that the information is intended for a different wireless device. The wireless device that was unsuccessful in its attempt to decode information may continue to monitor the one or more channels.

[180] A two-step RA procedure may comprise two pairs of transmission, e.g., a first pair for a preamble transmission and a second pair for data transmission. Four overall outcomes may be possible from these pairs of transmission: both pairs succeed, both pairs fail, the first pair succeeds but the second pair fails, or the second pair succeeds but the first pair fails. A wireless device may determine, based on an indication in a MAC subheader such as described above, whether one or more preamble transmissions are successfully received by a base station. A wireless may determine, based on an indication in a MAC RAR such as described above, whether one or more data transmissions are successfully received by a base station. If either one or more preamble transmissions are not successfully received by a base station, and/or if either one or more data transmissions are not successfully received by a base station, a wireless device may determine whether to perform a retransmission of at least one of the first pair and/or the second pair of transmissions. If a wireless device determines to perform a retransmission, the wireless device may determine when to perform the retransmission.

[181] A contention resolution may be completed based on, e.g., either a C-RNTI or a wireless device contention resolution identity in an RAR. If a base station detects an RAP and decodes one or more TBs or portion thereof that a wireless device transmits, the base station may respond with an RAR that comprises the C-RNTI and/or other wireless device identifiers that the wireless device transmits in the first step of a two-step RA procedure. By detecting the C-RNTI and/or other wireless device identifiers in the received RAR, the wireless device may determine the success of the two-step RA procedure. The wireless device may start monitoring the downlink control channel associated with the C-RNTI (or Temporary C-RNTI) from the time the wireless device detects the C-RNTI (or Temporary C-RNTI) in the RAR such as shown in FIG. 21.

[182] If a base station detects an RAP but fails to decode one or more TBs or portion thereof that a wireless device transmits in the UL transmission of the two-step RA procedure, the base station may indicate such a failure. The base may transmit a MAC PDU that comprises a TC-RNTI, and/or one or more indicators in a MAC subheader and/or in an RAR, that may indicate a decoding failure to the wireless device of the RAP that the base station detected but failed to decode. A wireless device may determine, based on the one or more indicators, that the RAP was not successfully received or decoded by the base station. The wireless device may re-transmit the one or more transport blocks, e.g., by performing HARQ retransmission. The wireless device may start a *mac-ContentionResolutionTimer* when the wireless device retransmits, based on uplink grant in the RAR, the one or more transport blocks. The wireless device may not start a *mac-ContentionResolutionTimer* when the wireless device transmits one or more transport blocks based on uplink grant in the RAR, if the RAR indicates that one or more transport blocks are received and decoded successfully by the base station.

[183] A wireless device may restart the *mac-ContentionResolutionTimer* at a HARQ retransmission. If a wireless device starts or restarts the *mac-ContentionResolutionTimer*, the wireless device may start monitoring a downlink control channel using the C-RNTI or TC-RNTI. The wireless device may start this monitoring at a subframe and/or at a time offset from a start or restart of the *mac-ContentionResolutionTimer*. If an RAR indicates that one or more transport blocks are received successfully by a base station, the wireless device may monitor the C-RNTI and/or TC-RNTI. The wireless device may start this monitoring at a subframe and/or at a time offset from receiving the RAR.

[184] If a wireless device transmits a C-RNTI in the first step of a two-step RA procedure, the wireless device may monitor a downlink control channel using the C-RNTI. If a wireless device does not transmit a C-RNTI in the first step of a two-step RA procedure, the wireless device may monitor a downlink control channel using the TC-RNTI. If the *mac-ContentionResolutionTimer* expires, a wireless device may determine that the two-step RA procedure has failed.

[185] FIG. 21 shows an example of contention resolution for a two-step RA procedure. At step 2101, a wireless device may transmit, to a base station and via a cell, a random access preamble (RAP) and data. The base station associated with the cell may receive the RAP and the data. The RAP may include an identifier (e.g., RAPID = xxx). The data may comprise UL data and a redundancy version (e.g., RV = aa). The data may comprise an identifier of the wireless device (e.g., UE ID = yyy). The wireless device may start an RAR response timer (e.g., *mac-ContentionResolutionTimer*) at or near the time the wireless device transmits the RAP and data. At step 2102, the base station may transmit, and the wireless device may receive, a MAC PDU comprising a subheader that includes a RAP identifier of the RAP (e.g., RAPID = xxx). The MAC PDU may also comprise an RAR that may correspond to the subheader comprising an uplink grant. The RAR may include one or more indications of a decoding failure by the base station of the UL data. If an indication of a decoding failure is turned off, the wireless device may start monitoring a downlink control channel with a C-RNTI of the wireless device. At step 2103, if an indication of a decoding failure is turned on, the wireless device may perform a HARQ retransmission of the RAP and data, the wireless device may start monitoring the downlink control channel with the C-RNTI of the wireless device, and/or the wireless device may start and/or restart a timer (e.g., the *mac-ContentionResolutionTimer*).

[186] The wireless device may transmit one or more transport blocks in a first subframe and via radio resources indicated in an uplink grant. The wireless device may start a contention resolution timer in the first subframe depending on whether the RAR comprises the identifier of the wireless device. The wireless device may stop monitoring for RAR(s), e.g., after decoding a MAC packet data unit for an RAR and determining that the RAP identifier matches the RAP transmitted by the wireless device. The MAC PDU may comprise one or more MAC RARs and a MAC header. The MAC header may comprise a subheader having a backoff indicator and one or more subheaders that comprises RAPIDs.

[187] If one or more data transmissions are successfully received by a base station, the base station may transmit a MAC PDU comprising one or more corresponding RARs that each comprise an uplink grant. The uplink grant may indicate a particular subframe for a wireless device to transmit uplink data. The wireless device may start monitoring a downlink control channel from a second subframe. The wireless device may determine the second subframe based on, e.g.: a third subframe in which an RAR is received, if the RAR comprises the wireless device identifier; and/or the first subframe in which the wireless device transmits uplink resources based on the uplink grant. The wireless device may monitor the data for a C-RNTI, if the data comprises a C-RNTI; and/or the wireless device may monitor the RAR for a Temporary C-RNTI (TC-RNTI), if the data does not comprise a C-RNTI.

[188] If a wireless device does not receive any MAC PDU that comprises the RAPID and/or the wireless device identifier associated with the RAP, and if an RAR response timer has expired, the wireless device may retry the first step of a two-step RA procedure. The wireless device may retransmit the RAP and the data on the same cell.

[189] If the wireless device receives a MAC PDU that comprises a BI, the wireless device may select a backoff time. The backoff time may be random, and it may be determined according to a uniform distribution, e.g., between 0 and a BI value. The wireless device may delay the subsequent re-transmission of the RAP and the data by the selected backoff time. If the wireless device receives a MAC PDU that does not comprise any backoff indicator until an RAR response timer has expired, the backoff time may be set to zero. The wireless device may have a counter for counting the number of retransmissions of RAP and data. The wireless device may set the counter to zero (or 1) in the initial RAP transmission, and the wireless device may increase the counter by one whenever the wireless device re-tries the first step of a two-step RA procedure. The wireless device may reset the counter to zero (or 1) when the wireless device receives any MAC PDU that comprises the RAP ID or the wireless device ID, and/or when an RAR response timer expires. Two-step RA configuration parameters may have a parameter limiting an allowed maximum number of the retransmissions of RAP and data. If the counter reaches the maximum number, the wireless device may stop retransmission. The wireless device may perform a new RA on another cell with two-step or four-step RA procedure depending on two-step RA configuration parameters of a cell associated with the another cell.

[190] FIG. 22 shows an example of a two-step RA procedure and the failure of UL transmission for n times. At step 2201, a first base station (e.g., base station A) may transmit, via a first cell (e.g., cell A_a), two-step RA configuration parameters to a wireless device. The wireless device may determine a RAP selection, at step 2202, e.g., comprising one or more RAP selections procedures described herein. At step 2203, the wireless device may transmit a RAP and data (e.g. one or more transport blocks) of a two-step RA procedure to a base station. The RAP may comprise an identifier (RAP ID = xxx), and the data may comprise a wireless device identifier (UE ID = yyy). At or near the time the wireless device transmits the RAP and the data, the wireless device may start an RAR response timer. The base station may successfully decode and identify a RAP ID associated with the RAP, but the base station may fail to decode the data. Failure to decode the data may result from, e.g., collision or low signal quality. The base station may not transmit an RAR to the wireless in response to the RAP and data, or the base station may transmit an RAR comprising an indication of a decoding failure of the data. If the RAR response timer expires, and if the wireless device has not received an RAR indicating that the RAP and the data were successfully received by the base station, at step 2204, the wireless device may retransmit the RAP and the data after a time period corresponding to a backoff time. The wireless device may perform the above steps 2203 through 2204, to retransmit the RAP and the data, n number of times, where n may be any whole number. After the nth retransmission at step 2205, and after the RAR response timer expires with the wireless device not receiving an RAR indicating that the RAP and the data were successfully received by the base station, the wireless device may receive RA configuration parameters from a second base station (e.g., base station B) via a second cell (e.g., cell B_a), at step 2206. The RA configuration parameters from the second base station may be for a two-step RA procedure or for a four-step RA procedure. At step 2207, the wireless device may determine, based on the RA configuration parameters from the second base station, a RAP selection, e.g., comprising one or more RAP selections procedures described herein. The wireless device may transmit, to the second base station, a new RAP (e.g., comprising RAP ID = zzz) and the data (e.g., comprising the UE ID = yyy). The wireless device may repeat any of the above steps until the wireless device determines that a RA procedure is successful.

[191] The wireless device may receive a MAC PDU comprising a subheader that includes a RAP ID that the wireless device transmitted, but that also includes a decoding failure indicator in the subheader or in the RAR associated with the subheader. The decoding

failure indicator may be implemented in different ways depending on a MAC PDU format. If RARs for data decoding failures and successes have the same size, a MAC PDU may have a dedicated field inserted in a subheader or in an RAR to indicate the data decoding success or failure. This field may comprise one bit, such that either zero or one may indicate data decoding success or failure. A special bit string may be also used in an existing field in an RAR to indicate data decoding success or failure. This special bit string may comprise, e.g., all zeros or a detectable pattern of ones and zeros in the field of a wireless device ID in an RAR to indicate data decoding failure, or to indicate data decoding success. If RARs for data decoding failure and success have the same size, a wireless device may determine, based on a pre-determined RAR size information, the boundary of an RAR in a MAC PDU. If RARs for data decoding failure and success have different sizes, the base station may insert a field, to indicate RAR size information, in a MAC subheader or in an RAR. A wireless device may determine the boundary of an RAR in a MAC PDU based on the field. If RARs for data decoding failure and successes have different sizes, the RARs may have different formats. For example, an RAR for a data decoding failure may comprise a field of Temporary Cell Radio Network Temporary Identity instead of a field of a contention resolution wireless device ID, and an RAR for a data decoding success may comprise a contention resolution wireless device ID instead of a TC-RNTI.

[192] A wireless device may transmit, to a base station and as a part of a two-step RA process, a random access preamble and one or more transport blocks. The wireless device may receive a MAC PDU comprising: one or more MAC PDU subheaders, wherein a subheader comprises an RAP identifier; and one or more RARs, wherein each RAR corresponds to a MAC PDU subheader in the one or more MAC PDU sub-headers. The wireless device may determine whether the one or more transport blocks are received successfully based on one or more of: a first field in the subheader (e.g., a bit in the subheader indicating a fall back to a four-step RA procedure); a second field in an RAR associated with a first sub-header comprising an RAR identifier associated with the RAR (e.g., a bit in the RAR indicating a fall back to a four-step RA procedure). The wireless device may retransmit one or more transport blocks, if the one or more transport blocks are not received successfully by a base station. The wireless device may determine a size of the RAR based on one or more indications in the first field and/or in the second field. The wireless device may determine whether to fall back to a four-step RA procedure based on one or more indications in the first field and/or in the second field.

[193] A wireless device may perform a method for determining whether a two-step RA procedure has failed based on one or more timers. A wireless device may receive, from a base station, RA configuration parameters. The wireless device may transmit, to a base station, an RAP and one or more first transport blocks. The one or more first transport blocks may comprise an identifier of the wireless device (e.g., UE ID). The wireless device may receive, from the base station, a MAC PDU comprising one or more MAC subheaders and one or more RARs. At least one of the one or more MAC subheaders may comprise a RAPID of the RAP transmitted by the wireless device. Each RAR of the one or more RARs may be associated with a MAC subheader of the one or more MAC subheaders. A first RAR may be associated with a first MAC header comprising an uplink grant for a first subframe. The wireless device may transmit, to the base station, in a first subframe, and via radio resources indicated by the uplink grant, one or more transport blocks. The wireless device may start, in response to transmitting one or more transport blocks, and based on whether the RAR comprises the identifier of the wireless device, a contention resolution timer. The contention resolution timer may be for determining whether a random access procedure is successful. The wireless device may stop, based on a determination that the RAPID of the MAC subheader matches the identifier of the wireless device, an RAR response timer that started in response to transmitting the RAP. The wireless device may stop, based on a determination that a downlink control information detected from a downlink control channel comprises the identifier of the wireless device, the contention resolution timer. The wireless device may perform one or more operations regarding the contention timer one or more times, and/or using one or more timers. The wireless device may restart, based on a retransmission of the one or more TBs, the contention resolution timer. The wireless device may determine that, based on an expiration of the contention resolution timer, a first RA procedure has failed. The wireless device may initiate, at a time period after determining that the first RA procedure has failed, a second RA procedure. The wireless device may determine, based on a backoff indicator in the RAR, the time period. The wireless device may monitor a downlink control channel associated with an RNTI. The wireless device may start the monitoring from a second subframe. The monitoring by the wireless device may comprise monitoring the downlink control channel for a downlink control information associated with the RNTI. The wireless device may determine the second subframe based on one or more of: a subframe in which an additional RAR is received that comprises the identifier of the wireless device; and/or a subframe in which the wireless device transmits uplink resources based on the uplink grant. The monitoring

may be performed after detecting the RAR comprising the RNTI. The RNTI may comprise one or more of a C-RNTI or a TC-RNTI. The wireless device may determine that an RAR associated with the RAP has not been received. The wireless device may perform the following one or more times: retransmitting the RAP and the one or more transport blocks; starting, based on the retransmitting the RAP and the one or more transport blocks, a second timer; and determining that an RAR associated with the retransmitted RAP has not been received. This determining may occur at a second time period after the starting of the second timer. The wireless device may determine, based on a determination that an RAR associated with one or more retransmissions of the RAP has not been received, that an RA procedure with the base station has failed. The wireless device may receive, from a second base station, RA parameters. The wireless device may transmit, to the second base station, the RAP and the one or more transport blocks. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[194] A base station may multiplex, in a MAC PDU, RARs for two-step and four-step RA procedures. If RARs for two-step and four-step RA procedure have the same size, a wireless device may not require an RAR length indicator field and/or the wireless device may determine the boundary of each RAR in the MAC PDU based on pre-determined RAR size information. The RAR may have a field to indicate a type of RAR (e.g., comprising one or bits in a reserved "R" field as shown in FIG. 23). An RAR may comprise different formats for two-step and four-step RARs with a fixed size. Some examples for different RAR formats are shown in FIG. 23 parts (a), (b), and (c). By using RARs with different formats, the size of the sub-header may be reduced and/or additional bits may be available for other fields. Encoding RARs with an indication of an RAR type may reduce downlink signaling overhead.

[195] FIG. 24 shows an example RAR format that may or may not comprise a field to indicate a type of RAR. The RAR shown in FIG. 24 may comprise a fixed size using the same format for two-step and four-step RA. If RARs for two-step and four-step RA procedures have different sizes, a field for indicating an RAR type may be included in a subheader (such as a MAC subheader) or in an RAR. An RAR may comprise different types of fields that may correspond with an indicator in a subheader or in an RAR. A wireless device may determine the boundary of one or more RARs in a MAC PDU based on one or more indicators.

[196] Different message formats may be used based on the type of device for communication. If a wireless device comprises, e.g., an IoT device, such as a smart appliance or other electronics equipment that may not require a large amount of data transmission, the format may include a small message space for transmissions by the device instead of including an uplink grant. If the wireless device comprises, e.g., a phone, tablet, or other device that requires a large amount of data transmissions, the format may include an uplink grant for larger transmissions.

[197] A wireless device may determine whether an RAR is a two-step RAR or a four-step RAR, at least based on the RAP identifier in the corresponding MAC PDU sub-header. Two-step and four-step RA preamble identifiers may be selected from two different preamble groups. The wireless device may determine whether an RAR is a two-step RAR or a four-step RAR, at least based on a field indicating an RAR type. The MAC PDU subheader may comprise the field indicating an RAR type. The field may comprise one bit indicating a two-step or a four-step RAR type. The RAR length may be predetermined for each RAR type. A wireless device may determine a size of an RAR based on a determination of whether the RAR is a two-step RAR or a four-step RAR.

[198] A wireless device may transmit, to a base station, a random access preamble via a random access channel in a subframe and using a frequency offset. A wireless device may determine an RA-RNTI based on one or more of a subframe number and/or a frequency index. A wireless device may monitor a control channel for a control packet associated with an RA-RNTI. A wireless device may receive a MAC PDU, associated with RA-RNTI, comprising: one or more MAC PDU subheaders, wherein a subheader may comprise an RAP identifier; one or more RARs, wherein each RAR of the one or more RARs may correspond to a MAC PDU subheader of the one or more MAC PDU sub-headers; and an uplink grant. The wireless device may transmit one or more transport blocks based on the uplink grant.

[199] Example RAR formats are shown in FIGS 19, 23, and 24. An RAR may include one or more fields, such as a timing advance command, an uplink grant, a TC-RNTI, a C-RNTI, a wireless device (e.g., a UE) contention resolution identity, and/or other parameters. An RAR format may be determined based on the fields that are needed in the RAR. A present bit may be used for a field to indicate whether the field is included in the RAR. For example, a presence field may indicate whether or not an RAR includes an uplink grant. Other fields may be associated with a presence field. Multiple RAR types may

include different fields that may be pre-defined. A field in the MAC subheader or in an RAR may determine the RAR type and a corresponding RAR length. A two bit field may indicate which of four or three RAR types are transmitted. Other fields, comprising any number of its, may be included in the MAC subheader and/or in an RAR to indicate information about an RA procedure.

[200] FIG. 19 shows example RAR formats with a fixed size (e.g., 6 bytes) for various RA procedures (e.g., two-step and four-step RA procedures). FIG. 23 parts (c) and (a) show example RAR formats with a fixed size (e.g., 6 bytes) for two-step and four-step RA procedures, respectively. FIG. 23 part (b) shows an example RAR format with a fixed size (e.g., 8 bytes) for a two-step RA procedure. FIG. 24 shows an example RAR format with a fixed size (e.g., 12 bytes) for two-step and four-step RA procedures. As shown in FIGS. 23 parts (a)-(c) and FIG. 24, an RAR format may comprise, e.g., one or more: reserved fields (e.g., "R"), timing advance command, uplink grant, temporary C-RNTI (TC-RNTI), and/or wireless device (e.g., UE) contention resolution identity.

[201] A two-step RA procedure may comprise a hybrid automatic repeat request (HARQ), including, e.g., HARQ with soft combining, if a data decoding failure occurs. If a wireless device receives a MAC PDU that comprises a subheader with a RAP ID that matches or indicates the RAP that was transmitted by the wireless device, but a decoding failure indicator indicates a failure has occurred, the wireless device may perform HARQ. The wireless device may perform HARQ, e.g., by transmitting another redundancy version to the cell from which the wireless device received the MAC PDU. The HARQ transmission may occur at an a priori known subframe or time period, such as every eight subframes, after a prior HARQ transmission in the same HARQ process. The HARQ may predetermine a sequence of redundancy version numbers that the wireless device may transmit in a HARQ transmission in the same process. An RV number may start, e.g., from zero or one in an initial UL data transmission, and the next RV in the sequence may be transmitted if a wireless device determines that an RAR comprises an indicator requesting a next RV.

[202] FIG. 25 shows an example of an RA procedure using HARQ retransmission. A HARQ retransmission may occur if a wireless device detects a RAPID in a cell but determines that the base station failed to decode data transmitted by the wireless device. At step 2501, a wireless device may receive, from a base station and via a cell, RA configuration parameters. At step 2502, the wireless device may determine an RAP selection, e.g.,

comprising one or more RAP selections procedures described herein. At step 2503, the wireless device may transmit an RAP (e.g., comprising an RAP ID = xxx) and UL data (e.g., comprising a first RV = aa, and UE ID = yyy). At or near step 2503, the wireless device may start or restart an RAR response timer. At step 2504, the base station may transmit, and the wireless device may receive, a MAC PDU comprising a subheader (e.g., comprising RAP ID = xxx), such as a MAC subheader, with a TC-RNTI and a decoding failure indicator. Based on receiving the decoding failure indicator, the wireless device may stop the RAR response timer. At step 2505, the wireless device may transmit a HARQ retransmission of the RAP and the UL data. The HARQ retransmission may comprise a second RV (e.g., RV = bb). The wireless device may transmit the HARQ retransmission based on a determination that a decoding failure has occurred (e.g., which may be indicated by the decoding failure indicator). At or near step 2505, the wireless device may start a contention resolution timer. At step 2506, the base station may transmit, to the wireless device, a NACK. The base station may transmit the NACK transmission based on receiving the HARQ retransmission. Based on receiving the NACK, the wireless device may stop the contention resolution timer. At step 2507, the wireless device may transmit a second HARQ retransmission of the RAP and the UL data. The second HARQ retransmission may comprise a third RV (e.g., RV = cc). The wireless device may transmit the second HARQ retransmission based on the wireless device receiving the NACK. At or near step 2507, the wireless device may start or restart a contention resolution timer. At step 2508, the base station may transmit, to the wireless device, an ACK. The wireless device may receive the ACK. Based on receiving the ACK, the wireless device may determine that the second HARQ retransmission was successful. Based on receiving the ACK, the wireless device may stop the contention resolution timer.

[203] For RA procedures using HARQ retransmission, each RV may be transmitted in an adaptive or in a non-adaptive manner. A base station may transmit, to a wireless device and via a cell, one or more indicators of a HARQ transmission type. For example, the base station may transmit, to the wireless device and via a downlink control channel, a new data indicator (NDI) with downlink control information (DCI). Additionally or alternatively, the base station may transmit, to the wireless device and via a downlink HARQ indicator channel, a one-bit HARQ acknowledgement (ACK) or non-acknowledgement (NACK). The wireless device may determine, based on the ACK or NACK, whether to transmit, to the base station and via the cell, another RV. If the

wireless device detects an NDI that differs from a previously received NDI (e.g., an NDI bit has changed), the wireless device may, regardless of a HARQ ACK or NACK, transmit another RV specified in the DCI. The wireless device may transmit this RV using a resource and modulation and coding scheme (MCS) specified in the same DCI. If the wireless device detects a NDI non-toggled but receives a HARQ NACK message, the wireless device may transmit a predefined RV with the same resource and MCS as the previous HARQ transmission.

[204] The maximum number of HARQ transmissions may be determined for a two-step RA procedure, e.g., by maxHARQ-Msg3Tx in LTE. A wireless device may have a counter for counting the number of HARQ transmissions. A wireless device may set the counter to one based on transmitting the first RV. The wireless device may increase the counter by one based on transmitting a next RV in the cell. If the counter reaches the maximum number of HARQ transmissions configured in a cell (or a retransmission threshold and/or a HARQ transmission threshold), a wireless device may determine that the two-step RA procedure has failed. If the wireless determines that the two-step RA procedure has failed, the wireless device may perform a new RA procedure on a different cell, the same RA procedure but on a different cell, or a new RA procedure on the same cell. The new RA procedure may comprise a two-step or a four-step RA procedure.

[205] FIG. 26 shows an example of a two-step RA procedure failure as the number of HARQ retransmission reaches a threshold. Each of FIG. 26 steps 2601 through 2607 correspond to FIG. 25 steps 2501 through 2607, respectively, the descriptions of which are incorporated by reference here for FIG. 26 steps 2601 through 2607. At step 2608, the base station may transmit, and the wireless device may receive, a second NACK. Steps 2607 and 2608 may be repeated any number of times, wherein each HARQ retransmission may include a different RV, up to a final HARQ retransmission and NACK at steps 2609 and 2610, respectively. The final HARQ retransmission may be based on the total number of HARQ retransmissions reaching a threshold value, such as indicated by *maxHARQ-Msg3Tx*. At step 2611, if the threshold value for HARQ retransmissions is reached, and if a wireless device receives a NACK (e.g., at step 2610) and/or the contention resolution timer expires without the wireless device receiving an ACK, then the wireless device may determine that the RA procedure has failed. A base station may determine that an RA procedure has failed, e.g., if the base station is unsuccessful in decoding a threshold number of HARQ retransmissions, and/or if the

base station does not receive a HARQ retransmission from the wireless device after a threshold period of time.

[206] A wireless device may determine that a two-step RA procedure is successful, e.g., if, prior to the expiration of an RAR response timer, the wireless device receives a MAC PDU that comprises the same RAP ID and wireless device ID that a wireless device transmitted in the UL transmission. An RA procedure may be successful if a base station identifies the wireless device's transmitted RAP, decodes the wireless device's transmitted data, and transmits, to the wireless device and before the wireless device's RAR timer expires, a MAC PDU comprising the RAP ID and wireless device ID. A base station may identify an RAP ID based on a peak detector. The peak detector may detect a peak from correlation outputs between a received signal and a set of RAPs available to a cell. If the resource block, over which the data or portion thereof is transmitted during the UL transmission, is associated with an RAP, an RAP ID may also be detectable based on an energy detector. The energy detector may measure an energy level of the resource block for a UL data transmission.

[207] FIG. 27 shows an example of a successful two-step RA procedure, e.g., wherein a base station decodes an RAP and UL data, and a base station responds by transmitting an RAR to a wireless device. Each of FIG. 27 steps 2701 through 2703 correspond to FIG. 20 steps 2001 through 2003, respectively, the descriptions of which are incorporated by reference here for FIG. 27 steps 2701 through 2703. At or near step 2703, the wireless device may start or restart an RAR response timer. At step 2704, the base station may transmit, to the wireless device, a MAC PDU comprising one or more MAC subheaders and one of more RARs. At least one of the MAC subheaders in the MAC PDU may comprise a RAP ID (e.g., RAP ID = xxx) that may correspond to the RAP ID included in the RAP that was transmitted by the wireless device in step 2703. At least one of the RARs in the MAC PDU may comprise an identifier associated with the wireless device (e.g., UE ID = yyy) that may correspond to the identifier transmitted by the wireless device in step 2703. If the wireless device determines that the RAP ID included in at least one of the MAC subheaders corresponds to the wireless device's RAP IP; if the wireless device determines that an RAP, corresponding to the MAC subheader with the wireless device's RAP ID, comprises the wireless device's identifier; and if the RAR response time has not expired; then the wireless device may determine that the two-step RA procedure was successful.

[208] A wireless device may transmit in parallel, to a base station and via a first cell, a random access preamble, and one or more transport blocks with a first RV associated with a HARQ process, wherein the one or more TBs comprise the wireless device ID. The wireless device may receive an RAR MAC PDU comprising one or more of: a preamble identifier; an uplink grant; a field indicating whether the one or more TBs are received successfully; and/or an RNTI. The wireless device may transmit, using uplink resources, the one or more TBs with a second RV different from the first RV associated with the HARQ process. The uplink resources may be identified in the uplink grant. The wireless device may receive a downlink packet comprising the wireless device ID, if the one or more TBs are decoded successfully. The wireless device may receive one or more messages comprising configuration parameters of a RACH of a first cell.

[209] A wireless device may handover from a source base station to a target base station. A handover may occur, e.g., if the wireless device moves from a location in a first cell served by the source base station to a location in a second cell served by the target base station, if the source base station is unable to accommodate communications with the wireless device, if it is determined that a different base station is a better candidate for accommodating communications with the wireless device than the source base station, or for various other reasons.

[210] A random access procedure may be optimized for a handover of a wireless device from a source base station to a target base station. Such optimization may provide a faster handover, with reduced latency, and may provide a handover without suffering from collisions with other transmissions. A wireless device may perform, with a target base station, a contention-based four-step random access procedure that may take, e.g., 20 ms, a contention-free three-step random access procedure that may take, e.g., 14 ms, and/or a contention-based two-step random access procedure that may take, e.g., 4 ms. By communicating random access information from a target base station to a wireless device (e.g., via a source base station), prior to performing random access, the wireless device may employ a contention-free two-step random access procedure that may take, e.g., 1 ms. A contention-free, two-step random access procedure for handover with the above advantages may be achieved by communicating random access information with handover messaging described below.

[211] A source base station and a target base station for a possible handover may perform different operations for RA procedures to initiate communications with the wireless

device. Additionally or alternatively, a wireless device that is a candidate for a handover may be capable or incapable of one or more types of RA procedures, and/or conditions in a cell of the source base station may differ from conditions in a cell of a target base station. For one or more reasons, prior to initiating a handover of a wireless device from a source base station (e.g., an eNB, a gNB, etc.) to a target base station (e.g., an eNB, a gNB, etc.), a device may determine a type of random access procedure to use to perform the handover. The type of RA procedure may include, e.g., a two-step RA procedure or a 4-step RA procedure. Additionally or alternative, the type of RA procedure may include, e.g., whether the RA procedure is contention-based (such as a contention-based four-step RA procedure described above regarding FIG. 15 part (a)) or contention-free (such as a three-step contention-free RA procedure described above regarding FIG. 15 part (b), or a two-step contention-free RA procedure available that may be used for handover). The device that may determine the type of the RA procedure may be a target base station, a source base station, and/or a core network device (e.g., located at a Next Generation Core (NGC) network entity). Additionally or alternatively, a wireless device may determine the type of the RA procedure, e.g., based on random access information received in one or more messages. As an example, a source base station may send to a target base station information about the type of RA procedure (e.g., a contention-free two-step RA procedure) to perform for a wireless device that may be a candidate for a handover from the source base station to a target base station. Information about the type of RA procedure may also be sent by the target base station to the source base station, and by the source base station to the wireless device.

[212] A wireless device may receive random access information from a source base station for accessing a target cell. The random access information may comprise, e.g., an indication of a type of random access procedure, such as a two-step random access procedure or a four-step random access procedure, for the wireless device. The random access information may also comprise timing advance information for uplink transmissions and/or downlink transmissions for the wireless device in the target cell, such as for a random access preamble, a random access response, and/or one or more transport blocks. The timing advance information may indicate, e.g., whether the timing advance value is zero or not, and/or an estimated time advance value. Receiving the random access information from a source base station, as opposed to waiting to receive system information comprising random access information for a target base station, may enable a wireless device to reduce handover delay. The wireless device may perform a random

access procedure as part of a handover to a target cell based on one or more elements of received random access information.

[213] FIG. 28 shows an example of a random access procedure for handover, such as via a direct interface. At step 2810, a wireless device 2801 (e.g., a UE, or any device capable of communicating with a network) may send, to a source base station 2802 (e.g., a source gNB), a first message comprising a measurement report for one or more cells. The measurement report may be based on one or more attributes of the one or more cells. The measurement report may comprise, e.g., at least one of a list of cells, an RSRP (Reference Signal Received Power) for a cell or for each of a plurality of cells included in a list of cells, an RSRQ (Reference Signal Received Quality) for a cell or for each of a plurality of cells in a list of cells, cell priority of one or more base stations including a cell priority of the target base station 2803, or other information that may be used in a handover decision. The wireless device 2801 may generate the measurement report from measurements of neighboring cells, and the measurement report may indicate one or more base stations, of a plurality of neighboring base station, that may be candidates for a handover of the wireless device 2801 from the source base station 2802 based on power measurements for each base station. The wireless device 2801 may generate the measurement report using the procedures described below regarding FIG. 30.

[214] The source base station 2802 may determine a handover decision at step 2820. The handover decision may be based on the measurement report. The source base station 2802 may determine a target base station 2803, from among a plurality of potential target base stations. The source base station 2802 may determine, based on one or more elements of the measurement report, whether or not to initiate a handover procedure for the wireless device 2801. If the base station 2802 determines that a handover should be performed, the base station 2802 may send a second message, at step 2830, to a target base station 2803 (e.g., a target gNB). The second message may comprise a handover request message. The second message may also comprise one or more of the measurement report from the first message, an identifier of the wireless device 2801, a wireless device context (e.g., one or more bearers, one or more slices, subscriber information, security information, etc.), capability information of the wireless device 2801 (e.g., one or more types of RA procedures the wireless device 2801 is capable of performing), one or more cell identifiers of a cell or of a plurality of cells served by the target base station 2803, one or more elements of the measurement report received from the wireless device 2801, or other information that may be used for performing a

handover. The source base station 2802 may perform the handover decision in step 2820, and the source base station 2802 may receive and send the first and second messages in steps 2810 and 2830, respectively, using the procedures described below regarding FIG. 31.

[215] The target base station 2803 may receive the second message, at step 2830. The target base station 2803 may process the handover request. The target base station 2803 may determine, based on the second message, whether or not to accept the handover request for the wireless device 2801. The target base station 2803 may provide an acknowledgement of the handover request, e.g., by sending, at step 2840, a third message to the source base station 2802. The target base station 2803 may process the handover request, and the target base station 2803 may receive and send the second and third messages in steps 2830 and 2840, respectively, using the procedures described below regarding FIG. 32.

[216] The third message, that may be sent by the target base station 2803 to the source base station 2802, may comprise a handover request acknowledgement and random access information, including, e.g., an indication of a type of a random access procedure. The handover request acknowledgement may comprise an ACK that may be in response to the handover request. The target base station 2803 may determine random access information for inclusion in the handover request acknowledgement. The target base station 2803 may send the third message based on determining to accept the handover request. The target base station 2803 may include in the third message a handover request acknowledge message as well as random access information.

[217] In a handover procedure, the handover related information may be transmitted by an upper layer message, such as an RRC message. A type of a random access procedure, such as a two-step random access procedure or a four-step random access procedure, may be indicated, e.g., by one or more RACH type indication parameters in an RRC connection reconfiguration message. The RRC reconfiguration message may be included with a handover command. Additionally or alternatively, one or more RACH type indication parameters may comprise one or more indications of a capability (e.g., configured for a contention-free two-step RA procedure) or an incapability (e.g., not configured for a contention-free two-step RA procedure). With respect to one or more indications of incapability, one or more default RA procedures may be indicated in the random access information of the third message (e.g., instructing a wireless device to

default to a contention-based four-step RA procedure). Mobility control information (e.g., *mobilityControlInfo*) in an RRC connection reconfiguration message (e.g., *RRCConnectionReconfiguration*) may comprise one or more of the RACH type indication parameters. A target NG-RAN node to a source NG-RAN node transparent container may comprise RRC parameters comprising a handover command and/or one or more of the RACH type indication parameters. The handover command may comprise, e.g., an RRC E-UTRA handover command message, such as *handoverCommandMessage*. Additionally or alternatively, a type of a random access procedure may be indicated by one or more parameters in a mobility control information. The mobility control information may further indicate one or more of: *mobilityControlInfoV2X*, *handoverWithoutWT-Change*, *makeBeforeBreak*, *rach-Skip*, or *sameSFN-Indication*.

[218] The random access information may comprise, e.g., at least one of a first indication indicating that a random access procedure for handover execution should be performed with one of a two-step random access procedure or a four-step random access procedure, a second indication for performing a two-step random access process, a preamble identifier for a two-step random access procedure, and/or a preamble identifier for a four-step random access procedure. The preamble identifier for a two-step random access procedure and/or a four-step random access procedure may be used to determine radio resources, e.g., for channel access by the wireless device 2801. The preamble identifier may comprise one or more of a preamble index, PRACH mask index, root sequence, and/or the preamble, each of which may be used by the wireless device 2801 for a random access procedure. The random access information may further comprise a random access channel configuration information for a two-step random access procedure and/or radio resource configuration parameters for a two-step random access procedure. Additionally or alternatively, the third message may comprise, e.g., one or more of: a handover request acknowledgment, one or more bearers admitted, one or more slices admitted, one or more cells served by the target base station 2803, radio resource configuration information (e.g., RACH configuration, channel configuration information, etc.) for the wireless device 2801, one or more types of random access procedures, and/or mobility control information for the wireless device 2801. The third message may further comprise timing advance information, e.g., for transmission of uplink data. The timing advance information may comprise at least one of an indication of a zero timing advance and/or a first value for the timing advance. The first value for the timing

advance may be estimated by, e.g., the source base station 2802, the second base station 2803, and/or another device, such as a core network device described further below regarding FIG. 29.

[219] The second message and/or the third message may be exchanged directly, e.g., via a direct interface such as an Xn interface, between the source base station 2802 and the target base station 2803. Additionally or alternatively, one or more elements of the second message and/or one or more elements of the third message may be exchanged indirectly, e.g., via one or more core network entities.

[220] At step, 2840, the source base station 2802 may receive the third message. The source base station 2802 may send, to the wireless device 2801 and based on the third message, a fourth message, at step 2850. The fourth message may comprise, e.g., a handover command and random access information. The handover command may comprise a command for the wireless device 2801 to execute a handover towards a cell of the target base station 2803. The handover command may be based on one or more elements of the third message. The fourth message may comprise some or all of the information in the third message. The fourth message may be an RRC connection reconfiguration message. The fourth message may comprise, e.g., information associated with one or more cells served by a respective one or more base stations of a plurality of base stations that may comprise the target base station. Additionally or alternatively, the fourth message may comprise radio resource configuration information (e.g., RACH configuration, channel configuration information, etc.) for the wireless device 2801, and/or a mobility control information for the wireless device 2801. One or more elements of the fourth message may be based on an acknowledgement received by the source base station from the target base station for the handover request. The fourth message may comprise an indication indicating that a random access for a handover execution is performed with one of a two-step random access procedure and/or a four-step random access procedure. The wireless device 2801 may receive and process the fourth message using the procedures described below regarding FIG. 34.

[221] The wireless device 2801 may send, based on the random access information in the fourth message, a fifth message that may be part of a random access procedure with the target base station 2803, at step 2860. The wireless device 2801 may send a fifth message, e.g., comprising a random access preamble, to the target base station 2803, e.g., via a cell associated with the target base station 2803. The message comprising the

random access preamble may be part of a random access procedure that may be performed with, e.g., two messages (e.g., for two-step random access) or four messages (e.g., for four-step random access). The random access preamble may be transmitted in a first step of one of a two-step random access procedure and/or a four-step random access procedure. Timing advance information may be included in the fourth message. Timing advance information may comprise at least one of an indication of a zero timing advance and/or a first value for a timing advance. The first value of the timing advance may be estimated by the source base station and/or the target base station. The fifth message may comprise, e.g., one or more transport blocks that may comprise at least one of a handover complete message (e.g., an RRC connection reconfiguration complete message), uplink data, a buffer status report, and/or an identifier of the wireless device (e.g., C-RNTI). The fourth message may comprise, e.g., a preamble identifier. Radio resources for transmissions may be determined by the preamble identifier. The fourth message may comprise a random access channel configuration for a two-step random access procedure and/or radio resource configuration parameters for a two-step random access procedure. The random access preamble may be transmitted in a first step of one of a two-step random access procedure or a four-step random access procedure. The transmitting of the random access preamble message may be based on one or more elements of the random access information included in the third message and/or the fourth message from steps 2840 and/or 2850, respectively. The type of random access procedure may be, e.g., a two-step random access procedure or a four-step random access procedure described further herein. The type of random access procedure may be indicated by the random access information in the fourth message, including, e.g., in a handover command. The random access information in the fourth message may be the same as the random access information in the third message. Additionally or alternatively, the random access information in the fourth message may comprise additional information provided by the source base station 2802 and/or less than all of the random access information included in the third message.

[222] In a two-step random access procedure, a first random access message may be transmitted by the wireless device 2801 to the target base station 2803. The first random access message may comprise at least one of a random access preamble, a radio resource control message, and/or one or more uplink packets. A second random access message of a two-step random access procedure may be transmitted to the wireless device 2801 by the target base station 2803, e.g., if the target base station 2803 receives the first random

access message. The second random access message may comprise, e.g., an acknowledgement of a reception of the first random access message. The second random access message of the two-step random access procedure may further comprise a resource grant for uplink message transmission.

[223] In a four-step random access procedure, a first random access message may be transmitted by the wireless device 2801 to the target base station 2803, and the first random access message may comprise a random access preamble. A second random access message of a four-step random access procedure may be transmitted to the wireless device 2801 by the target base station 2803, e.g., if the target base station 2803 receives the first message. The second random access message may comprise a resource grant for uplink message transmission. A third random access message of the four-step random access procedure may be transmitted by the wireless device 2801 to the target base station 2803, at least based on the resource grant in the second random access message. The third random access message may comprise a radio resource control message and/or one or more uplink packets. A fourth random access message may be transmitted by the target base station 2803 to the wireless device 2801, and the fourth random access message may comprise an acknowledgement of a reception of the third random access message. The fourth random access message of the four-step random access procedure may further comprise a resource grant for uplink message transmission.

[224] After completing the random access procedure initiated by the wireless device 2801, the target base station 2803 may send a sixth message to network device. The network device may comprise a core network entity. The sixth message may be transmitted to the network device, e.g., to update downlink packet destination information such as a tunnel endpoint identifier and/or an IP address and/or another address. The sixth message may comprise a path switch request message and/or a downlink packet destination information for one or more bearers for the wireless device 2801. The network device may send a seventh message to the target base station 2803 that may be in response to the sixth message. The seventh message may comprise a path switch request acknowledge message. Additionally or alternatively, the seventh message may comprise an uplink packet destination information, such as a tunnel endpoint identifier and/or an IP address and/or another address, for one or more bearers for the wireless device 2801, and/or a list of bearers to be released.

[225] After completing a random access procedure initiated by the wireless device 2801, the target base station 2803 may notify the source base station 2802 that the handover has completed. The target base station 2803 may notify the source base station 2802, e.g., by sending an eighth message to the source base station 2802. The eighth message may comprise a UE context release message and/or an identifier of the wireless device 2801. The eighth message may be sent, e.g., via a direct interface between the target base station 2803 and the source base station 2802. Additionally or alternatively, one or more elements of the eighth message may be sent to the source base station 2802 indirectly, e.g., via one or more core network entities. In response to receiving the eighth message and/or the one or more elements of the eighth message, the source base station 2802 may release a wireless device context for the wireless device 2801. Any one or more of the above described messages may be exchanged among one or more communication nodes between one or more of the wireless device 2801, the source base station 2802, and/or the target base station 2803.

[226] FIG. 29 shows an example of a random access procedure for handover, e.g., using a core network device 2904. The core network device 2904 may be located at a Next Generation Core (NGC) network entity that may be configured to communicate, e.g., via an NG interface, with one or both of the source base station 2902 and the target base station 2903. One or more of a wireless device 2901, a source base station 2902 (e.g., an eNB, a gNB, etc.), and/or a target base station 2903 (e.g., an eNB, a gNB, etc.), and operations thereof, may correspond to the wireless device 2801, the source base station 2802, and/or the target base station 2803, respectively, described above regarding FIG. 28, descriptions of which are incorporated herein with respect to FIG. 29. The messages sent in steps 2810, 2830, 2840, 2850, and 2860 of FIG. 28 may correspond to messages sent in similarly numbered steps 2910, 2930, 2940, 2950, and 2960, respectively, of FIG. 29. The handover decision in step 2820 of FIG. 28 may also correspond to the handover decision in step 2920 of FIG. 29.

[227] The core network device 2904 may communicate with the source base station 2902 and the target base station 2903. The core network device 2904 may comprise one or more devices located at a core network entity, such as an NGC, one or more devices at an access and mobility management function (AMF) network entity, one or more devices at a mobility management entity (MME), or one or more devices at any other location. The core network device 2904 may determine an availability of base stations, including a determining whether a target base station, such as the target base station 2903, is

available. The core network device 2904 may communicate with the source base station 2902 and the target base station 2903 via an NG interface and/or via an S1 interface (e.g., for an MME), and the core network device 2904 may operate as an intermediary for communications between the source base station 2902 and the target base station 2903. Processing in the core network device 2904, and potential latency in communicating information to and from the core network device 2904, may not delay a handover when, e.g., some or all of such processes and communications may occur prior to a handover.

[228] At step 2910 the wireless device 2901 may send, to a source base station 2902, a first message comprising a measurement report for one or more cells, including, e.g., a cell for the target base station 2903. The first message in step 2910 may comprise some or all of the information in the first message in step 2810 described above. The wireless device may generate the measurement report using the procedures described below regarding FIG. 30.

[229] The source base station 2902 may receive the first message at step 2910. At step 2920, the source base station 2902 may make a handover decision. The handover decision may be based on the measurement report in the first message. The handover decision may also be based on a determination whether to use a core network device 2904 for a handover. As an example, if an Xn connection is established between the source base station 2902 and the target base station 2903, the source base station 2902 may determine to send a second message, e.g., comprising a handover request, to the target base station 2903 without involving the core network device 2904; and if an Xn connection is not established between the source base station 2902 and the target base station 2903, then the source base station 2902 may send a second message, e.g., comprising a handover required message, to the core network device 2904 at step 2925. The second message may be based on the measurement report. The second message (e.g., a handover request message and/or a handover required message) may further comprise one or more measurements results of a measurement report (e.g., that may be provided by the wireless device step 2810) and/or one or more of: timing advance information for transmission of uplink data, a random access preamble, and/or random access information. The second message in step 2925 may comprise some or all of the information in the second message in step 2830 described above. The source base station 2902 may perform the handover decision in step 2920, and receive and send the first and second messages in steps 2910 and 2925, respectively, using the procedures described below regarding FIG. 31.

[230] The core network device 2904 may receive the second message at step 2925. The core network device 2904 may process the second message, including, e.g., to determine whether the wireless device may require latency sensitive service. The core network device 2904 may determine whether the wireless device may require latency sensitive service based on, e.g., packet data unit session information of the wireless device. At step 2930, the core network device 2904 may send, to the target base station 2903, a third message comprising a handover request. The third message in step 2930 may comprise some or all of the information in the second message in step 2830 described above. The core network device 2904 may receive and process the second message in step 2925, and determine and send the third message in step 2930, using the procedures described below regarding FIG. 33.

[231] The target base station 2903 may receive the third message at step 2930. The target base station 2903 may determine whether the handover request is acceptable. The target base station 2903 may process a handover request in a direct handover from a source base station 2902, e.g., via an Xn interface, using one or more of the same procedures as the target base station 2903 uses to process a handover request from a core network device 2904, e.g., via an NG interface. The target base station 2903 may also determine characteristics that may be relevant for a handover, such as power, latency sensitive service type, cell size, and/or availability of one or more types of random access procedures. Based on one or more determinations, at step 2940, the target base station 2903 may send, to the core network device 2904, a fourth message comprising a handover request acknowledgement and random access information. The fourth message in step 2940 may comprise some or all of the information in the third message in step 2840 described above. The target base station 2903 may receive and process the third message in step 2930, and determine and send the fourth message in step 2940, using the procedures described below regarding FIG. 32.

[232] The core network device 2904 may receive the fourth message at step 2940. The core network device 2904 may process the fourth message to generate a fifth message comprising a handover request acknowledgement and random access information. At step 2945, the core network device 2904 may send the fourth message to the source base station 2902. The fifth message in step 2945 may comprise some or all of the information in the third message in step 2840 described above. The core network device 2904 may receive and process the fourth message in step 2940, and determine and send the fifth message in step 2945, using the procedures described below regarding FIG. 33.

[233] The source base station 2902 may receive the fifth message at step 2945. The source base station 2902 may process the fifth message to determine a sixth message, e.g., comprising a handover command and random access information. At step 2950, the source base station may send, to the wireless device 2901, the sixth message. The sixth message in step 2950 may comprise some or all of the information in the fourth message in step 2850 described above. The source base station 2902 may receive and process the fifth message in step 2945, and determine and send the sixth message in step 2950, using procedures described below regarding FIG. 31.

[234] The wireless device 2901 may receive, from the source base station 2902, the sixth message at step 2950. The sixth message may comprise a handover command and random access information. The handover command may comprise a command for a handover a cell of the source base station 2902 to a cell of the target base station 2903. At step 2960, the wireless device 2901 may obtain channel access by proceeding with a random access procedure with the target base station 2903. The wireless device 2901 may initiate the random access procedure by sending, to the target base station 2903, a seventh message comprising a random access preamble and data. The wireless device may transmit, to the target base station 2903, one or more transport blocks via radio resources of the cell of the target base station 2903, wherein the radio resources may be determined at least based on one or more elements of the sixth message. The transmitting, by the wireless device 2901, may further comprise transmitting a random access preamble overlapping in time with transmission of the one or more transport blocks. The sixth message may comprise, e.g., an indication for performing a two-step random access procedure, and/or a preamble identifier for a two-step random access procedure. The seventh message may comprise some or all of the information in step 2003 of the two-step random access procedure described above regarding FIG. 20. The wireless device 2901 may receive and process the sixth message in step 2950, and determine and send the seventh message in step 2960, using the procedures described below regarding FIG. 34.

[235] FIG. 30 shows an example of handover procedures 3000 for a wireless device. The procedures may start with step 3001 during which a wireless device, such as the wireless device 2801 and/or the wireless device 2901, measures target cell quality and serving cell quality. The wireless device may also measure cell quality of one or more neighboring cells that may become a target cell. The wireless device may make measurements to determine power of transmissions from one or more base stations in a respective one or

more neighboring cells. The wireless device may also measure the power of transmissions by a source base station, such as the source base station 2802 and/or the source base station 2902, that may be serving the wireless device. At step 3002, the wireless device may determine whether one or more measurement events have occurred. A measurement event may be an indication that a target cell quality may exceed a serving cell quality and/or may exceed a serving cell quality by an offset value. A measurement event may comprise, e.g., one or more of a determination that an RSRP and/or an RSRQ of a target cell (e.g., a cell of a target base station) is greater than a first threshold; a determination that an RSRP and/or an RSRQ of a source cell (e.g., a cell of a source base station) is less than a second threshold; a determination that an RSRP and/or an RSRQ of a target cell exceeds a an RSRP and/or RSRQ of a source cell and/or exceeds an RSRP and/or RSRQ of a source cell by an offset power value; and/or a determination that a time duration of maintaining a condition, such as one or more of the above conditions, is greater than or equal to a time threshold value. If the wireless device determines that one or more measurement events have not occurred, the wireless device may return to step 3001. If the wireless device determines that one or more measurement events have occurred, then the wireless device may send a measurement report to the source base station at step 3003, such as described above regarding step 2810 in FIG. 28 and/or step 2910 in FIG. 29. The wireless device may receive a handover command and RA information from a source base station at step 3004, such as described above regarding step 2850 in FIG. 28 and/or step 2950 in FIG. 29. The handover command and/or RA information may comprise an indication of a type of RA procedure that the wireless device is to perform for a handover to a target base station. The wireless device may proceed with a RA procedure for channel access with the target base station. The RA procedure may be based on the handover command and RA information received from the source base station. The process 3000 may end after step 3005, or the process 3000 may repeat after a time period or after an event that may trigger a measurement of target cell quality and/or serving cell quality, such as one or more indications of a transmission failure and/or one or more indications of a neighbor cell transmission.

[236] One or more additional steps (not shown) may also be performed by the wireless device, in between, before, or after, any of steps 3001-3005, e.g., to determine whether to initiate a handover, and/or to determine a type of RA procedure to use. Such additional steps may include power measurements, distance measurements, traffic measurements, moving speed of the wireless devices, determination of other cells available to the wireless

device, and any other network condition that may be used to determine a handover and/or a type of RA procedure.

[237] FIG. 31 shows an example of handover procedures 3100 for a source base station. The procedures may start with step 3101 during which a source base station, such as the source base station 2802 and/or the source base station 2902, receives a measurement report from a wireless device. Based on the measurement report, the source base station may determine, at step 3102, whether one or more handover triggering condition have been satisfied. The one or more handover triggering conditions may comprise some or all of the measurement events described above in step 3002 of FIG. 30. Additionally or alternatively, the one or more handover triggering conditions may comprise a determination that an RSRP and/or RSRQ of a target cell indicates better performance for a wireless device than an RSRP and/or RSRQ of other candidate target cells; a determination that a moving speed of a wireless device is slower than a threshold speed value; and/or a cell identifier of a target cell is, or is not, among one or more cells in a handover restriction. If the source base station determines that one or more handover triggering conditions have not occurred, the source base station may end the process 3100. If the source base station determines that one or more handover triggering conditions have occurred, then the source base station may proceed to step 3103.

[238] The source base station may determine, at step 3103, whether to proceed with handover procedures via direct communications (e.g., employing an Xn interface) with a target base station, or via indirect communications with a target base station, e.g., using a core network device such as 2904 as an intermediary. The source base station may base its determination of direct or indirect communications with the target base station on the type of connection it may have with the target base station. If the source base station and the target base station are capable of sufficiently timely direct communications with each other, such as via an Xn interface, then the source base station may determine to proceed with direct communications with the target base station, e.g., via steps 3104 and 3105, and/or via the process described above regarding FIG. 28. If the source base station and the target base station are not capable of sufficiently timely direct communications with each other, such as via an Xn interface (e.g., if these two base stations only communicate with each other via an X2 interface or if an X2 interface between these two base stations is not operating sufficiently to accommodate sufficiently timely communications), then the source base station may determine to proceed with indirect communications with the

target base station, e.g., via steps 3106 and 3107, and/or via the process described above regarding FIG. 29.

[239] At step 3104, a source base station may send a handover request message to a target base station, as described above regarding step 2830. At step 3105, the source base station may receive a handover request acknowledgement and RA information, as described above regarding step 2840. At step 3106, a source base station may send a handover required message to a core network device, such as core network device 2904, as described above regarding step 2925. At step 3107, the source base station may receive a handover required acknowledgement and RA information, as described above regarding step 2945. After step 3105 and/or after step 3107, the process may continue to step 3108. At step 3108, the source base station may process the handover request acknowledgement and/or RA information, and the source base station may send a handover command and RA information to the wireless device for handover to the target base station, as described above regarding step 2850. The process 3100 may end after step 3108.

[240] One or more of steps 3102-3103 may be omitted, or performed before or after other steps. Additional steps (not shown) may also be performed by the source base station, in between, before, or after, any of steps 3102-3103, e.g., to determine whether to initiate a handover of the wireless device, to determine whether to send one or more handover-related messages to a target base station and/or to a core network device, and/or to determine a type of RA procedure. Such additional steps may include power measurements, distance measurements, service type measurements (e.g., slice type, packet data unit session type, QoS flow type, bearer type, and/or QoS requirement), traffic measurements, moving speed of the wireless devices, determination of other cells available to the wireless device, and any other network condition that may be used to determine a handover and/or a type of RA procedure.

[241] FIG. 32 shows an example of handover procedures 3200 for a target base station. The procedures may start with step 3201 during which a target base station, such as the target base station 2803 and/or the target base station 2903, receives a handover request message for a wireless device. Based on the handover request message, the target base station may determine, at step 3202, whether the handover request is acceptable. The determination of whether the handover request is acceptable may be based on one or more of: whether radio resources are available for at least a default packet data unit session of the wireless device; whether a particular one or more service type are

supported at the target cell; whether an RSRP and/or an RSRQ satisfies a threshold; whether a moving speed of the wireless device is below a speed threshold; and/or whether a cause for the handover is reasonable, such as to provide emergency service or to reduce traffic load of a source cell (e.g., if an RSRP and/or RSRQ does not satisfy a threshold). If a determination is made that the handover request is not acceptable, then the process may continue to step 3203 and the target base station may send a handover failure message, after which the process 3200 may end. If a determination is made that the handover request is acceptable, then the process may continue to step 3204.

[242] At step 3204, the target base station may determine whether RSRP exceeds a power threshold. If RSRP exceeds a power threshold, the process may continue to step 3205, in which case the target base station may send a handover request acknowledgement message indicating a four-step random access procedure for handover. A four-step random access procedure may use less power per transmission than a two-step random access procedure, e.g., because a two-step random access procedure may transmit more information in each step relative to a four-step random access procedure. If RSRP does not exceed a power threshold, the process may continue to step 3206.

[243] At step 3206, the target base station may determine whether the wireless device requires latency sensitive service, such as for emergency or other time-sensitive messages. If the target base station determines that the wireless device does not require latency sensitive service, the target base station may determine, at step 3207, whether the size of the handover target cell is small, or below a threshold size (e.g., a time alignment may less (or not) affect communication between the target base station and the wireless device). If the target base station determines that the size of the target cell is below a threshold size, the target base station may determine, at step 3208, whether the wireless device supports a two-step RA procedure (e.g., based on UE capability information of the wireless device in the handover request message). If the target base station determines that the wireless device supports a two-step RA procedure, the target base station may determine, at step 3209, whether one or more random access resources for two-step RA are available at the target cell. If the target base station determines that each condition in steps 3204-3209 is satisfied, the target base station may send, at step 3210, a handover request acknowledgement message (e.g., to the source base station 2802 in step 2840 FIG. 28 and/or to the core network device 2904 in step 2940 FIG. 29) indicating a two-step RA procedure for the handover. If the target base station determines any one or more of the conditions in steps 32094-3209 are not satisfied, the target base station may send, at step

3205, a handover request acknowledgement (e.g., to the source base station 2802 in step 2840 FIG. 28 and/or to the core network device 2904 in step 2940 FIG. 29) indicating a four-step RA procedure for the handover. After sending a handover request acknowledgement message, in step 3205 or in step 3210, the target base station may proceed with a RA procedure (e.g., as in step 2860 in FIG. 28 and/or as in step 2960 in FIG. 29) with the wireless device for channel access, in step 3211 (e.g., by receiving a corresponding RA preamble from the wireless device). The process 3200 may end after step 3211.

[244] One or more of steps 3204-3209 may be omitted, or performed before or after any of the other steps 3204-3209. Additional steps (not shown) may also be performed by the target base station, in between, before, or after, any of steps 3204-3209, to determine whether to indicate, in a handover request acknowledgement, a four-step RA procedure or a two-step RA procedure. Such additional steps may include power measurements, distance measurements, traffic measurements, moving speed of the wireless devices, determination of other cells available to the wireless device, and any other network condition that may be used to determine a handover and/or a type of RA procedure.

[245] FIG. 33 shows an example of handover procedures 3300 for a core network device. The procedures may start with step 3301 during which a core network device, such as the core network device 2904 in FIG. 29, receives a handover required message from a source base station (e.g., a message in step 2925 in FIG. 29). At step 3302, the core network device may determine whether the wireless device requires latency sensitive service, such as for emergency or other time-sensitive messages. The core network device 2904 may determine whether the wireless device requires latency sensitive service based on, e.g., packet data unit session information of the wireless device. If latency services are not required, the process may continue to step 3304. If latency services are required by the wireless device, then at step 3303, the core network device may include a latency sensitive service indication in a handover request message, before continuing to step 3304. At step 3304, the core network device may send a handover request message to a target base station (e.g., as in step 2930 in FIG. 29). At step 3305, the core network device may receive a handover request acknowledgement and random access information from the target base station (e.g., as in step 2940 in FIG. 29). At step 3306, the core network device may send a handover required acknowledgement and random access information to the source base station (e.g., as in step 2945). The process 3300 may end after step 3306.

[246] One or more additional steps (not shown) may also be performed by the core network device, in between, before, or after, any of steps 3301-3305, e.g., to determine whether to send one or more handover messages, to determine what to include in one or more handover messages, and/or to determine a type of RA procedure to indicate in one or more handover messages. Such additional steps may include power measurements, distance measurements, traffic measurements, moving speed of the wireless devices, determination of other cells available to the wireless device, and any other network condition that may be used to determine a handover and/or a type of RA procedure.

[247] FIG. 34 shows an example of handover procedures 3400 for a wireless device. The procedures may start with step 3401 during which a wireless device, such as the wireless device 2801 and or the wireless device 2901, receives a handover command message from a source base station (e.g., as in step 2850 in FIG. 28 and/or as in step 2950 in FIG. 29). The handover command message may comprise random access information. At step 3402, the wireless device may determine, based on the random access information, whether the handover command message indicates a two-step random access procedure. If the wireless device determines that a two-step random access procedure is indicated, the wireless device, at step 3404, may send to a target base station a random access preamble for a two-step RA procedure. If the wireless device determines that a two-step random access procedure is not indicated in the handover command message, then the wireless device, at step 3403, may send to the target base station a random access preamble for a four-step RA procedure. After sending a random access preamble, the wireless device may continue with the particular random access procedure (e.g., a two-step RA procedure or a four-step RA procedure) at step 3405 (e.g., as in step 2860 in FIG. 28 and/or as in step 2960 in FIG. 29). The process 3400 may end after step 3405.

[248] One or more additional steps (not shown) may also be performed by the wireless device, in between, before, or after, any of steps 3401-3405, e.g., to determine whether to proceed with a handover, to determine one or more RA transmissions, and/or to determine a type of RA procedure to use. Such additional steps may include power measurements, distance measurements, traffic measurements, moving speed of the wireless devices, determination of other cells available to the wireless device, and any other network condition that may be used to determine a handover and/or a type of RA procedure.

[249] A wireless device may perform a method for determining a type of random access procedure to use for a handover from a source base station to a target base station. The wireless device may receive, from one or more cells, a plurality of messages comprising one or more of an indication of a power associated with a cell, an indication of a quality associated with a cell, and/or an indication of a cell priority. The wireless device may determine, based on the plurality of messages, a measurement report. The wireless device may transmit, to a first base station, a first message comprising a measurement report based on one or more second cells. The wireless device may receive, from the first base station, a second message comprising a command for a handover from the first cell to a second cell of the one or more second cells. The first cell may be a source cell for the wireless device, and the second cell may be a target cell. The second message may comprise one or more parameters indicating a type of a random access procedure for the handover. Additionally or alternatively, the second message may comprise timing advance information, e.g., for transmission of one or more uplink data and/or a random access preamble. The timing advance information may comprise one or more of an indication of a zero timing advance, or a value for a timing advance. The value for the timing advance may be estimated by the first base station and/or the second base station. One or more elements of the second message may be based on an acknowledgement received by the first base station, from the second base station, for the handover request. For a two-step random access procedure, the second message may comprise one or more of a preamble identifier for the RA procedure, random access channel configuration information for the RA procedure, random access resource information for the RA procedure, or radio resource configuration parameters. The wireless device may determine, based on the preamble identifier, radio resources to use for the RA procedure. For a four-step random access procedure, the second message may comprise a root sequence that the wireless may use to generate a random access preamble that the wireless device may transmit in a first step of the four-step RA procedure. The type of the random access procedure may comprise a two-step random access procedure or a four-step random access procedure. The wireless device may transmit, to the second base station, a random access preamble employing the type of random access procedure indicated in the second message. The wireless device may transmit, to the second base station, one or more transport blocks. The one or more transport blocks may comprise one or more of a handover complete message, uplink data, a buffer status report, or an identifier of the wireless device. The wireless device may transmit, to the second base station, a random access preamble overlapping in time with the one or more transport

blocks. The wireless device may transmit, in a first step of a four-step random access procedure, a second random access preamble. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[250] A first base station may perform a method for indicating a type of random access procedure in a handover from the first base station (e.g., a source base station) to a second base station (e.g., a target base station). The first base station may receive, from a wireless device, a first message comprising a measurement report based on one or more second cells. The first base station may be associated with a first cell. The first base station may determine, based on the measurement report, to handover the wireless device from the first cell to a second cell of the one or more second cells. The first cell may be a source cell for the wireless device, and the second cell may be a target cell. The first base station may transmit, to a third device, a second message comprising an indication for the handover. The third device may comprise the second base station that may be associated with the second cell. Additionally or alternatively, the third device may comprise a core network device. The third device may determine the second cell from a plurality of cells. The second message may comprise a handover request and/or an indication that a handover is requested. The first base station may receive, from the third device, a third message indicating a type of a random access procedure for the handover. The type of the random access procedure may comprise a two-step random access procedure or a four-step random access procedure. The first base station may transmit, to the wireless device, a fourth message. The fourth message may comprise one or more parameters indicating the type of the random access procedure for the handover and/or the fourth message may comprise a command to proceed with the handover. The fourth message may comprise timing advance information, e.g., for transmission of one or more uplink data or a random access preamble. The timing advance information may comprise one or more of an indication of a zero timing advance, or a value for a timing advance. The value for the timing advance may be estimated by the first base station and/or the third device. For a two-step random access procedure, the fourth message may comprise a preamble identifier for the RA procedure. The third device may transmit, to a second base station and based on the second message, a fifth message comprising a handover request. The third device may receive, from the second base station, a sixth message indicating the type of the random access procedure for the handover and comprising an

acknowledgement of the handover request. One or more base stations (e.g., a source base station, a target base station, etc.) may perform any combination of one or more of the above steps. A wireless device, a core network device, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[251] A network device may perform a method for indicating a type of random access procedure in a handover from a first base station (e.g., a source base station 2902) to a second base station (e.g., a target base station 2903). The network device may comprise a core network device (e.g., core network device 2904). Additionally or alternatively, the network device may comprise the second base station. The network device may receive, from a first base station, a first message comprising an indication for a handover of a wireless device from a first cell associated with the first base station to a second cell of one or more second cells. The second base station may be associated with the second cell. The first cell may be a source cell for the wireless device, and the second cell may be a target cell. The network device may determine the second cell from a plurality of cells. The network device may determine, based on the first message, to proceed with the handover. The network device may transmit, to the first base station a second message. The second message may comprise one or more of an acknowledgement for the handover, a handover request, an indication that a handover is required, or an indication of a type of a random access procedure for the handover. The type of the random access procedure may comprise a two-step random access procedure or a four-step random access procedure. The network device may transmit, to a second base station and based on the first message, a third message comprising a handover request. The network device may receive, from the second base station, a fourth message. The fourth message may indicate the type of the random access procedure for the handover. The fourth message may comprise an acknowledgement of the handover request. One or more network devices may perform any combination of one or more of the above steps. A wireless device, a base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[252] One or more of the messages described herein may be exchanged among one or more devices at a communication node in a network. One or more of the processes described herein may be performed in one or more devices in a network. For example, if an interface between a target base station (e.g., the target base station 2903) and a source base station (e.g., the source base station 2902) cannot accommodate sufficiently timely communications, such as if the interface between these base stations is not an Xn

interface of if an X2 interface between them is not operative, a core network device (e.g., the core network device 2904) may be used to perform handover processes and send and receive handover related messages described herein with respect to a target base station and/or a source base station. As another example, if a wireless device (e.g., the wireless device 2801 and/or the wireless device 2901) is a fast moving device, a source base station (e.g., the source base station 2801 and/or the source base station 2902) may be used to perform handover processes and send and receive handover related messages described herein with respect to a target base station and/or a core network device. As another example, if a wireless device (e.g., the wireless device 2801 and/or the wireless device 2901) has latency sensitive information, such as emergency information, and if a source base station cannot accommodate the wireless device transmissions and cannot perform a handover decision in a sufficiently timely manner, the wireless device may perform handover processes and send and receive handover related messages described herein with respect to a source base station, a target base station, and/or a core network device.

[253] A wireless device within a network may utilize power demands for transmissions and a power threshold to determine a type of random access (RA) procedure with which to communicate with a base station of the network. The type of RA procedure may be indicated by one or more indicators in one or more messages sent from the base station. The one or more indicators may correspond with transmission power levels associated with random access procedure parameters.

[254] FIG. 35 shows an example of a network 3500 comprising a base station 3502, a first wireless device 3504, and a second wireless device 3506. The network 3500 may comprise any number and/or type of devices, such as, for example, wireless devices, mobile devices, handsets, tablets, laptops, Internet-of-Things (IoT) devices, hotspots, cellular repeaters, computing devices, and/or, more generally, user equipment (UE). Although one or more of the above types of devices may be referenced herein (e.g., UE, wireless device, etc.), it should be understood that any device herein may comprise one or more of the above types of devices or similar devices.

[255] The first wireless device 3504 may be a first distance D1 from the base station 3502. The second wireless device 3506 may be a second distance D2 from the base station 3502. The second wireless device 3506 may be farther from the base station 3502 than the first wireless device 3504. The second wireless device 3506 may be at or near an edge of a

cell 3508, which may be a maximum range at which the wireless device 3506 may be able to communicate, via the cell 3508, with the base station 3502. As the distance between a wireless device (e.g., the first wireless device 3504 or the second wireless device 3506) and the base station 3502 increases, the power required by a wireless device to transmit messages, via the cell 3508, to the base station 3502 may increase. Larger distances may require additional power due to path loss. Wireless devices (e.g., the first wireless device 3504 and/or the second wireless device 3506) may have a maximum transmission power that may not be exceeded for transmissions, via a cell (e.g., the cell 3508), to a base station (e.g., the base station 3502). The maximum transmission power may not be exceeded by the wireless device when transmitting, e.g., a preamble and data at the same time and/or within a same transmission, such as during a two-step random access procedure.

[256] The base station 3502 may initially send configuration parameters to one or more wireless devices 3504, 3506. The configuration parameters may comprise, e.g., one or more target power levels requested by the base station 3502 to ensure preamble and/or data transmissions are successfully received and decoded by the base station 3502 (e.g., preamble_received_target_power for preamble transmissions and/or $P_{\text{O_PUSCH},c}(j)$ for PUSCH data transmissions), a reference signal that allows each of the one or more wireless devices 3504, 3506 to determine its estimated path loss (e.g., a reduction of power of a transmission as it travels through space), a maximum power level that the one or more wireless devices 3504, 3506 may not exceed during a transmission, and/or offset data. The one or more wireless devices 3504, 3506 may utilize one or more of these configuration parameters to determine, e.g., one or more of a type of random access procedure, a power level for a transmission, a power priority for a transmission, a power adjustment, and/or whether to drop a configured transmission.

[257] Power control mechanisms may be used by a wireless device and/or a base station, e.g., when the wireless device transmission power nears a maximum threshold. The following processes may be implemented in technologies such as LTE, 5G or New Radio, and/or other technologies, each of which may have its own specific parameters. Physical layer power control mechanisms may be enhanced, such as when layer 2 parameters are taken into account. Downlink power control may determine, e.g., an Energy Per Resource Element (EPRE). The term resource element energy may correspond to the energy prior to CP insertion. The term resource element energy may correspond to an average energy

taken over all constellation points for an applied modulation scheme. Uplink power control may determine e.g., the average power over a SC-FDMA symbol in which the physical channel may be transmitted. Uplink power control may control the transmit power of different uplink physical channels.

[258] If a UE (e.g., one of the one or more wireless devices 3504, 3506) is configured with an LAA SCell for uplink transmissions, the UE may apply the procedures described for a Physical Uplink Shared Channel (PUSCH) transmission and/or a Sounding Reference Signal (SRS) transmission, e.g., based on a frame structure type 1 for the LAA SCell. For PUSCH data, the transmit power, $\hat{P}_{\mathrm{PUSCH},c}(i)$, may be first scaled by the ratio of the number of antennas ports with a non-zero PUSCH transmission to the number of configured antenna ports for the transmission scheme. The resulting scaled power may be split equally across the antenna ports on which the non-zero PUSCH is transmitted. For Physical Uplink Control Channel (PUCCH) and/or SRS, the transmit power, $\hat{P}_{\mathrm{PUCCH}}(i)$ and/or $\hat{P}_{\mathrm{SRS},c}(i)$, may be split equally across the configured antenna ports. $\hat{P}_{\mathrm{SRS},c}(i)$ may correspond to a linear value of $P_{\mathrm{SRS},c}(i)$. A cell wide overload indicator and a High Interference Indicator to control UL interference may be parameters used, e.g., in LTE technology, for making power determinations.

[259] For a serving cell with frame structure type 1, a UE may not be configured with *UplinkPowerControlDedicated-v12x0*. If the UE is configured with a secondary cell group (SCG), the UE may apply the procedures described for both a master cell group (MCG) and the SCG. When the procedures are applied for MCG, the terms secondary cell(s) and/or serving cell(s) may refer to secondary cell(s) and/or serving cell(s) belonging to the MCG respectively. When the procedures are applied for a SCG, the terms secondary cell(s) and/or serving cell(s) may refer to secondary cell(s) (not including PSCell) and/or serving cell(s) belonging to the SCG, respectively. The term primary cell may refer to the PSCell of the SCG.

[260] If the UE is configured with a PUCCH-SCell, the UE may apply the procedures described for both the primary PUCCH group and the secondary PUCCH group. When the procedures are applied for the primary PUCCH group, the terms secondary cell(s) and/or serving cell(s) may refer to secondary cell(s) and/or serving cell(s) belonging to the primary PUCCH group, respectively. When the procedures are applied for the secondary PUCCH group, the terms secondary cell(s) and/or serving cell(s) may refer to

secondary cell(s) and/or serving cell(s) belonging to the secondary PUCCH group, respectively.

[261] The setting of the UE Transmit power for a PUSCH transmission may be determined as follows. If the UE transmits a PUSCH transmission without a simultaneous or overlapping Physical Uplink Control Channel (PUCCH) transmission, for the serving cell c and with a PRACH transmission ($\hat{P}_{\text{PRACH}}$=0 if no PRACH transmission), then the UE transmit power $P_{\text{PUSCH},c}(i)$ for a PUSCH transmission in subframe i for the serving cell c may be determined by:

$$P_{\text{PUSCH},c}(i) = \min\begin{Bmatrix} 10\log_{10}\left(\hat{P}_{\text{CMAX},c}(i) - \hat{P}_{\text{PRACH}}(i)\right), \\ 10\log_{10}(M_{\text{PUSCH},c}(i)) + P_{\text{O_PUSCH},c}(j) + \alpha_c(j)\cdot PL_c + \Delta_{\text{TF},c}(i) + f_c(i) \end{Bmatrix} \text{ [dBm]}$$

wherein $\hat{P}_{\text{CMAX},c}(i)$ may correspond to the UE maximum transmit power, $\hat{P}_{\text{PRACH}}(i)$ may correspond to the preamble transmission power, $P_{\text{O_PUSCH},c}(j)$ may correspond to a target power required by the base station for decoding a message sent by a UE, PL_c may correspond to an estimated path loss based on a distance that the UE is from a base station, $M_{\text{PUSCH},c}(i)$ may correspond to the bandwidth of the PUSCH resource assignment (e.g., expressed in number of resource blocks valid for subframe i and serving cell c), and $\Delta_{\text{TF},c}(i) + f_c(i)$ may correspond to offset data. The path loss may increase exponentially based on the distance that the UE is from a corresponding base station.

[262] If the UE transmits a PUSCH transmission simultaneously with or at least partially overlapping with a PUCCH transmission and a PRACH transmission, for the serving cell c, then the UE transmit power $P_{\text{PUSCH},c}(i)$ for the PUSCH transmission in subframe i for the serving cell c may be determined by:

$$P_{\text{PUSCH},c}(i) = \min\begin{Bmatrix} 10\log_{10}\left(\hat{P}_{\text{CMAX},c}(i) - \hat{P}_{\text{PUCCH}}(i) - \hat{P}_{\text{PRACH}}(i)\right), \\ 10\log_{10}(M_{\text{PUSCH},c}(i)) + P_{\text{O_PUSCH},c}(j) + \alpha_c(j)\cdot PL_c + \Delta_{\text{TF},c}(i) + f_c(i) \end{Bmatrix} \text{ [dBm]}$$

where $\hat{P}_{\text{PUCCH}}(i)$ may correspond to a linear value of $P_{\text{PUCCH}}(i)$.

[263] If the UE is not transmitting a PUSCH transmission for the serving cell c, then for the accumulation of a transmit power control (TPC) command received with DCI format 3 or

format 3A for PUSCH, the UE may determine a virtual transmit power $P_{\text{PUSCH},c}(i)$ for the PUSCH transmission in subframe i for the serving cell c according to:

$$P_{\text{PUSCH}c}(i) = \min\left\{P_{\text{CMAX}c}(i),\ P_{\text{O_PUSCH}c}(1) + \alpha_c(1)\cdot PL_c + f_c(i)\right\} \quad \text{[dBm]}$$

[264] One or more transmission powers may be prioritized, e.g., when simultaneous or at least partially overlapping transmissions may otherwise cause a UE to reach or exceed a maximum allowable transmission power. For a two-step random access procedure, a PRACH transmission power may be assigned a higher priority than a PUSCH transmission power. A PRACH transmission power and a PUCCH transmission power may both have a higher priority than a PUSCH transmission power. A UE may not have enough power for overlapping transmissions (e.g., simultaneous or at least partially overlapping transmissions) of a PRACH transmission, a PUCCH transmission, and a PUSCH transmission. The UE may change a type of RA procedure used, adjust power (e.g., scale, decrease, and/or increase), re-transmit, and/or drop one or more transmissions to satisfy a transmission power threshold and/or to conserve power.

[265] If a UE does not have enough power to transmit both a PUSCH transmission and a PRACH transmission, e.g., in an overlapping transmission during a first step of a two-step RA procedure (e.g., $\hat{P}_{\text{CMAX},c}(i) \le \hat{P}_{\text{PUSCH}}(i) + \hat{P}_{\text{PRACH}}(i)$), the UE may fall back to a four-step random access procedure and transmit or retransmit the PRACH transmission (e.g., a random access preamble and/or a UE identifier) prior to a transmission or retransmission of the PUSCH transmission. Additionally or alternatively, the UE may determine resources for a four-step RA procedure (e.g., preamble, random access resource, subframe, etc.) to initiate a four-step RA procedure instead of a two-step RA procedure, e.g., based on a power determination. A bandwidth reduced low complexity or coverage enhanced (BL/CE) UE may set $\hat{P}_{\text{PRACH}}(i) = \hat{P}_{\text{CMAX},c}(i)$, and if so, the UE may not start the two-step RA procedure.

[266] The UE may perform one or more measurements to determine whether to use a two-step RA procedure or a 4-step RA procedure. The UE may measure, e.g., link signal strength and/or a quality of one or more cells, and use such measurements (that may be in addition to other parameters, e.g., logical channel, etc.) to make a decision on whether to use a two-step RA procedure or a four-step RA procedure. The base station may transmit one or more parameters, such as link quality and/or a power parameter, for use by the

wireless device in determining a type of RA procedure to use. The wireless device may use the parameters in making a decision on whether start a two-step RA procedure or a four-step RA procedure.

[267] FIG. 36 shows an example of a process 3600 that may be performed by one or more of the wireless devices (e.g., the second wireless device 3506) for determining whether to initiate a two-step or four-step random access procedure. While examples herein reference the second wireless device 3506, the methods, systems, and apparatuses disclosed herein may be applicable to all devices capable of communication with a base station. Additionally or alternatively, some or all of the steps in the process 3600 may be performed by a base station (e.g., the base station 3502) and/or one or more other devices (e.g., at a node in a 5G core network). The process 3600 may begin, at step 3602, with configuration of devices (e.g., the base station 3502, the first wireless device 3504, and/or the second wireless device 3506). At step 3604, the second wireless device 3506 may receive first parameters transmitted from the base station 3502 (3604). At step 3606, the second wireless device 3506 may perform one or more measurements for one or more cells to obtain second parameters, such as link signal strength and/or quality of the cell 3508 and/or of one or more neighbouring cells. After receiving the first and/or second parameters, the second wireless device 3506 may determine to perform a two-step random access procedure and, at step 3608, the second wireless device 3506 may initiate the two-step random access procedure.

[268] Based on the parameters received at step 3604 and/or the measurements determined at step 3606, the second wireless device 3506 may select resources for the two-step random access procedure at step 3610. The second wireless device 3506 may determine, at step 3612, whether current parameters (e.g., link signal strength, quality of one or more cells, transmission power for selected resources, etc.) are sufficient for sending messages via the two-step random access procedure. For example, the second wireless device 3506 may compare a transmission power for selected resources (e.g., preamble transmission power $\hat{P}_{\mathrm{PRACH}}(i)$, data transmission power, $P_{\mathrm{PUSCH},c}(i)$ and/or $\hat{P}_{\mathrm{PUCCH}}(i)$, etc.) to a maximum transmission power of the second wireless device 3506 in the cell 3508 (e.g., $P_{\mathrm{CMAX},c}$). If the current parameters are sufficient for sending messages via the two-step random access procedure (e.g., 3612: YES), the process may proceed to step 3618. If the current parameters are not sufficient for sending messages via the two-step random access procedure (e.g., 3612: NO), then the second wireless device 3506 may initiate a

four-step random access procedure at step 3614. The second wireless device 3506 may select resources for the four-step random access procedure, at step 3616. At step 3618, the second wireless device 3506 may transmit one or more messages based on the selected resources (e.g., two-step RA resource or four-step RA resources) and parameters of the second wireless device 3506 (e.g., link signal strength, quality of one or more cells, transmission power for selected resources, etc.). Thereafter, the process 3600 may end. Process 3600 may be repeated, looped, combined, paused, or performed in parallel with other processes.

[269] If $\hat{P}_{\text{CMAX},c}(i) \leq \hat{P}_{\text{PRACH}}(i)$, then PUSCH (e.g. at least one data transport block) may be dropped and may not be transmitted. If $\hat{P}_{\text{CMAX},c}(i) \leq \hat{P}_{\text{PUCCH}}(i) + \hat{P}_{\text{PRACH}}(i)$, then PUSCH may be dropped and may not be transmitted.

[270] FIG. 37 shows an example of a process 3700 that may be performed by one or more of the wireless devices (e.g., the second wireless device 3506) for determining whether to drop data transmissions, e.g., in order to successfully perform a two-step random access procedure. While examples herein reference the second wireless device 3506, the methods, systems, and apparatuses disclosed herein may be applicable to all devices capable of communication with a base station. Additionally or alternatively, some or all of the steps in the process 3700 may be performed by a base station (e.g., the base station 3502) and/or one or more other devices (e.g., at a node in a 5G core network). The process 3700 may begin, at step 3702, with configuration of devices (e.g., the base station 3502, the first wireless device 3504, and/or the second wireless device 3506). The second wireless device 3506 may receive first parameters transmitted from the base station 3502 (3704). The second wireless device AA06 may measure second parameters such as, for example, link signal strength and/or quality of the cell 3508 (3706). After receiving the first and/or second parameters, the second wireless device 3506 may initiate a two-step random access procedure (3708).

[271] Based on the first and/or second parameters, the second wireless device 3506 may select resources for the two-step random access procedure (3710). The second wireless device 3506 may determine whether the current (e.g., first and/or second) parameters (e.g., link signal strength, quality of cell, transmission power for selected resources, etc.) are sufficient for sending messages via the two-step random access procedure (3712). If the current parameters are sufficient for sending messages via the two-step random access

procedure (3712: YES), the process 3700 may proceeds to step 3722. If the current parameters are not sufficient for sending messages via the two-step random access procedure (3712: NO), then the second wireless device 3506 may determine whether a PUCCH transmission is scheduled (3714). At step 3714, if it is determined that there are no PUCCH transmissions scheduled (3714: NO), then the second wireless device 3506 may drop a configured PUSCH transmission, at step 3716, and the process 3700 may return to step 3712.

[272] If there is a PUCCH transmission scheduled (3714: YES), then, at step 3718, the second wireless device 3506 may determine whether a PUSCH transmission is scheduled for a transmission overlapping with the PUCCH transmission. If there is a PUSCH transmission scheduled (3718: YES), then the process 3700 may return to step 3716. If there are no PUSCH transmissions scheduled (3718: NO), then the second wireless device 3506 may drop the configured PUCCH transmission (3720), and the process 3700 may return to step 3712. At step 3722, the second wireless device 3506 may transmit, via the two-step random access procedure, one or more messages based on the selected resources and first and/or second parameters. Thereafter, the process 3700 may end. Process 3700 may be repeated, looped, combined, paused, or performed in parallel with other processes.

[273] If the preamble and data transmitted by a UE are not successfully decoded by the base station, the UE may ramp up a preamble power and/or a data power. The UE may retransmit the preamble and/or the data (e.g., with the same HARQ RV or different HARQ RV depending on UE implementation) to the base station. The base station may transmit, to the wireless device (e.g., via a broadcast such as a SIB message, and/or via dedicated RRC signalling), a first ramp up power for the preamble and a second ramp up power for the data. The UE may employ the ramp up power parameters to calculate one or more re-transmission powers.

[274] FIG. 38 shows an example of a process 3800 that may be performed by one or more of the wireless devices (e.g., the second wireless device 3506) for determining whether to adjust transmission power for preamble and/or data transmissions, e.g., in order to successfully perform a two-step random access procedure. While examples herein reference the second wireless device 3506, the methods, systems, and apparatuses disclosed herein may be applicable to all devices capable of communication with a base station. Additionally or alternatively, some or all of the steps in the process 3800 may be

performed by a base station (e.g., the base station 3502) and/or one or more other devices (e.g., at a node in a 5G core network). The process 3800 may begin with configuration of devices (e.g., the base station 3502, the first wireless device 3504, and/or the second wireless device 3506) (3802). The second wireless device 3506 may receive first parameters transmitted from the base station 3502 (3804). The received first parameters may comprise a first ramp-up power value associated with a preamble transmission power and a second ramp-up power value associated with a data transmission power. The second wireless device 3506 may measure second parameters such as, for example, link signal strength and/or quality of the cell 3508 (3806). After receiving the first and/or second parameters, the second wireless device 3506 may initiate a two-step random access procedure (3808).

[275] Based on the first and/or parameters, the second wireless device 3506 may select resources for the two-step random access procedure (3810). At step 3812, the second wireless device 3506 may transmit, via the two-step random access procedure, one or more messages based on the selected resources and first and/or second parameters. At step 3814, the second wireless device 3506 may wait a threshold amount of time for a response to the one or more transmitted messages. If the second wireless device 3506 receives a response to the one or more transmitted messages within the threshold amount of time (3814: YES), the process 3800 may end. At step 3816, if the second wireless device 3506 does not receive a response to the one or more transmitted messages within the threshold amount of time (3814: NO), or if the second wireless device 3506 receives one or more messages indicating a failure of the base station receiving and/or decoding the one or more transmitted messages, the second wireless device may adjust (e.g., scale, increase, etc.), based on the first ramp-up power value, the transmission power for the preamble transmission, and/or adjust, based on the second ramp-up power value, the transmission power for the data transmission. The process 3800 may return to step 3812, and the second wireless device 3506 may retransmit the one or more messages using an adjusted transmission power determined from step 3816. Steps 3812-3816 may be repeated one or more times, and/or the process may end after a threshold number of times step 3814 is performed. The process 3800 may be repeated, looped, combined, paused or performed in parallel with other processes.

[276] The UE may fall back to a four-step random access procedure if a total calculated power of at least the preamble and/or data exceeds a predetermined value (e.g. a maximum allowable transmission power of the UE). If the preamble power and/or a data power in a

re-transmission exceeds a predetermine value (e.g., a maximum allowable transmission power of the UE), the UE may adjust (e.g., scale, decrease, etc.) the data transmission power such that the total transmission power of the UE may be below the predetermined value. The UE may fall back to a four-step RA procedure, e.g., if a calculated data power is below a threshold value (e.g. a minimum transmission power level indicated by the base station).

[277] FIG. 39 shows an example of a process 3900 that may be performed by one or more of the wireless devices (e.g., the second wireless device 3506) for recalculating transmission power for preamble and/or data transmissions, adjusting transmission power for data transmissions, and/or determining whether to perform a four-step random access procedure based on the transmission power for the data transmissions. While examples herein reference the second wireless device 3506, the methods, systems, and apparatuses disclosed herein may be applicable to all devices capable of communication with a base station. Additionally or alternatively, some or all of the steps in the process 3900 may be performed by a base station (e.g., the base station 3502) and/or one or more other devices (e.g., at a node in a 5G core network). At step 3902, the process 3900 may begin with configuration of devices (e.g., the base station 3502, the first wireless device 3504, and/or the second wireless device 3506). The second wireless device 3506 may receive first parameters transmitted from the base station 3502 (3904). The second wireless device 3506 may measure second parameters, such as, for example, link signal strength and/or quality of the cell (3906). After receiving the first and/or second parameters, the second wireless device 3506 may initiate a two-step random access procedure (3908).

[278] Based on the parameters received at 3904, the second wireless device 3506 may select resources for the two-step random access procedure (3910). The second wireless device 3506 may transmit, via the two-step random access procedure, one or more messages based on the selected resources and first and/or second parameters (3912). The second wireless device 3506 may wait a threshold amount of time for a response to the one or more transmitted messages from a base station. If the second wireless device 3506 receives a response to the one or more transmitted messages within the threshold amount of time (3914: YES), the process 3900 may cease.

[279] At step 3916, if the second wireless device 3506 does not receive a response to the one or more transmitted messages within the threshold amount of time (3914: NO), or if the second wireless device 3506 receives one or more messages indicating a failure of the

base station receiving and/or decoding the one or more transmitted messages, the second wireless device may recalculate total transmission power for the second wireless device 3506. The total transmission power may comprise a first power for the preamble transmission and a second power for the data transmission. At step 3918, the second wireless device 3506 may determine whether the recalculated total transmission power exceeds a first threshold power value (e.g., $P_{CMAX,c}(i)$). If the recalculated total transmission power does not exceed the first threshold power value (3918: NO), the process 3900 may return to step 3912. If the recalculated total transmission power exceeds the first threshold power value (3918: YES), then, at step 3920, the second wireless device 3506 may adjust (e.g., scale, decrease, etc.) the second power for the data transmission. At step 3922, the second wireless device 3506 may determine whether the scaled second power is below a second threshold value (e.g., a minimum power for a successful transmission).

[280] If the scaled second power is not below the second threshold value (3922: NO), then the process 3900 may return to step 3912. If the scaled second power is below the second threshold value (3922: YES), then, at step 3924, the second wireless device may initiate a four-step random access procedure. At step 3926, the second wireless device 3506 may select resources for the four-step random access procedure. Thereafter, at step 3928, the second wireless device 3506 may transmit, via the four-step random access procedure, one or more messages based on the selected resources and first and/or second parameters. After step 3928, the process 3900 may end. Process 3900 may be repeated, looped, combined, paused, or performed in parallel with other processes.

[281] The base station 3502 may communicate with the wireless devices 3504, 3506. For example, with reference to FIG. 20, the base station 3502 may send parameters to one or more of the wireless devices 3504, 3506. The parameters may include one or more parameters for a two-step random access procedure and one or more parameters for a four-step random access procedure. The base station 3502 may receive, from one of the one or more wireless devices 3504, 3506, a message indicating one of the two-step random access procedure or the four-step random access procedure. Based on the message, the base station 3502 may determine that further communications with that particular wireless device may continue or default to the random access procedure indicated in the message. The base station may communicate with other base stations to

provide such information as a wireless device preferences such as, for example, during a handover procedure.

[282] Various equations are set forth below for determining the parameters discussed above in a variety of examples. For example, $\hat{P}_{\text{PRACH}}(i)$ may correspond to a linear value of a preamble transmission power, $P_{\text{PRACH}}(i)$. For a BL/CE UE, a number of PRACH repetitions for a preamble transmission attempt may be indicated by higher layers, e.g., as part of the request. For a non-BL/CE UE, or for a BL/CE UE with the PRACH coverage enhancement level 0/1/2, a preamble transmission power P_{PRACH} may be determined by:

$$P_{\text{PRACH}}(i) = \min\{ P_{\text{CMAX},c}(i),\ \text{PREAMBLE_RECEIVED_TARGET_POWER} + PL_c \}\ \text{[dBm]},$$

where $P_{\text{CMAX},c}(i)$ may correspond to a configured UE transmit power for subframe i of serving cell c, PL_c may correspond to a downlink path loss estimate that may be calculated (e.g., based on a distance the UE is from a base station) by the UE for serving cell c, and PREAMBLE_RECEIVED_TARGET_POWER may correspond to a target preamble received power that may be indicated by higher layers (e.g., via broadcast system information) as part of the request. For a BL/CE UE, P_{PRACH} may be set to $P_{\text{CMAX},c}(i)$ for the highest PRACH coverage enhancement level 3. The downlink path loss may increase exponentially based on the distance of the wireless device from a corresponding base station.

[283] PREAMBLE_RECEIVED_TARGET_POWER may be determined by:

preambleInitialReceivedTargetPower + DELTA_PREAMBLE +
(PREAMBLE_TRANSMISSION_COUNTER – 1) * powerRampingStep;

[284] If the UE is a BL/CE UE, then the PREAMBLE_RECEIVED_TARGET_POWER may be determined by:

PREAMBLE_RECEIVED_TARGET_POWER - 10 *
log10(numRepetitionPerPreambleAttempt)

[285] If the UE is an narrowband Internet-of-Things (NB-IoT) device in enhanced coverage level 0, the PREAMBLE_RECEIVED_TARGET_POWER may be determined by:

PREAMBLE_RECEIVED_TARGET_POWER - 10 *
log10(numRepetitionPerPreambleAttempt)

For other enhanced coverage levels (e.g., not enhanced coverage level 0), the PREAMBLE_RECEIVED_TARGET_POWER for an NB-IoT UE may be determined based on the maximum allowable UE transmission power.

[286] If the UE is an NB-IoT UE or a BL/CE UE, the UE may select a preamble from a preamble group and instruct the physical layer to transmit the selected preamble according to a number of repetitions for preamble transmission (e.g., numRepetitionPerPreambleAttempt). numRepetitionPerPreambleAttempt may correspond to the preamble group. The UE may instruct the physical lay to transmit the selected preamble using the selected PRACH corresponding to a selected enhanced coverage level, corresponding RA-RNTI, preamble index or for NB-IoT subcarrier index, and PREAMBLE_RECEIVED_TARGET_POWER.

[287] If the UE is not an NB-IoT UE or a BL/CE UE, the UE may instruct the physical layer to transmit a preamble using the selected PRACH, corresponding RA-RNTI, preamble index and PREAMBLE_RECEIVED_TARGET_POWER.

[288] The DELTA_PREAMBLE preamble format based power offset values may correspond to one or more values in Table 1, which may be determined by *prach-ConfigIndex*.

Preamble Format	DELTA_PREAMBLE value
0	0 dB
1	0 dB
2	-3 dB
3	-3 dB
4	8 dB

Table 1: DELTA_PREAMBLE values.

[289] The UE may acquire *preambleInitialReceivedTargetPower*, *powerRampingStep* and/or *prach-ConfigIndex* via a system information broadcast by a base station.

[290] $P_{\mathrm{CMAX},c}(i)$ may correspond to a configured UE transmit power in subframe i for serving cell c, and $\hat{P}_{\mathrm{CMAX}c}(i)$ may correspond to a linear value of $P_{\mathrm{CMAX},c}(i)$. If the UE transmits a PUCCH transmission without an overlapping PUSCH transmission, in subframe i for the serving cell c, then for the accumulation of TPC command received with DCI format 3 or format 3A for PUSCH, the UE may assume the value of $P_{\mathrm{CMAX},c}(i)$, based on a standards document. If the UE does not transmit a PUCCH transmission and an

overlapping PUSCH transmission, in subframe i for the serving cell c, then for the accumulation of TPC command received with DCI format 3 or format 3A for PUSCH, the UE may determine $P_{CMAX,c}(i)$ based on MPR=0dB, A-MPR=0dB, P-MPR=0dB and ΔT_C =0dB, where MPR, A-MPR, P-MPR and ΔT_C may be pre-defined in LTE technology.

[291] If the UE is configured with a higher layer parameter, e.g., *UplinkPowerControlDedicated-v12x0* for serving cell c, and if subframe i belongs to uplink power control subframe set 2, such as may be indicated by the higher layer parameter *tpc-SubframeSet-r12*, then: for j=2, $\alpha_c(j) = 1$; for j=0 or 1, $\alpha_c(j) = \alpha_{c,2} \in \{0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1\}$. $\alpha_{c,2}$ may correspond to the parameter *alpha-SubframeSet2-r12* that may be provided by higher layers for each serving cell c.

[292] If the UE is not configured with a higher layer parameter, e.g., *UplinkPowerControlDedicated-v12x0* for serving cell c, or if subframe i belongs to uplink power control subframe set 2, then, for j=2, $\alpha_c(j) = 1$.; for j =0 or 1, $\alpha_c \in \{0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1\}$ may correspond to a 3-bit parameter provided by higher layers for serving cell c.

[293] PL_c may correspond to the downlink path loss estimate that may be calculated by the UE for serving cell c, e.g., in dB. The downlink path loss estimate may be determined by PL_c = *referenceSignalPower*–higher layer filtered reference signal received power (RSRP). *referenceSignalPower* may be provided by higher layers and may correspond to an initial power level that the base station may use to transmit a reference signal. The base station may send the *referenceSignalPower* as a configuration parameter. The higher layer filtered RSRP may correspond to a power level of the reference signal as received by UE. By subtracting the received power level (e.g., higher layer filtered RSRP) from the initial power level (*referenceSignalPower*), the UE may determine the power lost during transmission (e.g., the downlink path loss PL_c).

[294] If serving cell c belongs to a TAG containing the primary cell, then, for the uplink of the primary cell, the primary cell may be used as the reference serving cell for determining *referenceSignalPower* and higher layer filtered RSRP. For the uplink of the secondary cell, the serving cell configured by the higher layer parameter *pathlossReferenceLinking*

may be used as the reference serving cell for determining *referenceSignalPower* and higher layer filtered RSRP.

[295] If serving cell c belongs to a TAG comprising the PSCell, then, for the uplink of the PSCell, the PSCell may be used as the reference serving cell for determining *referenceSignalPower* and higher layer filtered RSRP; and for the uplink of the secondary cell other than PSCell, the serving cell configured by the higher layer parameter *pathlossReferenceLinking* may be used as the reference serving cell for determining *referenceSignalPower* and higher layer filtered RSRP. If serving cell c belongs to a TAG that does not comprise the primary cell or the PSCell, then serving cell c may be used as the reference serving cell for determining *referenceSignalPower* and higher layer filtered RSRP.

[296] If the UE is configured with a higher layer parameter, e.g., *UplinkPowerControlDedicated-v12x0*, for serving cell c, and if subframe i belongs to uplink power control subframe set 2, as may be indicated by the higher layer parameter *tpc-SubframeSet-r12*, then:

[297] When j=0, $P_{O_PUSCH,c}(0) = P_{O_UE_PUSCH,c,2}(0) + P_{O_NOMINAL_PUSCH,c,2}(0)$, where j=0 may be used for PUSCH (re)transmissions corresponding to a semi-persistent grant. $P_{O_UE_PUSCH,c,2}(0)$ and $P_{O_NOMINAL_PUSCH,c,2}(0)$ may correspond to parameters *p0-UE-PUSCH-Persistent-SubframeSet2-r12* and *p0-NominalPUSCH-Persistent-SubframeSet2-r12* respectively provided by higher layers, for each serving cell c.

[298] When j=1, $P_{O_PUSCH,c}(1) = P_{O_UE_PUSCH,c,2}(1) + P_{O_NOMINAL_PUSCH,c,2}(1)$, where j=1 may be used for PUSCH (re)transmissions corresponding to a dynamic scheduled grant. $P_{O_UE_PUSCH,c,2}(1)$ and $P_{O_NOMINAL_PUSCH,c,2}(1)$ may correspond to parameters *p0-UE-PUSCH-SubframeSet2-r12* and *p0-NominalPUSCH-SubframeSet2-r12* respectively, provided by higher layers for serving cell c.

[299] When j=2, $P_{O_PUSCH,c}(2) = P_{O_UE_PUSCH,c}(2) + P_{O_NOMINAL_PUSCH,c}(2)$ where $P_{O_UE_PUSCH,c}(2) = 0$ and $P_{O_NOMINAL_PUSCH,c}(2) = P_{O_PRE} + \Delta_{PREAMBLE_Msg3}$, where the parameter *preambleInitialReceivedTargetPower* (P_{O_PR}) and $\Delta_{PREAMBLE_Msg3}$ may be

signalled from higher layers for serving cell c, where j=2 may be used for PUSCH transmissions and/or PUSCH retransmissions corresponding to the random access response grant.

[300] When j ≠0, 1, or 2, $P_{O_PUSCH,c}(j)$ may be a parameter composed of the sum of a component $P_{O_NOMINAL_PUSCH,c}(j)$ provided from higher layers for $j=0$ and 1 and a component $P_{O_UE_PUSCH,c}(j)$ provided by higher layers for $j=0$ and 1 for serving cell c. For PUSCH transmissions and/or PUSCH retransmissions corresponding to a semi-persistent grant then $j=0$, for PUSCH transmissions and/or PUSCH retransmissions corresponding to a dynamic scheduled grant then $j=1$ and for PUSCH transmissions and/or PUSCH retransmissions corresponding to the random access response grant then $j=2$. $P_{O_UE_PUSCH,c}(2)=0$ and $P_{O_NOMINAL_PUSCH,c}(2)=P_{O_PRE}+\Delta_{PREAMBLE_Msg3}$, where the parameter *preambleInitialReceivedTargetPower* (P_{O_PR}) and $\Delta_{PREAMBLE_Msg3}$ may be signalled from higher layers for serving cell c.

[301] $\Delta_{TF,c}(i)=10\log_{10}\left(\left(2^{BPRE\cdot K_s}-1\right)\cdot\beta_{offset}^{PUSCH}\right)$ for $K_S=1.25$ and 0 for $K_S=0$ where K_S may be determined based on the parameter *deltaMCS-Enabled* provided by higher layers for each serving cell c. $BPRE$ and β_{offset}^{PUSCH}, for each serving cell c, may be determined as below. $K_S=0$ for transmission mode 2.

[302] $BPRE=O_{CQI}/N_{RE}$ for control data sent via PUSCH without UL-SCH data and $\sum_{r=0}^{C-1}K_r/N_{RE}$ for other cases. C may correspond to a number of code blocks, K_r may correspond to a size for code block r, O_{CQI} may correspond to a number of CQI/PMI bits including CRC bits and N_{RE} may correspond to a number of resource elements determined as $N_{RE}=M_{sc}^{PUSCH-initial}\cdot N_{symb}^{PUSCH-initial}$, where C, K_r, $M_{sc}^{PUSCH-initial}$ and $N_{symb}^{PUSCH-initial}$ may be pre-defined in a standards document. $\beta_{offset}^{PUSCH}=\beta_{offset}^{CQI}$ for control data sent via PUSCH without UL-SCH data and 1 for other cases.

[303] $\delta_{PUSCH,c}$ may correspond to a correction value, also referred to as a TPC command and may be included in PDCCH/EPDCCH with DCI format 0, 0A, 0B, 4, 4A, or 4B or in MPDCCH with DCI format 6-0A for serving cell c or jointly coded with other TPC commands in PDCCH/MPDCCH with DCI format 3 or format 3A whose CRC parity bits

may be scrambled with TPC-PUSCH-RNTI. If the UE may be configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c and if subframe i belongs to uplink power control subframe set 2 as indicated by the higher layer parameter *tpc-SubframeSet-r12*, the current PUSCH power control adjustment state for serving cell c may be determined based on $f_{c,2}(i)$, and the UE may use $f_{c,2}(i)$ instead of $f_c(i)$ to determine $P_{\mathrm{PUSCH},c}(i)$. Otherwise, the current PUSCH power control adjustment state for serving cell c may be determined by $f_c(i)$.

[304] $f_{c,2}(i)$ and $f_c(i)$ may be defined by: $f_c(i) = f_c(i-1) + \delta_{\mathrm{PUSCH},c}(i - K_{\mathrm{PUSCH}})$ and $f_{c,2}(i) = f_{c,2}(i-1) + \delta_{\mathrm{PUSCH},c}(i - K_{\mathrm{PUSCH}})$ if accumulation may be enabled based on the parameter *Accumulation-enabled* provided by higher layers or if the TPC command $\delta_{\mathrm{PUSCH},c}$ may be included in a PDCCH/EPDCCH with DCI format 0 or in a MPDCCH with DCI format 6-0A for serving cell c where the CRC may be scrambled by the Temporary C-RNTI. $\delta_{\mathrm{PUSCH},c}(i - K_{\mathrm{PUSCH}})$ may be signalled on PDCCH/EPDCCH with DCI format 0, 0A, 0B, 4, 4A, or 4B or MPDCCH with DCI format 6-0A or PDCCH/MPDCCH with DCI format 3 or format 3A on subframe $i - K_{PUSCH}$. $f_c(0)$ may correspond to a first value after reset of accumulation. For a BL/CE UE configured with CEModeA, subframe $i - K_{PUSCH}$ may correspond to a last subframe in which the MPDCCH with DCI format 6-0A or MPDCCH with DCI format 3 or format 3A may be transmitted. The value of K_{PUSCH} may be predetermined based on frame structure and/or link parameters.

[305] $f_c(i)$ may equal zero when no power control data is available. For example, when a UE starts a 2-step random access process in RRC inactive state, the UE may consider that the closed loop power control factor for data transmission is zero. The base station may transmit an offset value for calculating (offsetting) the UE calculated transmission power (in addition to power values in the power control formula) for transmission of data in the two-stage random access process.

[306] For serving cell c and a non-BL/CE UE, the UE may attempt to decode a PDCCH/EPDCCH of DCI format 0, 0A, 0B, 4, 4A, or 4B with the UE's C-RNTI or DCI format 0 for SPS C-RNTI or DCI format 0 for UL-V-SPS-RNTI and a PDCCH of DCI format 3 or format 3A with this UE's TPC-PUSCH-RNTI in every subframe except when

in DRX or where serving cell c may be deactivated. For serving cell c and a BL/CE UE configured with CEModeA, the UE may attempt to decode a MPDCCH of DCI format 6-0A with the UE's C-RNTI or SPS C-RNTI and a MPDCCH of DCI format 3 or format 3A with this UE's TPC-PUSCH-RNTI in every BL/CE downlink subframe except when in DRX

[307] For a non-BL/CE UE, if DCI format 0, 0A, 0B, 4, 4A, or 4B for serving cell c and DCI format 3 or3A may be both detected in the same subframe, then the UE may use the $\delta_{\mathrm{PUSCH},c}$ provided in DCI format 0, 0A, 0B, 4, 4A, or 4B. For a BL/CE UE configured with CEModeA, if DCI format 6-0A for serving cell c and DCI format 3 or format 3A may be both detected in the same subframe, then the UE may use the $\delta_{\mathrm{PUSCH},c}$ provided in DCI format 6-0A.

[308] $\delta_{\mathrm{PUSCH},c} = 0$ dB for a subframe where no TPC command may be decoded for serving cell c or where DRX occurs or i may be not an uplink subframe in TDD or FDD-TDD and serving cell c frame structure type 2. $\delta_{\mathrm{PUSCH},c} = 0$ dB if the subframe i may be not the first subframe scheduled by a PDCCH/EPDCCH of DCI format 0B or format 4B. The $\delta_{\mathrm{PUSCH},c}$ dB accumulated values signalled on PDCCH/EPDCCH with DCI format 0, 0A, 0B, 4, 4A, or 4B or MPDCCH with DCI format 6-0A may be as shown in Table 2. If the PDCCH/EPDCCH with DCI format 0 or MPDCCH with DCI format 6-0A may be validated as a SPS activation or release PDCCH/EPDCCH/MPDCCH, then $\delta_{\mathrm{PUSCH},c}$ may be 0dB.

[309] The δ_{PUSCH} dB accumulated values signalled on PDCCH/MPDCCH with DCI format 3 or format 3A may be one of SET1 as shown in Table 2 or SET2 as shown in Table 3,which may be determined by the parameter *TPC-Index* provided by higher layers. If UE has reached $P_{\mathrm{CMAX},c}(i)$ for serving cell c, positive TPC commands for serving cell c may not be accumulated. If UE has reached minimum power, negative TPC commands may not be accumulated.

[310] If the UE may be not configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c, the UE may reset accumulation when $P_{\mathrm{O_UE_PUSCH},c}$ value may be changed by higher layers or when the UE receives random access response message for serving cell c.

[311] If the UE is configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c, the UE may reset accumulation corresponding to $f_c(*)$ for serving cell c, when $P_{O_UE_PUSCH,c}$ value may be changed by higher layers, when the UE receives random access response message for serving cell c, the UE may reset accumulation corresponding to $f_{c,2}(*)$ for serving cell c, when $P_{O_UE_PUSCH,c,2}$ value may be changed by higher layers.

[312] If the UE is configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c and if subframe i belongs to uplink power control subframe set 2 as indicated by the higher layer parameter *tpc-SubframeSet-r12*, then $f_c(i) = f_c(i-1)$. If the UE is configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c and if subframe i does not belong to uplink power control subframe set 2 as indicated by the higher layer parameter *tpc-SubframeSet-r12*, then $f_{c,2}(i) = f_{c,2}(i-1)$.

[313] $f_c(i) = \delta_{\mathrm{PUSCH},c}(i - K_{\mathrm{PUSCH}})$ and $f_{c,2}(i) = \delta_{\mathrm{PUSCH},c}(i - K_{\mathrm{PUSCH}})$ if accumulation may be not enabled for serving cell c based on the parameter *Accumulation-enabled* provided by higher layers, where $\delta_{\mathrm{PUSCH},c}(i - K_{\mathrm{PUSCH}})$ was signalled on PDCCH/EPDCCH with DCI format 0, 0A, 0B, 4, 4A, or 4B or MPDCCH with DCI format 6-0A for serving cell c on subframe $i - K_{PUSCH}$. For a BL/CE UE configured with CEModeA, subframe $i - K_{PUSCH}$ may correspond to a last subframe in which the MPDCCH with DCI format 6-0A or MPDCCH with DCI format 3 or format 3A may be transmitted.

[314] The value of K_{PUSCH} may be predetermined based on frame structure and other link parameters. The $\delta_{\mathrm{PUSCH},c}$ dB absolute values signalled on PDCCH/EPDCCH with DCI format 0, 0A, 0B, 4, 4A, or 4B or a MPDCCH with DCI format 6-0A may be as shown in Table 2. If the PDCCH/EPDCCH with DCI format 0 or a MPDCCH with DCI format 6-0A may be validated as a SPS activation or release PDCCH/EPDCCH/MPDCCH, then $\delta_{\mathrm{PUSCH},c}$ may be 0dB.

[315] For a non-BL/CE UE, $f_c(i) = f_c(i-1)$ and $f_{c,2}(i) = f_{c,2}(i-1)$ for a subframe where no PDCCH/EPDCCH with DCI format 0, 0A, 0B, 4, 4A, or 4B may be decoded for serving

cell c or where DRX may occur or i may be not an uplink subframe in TDD or FDD-TDD and serving cell c frame structure type 2.

[316] For a BL/CE UE configured with CEModeA, $f_c(i) = f_c(i-1)$ and $f_{c,2}(i) = f_{c,2}(i-1)$ for a subframe where no MPDCCH with DCI format 6-0A may be decoded for serving cell c or where DRX occurs or i may be not an uplink subframe in TDD.

[317] If the UE is configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c and if subframe i belongs to uplink power control subframe set 2 as indicated by the higher layer parameter *tpc-SubframeSet-r12*, then $f_c(i) = f_c(i-1)$. If the UE is configured with higher layer parameter *UplinkPowerControlDedicated-v12x0* for serving cell c and if subframe i does not belong to uplink power control subframe set 2 as indicated by the higher layer parameter *tpc-SubframeSet-r12*, then $f_{c,2}(i) = f_{c,2}(i-1)$.

[318] For both types of $f_c(*)$ (accumulation or current absolute) the first value may be set as follows: if $P_{O_UE_PUSCH,c}$ value is changed by higher layers and serving cell c is the primary cell or, if $P_{O_UE_PUSCH,c}$ value may be received by higher layers and serving cell c may be a Secondary cell, then $f_c(0) = 0$, otherwise if the UE receives the random access response message for a serving cell c, then $f_c(0) = \Delta P_{rampup,c} + \delta_{msg2,c}$. $\delta_{msg2,c}$ may correspond to a TPC command indicated in the random access response corresponding to the random access preamble transmitted in the serving cell c. $\Delta P_{rampup,c}$ and $\Delta P_{rampuprequested,c}$ may be provided by higher layers and may correspond to the total power ramp-up requested by higher layers from the first to the last preamble in the serving cell c. $M_{PUSCH,c}(0)$ may correspond to a bandwidth of the PUSCH resource assignment expressed in number of resource blocks valid for the subframe of first PUSCH transmission in the serving cell c. $\Delta_{TF,c}(0)$ may correspond to a power adjustment of first PUSCH transmission in the serving cell c. If $P_{O_UE_PUSCH,c,2}$ value is received by higher layers for a serving cell c, then $f_{c,2}(0) = 0$.

1	1

Table 3: Example mapping of TPC Command Field in DCI format 3A/3B to accumulated $\delta_{PUSCH,c}$ values

[319] If the UE is not configured with an SCG or a PUCCH-SCell, and if the total transmit power of the UE would exceed $\hat{P}_{CMAX}(i)$, then the UE may scale $\hat{P}_{PUSCH,c}(i)$ for the serving cell c in subframe i such that $\sum_{c} w(i) \cdot \hat{P}_{PUSCH,c}(i) \leq \left(\hat{P}_{CMAX}(i) - \hat{P}_{PUCCH}(i)\right)$ is satisfied. $\hat{P}_{PUCCH}(i)$ may correspond to a linear value of $P_{PUCCH}(i)$, $\hat{P}_{PUSCH,c}(i)$ may correspond to a linear value of $P_{PUSCH,c}(i)$, $\hat{P}_{CMAX}(i)$ may correspond to a linear value of the UE total configured maximum output power P_{CMAX} in subframe i, and $w(i)$ may correspond to a scaling factor of $\hat{P}_{PUSCH,c}(i)$ for serving cell c where $0 \leq w(i) \leq 1$. In case there may be no PUCCH transmission in subframe i, $\hat{P}_{PUCCH}(i) = 0$.

[320] If the UE is not configured with an SCG or a PUCCH-Scell, and if the UE has PUSCH transmission with UCI on serving cell j and PUSCH without UCI in any of the remaining serving cells, and the total transmit power of the UE would exceed $\hat{P}_{CMAX}(i)$, the UE may scale $\hat{P}_{PUSCH,c}(i)$ for the serving cells without UCI in subframe i such that $\sum_{c \neq j} w(i) \cdot \hat{P}_{PUSCH,c}(i) \leq \left(\hat{P}_{CMAX}(i) - \hat{P}_{PUSCH,j}(i)\right)$ is satisfied. $\hat{P}_{PUSCH,j}(i)$ may correspond to

a PUSCH transmit power for the cell with UCI and $w(i)$ may be a scaling factor of $\hat{P}_{\text{PUSCH},c}(i)$ for serving cell c without UCI. Power scaling may be applied to $\hat{P}_{\text{PUSCH},j}(i)$ if $\sum_{c \neq j} w(i) \cdot \hat{P}_{\text{PUSCH},c}(i) = 0$ and the total transmit power of the UE still would exceed $\hat{P}_{CMAX}(i)$.

[321] For a UE not configured with a SCG or a PUCCH-SCell, note that $w(i)$ values may be the same across serving cells when $w(i) > 0$, but $w(i)$ may be zero for certain serving cells. If the UE is not configured with an SCG or a PUCCH-SCell, and if the UE has simultaneous or at least partially overlapping PUCCH and PUSCH transmissions with UCI on serving cell j and PUSCH transmission without UCI in any of the remaining serving cells, and the total transmit power of the UE would exceed $\hat{P}_{CMAX}(i)$, the UE may obtain $\hat{P}_{\text{PUSCH},c}(i)$ according to:

$$\hat{P}_{\text{PUSCH},j}(i) = \min\left(\hat{P}_{\text{PUSCH},j}(i), \left(\hat{P}_{\text{CMAX}}(i) - \hat{P}_{\text{PUCCH}}(i)\right)\right) \text{ ; and}$$

$$\sum_{c \neq j} w(i) \cdot \hat{P}_{\text{PUSCH},c}(i) \leq \left(\hat{P}_{\text{CMAX}}(i) - \hat{P}_{\text{PUCCH}}(i) - \hat{P}_{\text{PUSCH},j}(i)\right)$$

[322] If the UE is not configured with a SCG or a PUCCH-SCell,, if the UE is configured with multiple TAGs, and if the PUCCH/PUSCH transmission of the UE on subframe i for a serving cell in a TAG overlaps some portion of the first symbol of the PUSCH transmission on subframe $i + 1$ for a different serving cell in another TAG, then the UE may adjust its total transmission power to not exceed P_{CMAX} on any overlapped portion.

[323] If the UE is not configured with a SCG or a PUCCH-SCell, if the UE is configured with multiple TAGs, and if the PUSCH transmission of the UE on subframe i for a serving cell in a TAG overlaps some portion of the first symbol of the PUCCH transmission on subframe $i + 1$ for a different serving cell in another TAG, then the UE may adjust its total transmission power to not exceed P_{CMAX} on any overlapped portion.

[324] If the UE is not configured with a SCG or a PUCCH-SCell, if the UE is configured with multiple TAGs, and if the SRS transmission of the UE in a symbol on subframe i for a serving cell in a TAG overlaps with the PUCCH/PUSCH transmission on subframe i or

subframe $i + 1$ for a different serving cell in the same or another TAG, then the UE may drop SRS if its total transmission power exceeds P_{CMAX} on any overlapped portion of the symbol.

[325] If the UE is not configured with a SCG or a PUCCH-SCell, if the UE is configured with multiple TAGs and more than 2 serving cells, and if the SRS transmission of the UE in a symbol on subframe i for a serving cell overlaps with the SRS transmission on subframe i for a different serving cell(s) and with PUSCH/PUCCH transmission on subframe i or subframe $i + 1$ for another serving cell(s), then the UE may drop the SRS transmissions if the total transmission power exceeds P_{CMAX} on any overlapped portion of the symbol.

[326] If the UE is not configured with a SCG or a PUCCH-SCell, and if the UE is configured with multiple TAGs, the UE may, when requested by higher layers to transmit PRACH in a secondary serving cell in parallel with SRS transmission in a symbol on a subframe of a different serving cell belonging to a different TAG, drop SRS if the total transmission power exceeds P_{CMAX} on any overlapped portion in the symbol.

[327] If the UE is not configured with a SCG or a PUCCH-SCell, and if the UE is configured with multiple TAGs, the UE may, when requested by higher layers to transmit PRACH in a secondary serving cell in parallel with PUSCH/PUCCH in a different serving cell belonging to a different TAG, adjust the transmission power of PUSCH/PUCCH so that its total transmission power does not exceed P_{CMAX} on the overlapped portion.

[328] If the UE is configured with a LAA SCell for uplink transmissions, the UE may compute the scaling factor $w(i)$ under the assumption that the UE may perform a PUSCH transmission on the LAA SCell in subframe i irrespective of whether the UE may access the LAA SCell for the PUSCH transmission in subframe i according to the channel access procedures.

[329] For a BL/CE UE configured with CEModeA, if the PUSCH is transmitted in more than one subframe i_0, i_1, ..., i_{N-1} where $i_0 < i_1 < \ldots < i_{N-1}$, then the PUSCH transmit power in subframe i_k, k=0, 1, ..., N-1, may be determined by $P_{\mathrm{PUSCH},c}(i_k) = P_{\mathrm{PUSCH},c}(i_0)$. For a BL/CE UE configured with CEModeB, the PUSCH transmit power in subframe i_k may be determined by $P_{\mathrm{PUSCH},c}(i_k) = P_{\mathrm{CMAX},c}(i_0)$.

[330] A wireless device may perform a method for determining a type of random access procedure. The wireless device may receive, from a base station, one or more first messages comprising one or more first parameters for a two-step random access procedure, one or more second parameters for a four-step random access procedure, and a first threshold power level. The one or more first messages may comprise a ramp up power parameter. The one or more first parameters for the two-step random access procedure may indicate at least one first preamble for the two-step random access procedure and at least one first random access procedure resource for the two-step random access procedure. The one or more second parameters for the four-step random access procedure indicate at least one second preamble for the four-step random access procedure and at least one second random access procedure resource for the four-step random access procedure. The wireless device may determine, based on the one or more first parameters for a two-step random access procedure, a first transmission power associated with the two-step random access procedure. The first transmission power associated with the two-step random access procedure may be proportional to a distance or a path loss between the wireless device and the base station. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[331] The wireless device may determine, based on a comparison of the first transmission power and the first threshold power level, a type of random access procedure. The wireless device may determine, based on the first transmission power not exceeding the first threshold power level, the type of random access procedure comprises the two-step random access procedure. The wireless device may determine, based on the first transmission power exceeding the first threshold power level, the type of random access procedure comprises the four-step random access procedure. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[332] The wireless device may transmit, to the base station, a second message employing the determined type of random access procedure. Additionally or alternatively, the wireless device may drop, based on the first transmission power associated with the two-step random access procedure exceeding the first threshold power level, at least one transport block from the second message. Transmitting the second message may comprise

transmitting, using the at least one first random access procedure resource for the two-step random access procedure, the at least one first preamble for the two-step random access procedure or transmitting, using the at least one second random access procedure resource for the four-step random access procedure, the at least one second preamble for the four-step random access procedure. The determined type may be the four-step random access procedure, and the second message may comprise a random access preamble indicated by the one or more second parameters for the four-step random access procedure. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[333] The wireless device may determine, based on the ramp up power parameter and after a response to the second message has not been received within a threshold amount of time, a second transmission power for re-transmitting the second message. The wireless device may adjust, based on the second transmission power for the wireless device exceeding the first threshold power level, a third transmission power for at least one transport block of the second message. The wireless device may compare the third transmission power with a second threshold power level. The wireless device may re-transmit, based on the third transmission power being below the second threshold power level, the second message via the four-step random access procedure. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[334] A wireless device may receive, from a base station, one or more first messages comprising one or more first parameters for a two-step random access procedure, and one or more second parameters for a four-step random access procedure. The one or more first messages may comprise a ramp up power parameter. The one or more first parameters for the two-step random access procedure may indicate at least one first preamble for the two-step random access procedure, and at least one first random access procedure resource for the two-step random access procedure. The one or more second parameters for the four-step random access procedure may indicate at least one second preamble for the four-step random access procedure, and at least one second random access procedure resource for the four-step random access procedure. A wireless device may perform any combination of one or more of the above steps. A base station, or any

other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[335] The wireless device may determine, during a first time period, a first transmission power for transmitting a second message, wherein the second message is based on the one or more first parameters for the two-step random access procedure. The first transmission power may be proportional to a distance or a path loss between the wireless device and the base station. The wireless device may compare the first transmission power to a threshold to determine whether the first transmission power exceeds the threshold. The wireless device may transmit, to the base station and based on determining that the first transmission power exceeds the threshold, a third message, wherein the third message is based on the one or more second parameters for the four-step random access procedure. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[336] The wireless device may determine, based on the ramp up power parameter and after a response to the third message has not been received within a threshold amount of time, a second transmission power for re-transmitting the third message. The wireless device may adjust, based on the second transmission power exceeding the threshold, a third transmission power for at least one transport block of the third message. The wireless device may re-transmit, via the four-step random access procedure and after determining the third transmission power for the at least one transport block is below a minimum threshold power level, the third message. The wireless device may determine, during a second time period, a second transmission power for transmitting a fourth message, wherein the fourth message is based on the one or more first parameters for the two-step random access procedure. Additionally or alternatively, the wireless device may drop, based on the second transmission power exceeding the threshold, at least one transport block from the fourth message. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[337] A wireless device may receive, from a base station, one or more first messages comprising one or more parameters indicating at least one first preamble for a two-step random access procedure, one or more second parameters indicating at least one resource for the two-step random access procedure, one or more third parameters indicating at

least one preamble for a four-step random access procedure, one or more fourth parameters indicating at least one resource for the four-step random access procedure, and one or more fifth parameters indicating a first threshold. The one or more first messages may comprise a ramp up power parameter. The first threshold may correspond to a maximum transmission power of the wireless device. The wireless device may determine, during a first time period, a first transmission power comprising at least a second transmission power for a first preamble of the at least one first preamble for the two-step random access procedure and a third transmission power for at least one first transport block. The first transmission power for the first preamble of the at least one preamble for the two-step random access procedure may be proportional to a distance or a path loss between the wireless device and a base station. The wireless device may select, based on the first transmission power being higher than the first threshold, a first preamble of the at least one preamble for the four-step random access procedure and a first resource of the at least one resource for the four-step random access procedure. The wireless device may transmit, via the first resource of the at least one resource for the four-step random access procedure, a second message comprising the first preamble of the at least one preamble for the four-step random access procedure and the at least one transport block. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[338] The wireless device may determine, during a second time period, a fourth transmission power comprising a fifth transmission power for a second preamble of the at least one preamble for the two-step random access procedure and a sixth transmission power for at least one second transport block. The wireless device may select, based on the fourth transmission power being lower than or equal to the first threshold, the second preamble of the at least one preamble for the two-step random access procedure and a second resource of the at least one resource for the two-step random access procedure. The wireless device may transmit, via the second resource of the at least one resource for the two-step random access procedure, the second preamble of the at least one preamble for the two-step random access procedure. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[339] The wireless device may determine, based on the ramp up power parameter and after a response to the second message has not been received within a threshold amount of time,

a seventh transmission power for re-transmitting the second message. The wireless device may adjust, based on the seventh transmission power exceeding the first threshold, an eighth transmission power for the at least one transport block of the second message. Additionally or alternatively, the wireless device may drop, based on the seventh transmission power exceeding the first threshold, the at least one transport block of the second message. A wireless device may perform any combination of one or more of the above steps. A base station, or any other device, may perform any combination of a step, or a complementary step, of one or more of the above steps.

[340] Many of the elements in examples may be implemented as modules. A module may be an isolatable element that performs a defined function and has a defined interface to other elements. The modules may be implemented in hardware, software in combination with hardware, firmware, wetware (i.e., hardware with a biological element) or a combination thereof, all of which may be behaviorally equivalent. For example, modules may be implemented as a software routine written in a computer language configured to be executed by a hardware machine (such as C, C++, Fortran, Java, Basic, Matlab or the like) or a modeling/simulation program such as Simulink, Stateflow, GNU Octave, or LabVIEWMathScript. Additionally or alternatively, it may be possible to implement modules using physical hardware that incorporates discrete or programmable analog, digital and/or quantum hardware. Examples of programmable hardware may comprise: computers, microcontrollers, microprocessors, application-specific integrated circuits (ASICs); field programmable gate arrays (FPGAs); and complex programmable logic devices (CPLDs). Computers, microcontrollers, and microprocessors may be programmed using languages such as assembly, C, C++ or the like. FPGAs, ASICs, and CPLDs may be programmed using hardware description languages (HDL), such as VHSIC hardware description language (VHDL) or Verilog, that may configure connections between internal hardware modules with lesser functionality on a programmable device. The above mentioned technologies may be used in combination to achieve the result of a functional module.

[341] Systems, apparatuses, and methods may perform operations of multi-carrier communications described herein. Additionally or alternatively, a non-transitory tangible computer readable media may comprise instructions executable by one or more processors configured to cause operations of multi-carrier communications described herein. An article of manufacture may comprise a non-transitory tangible computer readable machine-accessible medium having instructions encoded thereon for enabling

programmable hardware to cause a device (e.g., a wireless communicator, a UE, a base station, and the like) to enable operation of multi-carrier communications described herein. The device, or one or more devices such as in a system, may include one or more processors, memory, interfaces, and/or the like. Other examples may comprise communication networks comprising devices such as base stations, wireless devices or user equipment (UE), servers, switches, antennas, and/or the like. Any device (e.g., a wireless device, a base station, or any other device) or combination of devices may be used to perform any combination of one or more of steps described herein, including, e.g., any complementary step or steps of one or more of the above steps.

[342] Although examples are described above, features and/or steps of those examples may be combined, divided, omitted, rearranged, revised, and/or augmented in any desired manner. Various alterations, modifications, and improvements will readily occur to those skilled in the art. Such alterations, modifications, and improvements are intended to be part of this description, though not expressly stated herein, and are intended to be within the spirit and scope of the disclosure. Accordingly, the foregoing description is by way of example only, and is not limiting.

CLAIMS

1. A method comprising:

transmitting, by a wireless device and to a base station, one or more preambles in parallel with one or more transport blocks;

receiving, by the wireless device, a media access control (MAC) packet data unit comprising:

one or more MAC subheaders; and

one or more random access responses (RARs), wherein each RAR of the one or more RARs is associated with a MAC subheader of the one or more MAC subheaders;

determining, based on a first field in a first MAC subheader of the one or more MAC subheaders, a type of a random access procedure of a first RAR of the one or more RARs, wherein the first RAR is associated with the first MAC subheader, and wherein the type of the random access procedure is determined from among a plurality of types of random access procedures comprising at least a two-step random access procedure and a four-step random access procedure; and

determining, based on the first field, that the random access procedure has completed.

2. The method of claim 1, wherein the determining that the random access procedure has completed is based on:

the first MAC subheader comprising a random access preamble identifier of the one or more preambles; and

a second field in the first RAR that indicates that the one or more transport blocks have been successfully received by the base station.

3. The method of claim 1, wherein the determining that the random access procedure has completed is based on the type of the random access procedure of the first RAR being a two-step random access procedure.

4. The method of claim 1 further comprising:

transmitting, based on a second field in the first RAR that indicates that at least one of the one or more transport blocks have not been successfully received by the base station, one or more messages using a four-step random access procedure.

5. The method of claim 1, further comprising determining, based on the first field, a size of the first RAR.

6. The method of claim 1, further comprising receiving, by the wireless device, one or more messages comprising configuration parameters of the two-step random access procedure.

7. The method of claim 1, wherein the first RAR further comprises an uplink grant, and wherein the method further comprises:

retransmitting, in response to a second field of the first RAR indicating that the one or more transport blocks have not been successfully received by the base station, the one or more transport blocks.

8. A method comprising:

transmitting, by a wireless device and to a base station, a first transmission comprising:

a first random access preamble (RAP) comprising a first random access preamble identifier (RAPID); and

one or more transport blocks;

receiving a media access control (MAC) packet data unit comprising:

one or more MAC subheaders; and

one or more random access responses (RARs), wherein each RAR of the one or more RARs is associated with a MAC subheader of the one or more MAC subheaders;

determining, based on a first field in a first MAC subheader of the one or more MAC subheaders, a type of a random access procedure of a first RAR of the one or more RARs, wherein the first RAR is associated with the first MAC subheader, and wherein the type of the random access procedure is determined from among a plurality of types of random access procedures comprising at least a two-step random access procedure and a four-step random access procedure;

determining, based on the type of the random access procedure of the first RAR and based on the first RAPID of the first RAP, whether the first transmission was successful in delivering the one or more transport blocks to the base station; and

transmitting, to the base station and based on the type of the random access procedure of the first RAR, one or more messages.

9. The method of claim 8, further comprising determining, based on the type of the random access procedure of the first RAR being a two-step random access procedure, that the random access procedure was successful in delivering the one or more transport blocks to the base station.

10. The method of claim 8, wherein the determining whether the first transmission was successful in delivering the one or more transport blocks to the base station is based on:

the first MAC subheader comprising a random access preamble identifier of the first RAP; and

a second field in the first RAR that indicates whether the one or more transport blocks have been successfully received by the base station.

11. The method of claim 8, further comprising:

transmitting, based on a second field in the first RAR that indicates that at least one of the one or more transport blocks have not been successfully received by the base station, one or more messages using a four-step random access procedure.

12. The method of claim 8, further comprising determining, based on the first field, a size of the first RAR.

13. The method of claim 8, further comprising receiving, by the wireless device, one or more messages comprising configuration parameters of the two-step random access procedure.

14. The method of claim 8, wherein the first RAR further comprises an uplink grant, and wherein the method further comprises:

retransmitting, in response to the first field indicating that the one or more transport blocks have not been successfully received by the base station, the one or more transport blocks.

15. A method comprising:

receiving, by a base station and from a wireless device, a random access preamble (RAP);

determining a type of a random access procedure, from among a plurality of types of random access procedures comprising at least a two-step random access procedure and a four-step random access procedure, for communicating with the wireless device; and

transmitting, based on the RAP, a media access control (MAC) packet data unit comprising:

one or more MAC subheaders, wherein a first field in a first MAC subheader of the one or more MAC subheaders comprises an indication of the type of the random access procedure; and

one or more random access responses (RARs), wherein each RAR of the one or more RARs is associated with a MAC subheader of the one or more MAC subheaders.

16. The method of claim 15, wherein a second field in the MAC subheader comprises:

the first field; and

the first RAPID.

17. The method of claim 15, further comprising:

receiving, by the base station and based on the indication of the type of the random access procedure indicating the two-step random access procedure, a first transmission comprising a second RAP and one or more transport blocks.

18. The method of claim 15, further comprising:

receiving, by the base station and based on the indication of the type of the random access procedure indicating the four-step random access procedure, a first transmission comprising a second RAP;

transmitting, by the base station and based on the first transmission, a second transmission comprising a first random access response;

receiving, by the base station and based on the second transmission, a third transmission comprising one or more transport blocks; and

transmitting, by the base station and based on the third transmission, a fourth transmission comprising contention resolution information.

19. The method of claim 15, determining, based on the type of a random access procedure, a size of a first RAR of the one or more RARs.

20. The method of claim 15, wherein the indication of the type of the random access procedure is based on a random access preamble identifier (RAPID) in the RAP.

21. A method comprising:

transmitting, by a wireless device and to a first base station associated with a first cell, a first message comprising a measurement report based on one or more second cells;

receiving, by the wireless device and from the first base station, a second message comprising a command for a handover from the first cell to a second cell of the one or more second cells, wherein the second message comprises one or more parameters indicating a type of a random access procedure for the handover, and wherein the type of the random access procedure comprises a two-step random access procedure or a four-step random access procedure; and

transmitting, by the wireless device and to a second base station associated with the second cell, a random access preamble employing the type of the random access procedure indicated in the second message.

22. The method of claim 21, further comprising transmitting, by the wireless device, one or more transport blocks overlapping in time with the random access preamble.

23. The method of claim 22, wherein the one or more transport blocks comprise one or more of:

a handover complete message;

uplink data;

a buffer status report; or

an identifier of the wireless device.

24. The method of claim 21, wherein the one or more parameters of the second message comprise, for the random access procedure, one or more of:

a preamble identifier; or

random access resource information.

25. The method of claim 21, wherein the second message further comprises:

timing advance information for transmission of one or more of the random access preamble or one or more transport blocks.

26. The method of claim 25, further comprising:

receiving, from the one or more second cells, a plurality of third messages comprising one or more of:

an indication of a power associated with a cell;

an indication of a quality associated with a cell; or

an indication of a cell priority.

27. The method of claim 21, further comprising transmitting, by the wireless device and in a first step of a four-step random access procedure, a second random access preamble.

28. The method of claim 21, wherein the second message comprises a preamble identifier, and wherein the method further comprises:

determining, based on the preamble identifier, radio resources associated with the random access procedure.

29. The method of claim 21, wherein the second message comprises:

random access channel configuration information for a two-step random access procedure; and

radio resource configuration parameters for the two-step random access procedure.

30. A method comprising:

receiving, by a first base station associated with a first cell and from a wireless device, a first message comprising a measurement report based on one or more second cells;

determining, based on the measurement report, to handover the wireless device from the first cell to a second cell of the one or more second cells;

transmitting, by the first base station and to a third device, a second message comprising an indication for the handover;

receiving, by the first base station and from the third device, a third message indicating a type of a random access procedure for the handover, wherein the type of the random access procedure comprises a two-step random access procedure or a four-step random access procedure; and

transmitting, by the first base station and to the wireless device, a fourth message comprising:

one or more parameters indicating the type of the random access procedure for the handover; and

a command to proceed with the handover.

31. The method of claim 30, wherein:

the third device comprises a second base station associated with the second cell; and

the second message comprises a handover request.

32. The method of claim 30, wherein:

the third device comprises a core network device; and

the second message indicates that the handover is requested.

33. The method of claim 32, further comprising:

transmitting, by the core network device, to a second base station, and based on the second message, a fifth message comprising a handover request; and

receiving, by the core network device and from the second base station, a sixth message indicating the type of the random access procedure for the handover and comprising an acknowledgement of the handover request.

34. The method of claim 30, wherein the one or more parameters of the fourth message comprise, for the random access procedure, one or more of:

a preamble identifier; or

random access resource information.

35. The method of claim 30, wherein the fourth message further comprises timing advance information for transmission, by the wireless device, of one or more of a random access preamble or one or more transport blocks.

36. The method of claim 35, wherein the timing advance information comprises one or more of:

an indication of a zero timing advance; or

a value for a timing advance, wherein the value is estimated by the first base station or the third device.

37. A method comprising:

receiving, by a network device and from a first base station associated with a first cell, a first message comprising an indication for a handover of a wireless device from the first cell to a second cell of one or more second cells;

determining, by the network device and based on the first message, to proceed with the handover; and

transmitting, by the network device and to the first base station, a second message comprising:

an acknowledgement for the handover; and

one or more parameters indicating a type of a random access procedure for the handover, wherein the type of the random access procedure comprises a two-step random access procedure or a four-step random access procedure.

38. The method of claim 37, wherein:

the network device comprises a second base station that is associated with the second cell; and

the second message comprises a handover request.

39. The method of claim 37, wherein:

the network device comprises a core network device; and

the second message comprises an indication that the handover is required.

40. The method of claim 39, further comprising:

transmitting, by the core network device, to a second base station, and based on the first message, a third message comprising a handover request; and

receiving, by the core network device and from the second base station, a fourth message indicating the type of the random access procedure for the handover and comprising an acknowledgement of a request for a handover request.

41. A method comprising:

receiving, by a wireless device and from a base station, one or more first messages comprising:

one or more first parameters for a two-step random access procedure;

one or more second parameters for a four-step random access procedure; and

a first threshold power level;

determining, based on the one or more first parameters for the two-step random access procedure, a first transmission power associated with the two-step random access procedure;

determining, based on a comparison of the first transmission power and the first threshold power level, a type of random access procedure, wherein the type of random access procedure comprises the two-step random access procedure or the four-step random access procedure; and

transmitting, by the wireless device and to the base station, a second message employing the determined type of random access procedure.

42. The method of claim 41, wherein determining the type of random access procedure comprises:

determining, based on the first transmission power exceeding the first threshold power level, the type of random access procedure to be the four-step random access procedure.

43. The method of claim 41, wherein determining the type of random access procedure comprises:

determining, based on the first transmission power not exceeding the first threshold power level, the type of random access procedure to be the two-step random access procedure.

44. The method of claim 41, wherein the one or more first messages comprise a ramp up power parameter, the method further comprising:

determining, by the wireless device, that a response to the second message has not been received within a threshold amount of time;

determining, based on the ramp up power parameter, a second transmission power for re-transmitting the second message; and

adjusting, based on the second transmission power for the wireless device exceeding the first threshold power level, a third transmission power for at least one transport block of the second message.

45. The method of claim 44, further comprising:

comparing the third transmission power with a second threshold power level; and

re-transmitting, based on the third transmission power being below the second threshold power level, the second message via the four-step random access procedure.

46. The method of claim 41, wherein:

the one or more first parameters for the two-step random access procedure indicate:

at least one first preamble for the two-step random access procedure; and

at least one first random access procedure resource for the two-step random access procedure; and

the one or more second parameters for the four-step random access procedure indicate:

at least one second preamble for the four-step random access procedure; and

at least one second random access procedure resource for the four-step random access procedure,

wherein the transmitting the second message comprises:

transmitting, using the at least one first random access procedure resource for the two-step random access procedure, the at least one first preamble for the two-step random access procedure; or

transmitting, using the at least one second random access procedure resource for the four-step random access procedure, the at least one second preamble for the four-step random access procedure.

47. The method of claim 41, further comprising:

dropping, based on the first transmission power associated with the two-step random access procedure exceeding the first threshold power level, at least one transport block from the second message.

48. A method comprising:

receiving, by a wireless device and from a base station, one or more first messages comprising:

one or more first parameters for a two-step random access procedure; and

one or more second parameters for a four-step random access procedure;

determining, during a first time period, a first transmission power for transmitting a second message, wherein the second message is based on the one or more first parameters for the two-step random access procedure;

comparing the first transmission power to a threshold to determine whether the first transmission power exceeds the threshold; and

transmitting, to the base station and based on determining that the first transmission power exceeds the threshold, a third message, wherein the third message is based on the one or more second parameters for the four-step random access procedure.

49. The method of claim 48, further comprising:

determining, during a second time period, a second transmission power for transmitting a fourth message, wherein the fourth message is based on the one or more first parameters for the two-step random access procedure; and

transmitting, to the base station and based on determining that the second transmission power does not exceed the threshold, the fourth message.

50. The method of claim 49, further comprising:

dropping, based on the second transmission power exceeding the threshold, at least one transport block from the fourth message.

51. The method of claim 48, wherein the one or more first messages comprise a ramp up power parameter, the method further comprising:

determining by the wireless device, that a response to the third message has not been received within a threshold amount of time;

determining, based on the ramp up power parameter, a second transmission power for re-transmitting the third message; and

adjusting, based on the second transmission power exceeding the threshold, a third transmission power for at least one transport block of the third message.

52. The method of claim 51, further comprising:

comparing the third transmission power with a minimum threshold power level; and re-transmitting, via the four-step random access procedure and after determining the third transmission power for the at least one transport block is below the minimum threshold power level, the third message.

53. The method of claim 48, wherein:

the one or more first parameters for the two-step random access procedure indicate:

at least one first preamble for the two-step random access procedure; and

at least one first random access procedure resource for the two-step random access procedure; and

the one or more second parameters for the four-step random access procedure indicate:

at least one second preamble for the four-step random access procedure; and

at least one second random access procedure resource for the four-step random access procedure,

wherein the transmitting the third message comprises:

transmitting, using the at least one second random access procedure resource for the four-step random access procedure, the at least one second preamble for the four-step random access procedure.

54. The method of claim 48, wherein the first transmission power is proportional to a path loss between the wireless device and the base station.

55. A method comprising:

receiving, by a wireless device and from a base station, one or more first messages comprising:

one or more first parameters for a two-step random access procedure;

one or more second parameters for a four-step random access procedure; and

one or more third parameters indicating a first threshold;

determining, during a first time period, a first transmission power comprising at least a second transmission power for a first preamble for the two-step random access procedure and a third transmission power for at least one first transport block;

selecting, based on the first transmission power being higher than the first threshold:

a second preamble for the four-step random access procedure; and

a first resource for the four-step random access procedure; and

transmitting, by the wireless device and via the first resource for the four-step random access procedure, a second message comprising:

the second preamble for the four-step random access procedure; and

the at least one first transport block.

56. The method of claim 55, wherein:

the one or more first parameters for the two-step random access procedure indicate:

at least one preamble for the two-step random access procedure; and

at least one resource for the two-step random access procedure; and

the one or more second parameters for the four-step random access procedure indicate:

at least one preamble for the four-step random access procedure; and

at least one resource for the four-step random access procedure.

57. The method of claim 55, further comprising:

determining, during a second time period, a fourth transmission power comprising:

a fifth transmission power for a second preamble for the two-step random access procedure; and

a sixth transmission power for at least one second transport block;

selecting, based on the fourth transmission power being lower than or equal to the first threshold:

the second preamble for the two-step random access procedure; and

a second resource for the two-step random access procedure; and

transmitting, by the wireless device and via the second resource for the two-step random access procedure, the second preamble for the two-step random access procedure.

58. The method of claim 55, wherein the first transmission power for the first preamble for the two-step random access procedure is proportional to a path loss between the wireless device and the base station.

59. The method of claim 55, wherein the one or more first messages comprise a ramp up power parameter, the method further comprising:

determining, by the wireless device, that a response to the second message has not been received within a threshold amount of time;

determining, based on the ramp up power parameter, a fourth transmission power for re-transmitting the second message; and

adjusting, based on the fourth transmission power exceeding the first threshold, a fifth transmission power for the at least one first transport block of the second message.

60. The method of claim 55, wherein the first threshold corresponds to a maximum transmission power of the wireless device.

INTERNATIONAL SEARCH REPORT

International application No
PCT/US2018/023886

A. CLASSIFICATION OF SUBJECT MATTER
INV. H04W74/08
ADD.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
H04W

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
EPO-Internal, INSPEC, IBM-TDB, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	CATT: "Consideration on 2-step RA", 3GPP DRAFT; R2-1700205 2-STEP RA, 3RD GENERATION PARTNERSHIP PROJECT (3GPP), MOBILE COMPETENCE CENTRE ; 650, ROUTE DES LUCIOLES ; F-06921 SOPHIA-ANTIPOLIS CEDEX ; FRANCE , vol. RAN WG2, no. Spokane, USA; 20170117 - 20170119 17 January 2017 (2017-01-17), XP051210789, Retrieved from the Internet: URL:http://www.3gpp.org/ftp/Meetings_3GPP_SYNC/RAN2/Docs/ [retrieved on 2017-01-17]	1-3,5,8, 9,12, 14-20

-/--

[X] Further documents are listed in the continuation of Box C.

[ ] See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Form PCT/ISA/210 (second sheet) (April 2005)

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US2018/023886

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1-20

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-20

   Methods comprising transmitting resp. receiving a MAC PDU comprising one or more MAC sub-headers and one or more Random Access Responses, RARs, a field in a MAC sub-header indicating a type of random access procedure.

   ---

2. claims: 21-40

   Methods comprising transmitting resp. receiving a message indicating a type of random access procedure for a handover.

   ---

3. claims: 41-60

   Methods comprising determining a type of random access procedure based on the transmission power associated therewith.

CERTIFICATION STATEMENT

Please see 37 CFR 1.97 and 1.98 to make the appropriate selection(s):

☐ That each item of information contained in the information disclosure statement was first cited in any communication from a foreign patent office in a counterpart foreign application not more than three months prior to the filing of the information disclosure statement. See 37 CFR 1.97(e)(1).

OR

☐ That no item of information contained in the information disclosure statement was cited in a communication from a foreign patent office in a counterpart foreign application, and, to the knowledge of the person signing the certification after making reasonable inquiry, no item of information contained in the information disclosure statement was known to any individual designated in 37 CFR 1.56(c) more than three months prior to the filing of the information disclosure statement. See 37 CFR 1.97(e)(2).

☐ See attached certification statement.

☒ The fee set forth in 37 CFR 1.17 (p) has been submitted herewith.

☒ A certification statement is not submitted herewith.

SIGNATURE

A signature of the applicant or representative is required in accordance with CFR 1.33, 10.18. Please see CFR 1.4(d) for the form of the signature.

Signature	/JIALIN ZHONG/	Date (YYYY-MM-DD)	2023-11-19
Name/Print	JIALIN ZHONG	Registration Number	62937

This collection of information is required by 37 CFR 1.97 and 1.98. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 1 hour to complete, including gathering, preparing and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these record s.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

PTO/SB/08a (01-10)
Approved for use through 07/31/2012. OMB 0651-0031
U.S. Patent and Trademark Office; U.S. DEPARTMENT OF COMMERCE

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it contains a valid OMB control number.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these record s.

2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.

3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.

4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).

5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.

6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).

7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.

8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.

9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

(54) **Title**: IMPROVED PAGING PROCEDURES FOR USER EQUIPMENTS REQUIRING COVERAGE EXTENSION

(57) **Abstract**: The present disclosure relates to a method for paging coverage extension UEs in a cell controlled by a radio base station. At least one regularly-occurring coverage-extension-specific paging possibility (CE-specific paging possibility), is defined for paging CE UEs. The CE-UEs in the cell regularly monitor the at least one CE-specific paging possibility. When the radio base station determines to page all the user equipments in the cell, it pages the CE user equipments in the cell at the CE-specific paging possibility, using a coverage extension technique. The present disclosure also relates to a method for paging a CE UE, which performs radio measurements by the CE-capable user equipment to determine whether coverage extension is necessary. The radio base station is informed about whether the CE-capable user equipment needs coverage extension or not and then pages the CE UEs applying or not applying a CE technique depending on whether coverage extension is necessary or not.

WO 2016/136143 A1

Description

Title of Invention: IMPROVED PAGING PROCEDURES FOR USER EQUIPMENTS REQUIRING COVERAGE EXTENSION

Technical Field

[0001] The present disclosure relates to methods for paging one or several user equipments in a cell of a radio base station, where the user equipment(s) do require coverage extension to be reliably paged. The present disclosure is also providing the user equipment and radio base station for participating in the methods described herein.

Background

[0002] Long Term Evolution (LTE)

Third-generation mobile systems (3G) based on WCDMA radio-access technology are being deployed on a broad scale all around the world. A first step in enhancing or evolving this technology entails introducing High-Speed Downlink Packet Access (HSDPA) and an enhanced uplink, also referred to as High Speed Uplink Packet Access (HSUPA), giving a radio access technology that is highly competitive.

[0003] In order to be prepared for further increasing user demands and to be competitive against new radio access technologies, 3GPP introduced a new mobile communication system which is called Long Term Evolution (LTE). LTE is designed to meet the carrier needs for high speed data and media transport as well as high capacity voice support for the next decade. The ability to provide high bit rates is a key measure for LTE.

[0004] The work item (WI) specification on Long-Term Evolution (LTE) called Evolved UMTS Terrestrial Radio Access (UTRA) and UMTS Terrestrial Radio Access Network (UTRAN) is finalized as Release 8 (LTE Rel. 8). The LTE system represents efficient packet-based radio access and radio access networks that provide full IP-based functionalities with low latency and low cost. In LTE, scalable multiple transmission bandwidths are specified such as 1.4, 3.0, 5.0, 10.0, 15.0, and 20.0 MHz, in order to achieve flexible system deployment using a given spectrum. In the downlink, Orthogonal Frequency Division Multiplexing (OFDM) based radio access was adopted because of its inherent immunity to multipath interference (MPI) due to a low symbol rate, the use of a cyclic prefix (CP) and its affinity to different transmission bandwidth arrangements. Single-carrier frequency division multiple access (SC-FDMA) based radio access was adopted in the uplink, since provisioning of wide area coverage was prioritized over improvement in the peak data rate considering the restricted transmit power of the user equipment (UE). Many key packet radio access techniques are employed including multiple-input multiple-output

(MIMO) channel transmission techniques and a highly efficient control signaling structure is achieved in LTE Rel. 8/9.

[0005] LTE architecture

The overall architecture is shown in Fig. 1 and a more detailed representation of the E-UTRAN architecture is given in Fig. 2. The E-UTRAN consists of an eNodeB, providing the E-UTRA user plane (PDCP/RLC/MAC/PHY) and control plane (RRC) protocol terminations towards the user equipment (UE). The eNodeB (eNB) hosts the Physical (PHY), Medium Access Control (MAC), Radio Link Control (RLC) and Packet Data Control Protocol (PDCP) layers that include the functionality of user-plane header-compression and encryption. It also offers Radio Resource Control (RRC) functionality corresponding to the control plane. It performs many functions including radio resource management, admission control, scheduling, enforcement of negotiated uplink Quality of Service (QoS), cell information broadcast, ciphering/ deciphering of user and control plane data, and compression/ decompression of downlink/uplink user plane packet headers. The eNodeBs are interconnected with each other by means of the X2 interface.

[0006] The eNodeBs are also connected by means of the S1 interface to the EPC (Evolved Packet Core), more specifically to the MME (Mobility Management Entity) by means of the S1-MME and to the Serving Gateway (SGW) by means of the S1-U. The S1 interface supports a many-to-many relation between MMEs/Serving Gateways and eNodeBs. The SGW routes and forwards user data packets, while also acting as the mobility anchor for the user plane during inter-eNodeB handovers and as the anchor for mobility between LTE and other 3GPP technologies (terminating S4 interface and relaying the traffic between 2G/3G systems and PDN GW). For idle state user equipments, the SGW terminates the downlink data path and triggers paging when downlink data arrives for the user equipment. It manages and stores user equipment contexts, e.g. parameters of the IP bearer service, network internal routing information. It also performs replication of the user traffic in case of lawful interception.

[0007] The MME is the key control-node for the LTE access-network. It is responsible for idle mode user equipment tracking and paging procedure including retransmissions. It is involved in the bearer activation/deactivation process and is also responsible for choosing the SGW for a user equipment at the initial attach and at time of intra-LTE handover involving Core Network (CN) node relocation. It is responsible for authenticating the user (by interacting with the HSS). The Non-Access Stratum (NAS) signaling terminates at the MME and it is also responsible for generation and allocation of temporary identities to user equipments. It checks the authorization of the user equipment to camp on the service provider's Public Land Mobile Network (PLMN) and enforces user equipment roaming restrictions. The MME is the ter-

mination point in the network for ciphering/integrity protection for NAS signaling and handles the security key management. Lawful interception of signaling is also supported by the MME. The MME also provides the control plane function for mobility between LTE and 2G/3G access networks with the S3 interface terminating at the MME from the SGSN. The MME also terminates the S6a interface towards the home HSS for roaming user equipments.

[0008] LTE RRC states

LTE is based on only two main states: "RRC_IDLE" and "RRC_CONNECTED".

[0009] In RRC_IDLE the radio is not active, but an ID is assigned and tracked by the core network. More specifically, a mobile terminal in RRC_IDLE performs cell selection and reselection — in other words, it decides on which cell to camp. The cell (re)selection process takes into account the priority of each applicable frequency of each applicable Radio Access Technology (RAT), the radio link quality and the cell status (i.e. whether a cell is barred or reserved). An RRC_IDLE mobile terminal monitors a paging channel to detect incoming calls, and also acquires system information. The system information mainly consists of parameters by which the network (E-UTRAN) can control the cell (re)selection process and also how the mobile terminal accesses the network. RRC specifies the control signalling applicable for a mobile terminal in RRC_IDLE, namely paging and system information. The mobile terminal behaviour in RRC_IDLE is specified in more detail e.g. in TS 36.304, current version 12.0.0(NPL 1), chapter 4 "General description of Idle mode" incorporated herein by reference.

[0010] In RRC_CONNECTED the mobile terminal has an active radio operation with contexts in the eNodeB. The E-UTRAN allocates radio resources to the mobile terminal to facilitate the transfer of (unicast) data via shared data channels. To support this operation, the mobile terminal monitors an associated control channel which is used to indicate the dynamic allocation of the shared transmission resources in time and frequency. The mobile terminal provides the network with reports of its buffer status and of the downlink channel quality, as well as neighbouring cell measurement information to enable E-UTRAN to select the most appropriate cell for the mobile terminal. These measurement reports include cells using other frequencies or RATs. The UE also receives system information, consisting mainly of information required to use the transmission channels. To extend its battery lifetime, a UE in RRC_CONNECTED may be configured with a Discontinuous Reception (DRX) cycle. RRC is the protocol by which the E-UTRAN controls the UE behaviour in RRC_CONNECTED.

[0011] The various functions of the mobile terminal in RRC Protocol for and including Connected Mode are described in 3GPP TS 36.331, current version 12.4.1(NPL 2), in

Ch. 4 "Functions", incorporated herein by reference.

[0012] Paging

The present application will differentiate between two types of paging, namely the paging initiated from the non-access stratum (NAS) (termed exemplarily in the following "Paging-NAS") and the paging initiated from the eNodeB (termed exemplarily in the following "Paging-eNB"). Paging-NAS relates to the paging of a particular UE e.g. when paging a UE in connection with an incoming data connection e.g. a mobile-terminating (MT) call. On the other hand, paging-eNB relates to the paging of all the UEs in the cell, and e.g. is used to inform them about a system information change, ETWS message (Earthquake and Tsunami Warning System), CMAS message (Commercial Mobile Alert System) etc. Furthermore, depending on whether the UE is in RRC idle or connected state, the actual paging messages are transmitted differently to the UE. However, the two paging procedures have a lot in common too.

[0013] In general, the UE in RRC_Idle state monitors for paging to detect incoming calls, system information change, for ETWS capable UEs, ETWS notification, and for CMAS capable UEs, CMAS notification. The UE in RRC_Connected state monitors for paging and/or System Information Block Type 1 contents to detect system information change, for ETWS capable UEs, ETWS notification, and for CMAS capable UEs, CMAS notification (see 3GPP TS 36.331, current version v12.4.1, subclause 4.2.1, incorporated herein by reference).

The general paging procedure for transmitting the paging message from EUTRAN to the UE is defined in TS 36.331, current version 12.4.1, subclause 5.3.2 incorporated herein by reference, describing that the purpose of the paging procedure is:

[0014] - to transmit paging information to a UE in RRC_IDLE (Paging-NAS) and/ or;

- to inform UEs in RRC_IDLE and UEs in RRC_CONNECTED about a system information change (Paging-eNB) and/ or;

- to inform about an ETWS primary notification and/ or ETWS secondary notification (Paging-eNB) and/ or;

- to inform about a CMAS notification (Paging-eNB).

[0015] The paging information received in the UE is provided to upper layers, which in response e.g. may the initiate RRC connection establishment to receive an incoming call.

[0016] E-UTRAN performs the paging procedure by transmitting the Paging message at the UE's paging occasion as specified in TS 36.304. E-UTRAN may address multiple UEs within a Paging message by including one PagingRecord for each UE.

[0017] To receive paging messages from E-UTRAN, UEs in idle mode monitor the PDCCH channel for an RNTI value used to indicate paging: the P-RNTI (Paging radio network

temporary identity) which is a common RNTI, i.e. not allocated to any UE explicitly. The UE only needs to monitor the PDCCH channel at certain UE-specific paging possibilities, i.e. at specific subframes within specific radio frames as will be discussed in more detail in the following. The E-UTRAN configures which of the radio frames and subframes can be used for paging in its cell. Each cell broadcasts a default paging cycle Tc, and in addition, upper layers may use dedicated signaling to configure a UE-specific paging cycle TUE; if both are configured, the UE applies the lowest value for the DRX cycle T of the UE.

[0018] In order to explain the procedure for paging as currently defined for LTE-A, the following exemplary cases A, B, and C are defined, as taken from the book LTE – The UMTS Long Term Evolution – From Theory to Practice, Edited by: Stefania Sesia, Issam Toufik, and Matthew Baker, Second Edition, ISBN 9780470660256, section 3.4(NPL 3).

[0019] [Table 1]

Case	UE_ID	T_C	T_{UE}	T	nB	N	Ns	PF	i_s	PO
A	147	256	256	256	64	64	1	76	0	9
B	147	256	128	128	32	32	1	76	0	9
C	147	256	128	128	256	128	2	19	1	4

[0020] The following parameters are used in said respect:

- "TC" is the cell-specific default paging cycle, and can be 32, 64, 128, or 256 radio frames,
- "TUE" is the UE-specific paging cycle of the UE, and can be 32, 64, 128, or 256 radio frames,
- "N" is the number of paging frames within the paging cycle of the UE, and is min (T, nB),
- Ns is the number of paging subframes in a radio frame that may be used for paging, and is max (1, nB/T),

[0021] - nB is the number of paging subframes per paging cycle (across all UEs in the cell), and can be 4T, 2T, T, T/2, T/4, T/8, T/16, T/32; the parameter determines to a large extent the paging capability of the eNB across all UEs in the cell. In general, if nB is set equal to or larger than T, all radio frames may be used for paging (see also parameter N), and there are nB/T POs per PF (see also parameter Ns). In turn, if nB is set lower than T, only a fraction nB/T of the radio frames may be used for paging (see also parameter N), and there is one PO per PF (see also parameter Ns).

[0022] - "T" is the DRX cycle of the UE (also termed paging cycle), is min of TC and TUE,

and specifies how frequently a UE monitors for paging, where a shorter DRX cycle decreases the time for paging but increases battery consumption.

[0023] For example, for cases A and B E-UTRAN has configured one out of every four radio frames and specifically one subframe in each of those radio frames, to be used for paging (see T, Ns, respectively). For case C, there are two subframes in each radio frame that can be used for paging, i.e. Ns=2, and 128 paging frames within the UE's paging cycle, i.e. N=128, available for paging the UEs in the cell. Furthermore, for case B, there are 32 paging frames within the UE's paging cycle (N=32). Across these generally-available paging opportunities configured by the eNB, the paging possibilities for paging the UEs are distributed based on the UE identity.

[0024] In said respect, the particular radio frame and subframe used for paging a particular UE is calculated as follows. A Paging Occasion (PO) is a subframe where there may be a P-RNTI (Paging radio network temporary identity) transmitted on PDCCH addressing the paging message. A Paging Frame (PF) is a radio frame, which may contain one or multiple Paging Occasion(s). In the context of this patent application, the term paging possibility shall refer to the combination of the paging frame and paging subframe.

[0025] The paging frames and paging occasions are defined for example in 3GPP TS 36.304, current version 12.0.0, subclause 7, incorporated herein by reference. Accordingly, the paging frame number (SFN) is calculated according to the following formula:

SFN mod T = (T div N)*(UE_ID mod N)

where UE_ID is IMSI mod 1024.

[0026] When assuming an UE_ID of 147 for all three cases A, B, and C, calculating the above formula results in the paging frame 76 for cases A and B, and paging frame 19 for case C. Furthermore, i_s would be calculated to be 0 for cases A and B, and be 1 for case C.

[0027] The paging occasion has values in the range of [0, 1, ... 9], as in LTE there are 10 subframes within one radio frame. The paging occasion number is selected from a preconfigured table based on the parameters Ns and i_s calculated according to the following formula:

i_s= floor(UE_ID / N) mod Ns.

[0028] The following table is taken from TS 36.304, current version 12.0.0, and is used to determine the Paging Occasion for a particular UE, based on the above parameters Ns and i_s. The following table is intended for FDD.

[0029]

[Table 2]

	PO when i_s=0	PO when i_s=1	PO when i_s=2	PO when i_s=3
1	9	N/A	N/A	N/A
2	4	9	N/A	N/A
4	0	4	5	9

[0030] Therefore, for case A and B, with Ns=1 and i_s=0, the table would yield the subframe number 9, such that the UE for cases A and B would be paged regularly in subframe 9 of radio frame 76 of every paging cycle; i.e. for case A next radio frame 332 and for case B next radio frame 204 etc. For case C, the UE would be paged regularly in subframe 4 of radio frame 19 of every paging cycle, i.e. next radio frame 147 etc.

[0031] The paging frame and paging occasion for the above-discussed cases B and C, is exemplarily depicted in Fig. 3.

[0032] Paging-NAS

For instance, in order to re-establish a connection towards a UE in idle mode, the MME - having been informed e.g. by the UE's P/SGW - sends a paging request message to all eNBs that are part of the so-called tracking area(s) to which the UE belongs and within which the UE can move without having to perform the Tracking Area Update (TAU) procedure (except the periodic TAU procedure).

[0033] When receiving the paging request, the eNodeB(s) of the tracking area(s) then broadcast(s) another paging message over the radio interface in the cells The UE is notified about the paging based on the P-RNTI on the PDCCH and then receives the paging message transmitted over the PDSCH, in the radio resources as indicated by the PDCCH paging notification. When the UE in RRC idle receives the paging message/ signal, it transfers from IDLE to CONNECTED state and establishes an RRC connection with that eNB where it is camped in IDLE mode (e.g. the UE initiates the RRC connection establishment procedure).

[0034] A system overview and message exchange is exemplarily illustrated in Fig. 4, assuming that the UE to be paged by the MME (as triggered by the SGW) is registered at tracking areas TAC1 and TAC3. Consequently, the MME will provide the S1AP paging request to the eNBs of those tracking areas, which in turn will transmit a page at the UE-specific paging possibility (i.e. the PDCCH notification) and then the paging message on the PDSCH resources. The UE is consequently notified about the paging, receives the paging message on the PDSCH, and after confirming its own identity in the paging message, processes the paging message and responds to the paging by e.g. by sending a service request to the MME.

[0035] In the current LTE system, the paging message transmitted from the MME to the eNB, and its content, are defined e.g. by 3GPP TS 36.413, current version 12.4.0(NPL 4), in sub-clauses 8.5 and 9.1.6, incorporated herein by reference. The paging message from the MME to the eNB contains amongst other the following information:

[0036] - UE_ID Index Value: known as UE_ID, which is calculated by (IMSI mod 1024). Correspondingly, the UE_ID may have values in the range of [0, 1 ... 1023].

[0037] - UE Paging Identity: can be the IMSI (as stored on the SIM card) or the SAE-Temporary Mobile subscriber ID (S-TMSI) assigned to the UE during the attach procedure. The UE Paging Identity is transmitted from the eNB to the UE in a paging message over the radio interface (i.e. Uu interface).

[0038] - Paging DRX cycle: is the Discontinuous Reception (DRX) cycle configured in the UE (using NAS signalling) or the default DRX cycle broadcast in the System Information Block (SIB). The default DRX cycle is also known as Paging Cycle in the RadioResourceConfigCommon SIB. The UE may use discontinued reception in IDLE mode in order to reduce power consumption. The DRX cycle is a time interval between monitoring Paging Occurrences for a specific UE. The values of the default DRX/paging cycle broadcast in the SIB are 32, 64, 128 or 256 radio frames.

- UE radio Capability for paging: including the radio access capabilities of the UE, including the coverage extension capability.

[0039] The paging message transmitted from the eNodeB is broadcast in a defined paging possibility as explained above. Paging possibilities are known to the eNodeB and the UE so that they send/listen to the paging message at the same time.

[0040] When Discontinues Reception (DRX) is used, the UE needs only to monitor one PO per DRX cycle.

[0041] As mentioned before, the paging initiated by the non-access stratum (NAS) is UE specific. Consequently, the UE is paged by using the IMSI (or S-TMSI) of the UE as paging identity in the paging message sent in the PDSCH. Therefore, for each UE a separate paging message has to be transmitted from the MME to the eNB(s), which has then to be broadcast from the corresponding eNB(s).

[0042] The paging message transmitted from the eNodeB to the UE is defined in TS 36.331, current version 12.4.1, subclause 6.2.2 Message definition, section "Paging", incorporated herein by reference. This message may contain the following:

[0043] - cmas-Indication: if present, indication of a CMAS notification

- cn-Domain: indicates the origin of paging

- eab-ParamModification: if present, indication of an EAB parameter (SIB14) modification

- etws-Indication: if present, indication often ETWS primary/secondary notification

- imsi: The International Mobile Subscriber Identity, a globally unique permanent

subscriber identity; can also be part of the Paging UE-Identity below
- systemInfoModification: if present, indication of a BCCH modification, other than SIB10-SIB12, SIB14
- ue-Identity: provides the NAS identity of the UE that is being paged

[0044] In the above description, it has been assumed that the UE is in an idle state when receiving the paging, such that the paging message is sent to the UE addressed to the P-RNTI on PDCCH at the UE-specific paging possibilities (based on IMSI of this UE) where the UE verifies that the paging message is indeed intended for it by checking the IDs in the included paging records.

[0045] However, also UEs in RRC connected state may be paged. In this case a downlink information transfer (DLInformationTransfer), containing the paging related information from the NAS, is sent to the UE addressed to the C-RNTI (Cell-RNTI, a unique ID used for identifying RRC connection and scheduling dedicated to a particular UE) on the PDCCH. The DLInformationTransfer message is used for the downlink transfer of NAS or non-3GPP dedicated information. The RRC layer is transparent for this information. For more information, reference is made to TS 36.331, current version 12.4.1, subclause 5.6.1 "DL information transfer" and 6.2.2 "Message definitions" section DLInformationTransfer, incorporate herein by reference.

[0046] Paging from eNB

One of the reasons for an eNodeB to page the UE is a change of system information. In general a change of system information only occurs at specific radio frames, thus implementing the concept of a modification period. System information may be transmitted a number of times with the same content within a modification period. When the network changes (some of) the system information, it first notifies the UEs about this change, which may be done throughout a modification period. In the next modification period, the network then transmits the updated system information. Upon receiving a change notification, the UE acquires the new system information immediately from the start of the next modification period. A paging message is used to inform the UEs in RRC idle and UEs in RRC connected state about a system information change (as mentioned e.g. in TS 36.304, current version 12.0.0, subclause 6.1). If the UE receives a paging message including the systemInfoModification, it knows that the system information will change at the next modification period and boundary. In said case, the UE does not need to check for the UE_ID (not included in the paging message), in view of the presence of the systemInfoModification. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.3, incorporated herein by reference.

[0047] Another reason for the eNodeB to page the UEs is an ETWS (Earthquake and Tsunami Warning system) notification, where the paging message is used to inform

ETWS-capable UEs in RRC idle and in RRC connected state about the presence of an ETWS primary/secondary notification. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.4, incorporated herein by reference. The paging message may also be used to inform CMAS-capable UEs in RRC idle and RRC connected state about the presence of one or more CMAS (Commercial Mobile Alert System) notifications. Further information in said respect can be found in TS 36.331, current version 12.4.1, subclause 5.2.1.5, incorporated herein by reference. Still another reason for the eNB to page UEs in its cell relates e.g. to Enhanced Access Barring for MTC devices, EAB, as explained for example in TS 36.331, current version 12.4.1, subclause 5.2.1.6 incorporated herein by reference.

[0048] For UEs in both RRC connected and idle state the eNB sends a paging notification to the UE(s) addressed to the P-RNTI on the PDCCH at all possible paging occasions (e.g. at subframes 0, 4, 5, and 9) and at all possible paging frames (e.g. N different radio frames in total, calculated according to SFN mod T=T/N (UE_ID mod N) for every possible "UE_ID mod N" value) irrespective of the IMSI of a particular UE in the cell. By transmitting the paging message at all possible paging possibilities within a paging cycle, the eNB ensures that all the UEs receive the paging message. The detailed definitions for determining the paging occasions and paging frames are given above.

[0049] Machine Type Communication (MTC)

As LTE deployments evolve, operators strive to reduce the cost of overall network maintenance by minimizing the number of RATs. In this respect, Machine-Type Communications (MTC) devices is a market that is likely to continue expanding in the future.

[0050] Many MTC devices are targeting low-end (low cost, low data rate) applications that can be handled adequately by GSM/GPRS. Owing to the low cost of these devices and good coverage of GSM/GPRS, there is very little motivation for MTC device suppliers to use modules supporting the LTE radio interface.

[0051] As more and more MTC devices are deployed in the field, this naturally increases the reliance on GSM/GPRS networks. This will cost operators not only in terms of maintaining multiple RATs, but also prevent operators reaping the maximum benefit out of their spectrum (given the non-optimal spectrum efficiency of GSM/GPRS). With users and traffic becoming denser, using more spectral-efficient technologies, such as Long Term Evolution (LTE), allow the operators to utilize their spectrum in a much more efficient way.

[0052] Given the likely high number of MTC devices, the overall resource they will need for service provision may be correspondingly significant, and inefficiently assigned (for further details on objectives for MTC, see for example 3GPP, RP-111112, Vodafone:

"Provision of low-cost MTC UEs based on LTE"(NPL 5), section 4, available at http://www.3gpp.org and incorporated herein by reference).

[0053] Approaches to lower the cost of LTE presently regard the volume of products as the primary reason. The impact of volume can be seen in two possible ways, depending on how low-cost MTC is developed. Firstly, if low-cost MTC may be very similar to mainline LTE and included in LTE chipsets, MTC has the benefit of the volume of LTE. Secondly, a low-cost MTC based on LTE may have significantly lower cost than mainline LTE. Although it appears not to have the volume benefit of LTE, the volume of MTC devices can be even larger due to a potentially greater number of supported MTC applications and scenarios.

[0054] In this respect, the following approaches to lower the cost of LTE, i.e. defining low-cost MTC are discussed and found to have significant UE cost impact (for further details on low-cost MTC devices, see for example 3GPP, R1-112912, Huawei, HiSilicon, CMCC: "Overview on low-cost MTC UEs based on LTE"(NPL 6), section 4, available at http://www.3gpp.org and incorporated herein by reference):

[0055] - Reduction in supported bandwidth for the low-cost LTE: The low cost of 1.4 MHz (6 RB) downlink bandwidth could cover most application scenarios of MTC. However, 3 MHz (15 RB) or 5 MHz (25 RB) could be considered given that the complexity does not increase much. Given that the uplink may have a larger requirement for MTC services, the possibility of reduced transmit power, and small baseband complexity (relative to downlink reception), any reduction in minimum transmission bandwidth in the UE should be carefully justified.

[0056] - Modified PDCCH-related design for the low-cost LTE to simplify the PDCCH blind decoding and give efficient channel access for a large number of MTC devices. A reduction in maximum bandwidth (e.g., 1.4MHz) decreases PDCCH blind decoding naturally.

[0057] - Protocol simplification including HARQ consideration, MAC, RLC and RRC protocol. Signaling reduction between low duty cycle MTC devices and the base station.

- Transmission modes down-selection to maintain coverage and balance complexity.

[0058] Further considerations on low-cost MTC devices relate to an improved indoor coverage. A number of applications require indoor deployment of Machine Type Communication, MTC, devices, e.g. in an apartment basement, or on indoor equipment that may be close to the ground floor etc. These UEs would experience significantly greater penetration losses on the radio interface than normal LTE devices. This effectively means that indoor coverage should be readily available and reliable: i.e. should provide a significant improvement on existing coverage.

[0059] Additionally, regarding the power consumption of low-cost MTC devices it is noted

that many applications require devices to have up to ten years of battery life. In this respect, presently available Power Save Modes appear not sufficient to achieve the envisaged battery life. In this respect, it is anticipated that further techniques are proposed to significantly cut down the power usage of MTC devices e.g. by optimizing signaling exchanges in the system, in order to realize battery life of up to ten years.

[0060] Enhanced Coverage mode (EC mode)

For improving indoor coverage (for low-cost MTC devices), recent developments have focused on an Enhanced Coverage, EC, mode that is applicable to UEs e.g. operating delay tolerant MTC applications. Another term is "Coverage Extension". The corresponding Work Item in 3GPP Release 12 "Low cost & enhanced coverage MTC UE for LTE" came to the conclusion that further complexity reduction of LTE devices for MTC can be achieved if additional complexity reduction techniques are supported, as apparent from the study report TR 36.888. The study report TR 36.888 concluded that a coverage improvement target of 15-20 dB for both FDD and TDD in comparison to a normal LTE footprint could be achieved to support the use cases where MTC devices are deployed in challenging locations, e.g. deep inside buildings, and to compensate for gain loss caused by complexity-reduction techniques. MTC coverage enhancements are now expected to be introduced in 3GPP Release 13.

[0061] The general objective is to specify a new UE for MTC operation in LTE that allows for enhanced coverage and lower power consumption. Some of the additional objectives are given below:

- Reduced UE bandwidth of 1.4 MHz in downlink and uplink.

-- Bandwidth reduced UEs should be able to operate within any system bandwidth.

-- Frequency multiplexing of bandwidth reduced UEs and non-MTC UEs should be supported.

-- The UE only needs to support 1.4 MHz RF bandwidth in downlink and uplink.

-- The allowed re-tuning time supported by specification (e.g. ~0 ms, 1 ms) should be determined by RAN4.

[0062] - Reduced maximum transmit power.

-- The maximum transmit power of the new UE power class should be determined by RAN4 and should support an integrated PA implementation.

[0063] - Reduced support for downlink transmission modes.

[0064] - The following further UE processing relaxations can also be considered within this work item:

-- Reduced maximum transport block size for unicast and/or broadcast signalling.

-- Reduced support for simultaneous reception of multiple transmissions.

-- Relaxed transmit and/or receive EVM requirement including restricted modulation scheme. Reduced physical control channel processing (e.g. reduced number of blind

decoding attempts).

-- Reduced physical data channel processing (e.g. relaxed downlink HARQ time line or reduced number of HARQ processes).

-- Reduced support for CQI/CSI reporting modes.

[0065] A relative LTE coverage improvement - corresponding to 15 dB for FDD - for the UE category/type defined above and other UEs operating delay-tolerant MTC applications with respect to their respective normal coverage shall be possible. At least some of the following techniques, which shall be applicable for both FDD and TDD, can be considered to achieve this:

[0066] - Subframe bundling techniques with HARQ for physical data channels (e.g. PDSCH, PUSCH)

- Elimination of use of control channels (e.g. PCFICH, PDCCH)
- Repetition techniques for control channels (e.g. PBCH, PRACH, (E)PDCCH)
- Either elimination or repetition techniques (e.g. PBCH, PHICH, PUCCH)
- Uplink PSD boosting with smaller granularity than 1 PRB
- Resource allocation using EPDCCH with cross-subframe scheduling and repetition (EPDCCH-less operation can also be considered)

[0067] - New physical channel formats with repetition for SIB/RAR/Paging

- A new SIB for bandwidth reduced and/or coverage enhanced UEs
- Increased reference symbol density and frequency hopping techniques
- Relaxed "probability of missed detection" for PRACH and initial UE system acquisition time for PSS/SSS/PBCH/SIBs can be considered as long as the UE power consumption impact can be kept on a reasonable level.
- Spreading: Spreading refers to spreading of information across resources including time-frequency domain resources or even spreading using Scrambling (or Channelization) codes.

[0068] There can be also other techniques than those listed above.

The amount of coverage enhancement should be configurable per cell and/or per UE and/or per channel and/or group of channels, such that different levels of coverage enhancements exist. The different levels of coverage enhancement could mean different level of CE techniques being applied to support the CE-device transmission and reception. Relevant UE measurements and reporting to support this functionality should be defined.

[0069] For more details, see for example 3GPP RP-141865 "Revised WI: Further LTE Physical Layer Enhancements for MTC"(NPL 7) sourced by Ericsson, available at http://www.3gpp.org and incorporated herein by reference.

[0070] Notably, coverage enhancements of 15/ 20 dB for UEs in the Enhanced Coverage mode with respect to their nominal coverage means that the UEs have to be capable of

receiving extremely low signal strengths. This applies not only to the initial scanning operation, the cell search and the cell selection operation but also the subsequent communication scheme to be performed by the UE.

[0071] Early attempts to define the Enhanced Coverage mode have focused on modifications of the radio transmissions. In this respect, discussions have focused on repeated transmissions as being the main technique to improve the coverage. Repetitions can be applied to every channel for coverage improvement.

[0072] An exemplary implementation of these repeated transmissions prescribes that the same data is transmitted across multiple sub-frames. Yet, it will become immediately apparent that these repeated transmissions will use more resource blocks (time-frequency) resources than required for normal coverage UEs.

Summary

[0074] One non-limiting and exemplary embodiment provides an improved method for paging all user equipments in a cell, particularly involving user equipments which need coverage extension. Another non-limiting and exemplary embodiment provides an improved method for paging one user equipment in a cell, particularly a user equipment which needs coverage extension.

The independent claims provide non-limiting and exemplary embodiments. Advantageous embodiments are subject to the dependent claims.

According to a first aspect, the present disclosure improves the paging procedure by which a radio base station can page the user equipments in its cell, particularly for the case where the paging shall also reach user equipments which require coverage extension, i.e. user equipments that are in poor radio conditions but support coverage extension techniques as explained in the background section. The first aspect refers to the case were paging is initiated by the radio base station and shall reach all user equipments in the cell of the radio base station; in other words, the paging is not UE specific but cell specific, and can be for example used so as to broadcast a warning message or to inform UEs about an imminent system information change.

[0075] Consequently, the paging must reach user equipments that require coverage extension as well as "normal" user equipments which do not require coverage extension. One main idea of the first aspect is the definition of a coverage-extension-specific paging possibility, which is specifically defined for those user equipments that support coverage extension techniques, and more precisely which need coverage extension to be reliably reached. Correspondingly, the CE-UEs not only monitor the UE-specific paging possibility, calculated based on their identities, but additionally monitor a (at least one) different paging possibility dedicated to achieve coverage extension paging. Both CE-user equipments in idle and connected state can be configured to monitor this CE-specific paging possibility. Consequently, in order to reach those CE-UEs, the radio base station pages the CE-UEs at said CE-specific paging possibility, and uses one of the plurality of available techniques (e.g. repetition or increased transmission power) for extending the coverage of the paging and thus to reliably reach the CE-UE.

[0076] Like a usual UE-specific paging possibility, this CE-specific paging possibility is defined by a particular radio frame number and subframe number, and occurs regularly e.g. at every paging cycle.

[0077] Since the CE-specific paging possibility shall preferably only be monitored by CE-UEs, the radio base station still needs to reach the other non-CE-UEs and can thus, as described in the background section, perform the paging at all possible paging possibilities of a paging cycle, so as to reach all UEs in the cell. In this case the radio base station would not use a coverage extension technique, since the radio base station can be sure that the CE-UEs will be reached by the paging at the CE-specific paging possibility and not for all possible.

[0078] One advantage of the above-described first aspect is that, by providing one dedicated paging possibility for CE-UEs, downlink resources can be saved. The coverage extension techniques, which can be a heavy burden to the radio base station(s) are applied in a very limited manner, namely for just one paging possibility.

[0079] One set of variants of the first aspect differs as to how this CE-specific paging pos-

sibility is defined. In general, it can be said that the CE-specific paging possibility must be known to both the CE-UE(s) and the radio base station(s), so as to ensure that the paging can be successful. However, how exactly the CE-specific paging possibility is defined can vary. One solution is that the radio frame number and the subframe number of the CE-specific paging possibility is fixed beforehand such that corresponding information can be e.g. pre-stored at the radio base station and the CE-UE (e.g. in the USIM), or the radio base station can broadcast same in its cell. Another possible solution is that a plurality of possible paging subframes, generally configured for the system by the radio base station, is divided to be used either as a UE-specific paging subframe or as a CE-specific paging subframe. By correspondingly configuring the paging parameter(s) (e.g. nB) of normal UEs and CE-UEs it is possible that CE-UEs are assigned e.g. one normal UE-specific paging subframe and one CE-specific paging subframe. Still another solution is based on an additional CE-specific UE identity that is assigned exclusively to CE-UEs and which can be used for calculating the CE-specific paging possibility; in addition, as in the prior art, the UE-specific paging possibility is calculated based on the usual identity of the CE-UE (e.g. IMSI).

[0080] According to a second aspect, the paging procedure by which a radio base station pages a user equipment which requires coverage extension in its cell is improved. This second aspect refers to the case where the paging is initiated in the core network (NAS) and is destined to a single UE (or a very limited number of UEs), in contrast to the first aspect dealing with cell-wide paging initiated by the eNB. The paging which is directed at a particular CE-UE shall reliably reach the CE-UE, and thus the radio base station shall use one appropriate coverage extension technique for the CE paging. In order to avoid unnecessary CE paging from the radio base station, the CE-capable UEs will implement a measurement and reporting procedure according to which the radio base station is informed as to the current CE status of the UE. The radio base station will thus only perform a CE paging for a CE-capable UE that is indeed currently in the CE status, i.e. currently requiring coverage extension. CE-UEs, although CE capable, will not be paged with a coverage extension technique, if the status of the CE-capable UE, informed to the radio base station, indicates that no coverage extension is actually required by this CE-capable UE at the moment.

[0081] Appropriate radio measurements are regularly performed by the CE-capable UE(s) to determine whether coverage extension is necessary or not at the moment. The measurements could also be triggered by the radio base station or a core network entity when being interested in the current CE status. These measurements could include e.g. at least one of RSRQ, RSRP, channel quality, block error rate, or any other suitable measurement parameter. Appropriate threshold(s) can be defined to which the CE-capable UE(s) compare(s) the measurement results to determine whether it requires or

not coverage extension.

[0082] Consequently, a particular CE-capable UE can change it CE-status, i.e. toggle between being a CE-UE (i.e. indeed requiring coverage extension) and a non-CE-UE (i.e. supporting CE but not requiring CE at the moment).

[0083] The radio base station is kept updated on the current CE status of the CE-capable UE and thus (should) knows at the time of paging whether coverage extension is indeed necessary or not for the paging. In order to limit uplink traffic, the informing of the radio base station could be limited to the cases where the CE status of the CE-capable UE is changed, i.e. from non-CE-UE to CE-UE and vice versa. Of course it should also be possible for the CE-capable UE to measure and report such information/ measurements periodically even in the absence of said toggling. In this case, the eNB could, based on its implementation, perform some averaging of the received information including measurement reports and determine that a toggling of CE state is indeed helpful. The step of informing may be done, e.g. directly between the CE-capable UE and the radio base station, e.g. for CE-capable UEs that are in connected state and thus may provide the corresponding CE status to the radio base station. Alternatively, the CE-capable UE may report to a core network entity, which in turn may inform the radio base station, at the latest when triggering for paging; this may be done e.g. for those cases where the CE-capable UE is in idle state and thus has no active connection with the radio base station.

[0084] Correspondingly, the paging for CE-UE is performed by the radio base station by using a CE technique, whereas paging for a non-CE-UE is performed without using a CE technique. The CE-capable UE appropriately receives the CE paging or normal paging.

[0085] Correspondingly, in one general first aspect, the techniques disclosed here feature a method for paging all user equipments in a cell controlled by a radio base station in a mobile communication system. At least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment. The CE user equipments in the cell regularly monitor the at least one CE-specific paging possibility. When the radio base station determines to page all the user equipments in the cell, the radio base station pages the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0086] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities is defined for paging a specific user equipment in the cell of the radio base station. The

CE user equipments and non-CE user equipments each monitor a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities. The radio base station — upon determining to page all the user equipments in the cell - additionally performs paging at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension. According to a further example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0087] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and subframe number and is repeated every paging cycle. The at least one CE-specific paging possibility is only monitored by CE user equipments. For example, the at least one CE-specific paging possibility is monitored by CE user equipments in idle state and CE user equipments in connected state.

[0088] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the step of paging includes transmitting by the radio base station a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and includes transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification. For example, the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[0089] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the plurality of techniques for achieving the coverage extension comprise at least one of a repetition technique where a message is repeated by the radio base station for a pre-configured number of times, an increase in transmission power, where a message is transmitted by the radio base station with an increased transmission power, a bundling technique where a .same message is transmitted in a plurality of consecutive subframes, and a spreading technique where a message is transmitted by a larger resource, e.g. via a larger frequency-time resource or channelization code.

[0090] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the step of determining by the radio base station to page all user equipments in the cell is triggered by a change of system information applicable to the cell controlled by the radio base station or by the presence of a message, e.g. a warning message, to be broadcast in the cell controlled by the radio base station.

[0091] According to an advantageous variant of the first aspect which can be used in

addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. For example, information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment, or broadcast by the radio base station in the cell. Further exemplary, the pre-configured subframe number is 1, 2, 3, 6, 7, or 8.

[0092] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of paging possibilities are defined for paging in the cell of the radio base station, wherein a first value of at least one parameter for calculating the UE-specific paging possibility is different from a second value of the at least one parameter for calculating a CE-specific paging possibility such that the plurality of paging possibilities are divided to be used either as the CE-specific paging possibility or the UE-specific paging possibility. CE user equipments are configured to use the first value of the at least one parameter for calculating the UE-specific paging possibility and to use the second value of the at least one parameter for calculating the CE-specific paging possibility. Non-CE user equipments are configured to use the first value of the at least one parameter for calculating the UE-specific paging possibility and to not calculate the CE-specific paging possibility.

[0093] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, 6, wherein CE user equipments are assigned a CE-specific user equipment identity based on which the CE-specific paging possibility is calculated by the radio base station and the CE user equipments. For example, the CE-specific user equipment identity is the same for all CE-configured user equipments, and the CE-specific user equipment identity is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment or broadcast by the radio base station in the cell. Further for example, a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific user equipment identity is defined.

[0094] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, wherein a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific paging possibility is defined for paging the CE user equipments configured for that level of coverage extension.

[0095] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the radio base station determines whether there are CE user equipments in idle state in its cell by performing a counting procedure

where the CE user equipments in idle state inform the radio base station about their presence in the cell controlled by the radio base station. For example, the determination is only performed in case there are no CE user equipments in connected state in the cell.

[0096] Correspondingly, in one general first aspect, the techniques disclosed here feature a user equipment located in a cell controlled by a radio base station in a mobile communication system. The user equipment, in short CE user equipment, requires coverage extension, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for the CE user equipment. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE user equipment. A processor of the CE user equipment regularly monitors the at least one CE-specific paging possibility. A receiver of the CE user equipment receives a paging from the radio base station at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0097] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities is defined for paging a specific user equipment in the cell of the radio base station. The processor of the CE user equipment monitors a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities. In a further example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0098] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and subframe number and is repeated every paging cycle. In a further example, the at least one CE-specific paging possibility is monitored by the CE user equipment when in idle state and when in connected state.

[0099] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the receiver receiving the paging includes: receiving a first paging notification at radio resources of a control channel specific by the at least one CE-specific paging possibility, and includes receiving a second paging message at radio resources of another channel specific by the first paging notification. In a further example, the technique for achieving the coverage extension is used by the CE user equipment to both receive the first paging notification and receive the second paging message.

[0100] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging pos-

sibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. In a further example, a memory of the CE user equipment is adapted to store information to determine the pre-configured radio frame number and the pre-configured subframe number. Exemplarily, the memory is a Universal Subscriber Identity Module, USIM, of the CE user equipment. Or, the receiver of the CE user equipment receives information to determine the pre-configured radio frame number and the pre-configured subframe number, broadcast by the radio base station in the cell.

[0101] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the CE user equipment is assigned a CE-specific user equipment identity, wherein the processor of the CE user equipment is adapted to calculate the CE-specific paging possibility based on the CE-specific user equipment identity. Exemplarily, the CE-specific user equipment identity is the same for all CE-configured user equipments. In a further example, a plurality of different levels of coverage extension is defined. For each level of coverage extension a different CE-specific user equipment identity is defined.

[0102] Correspondingly, in one general first aspect, the techniques disclosed here feature a radio base station for paging all user equipments in a cell controlled by the radio base station in a mobile communication system. At least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment. A processor of the radio base station determines whether to page all the user equipments in the cell. A transmitter of the radio base station pages the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[0103] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a plurality of UE-specific paging possibilities are defined for paging a specific user equipment in the cell of the radio base station, wherein transmitter of the radio base station — upon the processor determining to page all the user equipments in the cell —additionally pages at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension. For example, each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[0104] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the transmitter of the radio base station is

adapted to transmit a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and to transmit a second paging message at radio resources of another channel specified by the first paging notification. Exemplarily, the technique for achieving the coverage extension is applied to both the transmitting of the first paging notification and the transmitting of the second paging message.

[0105] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the processor determines to page all the user equipments in the cell when being triggered by a change of system information applicable to the cell controlled by the radio base station or by the presence of a message, e.g. a warning message, to be broadcast in the cell controlled by the radio base station.

[0106] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility. Exemplarily, information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in the radio base station, wherein the transmitter of the radio base station broadcasts the information to determine the pre-configured radio frame number and subframe number.

[0107] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, a CE-specific user equipment identity is assigned to the CE user equipments, wherein the processor of the radio base station is adapted to calculate the CE-specific paging possibility based on the CE-specific user equipment identity. Exemplarily, the transmitter of the radio base station is adapted to broadcast the CE-specific user equipment identity in the cell.

[0108] According to an advantageous variant of the first aspect which can be used in addition or alternatively to the above, the processor of the radio base station determines whether there are CE user equipments in idle state in its cell by performing a counting procedure. Exemplarily, the determination is only performed in case there are no CE user equipments in connected state in the cell.

[0109] Correspondingly, in one general second aspect, the techniques disclosed here feature a method for paging a user equipment in a cell controlled by a radio base station in a mobile communication system. The user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. Radio measurements are performed by the CE-capable user equipment, which determines whether coverage extension is necessary or not, based on the results of the

radio measurements. The radio base station is informed about whether the CE-capable user equipment needs coverage extension or not, based on the determination result. When paging the CE-capable user equipment, the radio base station applies or not applies one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[0110] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[0111] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of determining whether coverage extension is necessary comprises the step of comparing by the CE-capable user equipment the result of the radio measurements with a first threshold to determine whether coverage extension is necessary. For example, the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold. The step further comprises comparing by the CE-capable user equipment the result of the radio measurements with a second threshold to determine whether coverage extension is not necessary. For example, the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[0112] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of informing the radio base station about the CE-capable user equipment needing coverage extension or not, includes the steps of either transmitting by the CE-capable user equipment information about whether the CE-capable user equipment needs coverage extension or not to the radio base station. In this case, for example the CE-capable user equipment is in a connected state. In a further example, it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state. Alternatively, the step of informing includes the steps of transmitting by the CE-capable user equipment information about whether the CE-capable user equipment needs coverage extension or not to a core network entity. In this case, the core network entity provides the received information to the radio base station. For example, the CE-capable user equipment is in a connected state or in an idle state. In a further example, the core network entity is a mobility management entity.

[0113] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio base station is triggered to page the CE-capable user equipment by a core network entity that initiates and controls the paging,

preferably wherein the core network entity initiating the paging is a mobility management entity.

[0114] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the steps of performing the radio measurements and of determining whether coverage extension is necessary or not is performed regularly at a pre-configured time interval and/or triggered by the radio base station.

[0115] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of informing the radio base station is only performed when the result of the determination is different from the result of the determination previously informed to the radio base station.

[0116] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio base station determines whether the CE-capable user equipment needs coverage extension or not based on the radio resources selected by the CE-capable user equipment for initially attaching to the radio base station; for example, based on the selected preamble or access slot used for a random access procedure performed by the CE-capable user equipment when initially attaching to the radio base station.

[0117] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the step of paging the CE-capable user equipment comprises the steps of transmitting by the radio base station a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE-capable user equipment, and transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification. In a further example, the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[0118] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, upon successfully being paged by the radio base station, the CE-capable user equipment informs the radio base station about the successful paging, and the radio base station can inform a core network entity responsible for initiating the paging about the successful paging.

[0119] Correspondingly, in one general second aspect, the techniques disclosed here feature a user equipment located in a cell controlled by a radio base station in a mobile communication system. The user equipment, in short CE user equipment, supports coverage extension techniques. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. A processor of the CE user equipment performs radio measurements, and determines whether coverage extension is necessary or not, based on the results of the

radio measurements. A transmitter of the CE user equipment informs the radio base station about whether the CE-capable user equipment needs coverage extension or not, based on the determination result. A receiver of the CE user equipment receives paging from the radio base station, applying or not applying one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not.

[0120] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[0121] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the processor determines whether coverage extension is necessary or not by comparing the result of the radio measurements with a first threshold to determine whether coverage extension is necessary. For example, the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold. Furthermore, the result of the radio measurements is compared with a second threshold to determine whether coverage extension is not necessary. For example, the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[0122] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter informs the radio base station by transmitting information about whether the CE-capable user equipment needs coverage extension or not to the radio base station. For example, the CE-capable user equipment is in a connected state, and furthermore it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state. Alternatively, information about whether the CE-capable user equipment needs coverage extension or not is transmitted to a core network entity. The core network entity provides the received information to the radio base station, preferably wherein the CE-capable user equipment is in a connected state or in an idle state.

[0123] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the processor performing the radio measurements and determining whether coverage extension is necessary or not is performed regularly at a pre-configured time interval and/or triggered by the radio base station.

[0124] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter informs the radio base station

only when the result of the determination is different from the result of the determination previously informed to the radio base station.

[0125] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the receiver receiving the paging includes receiving a first paging notification at radio resources of a control channel specific by a paging possibility specific to the CE-capable user equipment, and receiving a second paging message at radio resources of another channel specific by the first paging notification. For example, the technique for achieving the coverage extension is used by the CE user equipment to both receive the first paging notification and receive the second paging message.

[0126] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter is further adapted to inform the radio base station about the successful paging.

[0127] Correspondingly, in one general second aspect, the techniques disclosed here feature a radio base station for paging a user equipment in a cell controlled by the radio base station in a mobile communication system. The user equipment supports coverage extension techniques. The radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment. A receiver of the radio base station receives information about whether the CE-capable user equipment needs coverage extension or not. A transmitter of the radio base station, when paging the CE-capable user equipment, applies or not applies one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[0128] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the receiver receiving the information includes receiving from the CE-capable user equipment or from a core network entity the information about whether the CE-capable user equipment needs coverage extension or not.

According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, the transmitter of the radio base station transmit a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE user equipment, and transmit a second paging message at radio resources of another channel specified by the first paging notification. For example, the technique for achieving the coverage extension is applied to both the transmitting of the first paging notification and the transmitting of the second paging message.

[0129] According to an advantageous variant of the second aspect which can be used in addition or alternatively to the above, a receiver of the radio base station receives in-

formation about the successful paging of the CE user equipment, and the transmitter of the radio base station informs a core network entity responsible for initiating the paging about the successful paging.

[0130] Additional benefits and advantages of the disclosed embodiments will be apparent from the specification and Figures. The benefits and/or advantages may be individually provided by the various embodiments and features of the specification and drawings disclosure, and need not all be provided in order to obtain one or more of the same.

[0131] These general and specific aspects may be implemented using a system, a method, and a computer program, and any combination of systems, methods, and computer programs.

Description of Embodiments

[0133] A mobile station or mobile node or user terminal or user equipment is a physical entity within a communication network. One node may have several functional entities. A functional entity refers to a software or hardware module that implements and/or offers a predetermined set of functions to other functional entities of a node or the network. Nodes may have one or more interfaces that attach the node to a commu-

nication facility or medium over which nodes can communicate. Similarly, a network entity may have a logical interface attaching the functional entity to a communication facility or medium over which it may communicate with other functional entities or correspondent nodes.

[0134] The term "radio resources" as used in the set of claims and in the application is to be broadly understood as referring to physical radio resources, such as time-frequency resources.

The term "paging possibility" as used in the set of claims and in the application is to be broadly understood as referring to physical radio resources (frequency-time resources) of a control channel (e.g. the PDCCH), which are defined by a radio frame number (also termed paging frame, PF) and a subframe number (also termed paging occasion, PO).

[0135] The expression "coverage-extension UE" (or "CE UE") as used in the set of claims and in the application is to be broadly understood as referring to a UE which requires coverage extension, e.g. because it is in a bad radio condition. The expression "CE-capable UE" shall be used for a UE supporting the coverage extension techniques, irrespective of whether or not the UE indeed requires coverage extension, i.e. a UE can support coverage extension techniques but can still be understood as a "non-CE UE" in case that no coverage extension is currently necessary. From eNB-perspective, it may be unclear at any particular point in time whether a CE-capable UE indeed requires coverage extension or not. The second embodiment is directed at said drawback.

[0136] Correspondingly, the expression "non-CE-UE" as used in the set of claims and in the application is to be broadly understood as referring to a UE which either does not require coverage extension (even when actually supporting the corresponding CE techniques) or does not support coverage extension techniques.

[0137] The expression "UE-specific paging possibility" as used in the set of claims and in the application is to be broadly understood as that paging possibility which is calculated based on the UE-ID (e.g. IMSI), and should be understood in the context of the CE-specific paging possibility which is specific to only coverage extension. As described in the background section, there is only a limited amount of paging possibilities available, across which the UEs are then disposed depending on their IDs. Although a particular paging possibility may be monitored by several UEs, the paging possibilities are UE-specific in the sense that the paging possibility to be monitored by a UE is determined based on the respective UE-ID.

[0138] The terms "paging notification" and "paging message" are distinguished in the set of claims and in the application to respectively refer to the first PDCCH message (which is basically an indication notifying about a paging message e.g. by use of the common P-RNTI) and the subsequent PDSCH message with the actual paging information. The

term "paging" does not make this distinction and shall cover both.

[0139] The term "CE-page" or "CE-paging" as used in the application shall refer broadly to a paging where one out of a plurality of coverage extension techniques is used. For example, when considering the repetition technique as the CE-technique used by an eNB, the "CE-page" will involve repeating the transmission of both paging messages, i.e. the paging notification on the PDCCH and the actual paging message on the PDSCH, for a pre-configured number of times as defined for the repetition technique.

[0140] As explained in the background section, coverage extension techniques are to be implemented for (MTC) devices, and it is unclear how the coverage extension shall be achieved for the paging procedure. However, expenditure is quite high for any of these techniques, such that they should be only used when necessary. For the paging which is initiated by the eNB, and is directed to all UEs in the cell, the currently-implemented paging is applied to all possible paging possibilities so as to reach all UEs. In order to reach also the CE-UEs, a coverage extension technique may be applied to the paging at all possible paging possibilities, which however results in a high expenditure of resources.

[0141] For the paging which is initiated by the NAS, and is directed to one UE only (or a very limited number of UEs), the MME inform the eNB over the S1 interface about the capability of a RRC_Connected UE to allow coverage extension and thus to support the coverage enhancement techniques mentioned above. However, it is unclear whether the UE is actually requiring coverage extension at the time of the page, (e.g. the UE, e.g. MTC device, moved from the cellar to open terrain). Consequently, the eNB might page the UE at the UE-specific paging possibility by using one of the CE techniques, even though the UE is in a good radio condition and would not have needed a coverage extension page. Again, resources are wasted.

[0142] The following exemplary embodiments are conceived by the inventors to mitigate the problems explained above.

[0143] Some of these are to be implemented in the wide specification as given by the 3GPP standards and explained partly in the background section, with the particular key features as explained in the following pertaining to the various embodiments. It should be noted that the embodiments may be advantageously used for example in a mobile communication system, such as 3GPP LTE-A (Release 10/11/12/13) communication systems as described in the Technical Background section above, but the embodiments are not limited to its use in this particular exemplary communication networks.

[0144] The explanations should not be understood as limiting the scope of the disclosure, but as a mere example of embodiments to better understand the present disclosure. A skilled person should be aware that the general principles of the present disclosure as laid out in the claims can be applied to different scenarios and in ways that are not ex-

plicitly described herein. Correspondingly, the following scenarios assumed for explanatory purposes of the various embodiments shall not limit the present disclosure and its embodiments as such.

[0145] In the following a set of embodiments will be explained. Although in the following embodiment, the broad expressions UE, CE-UE, CE-capable UE, are used, the embodiments may be equally applied for MTC devices, i.e. a CE-MTC device or CE-capable MTC device etc.

[0146] First embodiment

According to a first exemplary embodiment, a paging procedure according to which the eNB can page all the UEs in its cell, including those UEs which require coverage extension (and of course also support coverage extension), is presented.

[0147] For this first embodiment it is assumed that the paging is initiated (i.e. triggered) by the eNB itself; in contrast to paging being initiated by the Non-Access-Stratum for which the second embodiment provides an improved paging procedure. As already explained in the background section, paging may be initiated by the eNB for several reasons. For example, system information applicable to the cell may change, and the eNB wants to notify the UEs in its cell such that the UEs may acquire the updated system information immediately from the start of the next modification period. Another reason is that a warning message shall be broadcast in the cell, such as a message from the ETWS or CMAS system, or a message in relation to EAB (Enhanced Access Barring for MTC devices). More detailed information is omitted here, and reference is made to the corresponding passages in the background section which equally apply to the first embodiment.

[0148] Consequently, due to nature of those reasons, the eNB wants to make sure that the paging reaches all UEs in the cell, including those UEs which need coverage extension to be successfully reached. According to the first embodiment, a paging possibility is established for specifically paging those CE-UEs, termed in the following CE-specific paging possibility. More precisely, a CE-specific paging frame and a CE-specific subframe are defined referring to radio resources of the PDCCH that can be used for the CE-paging. In a similarly manner as for the UE-specific paging possibilities defined in the current systems, the CE-specific paging possibility shall occur regularly, e.g. in a cyclic manner according to the paging cycle followed by the UE. The CE-specific paging possibility can be defined in addition to the normal UE-specific paging possibilities already established by the prior art, as discussed in the background section. The CE-specific paging possibility is independent from the UE's identity and shall be the same for a plurality of CE-UEs, e.g. CE-UEs of a particular cell or all CE-UEs in general (or at least all CE-UEs of a specific CE level as will be explained later); this is different from the normal UE-specific paging possibility which – even though

several UEs may monitor the same paging possibility - is specific to the UE due to being calculating based on the ID of the UE(s). This CE-specific paging possibility is known at least to the eNB and the CE-UEs; non-CE-UEs may or may not be informed about this CE-specific paging possibility; however, these non-CE-UEs shall not monitor the CE-specific paging possibility since they may be reached by "normal", i.e. non-CE, paging.

[0149] Furthermore, the paging initiated by the eNB shall reach both UEs in RRC-idle state as well as UEs in RRC-connected state. Consequently, the CE-specific paging possibility shall be monitored by UEs in RRC-idle state and UEs in RRC-connected state.

[0150] The CE-UEs regularly monitor the CE-specific paging possibility to receive the CE-paging, thereby ensuring that they can be successfully paged.

[0151] From the perspective of the eNB, when a page is triggered (e.g. by a system information change), in order to reach the CE-UEs, the eNB will wait for the corresponding paging opportunity given by the CE-specific paging possibility and will then perform a CE page at the CE-specific paging possibility which is monitored by all the CE-UEs in its cell. In a similar manner as for the UE-specific paging possibility, this particularly involves the transmission of the paging notification on the PDCCH at that radio frame and subframe of the CE-specific paging possibility and the corresponding transmission of the paging message on resources of the PDSCH as indicated by the paging notification on the PDCCH. This transmission of the two messages of the CE page is performed by using one appropriate technique of the plurality of CE techniques which are foreseen for achieving the coverage extension, e.g. a repetition technique or a technique where a significantly increased power is used for the transmission.

[0152] The CE-UE(s) in the cell of the eNB monitor the CE-specific paging possibility and thus will receive the paging notification on the PDCCH and subsequently the paging message on the PDSCH. Furthermore, since the eNB will use a coverage extension technique for the paging, which is known to the CE-UE(s), the CE-UE(s) will correspondingly react to the CE-paging by e.g. additionally receiving the repetitions of the paging notification and paging message.

[0153] The paging message will inform the CE-UE(s) about e.g. the system information change or a warning message etc. Depending on the content of the paging message on the PDSCH, the CE-UE will react accordingly, e.g. by acquiring the system information at the next modification period or by providing the warning message to the user of the CE-UE.

[0154] Of course, in a preferred first embodiment the eNB will also want to page the other (non-CE) UEs and for said purpose will page them at all possible paging possibilities, as discussed in the background section, i.e. this will be done without using any CE technique. The non-CE-UEs will each monitor their UE-specific paging possibility and

will thus receive one of the paging performed by the eNB.

[0155] In general, the CE-specific paging possibility may be different from any of the UE-specific paging possibilities, assignable for the UEs, although this is not strictly necessary for the functioning of the first embodiment. For example, only subframes 1, 2, 3, 6, 7, and 8 might be possible for the CE-specific paging possibility, considering that the other subframes 0, 4, 5, 9 are candidates for being selected/calculated as the UE-specific paging possibilities.

[0156] In one possible embodiment, the CE-UEs may keep on regularly monitoring their UE-specific paging possibility, calculated based on their identity as explained in the background section, in addition to the CE-specific paging possibility. Alternatively, the CE-UEs may not monitor the CE-specific paging possibility and the UE-specific paging possibility at the same time, but may only monitor the CE-specific paging possibility.

[0157] Fig. 5 shows, in a similar manner as Fig. 3, the paging possibilities monitored by two different CE-UEs, UE1 and UE2. As apparent from Fig. 5, it is assumed that CE-UE1 monitors a UE-specific paging possibility at radio frame number 76 and number 204 (76+128) etc., respectively at subframe 9 (see also Fig. 3, case B), and that CE-UE2 monitors a UE-specific paging possibility at radio frame number 19 and 147 (19+128) etc., respectively at subframe 4 (see also Fig. 3, case C). In addition, both CE-UE1 and CE-UE2 monitor the same CE-specific paging possibility, which in this exemplary illustration, is assumed to occur at CE-specific paging frames 36, 164 (36+128) etc. and at respective CE-specific subframe 1.

[0158] Fig. 6 shows a sequence diagram for the behavior of a CE-UE for an exemplary variant of the first embodiment. Particularly, it is assumed, in concordance with Fig. 5, that the CE-UE monitors both the CE-specific paging possibility as well as the UE-specific paging possibility, and when it receives the paging notification, the CE-UE will proceed to receive the corresponding paging message at the PDSCH resources indicated by the PDCCH paging notification, either applying or not applying a CE technique. Depending on the content of the paging message, the CE-UE will then react accordingly.

[0159] Fig. 7 shows a sequence diagram for the corresponding behavior of an eNB which wants to perform a paging. After the eNB decides to perform a paging of all UEs in its cell (e.g. due to system information change), it will proceed to perform the usual page at all possible UE-specific paging possibilities to reach all non-CE-UEs, without using any CE technique. On the other hand, to also reach the CE-UEs, the eNB will perform the CE paging at the CE-specific paging possibility, by using one appropriate CE-technique (e.g. repetition or increased transmission power).

[0160] The first embodiment as explained above has the advantage that the use of the

coverage extension technique(s) is limited to one particular CE-specific paging possibility, instead of having to be applied to all possible UE-specific paging possibilities. By using one paging possibility, all (or at least a plurality) of CE-UEs can be paged at the same time. Corresponding downlink resources can thus be saved. Furthermore, the CE-specific paging possibility is independent from the real IMSI of any CE-UE.

[0161] The CE-specific paging possibility can be defined in a number of different ways, but must always provide a CE-specific paging radio frame number and CE-specific paging subframe number, known to both the CE-UE(s) and the eNB(s).

[0162] According to a first variant of the first embodiment, the CE-specific paging possibility is fixed beforehand, e.g. not calculated but directly indicated. In one example, the numbers for the CE-specific paging radio frame and subframe are directly defined e.g. in the CE-UE (e.g. in its USIM, UICC etc) and the eNB; in other words, the CE-UE and the eNB would have information indicating particular radio frame and subframe numbers (such as radio frame number 36 and subframe number 1, as for the example of Fig. 4) for the CE-specific paging possibility. This information need not be pre-stored in the CE-UE (e.g. by use of the USIM) but could also be broadcast by the eNB in its cell, e.g. as part of the system information or indicated with a dedicated message when possible, such that the CE-UE(s) learn about the CE-specific paging possibility to be used for CE-paging from the eNB. This would allow different CE-specific paging possibilities to be used by different eNBs.

[0163] Alternatively, instead of directly indicating the CE-specific subframe number, the parameters Ns and i_s (already known from the calculation of the UE-specific paging possibility) could be reused in said respect. In particular, the following exemplary extended table can be used, which, in comparison with the table available from TS 36.304 as explained in the background section, includes at least one additional row for e.g. Ns= 5 (any other unused Ns number can be used of course) with the possible POs at subframes 1, 2, 3, and 6.

[0164] [Table 3]

Ns	PO when i_s=0	PO when i_s=1	PO when i_s=2	PO when i_s=3
1	9	N/A	N/A	N/A
2	4	9	N/A	N/A
4	0	4	5	9
5	1	2	3	6

[0165] For this alternative, Ns and i_s values would be pre-configured for the CE-specific paging possibility such that the CE-UE and eNB could determine, based on the exemplary table above, which CE-specific paging subframe to use. The CE-specific

paging radio frame would in this example still be directly indicated by a corresponding radio frame number.

[0166] The advantage of this first variant is that the CE-UE(s) would not need to calculate Ns and i_s, but may directly use the indicated numbers for the radio frame and subframe of the CE-specific paging possibility.

[0167] According to a second variant of the first embodiment to define the CE-specific paging possibility vis-a-vis the UE-specific paging possibility, the CE-specific paging possibilities are defined by providing different parameter values to the CE-UE(s) than to the non-CE-UEs. It is assumed, that the CE-specific paging subframe is calculated following the equations and principles explained for the UE-specific paging possibility in the background section. By using different parameter values for the same UE, the calculation of the UE-specific paging subframe yields different subframe numbers than the corresponding subframe numbers of the CE-specific paging possibility. As with the first variant explained above, the radio frame number for the CE-specific paging possibility is fixed.

[0168] In one example, the parameter with the different value is "nB", i.e. indicating the number of paging subframes per paging cycle (across all UEs in the cell), where one value is defined for CE-UEs and another value is defined for non-CE-UEs. There could however be another parameter broadcasted by the network for indicating rather directly the segregation of paging subframes between CE-UEs and non-CE-UEs.

[0169] According to a third variant of the first embodiment to define the CE-specific paging possibility, a CE-specific UE identity (e.g. CE-IMSI) is introduced. When considering the various CE levels a CE-UE can be configured for, a CE-level-specific UE identity can be introduced for each CE level. In any case, the CE-IMSI(s) is known to both the eNB and the CE-UE(s). The CE-specific UE identity(ies) can be provided to the CE-UEs beforehand, e.g. broadcast in the cell, or pre-stored in the SIM/ USIM or UICC or even in the Mobile Device, ME. A particular CE-UE and the network will use one of these identities corresponding to the required level of coverage extension support required e.g. one CE-UE deep down in bad radio and the network will use UE-identity1; whereas the same UE when coming back in relatively better radio, but still requiring CE support, will rather use UE-identity2 which is the corresponding use UE-identity for this level of Coverage Extension required. For this to work, it is important that the UE-identity to be used and the corresponding coverage extension required is known to both the network and the CE-UE e.g. by way of specification, or broadcasting etc. and there is a hand-shake between the CE-UE and the network about what level applies to the particular CE-UE at any given point in time. The hand-shake includes the measurement configuration and reporting as described previously.

[0170] It is assumed that basically the same calculation and principles are applied when cal-

culating the CE-specific paging possibility as explained for the UE-specific paging possibility in the background section. Both the eNB and the CE-UE(s) can calculate the same CE-(level)-specific paging possibility by the CE-(level)-specific IMSI instead of using the CE-UE's real IMSI.

[0171] As already mentioned in the background section, different coverage extension levels can be defined (e.g. 15dB, 13 dB etc.), where the respective coverage extension technique can be adapted appropriately to ensure achieving the corresponding coverage extension level. When e.g. considering the repetition CE technique, a coverage extension level to ensure 15dB might require 100 repetitions, whereas less or more repetitions may be necessary to ensure a different CE level. Similarly considerations apply to the other CE-techniques.

[0172] A particular CE-UE is configured for one of those coverage extension levels. Correspondingly, according to further examples of the first embodiment, one CE-specific paging possibility is defined per CE level, i.e. a CE-level-specific paging possibility, such that a CE-UE will only monitor the CE-level-specific paging possibility of the CE-level for which it is configured but not other CE-level-specific paging possibilities that are defined for other CE-levels.

[0173] A further improvement to the first embodiment is that CE-UEs which are in RRC-connected mode may try to read and receive paging at the UE-specific paging possibilities of other UEs. The UE_ID, which is IMSI mod 1024, can only take up to 1024 different values, and the radio frame is calculated based on "UE_ID mod N" such that only N different radio frames are used in each paging cycle. Consequently, a CE-UE could be configured to monitor some or all of the possible radio frames and subframes available for other UEs. This allows the network to not make as many repetitions as would otherwise be required if the UE was not receiving paging other than the UE-specific paging possibilities.

[0174] A further improvement to the first embodiment focuses on when to actually perform a CE page. Until now it has been (silently) assumed that there would be always a CE-UE in a cell, such that any eNB, at any time when paging is triggered, would perform the CE-paging at the CE-specific paging possibility(ies). The eNB is aware of all (CE-)UEs that are in RRC-Connected mode, since these have an active connection with the eNB, and thus the eNB determines whether a CE-UE that require coverage extension is in its cell or not. However, the eNB is not aware of which CE-UEs in RRC-Idle mode are currently in its cell. Consequently, assuming that no CE-UEs in RRC-Connected mode are in the cell of the eNB, the eNB is unaware of whether there is at least one CE-UE in RRC-Idle mode in its cell. To make sure that any possible CE-UEs in Idle mode are reached too, in these cases, the eNB will always have to performing the CE paging. This however may result in a waste of resources for the

case where no CE-UE(s) in RRC-Idle mode were in its cell either.

[0175] According to this improvement, this waste of resources shall be avoided by providing a procedure that allows the eNB to determine whether any CE-UEs are in its cell, be it in RRC-Idle or RRC-Connected state. To said end, the eNB might first determine whether there are any CE-UEs in RRC-Connected mode, which could be done e.g. by maintaining a table with UE-capability information received from the MME or UE. Subsequently, in case the eNB determines that there are no CE-UEs in RRC-Connected mode, a counting procedure is initiated which allows the eNB to determine/ estimate the number of CE-UEs in RRC-idle state in its cell. In one example of a counting procedure the UEs in RRC-Idle on a more or less round robin fashion go to RRC-Connected state and inform the network about the presence of the CE UE in RRC-Idle mode (i.e. about itself). The round robin method can e.g. be implemented using a persistence check method wherein the Idle UEs compare a randomly drawn number against a number broadcasted by the network. Only the one(s) drawing a smaller value will transit to RRC Connected to inform the network. The network can keep the broadcasted value to be small enough so that only a very small percentage of UEs should really pass this test at a given time. This is similar to what is done in MBMS Counting procedure as depicted in RRC specification 3GPP TS 36.331, current version 12.4.1 incorporated herein by reference.

[0176] In consequence, the eNB will only perform the CE page when it has determined that there is at least one CE-UE in its cell, be it in RRC-Idle or RRC-Connected state. As a result, the additional resources for a CE-page are not used in vain.

[0177] Second embodiment

As explained above, the first embodiment relates to an improvement for a paging procedure initiated by the eNB, which then shall page all UEs in its cell. The second embodiment to be presented relates to an improvement for a paging procedure that is initiated by the NAS (Non-Access-Stratum), e.g. the MME, and which is dedicated to just a single UE, or a rather limited number of UEs.

[0178] In particular, for this second embodiment it is assumed that the paging is initiated by the NAS, for instance in order to establish a call with a particular CE-UE; details in said respect have already been provided in the background section (see also Fig. 4) and apply equally to the second embodiment. In this respect the "call" need not be just a voice call but can also refer to other terminating service like SMS, MMS or Pager etc. For instance, the MME — in response to a corresponding trigger from the SGW in the core network — sends a paging message to all eNBs that belong to the tracking area(s) for which the CE-UE is currently registered. Particularly, the MME does not know where a CE-UE in RRC idle is located. Each eNB belonging to one of the TAs in an associated TA-list, in turn, then has to perform paging so as to page this CE-UE to

which the call is destined. Finally, the CE-UE being paged can then establish a connection with the eNB where it is camped and then proceed to accept the incoming call (see also Fig. 4).

[0179] In the above-described scenario, the MME informs the eNBs (over the S1 interface) about the capability(ies) of a (CE-)UE, e.g. whether the UE is capable of supporting coverage extension (and optionally which level of coverage extension). As explained before, this general capability information however gives no information on whether a particular CE-capable UE indeed requires coverage extension at the moment or not; e.g. while a CE-capable UE might have been in a basement for a long time, i.e. thus requiring coverage extension for compensating the bad radio conditions, this very same CE-capable UE might in mean time have emerged from the basement and thus might no longer require coverage extension or still require coverage extension but corresponding to a less demanding coverage extension level.

[0180] Consequently, according to the second embodiment, a procedure is implemented according to which the eNB can learn whether a CE-capable UE is indeed requiring coverage extension or not at the time of paging. To said end, a new measurement and reporting procedure is implemented between the UE and the eNB as will be explained in detail below.

[0181] The CE-capable UE is configured to perform radio measurements that allow determining whether the CE-capable UE is currently indeed requiring coverage extension or not. The radio measurements could refer for example to one or more of the following: Reference Signal Received Power (RSRP), Reference Signal Received Quality (RSRQ), channel quality etc. e.g. as defined in Chapter 5 of 3GPP TS36.214 v10.1.0(NPL 8), or even current Block Error Rate (BLER) estimates or HARQ operating point and any other suitable measurement target. In any case, a skilled person is well aware of how to determine the current radio conditions of a CE-capable UE that allow, in a subsequent step, to determine whether coverage extension is indeed necessary or not.

[0182] After performing the appropriate radio measurements, the CE-capable UE shall then determine whether coverage extension is necessary based on the results of the measurements. In one example, two appropriate thresholds can be defined, to which the measurements results are compared by the CE-capable UE so as to determine the current CE status of the CE-capable UE. For example, an upper threshold can be defined, where if the measurements results (e.g. RSRP or RSRQ) exceed the upper threshold, the CE-capable UE would determine that it does not require coverage extension, i.e. that it currently is a non-CE-UE. Conversely, a different lower threshold can be defined, where if the measurement results (e.g. again RSRP or RSRQ) fall below the lower threshold, the CE-capable would conclude that it does require

coverage extension, i.e. that is currently is a CE-UE. Instead of using two thresholds, the determination of whether CE is required or not, could of course also be determined by simply using one threshold, where measurements results exceeding the threshold would mean that coverage extension is not necessary, and measurements results falling below the threshold would mean that coverage extension is necessary. The same technique can also be used for other measurement possibility like for HARQ operating point i.e. where HARQ operating point exceeding the corresponding HARQ operating point-threshold would mean that coverage extension is not necessary, and HARQ operating point falling below the HARQ operating point-threshold would mean that coverage extension is necessary.

[0183] The radio measurements and CE status determination can be performed regularly by the CE-capable UE, i.e. at specific, pre-configured, intervals, and/or event triggered (one even for exceeding the threshold in either direction as described above), e.g. , and/or triggered by the eNB. In addition to the absolute threshold for the corresponding measurement, the network might also provide the corresponding Hysteresis and Time to Trigger values as described in 3GPP TS 36.331, current version 12.4.1. Hysteresis basically gives a margin or allowance in breaching the threshold in either direction, and the Time to Trigger (TTT) indicates at least how long the said threshold should remain breached/ exceeded for the UE to trigger the corresponding event.

[0184] Which radio measurements shall be performed, at which intervals, against which threshold(s) the measurement results should be compared, and any other necessary information can be pre-configured in the CE-capable UE or provided to the CE-capable UEs from the eNB, e.g. within a corresponding control message which could be signaled by RRC or Layer2 (MAC) or Layer1 (Physical layer signal) and may contain additional parameters including Hysteresis, TTT and the target object like current/ serving and neighbor cell list.

[0185] The CE-capable UE has to make sure that the eNB is kept updated on the current CE status, i.e. on whether the CE-capable UE needs coverage extension or not. This may be done e.g. by reporting every change of CE status to the eNB, such that the eNB knows at the time of paging whether a coverage extension technique shall be applied to the paging or not. Of course the same information can be used for DL messages other than paging and also to UL messages including paging response and other non-paging related messages. Depending on whether the CE-capable UE is in idle mode or connected mode, the reporting of the CE status to the eNB may be different. If the CE-capable UE is in RRC connected state and thus has an active connection with the eNB, the CE-capable UE can directly transmit a CE-status report, e.g. RRC Measurement Report, to the eNB.

[0186] Since such a direct report is not possible for CE-capable UEs in RRC-IDLE (since no

active connection with the eNB is available), the CE-capable UE in idle will report the CE status to the MME, which thus knows whether coverage extension is indeed required or not (independent from the CE-capability of a UE). The MME may either keep the eNB(s) regularly up to date in said respect, or might only provide the corresponding information to the eNB(s) when also triggering the eNB for paging. Of course, also CE-capable UEs in RRC connected could inform the MME, instead of or in addition to the eNB.

[0187] In another alternative, the CE-capable UE in idle will report the CE status and UE NAS identity directly to the serving eNB where the UE is camped in currently e.g. upon cell Selection and Reselection(s), which thus knows whether coverage extension is indeed required or not by maintaining a new Table including the UE NAS identity and CE-requirement.

[0188] Alternatively, another improvement provides that the CE-capable UEs do not change into RRC-idle state and thus remain all the time in RRC-connected state, such that the CE-capable UE can always transmit the measurement report directly to the eNB. The eNB can ensure that the UE remains in connected state by never sending the RRC Connection Release message to the UE i.e. basically ignoring any inactivity timer in the eNB for this UE.

[0189] In any case, the eNB, when being triggered to page a particular CE-capable UE, will be informed about and will consider whether said CE-capable UE indeed requires coverage extension or not. Based on the thus known current CE status of the UE, the eNB will or will not apply an appropriate CE technique to the paging of the CE-capable UE. As explained in detail for the first embodiment already, applying the CE technique to paging involves applying the CE technique to both the paging notification transmitted on the PDCCH and the actual paging message transmitted on the PDSCH as addressed by the PDCCH.

[0190] In other words, two measurement events are defined, one referring to the case where the radio measurements indicate that coverage extension is required, and the other referring to the case where the radio measurements indicate that coverage extension is not required. When any of the two events occur, this is reported to the eNB (either directly or via the core network entity, e.g. MME).

[0191] Fig. 8 shows a message sequence diagram for an exemplary paging procedure according to the second embodiment. As apparent therefrom, a measurement control message is provided from the eNB to the UE, which is assumed to include all information necessary to configure the UE to perform the radio measurements and to determine the CE-status based on the measurement results. Fig. 8 also shows the measurement report message from the UE to the eNB, which is transmitted to the eNB to allow the eNB to update the CE status of the UE. This allows in consequence that the

eNB performs the paging of the UE by using or not using a CE technique depending on the CE status of the UE.

[0192] Fig. 9 shows a simplified sequence process diagram for the CE-capable UE for one particular exemplary second embodiment as explained above where the measurement and reporting procedure is depicted in parallel to the page monitoring procedure.

[0193] Fig. 10 shows a simplified sequence process diagram for the eNB as explained above including the reception and update procedure for the CE status of the UE, and the parallel paging procedure which depends on the CE status.

[0194] Fig. 8 additionally shows an optional determination of the initial coverage extension status of the UE, which can be done directly upon the initial access of the UE to the eNB (see dashed box). In particular, the UE when initially attaching to a cell (and to the corresponding eNB) usually performs a RACH procedure, which involves e.g. the selection of an appropriate preamble, access slot etc. The CE-capable UE would, during initial access, determine its CE status in order to appropriately select the RACH resources (e.g. preamble, access slot, etc). Now, the eNB can estimate the radio conditions of the UE, and thus the CE status of the UE, based on the parameters, like preambles, preamble format or even the physical resources that the UE selected to perform the RACH procedure.

[0195] Another improvement of the second embodiment, which is also illustrated in Fig. 8 by use of a dashed arrow, refers to a feedback message transmitted from the eNB to the UE about the successful reception of the measurement report, i.e. CE status update, and confirmation that the toggling (between CE and non-CE) is successfully applied at the network side and therefore the UE should also toggle and transmit/ receive according to the new toggled state. By e.g. sending back information on the current CE status, the eNB can make sure that the CE-capable UE and the eNB have the same understanding of the CE status, and behave accordingly in a same manner. For instance, if the measurement report is lost, or decoded incorrectly at the eNB, the eNB would not change the CE status, and the UE and eNB would have different CE status (e.g. until the next, successful, measurement report is received by the eNB). Also, even successful reception of the measurement report is not a guarantee that eNB is fine with the toggling for reasons like admission control or for independent toggling evaluation at the eNB side. In this respect, the triggering of a measurement event is just one of the input parameter for the eNB to decide about the said toggling of CE state, and eNB may take the final decision based on cell and System specific considerations. In absence of the feedback message transmitted from the eNB to the UE about the successful reception of the measurement report and confirming that the toggling (between CE and non-CE) is successfully applied at the network side, obviously, different CE status might lead to a waste of radio resources or to an unsuccessful

paging, which is avoided by providing a feedback on the successful CE status update.

[0196] Still a further improvement of the second embodiment is also illustrated in Fig. 8. As indicated by the dashed arrow, the UE can inform the eNB immediately when a CE page was successful. In particular, instead of waiting to receive e.g. all repetitions of the CE page, as soon as the CE page is successfully received (e.g. the actual paging message was successfully decoded/delivered to the higher layer), the CE-capable UE informs the eNB in said respect. In turn, the eNB can inform the MME in the core network, which may then abort the page in the other eNBs of all the tracking areas (not shown in Fig. 8) pertaining to a corresponding TA-list. Radio resources are thus not wasted by other eNBs.

[0197] Third embodiment

According to a third embodiment, the first embodiment and the second embodiments are combined such that CE devices can be paged both at the NAS level and the AS level (i.e. initiated by NAS and initiated by eNB). Thus, the separation of NAS and AS is maintained as in legacy systems. Furthermore, the first and second embodiments are simple to implement and have no impact on legacy procedures.

[0198] Hardware and Software Implementation of the present disclosure

Other exemplary embodiments relate to the implementation of the above described various embodiments using hardware and software. In this connection a user terminal (mobile terminal) and an eNodeB (base station) are provided. The user terminal and base station is adapted to perform the methods described herein, including corresponding entities to participate appropriately in the methods, such as receiver, transmitter, processors.

[0199] It is further recognized that the various embodiments may be implemented or performed using computing devices (processors). A computing device or processor may for example be general purpose processors, digital signal processors (DSP), application specific integrated circuits (ASIC), field programmable gate arrays (FPGA) or other programmable logic devices, etc. The various embodiments may also be performed or embodied by a combination of these devices.

[0200] Further, the various embodiments may also be implemented by means of software modules, which are executed by a processor or directly in hardware. Also a combination of software modules and a hardware implementation may be possible. The software modules may be stored on any kind of computer readable storage media, for example RAM, EPROM, EEPROM, flash memory, registers, hard disks, CD-ROM, DVD, etc.

[0201] It should be further noted that the individual features of the different embodiments may individually or in arbitrary combination be subject matter to another embodiment.

[0202] It would be appreciated by a person skilled in the art that numerous variations and/or

modifications may be made to the present disclosure as shown in the specific embodiments. The present embodiments are, therefore, to be considered in all respects to be illustrative and not restrictive.

Claims

[Claim 1] A method for paging all user equipments in a cell controlled by a radio base station in a mobile communication system, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment, the method comprising the steps of:
regularly monitoring by the CE user equipments in the cell the at least one CE-specific paging possibility,
determining by the radio base station to page all the user equipments in the cell, and
paging by the radio base station the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 2] The method according to claim 1, wherein a plurality of UE-specific paging possibilities are defined for paging a specific user equipment in the cell of the radio base station, wherein the CE user equipments and non-CE user equipments each monitor a respective UE-specific paging possibility out of the plurality of UE-specific paging possibilities,
wherein the radio base station — upon determining to page all the user equipments in the cell - additionally performs paging at all of the plurality of UE-specific paging possibilities without using one of the plurality of techniques for achieving coverage extension,
preferably wherein each of the plurality of UE-specific paging possibilities is different from the at least one CE-specific paging possibility.

[Claim 3] The method according to claim 1 or 2, wherein the step of paging includes:
transmitting by the radio base station a first paging notification at radio resources of a control channel specified by the at least one CE-specific paging possibility, and
transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification,
preferably wherein the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[Claim 4] The method according to one of claims 1 to 3, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility, preferably wherein information to determine the pre-configured radio frame number and the pre-configured subframe number is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment, or broadcast by the radio base station in the cell, and preferably wherein the pre-configured subframe number is 1, 2, 3, 6, 7, or 8.

[Claim 5] The method according to one of claims 1 to 3, wherein CE user equipments are assigned a CE-specific user equipment identity based on which the CE-specific paging possibility is calculated by the radio base station and the CE user equipments,
preferably wherein the CE-specific user equipment identity is the same for all CE-configured user equipments,
preferably wherein the CE-specific user equipment identity is stored in a Universal Subscriber Identity Module, USIM, of the CE user equipment or broadcast by the radio base station in the cell;
preferably wherein a plurality of different levels of coverage extension is defined, and wherein for each level of coverage extension a different CE-specific user equipment identity is defined.

[Claim 6] A user equipment located in a cell controlled by a radio base station in a mobile communication system, the user equipment, in short CE user equipment, requiring coverage extension, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for the CE user equipment, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE user equipment, the CE user equipment comprising:
a processor adapted to regularly monitor the at least one CE-specific paging possibility,
a receiver adapted to receive a paging from the radio base station at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 7] The user equipment according to claim 6, wherein each of the at least one CE-specific paging possibility refers to radio resources of a control

channel defined by a radio frame number and a subframe number which are pre-configured such that the radio frame number and the subframe number are fixed for the CE-specific paging possibility, preferably wherein a memory of the CE user equipment is adapted to store information to determine the pre-configured radio frame number and the pre-configured subframe number, preferably wherein the memory is a Universal Subscriber Identity Module, USIM, of the CE user equipment, or
preferably wherein the receiver of the CE user equipment is further adapted to receive information to determine the pre-configured radio frame number and the pre-configured subframe number, broadcast by the radio base station in the cell.

[Claim 8] A radio base station for paging all user equipments in a cell controlled by the radio base station in a mobile communication system, wherein at least one regularly-occurring coverage-extension-specific paging possibility, in short CE-specific paging possibility, is defined for paging user equipments that require coverage extension, in short CE user equipments, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for a CE user equipment, the radio base station comprising:
a processor adapted to determine whether to page all the user equipments in the cell, and
a transmitter adapted to page the CE user equipments in the cell at the CE-specific paging possibility, using one of the plurality of techniques for achieving the coverage extension.

[Claim 9] A method for paging a user equipment in a cell controlled by a radio base station in a mobile communication system, wherein the user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the method comprising the steps of:
performing radio measurements by the CE-capable user equipment,
determining by the CE-capable user equipment whether coverage extension is necessary or not, based on the results of the radio measurements,
wherein the radio base station is informed about whether the CE-capable user equipment needs coverage extension or not, based on the determination result,

when paging the CE-capable user equipment, applying or not applying by the radio base station one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.

[Claim 10] The method according to claim 9, wherein the radio measurements performed by the CE-capable user equipment include measurements of a Reference Signal Received Power, RSRP, and/or Reference Signal Received Quality, RSRQ, and/or a channel quality, and/or a block error rate and/ or HARQ operating point.

[Claim 11] The method according to claim 9 or 10, wherein the step of determining whether coverage extension is necessary comprises the steps of:
comparing by the CE-capable user equipment the result of the radio measurements with a first threshold to determine whether coverage extension is necessary, preferably wherein the comparison determines that coverage extension is necessary when the result of the radio measurements falls below the first threshold,
comparing by the CE-capable user equipment the result of the radio measurements with a second threshold to determine whether coverage extension is not necessary, preferably wherein the comparison determines that coverage extension is not necessary when the result of the radio measurement exceeds the second threshold.

[Claim 12] The method according to one of claims 9 to 11, wherein the step of paging the CE-capable user equipment comprises the steps of:
transmitting by the radio base station a first paging notification at radio resources of a control channel specified by a paging possibility specific to the CE-capable user equipment, and
transmitting by the radio base station a second paging message at radio resources of another channel specified by the first paging notification, preferably wherein the technique for achieving the coverage extension is applied to both steps of transmitting the first paging notification and of transmitting the second paging message.

[Claim 13] A user equipment located in a cell controlled by a radio base station in a mobile communication system, the user equipment, in short CE user equipment, supporting coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the user equipment comprising:
a processor adapted to perform radio measurements,

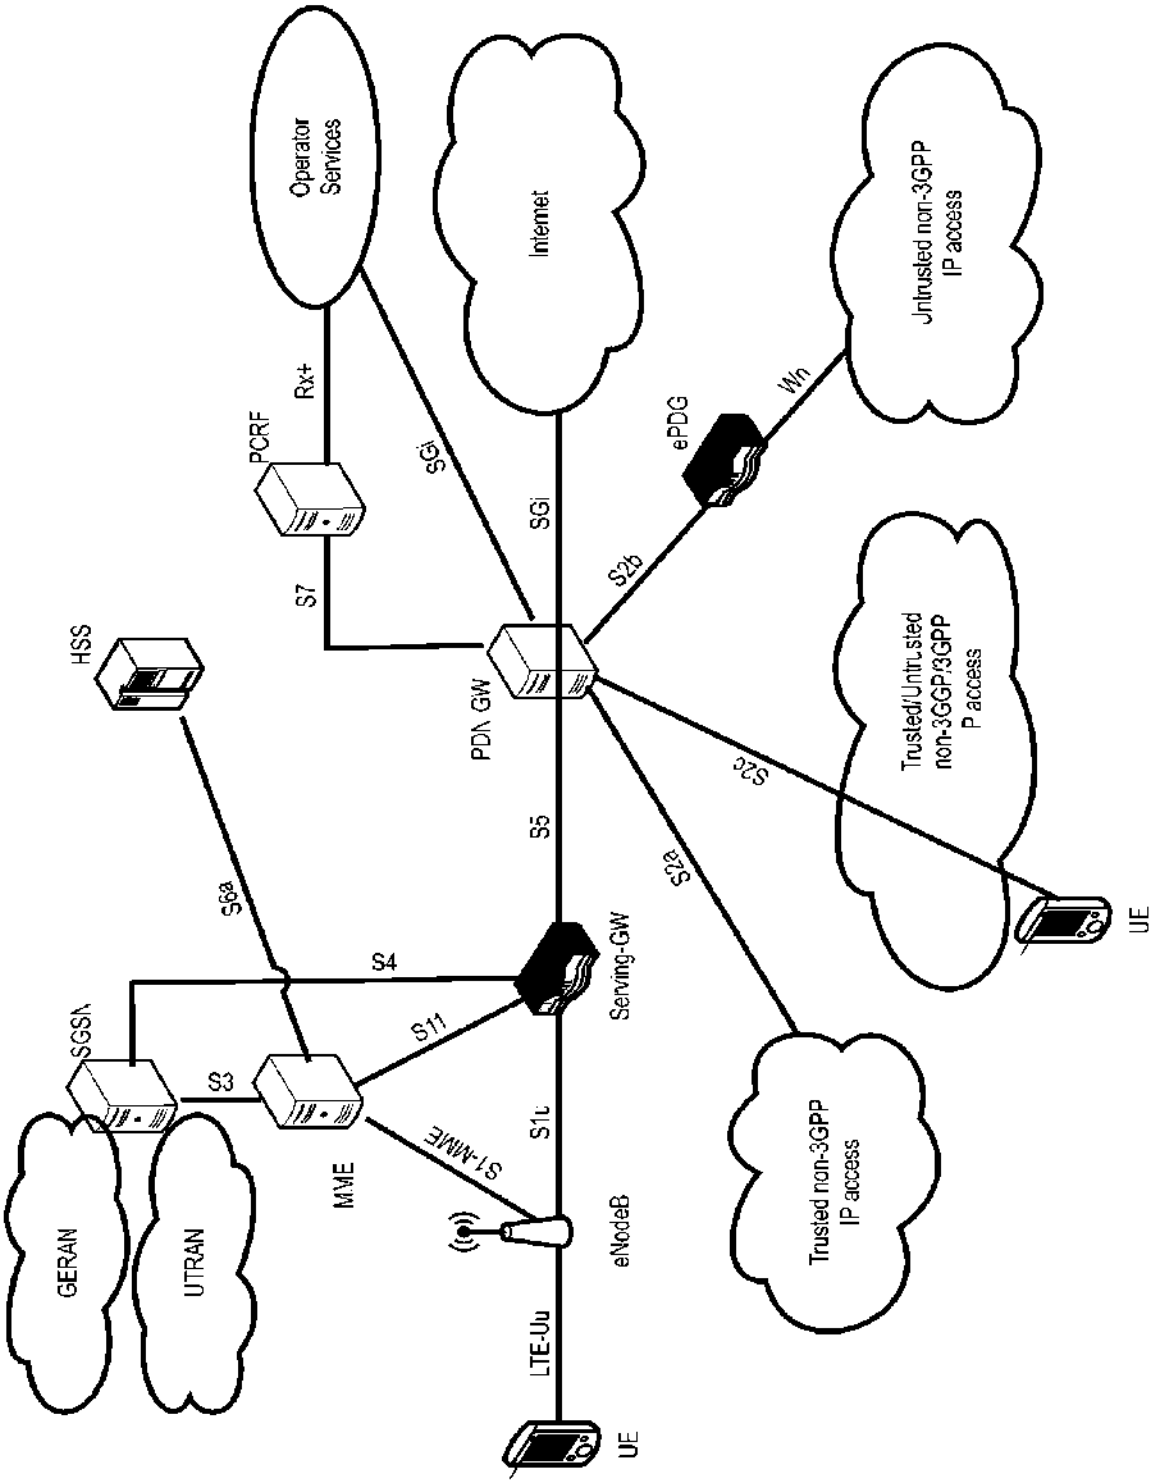
the processor being further adapted to determine whether coverage extension is necessary or not, based on the results of the radio measurements,

a transmitter adapted to inform the radio base station about whether the CE-capable user equipment needs coverage extension or not, based on the determination result,

a receiver adapted to receive paging from the radio base station, applying or not applying one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not.

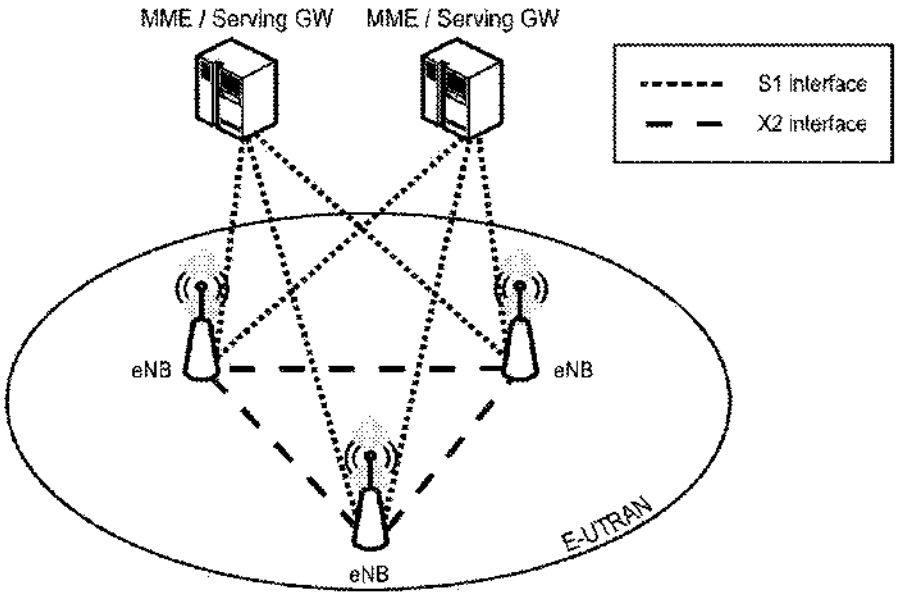
[Claim 14] The user equipment according to claim 13, wherein the transmitter informs the radio base station by:

transmitting information about whether the CE-capable user equipment needs coverage extension or not to the radio base station, preferably wherein the CE-capable user equipment is in a connected state, preferably wherein it is avoided that the CE-capable user equipment is changing into the idle state by keeping it in the connected state, or



transmitting information about whether the CE-capable user equipment needs coverage extension or not to a core network entity, and wherein the core network entity provides the received information to the radio base station, preferably wherein the CE-capable user equipment is in a connected state or in an idle state.

[Claim 15] A radio base station for paging a user equipment in a cell controlled by the radio base station in a mobile communication system, wherein the user equipment supports coverage extension techniques, wherein the radio base station is capable to use one of a plurality of techniques for achieving a coverage extension for the CE-capable user equipment, the radio base station comprising:



a receiver adapted to receive information about whether the CE-capable user equipment needs coverage extension or not,

a transmitter being adapted to, when paging the CE-capable user equipment, apply or not apply one of the plurality of techniques for achieving coverage extension depending on whether coverage extension is necessary or not for the CE-capable user equipment.
