   STATUS current
   DESCRIPTION
      "This is a status variable.
      It is written by the SME when a management report is completed.

      This attribute indicates a value that identifies the EAP Method. When the
      Authentication Type field is set to the value of either 00-0F-AC:1
      (Authentication negotiated over IEEE Std 802.1X or using PMKSA caching as
      defined in 12.6.10.3) or 00-0F-AC:3 (AKM suite selector for fast BSS
      transition as defined in 12.7.1.7), the EAP Method field contains the IANA
      assigned EAP type defined at http://www.iana.org/assignments/eap-numbers.
      The EAP type contains either the legacy type (1 octet) or the expanded
      type (1 octet type = 254, 3-octet Vendor ID, 4-octet Vendor-Type). The EAP
      Method field is set to 0 otherwise."

```
    DESCRIPTION
       "This is a status variable.
       It is written by the MAC when a group addressed frame is transmitted.

       This counter is incremented only when the group bit is set in the
       destination MAC address of a successfully transmitted MSDU. When operating
       as a STA in an infrastructure BSS, where these frames are directed to the
       AP, this implies having received an acknowledgment to all associated
       MPDUs."

    STATUS current
    DESCRIPTION
        "This is a control variable.

        It is written by the SME after the AP receives the permissions for the
        non-AP STA from the SSPN Interface.

        This attribute indicates the maximum authorized data rate the non-AP STA
        may use, either transmitting to an AP or receiving from an AP via HCCA or
        HEMM. The value '4294967295', which is the default value, means that the
        SSP is not requesting the AP to limit the data rate used by the non-AP
        STA. Local configuration of the AP, however, may cause the rate to be
        otherwise limited."
    DEFVAL {4294967295}

    MAX-ACCESS read-only
    STATUS current
    DESCRIPTION
        "This is a control variable.

        It is written by the SME after the AP receives the permissions for the
        non-AP STA from the SSPN Interface.

        This attribute indicates the delay bound for frames queued at an AP to a
        non-AP STA in the HCCA or HEMM queue. An AP should deliver frames to the
        non-AP STA within the time period specified in this attribute. When a non-
        AP STA requests admission control to the HCCA or HEMM queue, the requested
        delay will be equal to or higher than this value. The value '4294967295',
        which is the default value, means that the SSP is not requesting the AP
        limit the delay bound in this queue for transmissions to the non-AP STA."

   SYNTAX OCTET STRING (SIZE(0..255))
   MAX-ACCESS read-write
   STATUS current
   DESCRIPTION
      "This is a control variable.

      It is written by an external management entity or the SME.
      Changes take effect as soon as practical in the implementation.

      This attribute contains the national subdivisions (state, Region,
      province, prefecture). Example: California. The A1 element is used for the
      top level subdivision within a country. In the absence of a country-
      specific guide on how to use the A-series of elements, the second part of
      the ISO 3166-2 code for a country subdivision SHOULD be used. The ISO
      3166-2 code is a formed of a country code and hyphen plus a code of one,
      two or three characters or numerals. For the A1 element, the leading
      country code and hyphen are omitted and only the subdivision code is
      included.

      For example, the codes for Canada include CA-BC, CA-ON, CA-QC; Luxembourg
      has just three single character codes: LU-D, LU-G And LU-L; Australia uses
      both two and three character codes: AU-ACT, AU-NSW, AU-NT; France uses
      numerical codes for mainland France and letters for territories: FR-75,
      FR-NC."

```
      The SMTbase11 object class provides the necessary support at the STA to
      manage the processes in the STA so that the STA may work cooperatively as
      a part of an IEEE 802.11 network, when the STA is capable of multidomain
      operation. This object group should be implemented when the multidomain
      capability option is implemented."

Annex D

(normative)

Regulatory references

D.1 External regulatory references

This annex and Annex E provide information and specifications for operation in many regulatory domains.

WLANs implemented in accordance with this standard and the specifications and definitions referenced in it are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regional and national regulations are subject to revision or may be superseded. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Table D-1 for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

The documents listed in Table D-1 specify current regulatory requirements for various frequency bands and geographic areas at the time this standard was developed. They are provided for information only and are subject to change or revision at any time.

Table D-1—Regulatory requirement list

Geographic area	Approval standards	Documents	Approval authority
Canada	Minister of Industry	RSS-210 — License-exempt Radio Apparatus (All Frequency Bands): Category I Equipment	Industry Canada
China	Ministry of Industry and Information Technology (MIIT)	Xin Bu Wu [2002] #353, Xin Bu Wu [2002] #277, Gong Xin Bu Wu Han [2012] #620	MIIT
Europe	European Conference of Postal and Telecommunications (CEPT) Administrations and its Electronic Communications Committee (ECC). Also, European Radiocommunications Office, European Telecommunications Standards Institute (ETSI)	ECC DEC (04) 08, ETSI EN 300 328 [B13], ETSI EN 301 893, ETSI ES 202 663 [B15], ETSI EN 302 571 [B14], Clause 5	CEPT
Japan	Ministry of Internal Affairs and Communications (MIC)	MIC Equipment Ordinance (EO) for Regulating Radio Equipment Articles 7, 49.20, 49.21[a]	MIC

Table D-1—Regulatory requirement list *(continued)*

Geographic area	Approval standards	Documents	Approval authority
United States	Federal Communications Commission (FCC)	47 CFR [B9], Part 15, Sections 15.205, 15.209, 15.247 and 15.255; and Subpart E, Sections 15.401–15.407, and Subpart H, Sections 15.701–15.716, Section 90.210, Sections 90.371–383, Sections 90.1201–90.1217, Sections 90.1301–90.1337, Section 95.639, Sections 95.1501–1511	FCC

[a]Frequency planning for licensed STAs in Japan is performed by the regulatory authority and the licensees, addressing the coexistence among STAs operating with a variety of air propagation times and the coexistence between STAs using 20 MHz channel spacing, STAs operating with 10 MHz channel spacing, and STAs operating with 5 MHz channel spacing. Note also the CCA mechanism is preserved in licensed operation.

Behavior limits are listed in Table D-2.

Table D-2—Behavior limits

Behavior limit	Description
NomadicBehavior	The location of the station may change but is stationary while in use. The nomadic use EIRP power limits apply if the country allows more than one transmit power limit in the band. This behavior is specified only in bands where behavior 10 License Exempt bands is also allowed.
LicenseExemptBehavior	Frequency bands where some fixed stations can be operated without a license at a higher radiated transmit power than permitted for nomadic use. This behavior is specified only in bands where behavior 1 nomadic use is also allowed.
PrimaryChannelLowerBehavior[a]	20/40 MHz BSS primary channel with secondary channel above the primary channel or 20 MHz BSS primary channel operated by a 40MC HT AP and also 20 MHz operational channel for a non-AP STA when the non-AP STA is associated with a 40MC HT AP. See NOTE.
PrimaryChannelUpperBehavior[a]	14 20/40 MHz BSS primary channel with secondary channel below the primary channel or 20 MHz BSS primary channel operated by a 40MC HT AP and also 20 MHz operational channel for a non-AP STA when the non-AP STA is associated with a 40MC HT AP. See NOTE.
CCA-EDBehavior[b]	The PHY shall also indicate a medium busy condition when CCA-EnergyDetect detects a channel busy condition.
DFS_50_100_Behavior	A station operating in a band where radiolocation radar is primary, and station operation has in-service monitoring requirements for 50-100 μs radar pulses.
ITS_nonmobile_operations	Operations related to an ITS station operating at a fixed location registered with regulatory authorities, e.g., a Dedicated Short Range Communication Services (DSRCS) Roadside Unit (RSU).

Table D-2—Behavior limits *(continued)*

Behavior limit	Description
ITS_mobile_operations	Operations related to an ITS mobile station, e.g., a vehicle's DSRCS On-board Unit (OBU).
80+	In a channel width that contains two or more frequency segments, the frequency segment that does not contain the primary 80 MHz channel (see NOTE 2)
UseEirpForVHTTxPowEnv	A STA that sends one or more Transmit Power Envelope elements shall indicate EIRP in the Local Maximum Transmit Power Unit Interpretation subfield in one of the Transmit Power Envelope elements
GeoDB	A STA operating in a TVWS band where broadcast TV operation is primary and STA operation has GDB requirements. When operating in TVWS, channel numbers are as assigned in regulation.
NOTE 1—The fields that specify the 40 MHz channels are described in 19.3.15.4. NOTE 2—For an example using an operating class with an 80+ Behavior limit, see 9.4.2.9. The maximum number of frequency segments is PHY dependent.	

[a]For 20 MHz operation where the operating class signifies 40 MHz channel spacing, the 20 MHz channel corresponds to the channel number indicated.
[b]Procedures that may be used to improve sharing spectrum in addition to explicit regulatory requirements.

D.2 Radio performance specifications

D.2.1 Transmit and receive in-band and out-of-band spurious emissions

Spurious transmissions shall comply with national regulations.

D.2.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

The maximum allowable STA transmit power classifications for ITS nonmobile operations in the U.S. 5.85–5.925 GHz band are shown in Table D-3.

Table D-3—Maximum STA transmit power classification for the 5.85–5.925 GHz band in the United States

STA transmit power classification	Maximum STA transmit power (mW)	Maximum permitted EIRP (dBm)
A	1	23
B	10	23
C	100	33
D	760 Note that for this class higher power is permitted as long as the power level is reduced to this level at the antenna input and the emission mask specifications are met.	33 for nongovernment 44.8 for government

D.2.3 Transmit spectrum mask

Transmit spectrum masks defined in regulation are subject to change or revision at any time.

For operation in the 5.85–5.925 GHz band the transmitted spectrum shall be as follows:

a) For any STA using 5 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 4.5 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-4 for the transmit power class of the STA.

b) For any STA using 10 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 9 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-5 for the transmit power class of the STA.

c) For any STA using 20 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 18 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-6 for the transmit power class of the STA.

Table D-4—Spectrum mask data for 5 MHz channel spacing

STA transmit power class	Permitted power spectral density, dBr				
	± 2.25 MHz offset (±f1)	± 2.5 MHz offset (±f2)	± 2.75 MHz offset (±f3)	±5 MHz offset (±f4)	± 7.5 MHz offset (±f5)
Class A	0	–10	–20	–28	–40
Class B	0	–16	–20	–28	–40
Class C	0	–26	–32	–40	–50
Class D	0	–35	–45	–55	–65

Table D-5—Spectrum mask data for 10 MHz channel spacing

STA transmit power class	Permitted power spectral density, dBr				
	± 4.5 MHz offset (±f1)	± 5.0 MHz offset (±f2)	± 5.5 MHz offset (±f3)	± 10 MHz offset (±f4)	± 15 MHz offset (±f5)
Class A	0	–10	–20	–28	–40
Class B	0	–16	–20	–28	–40
Class C	0	–26	–32	–40	–50
Class D	0	–35	–45	–55	–65

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Table D-6—Spectrum mask data for 20 MHz channel spacing

STA transmit power class	Permitted power spectral density, dBr				
	± 9 MHz offset (±f1)	± 10.0 MHz offset (±f2)	± 11 MHz offset (±f3)	± 20 MHz offset (±f4)	± 30 MHz offset (±f5)
Class A	0	–10	–20	–28	–40
Class B	0	–16	–20	–28	–40
Class C	0	–26	–32	–40	–50
Class D	0	–35	–45	–55	–65

The transmit spectral mask is created and applied as shown in Figure D-1 about the channel center frequency (Fc) defined by the channel starting frequency and channel number from the operating class. The 0 dBr level is the maximum power spectral density measured in the channel. The measurements of transmit spectral density are made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

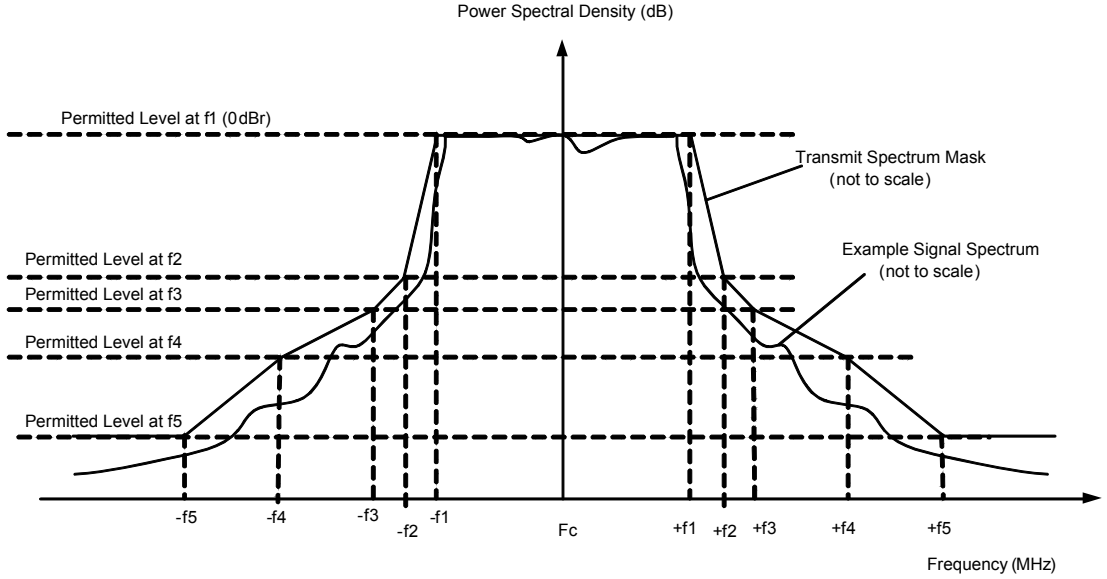

Figure D-1—Transmit spectrum mask and application

D.2.4 Transmit Mask M

This subclause defines the characteristics of transmit mask M.

The power spectral density of the emissions shall be attenuated below the output power of the transmitter as follows:

a) On any frequency removed from the center frequency between 0-45% of the channel bandwidth (BW): 0 dB.

b) On any frequency removed from the center frequency between 45-50% of the channel bandwidth: 568 log (% of (BW)/45) dB.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

c) On any frequency removed from the center frequency between 50-55% of the channel bandwidth: 26 + 145 log (% of BW/50) dB.

d) On any frequency removed from the center frequency between 55-100% of the channel bandwidth: 32 + 31 log (% of (BW)/55) dB.

e) On any frequency removed from the center frequency between 100-150% of the channel bandwidth: 40 + 57 log (% of (BW)/100) dB.

f) On any frequency removed from the center frequency between above 150% of the channel bandwidth: 50 dB or 55 + 10 log (P) dB, whichever is the lesser attenuation.

g) The 0 dB reference is measured relative to the highest average power of the fundamental emission measured across the designated channel bandwidth using a resolution bandwidth of 100 kHz and a video bandwidth of 30 kHz. The power spectral density is the power measured within the resolution bandwidth of the measurement device divided by the resolution bandwidth of the measurement device. Emission levels are also based on the use of measurement instrumentation employing a resolution bandwidth of at least one percent of the occupied bandwidth.

D.2.5 CCA-ED threshold

CCA-ED thresholds for operation in specific bands are given in E.2.

Annex E

(normative)

Country elements and operating classes

E.1 Country information and operating classes

WLANs implemented in accordance with this standard and the specifications and definitions referenced in it may be subject to equipment certification and operating requirements established by regional and national regulatory administrations. The specification establishes minimum technical requirements for interoperability, taking into consideration established regulations at the time this standard was issued. These regional and national regulations may be revised or may be superseded. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Table D-1 and their successors for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

The Country element (see 9.4.2.9) allows a STA to configure its PHY and MAC for operation when the Operating Triplet field is present. The Operating Triplet field indicates both PHY and MAC configuration characteristics and operational characteristics. The First Channel Number field of subsequent Subband Triplet fields is based on the dot11ChannelStartingFactor that is indicated by the Operating Class field.

The operating class is an index into a set of values for radio operation in a regulatory domain. The operating class tables also contain pointers to behaviors and signal detection limits in Annex D where further operational requirements may be found.

The channel starting frequency variable is a frequency, used together with an operating class number and a channel number, to calculate a channel center frequency. A "—" in the Channel starting frequency column of the operating classes tables (Table E-1 through Table E-5) indicates the channel starting frequency is not defined by the operating class and is derived from regulation.

Channel spacing is the frequency difference between nonoverlapping adjacent channel center frequencies when using the maximum bandwidth of one frequency segment allowed for this operating class.

The channel set is the list of integer channel numbers that are legal for a regulatory domain and class. A "—" in the Channel set column of the operating classes tables (Table E-1 through Table E-5) indicates either that the values in the channel center frequency index field apply for calculating channel center frequencies of this operating class, or where both the channel set field and the channel center frequency index field are "—" indicates that the channel set is not defined by the operating class and is derived from regulation.

The channel center frequency index is the set of integer channel numbers that correspond to frequency segments and that are allowed for the operating class. A"—" in the Channel center frequency index column of the operating classes tables (Table E-1 through Table E-5) indicates either that the values in the channel set field apply for calculating channel center frequencies of this operating class or, when both the Channel set and the Channel center frequency index column of the operating classes tables (Table E-1 through Table E-5) are "—", indicates that the channel center frequency index is not defined by the operating class and is derived from regulation.

A behavior limits set is an enumerated list, each element of which points to a row in Table D-2 containing behavior limits in various regulatory domains.

NOTE 1—The channel spacing for operating classes 22 to 33 specifies the maximum radio bandwidth of one frequency segment. In these operating classes, the AP operating in a 20/40 MHz BSS, and the operating channel width for a non-AP STA is either 20 MHz or 40 MHz.

NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

[a]This operating class specifies a list of channels in the 5.9 GHz band. Current regulations may only permit a subset of these channels.

[b]It is the responsibility of management layers outside the scope of this standard to ensure that channels in use at any location are nonoverlapping.

Operating classes for operation anywhere in the world are enumerated in Table E-4, and are used in addition to the operating classes enumerated in Table E-1, Table E-2, Table E-3 and (see 9.4.2.54). Where a BSS includes STAs that do not support global operating classes, then all requests and Action frames to those STAs that convey elements containing operating classes shall use nonglobal operating class values.

Table E-4—Global operating classes *(continued)*

Operating class	Nonglobal operating class(es)	Channel starting frequency (GHz)	Channel spacing (MHz)	Channel set	Channel center frequency index	Behavior limits set
192–254	—	Vendor specific	Vendor specific	Vendor specific	—	Vendor specific
255	—	Reserved	Reserved	Reserved	—	Reserved

NOTE 1—The channel spacing for operating classes 116, 117, 119, 120, 122, 123, 126, and 127 specifies the maximum radio bandwidth of one frequency segment In these operating classes, the AP operates in a 20/40 MHz BSS, and the operating channel width for a non-AP STA is either 20 MHz or 40 MHz.
NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

For Behavior limit GeoDB, the channel starting frequency shall be the frequency that results in the regulatory domain's channel number being the RLAN channel number.

Operating classes for operation in China are enumerated in Table E-5.

Table E-5—Operating classes in China

Operating class	Global operating class (see Table E-4)	Channel starting frequency (GHz)	Channel spacing (MHz)	Channel set	Channel center frequency index	Behavior limits set
1	115	5	20	36, 40, 44, 48	—	UseEirpForVHTTxPowEnv
2	118	5	20	52, 56, 60, 64	—	DFS_50_100_Behavior, UseEirpForVHTTxPowEnv
3	125	5	20	149, 153, 157, 161, 165	—	UseEirpForVHTTxPowEnv

Table E-5—Operating classes in China *(continued)*

Operating class	Global operating class (see Table E-4)	Channel starting frequency (GHz)	Channel spacing (MHz)	Channel set	Channel center frequency index	Behavior limits set
9	84	2.407	40	5-13	—	LicenseExemptBehavior, PrimaryChannelUpperBehavior
10–127	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
128	128	5	80	—	42, 58, 155	UseEirpForVHTTxPowEnv
129	129	5	160	—	50	UseEirpForVHTTxPowEnv
130	130	5	80	—	42, 58, 155	80+ UseEirpForVHTTxPowEnv
131–255	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved

NOTE 1—The channel spacing for operating classes 4 to 6 specifies the maximum radio bandwidth of one frequency segment In these operating classes, the AP operates in a 20/40 MHz BSS, and the operating channel width for a non-AP STA is either 20 MHz or 40 MHz.
NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

Nonglobal operating classes refer to the operating classes enumerated in the leftmost column of Table E-1, Table E-2, Table E-3, and Table E-5 (see 9.4.2.54).

NOTE 1—The following example Country element (see Figure 9-130) describes U.S. operation (‘55’, ‘53’) using both Table E-1 class 12 (nonglobal) and Table E-4 class 81 (global) for the 2.4 GHz band, 11 channels at 20 dBm limit (in hexadecimal): ‘07’, ‘0F’, ‘55’, ‘53’, ‘04’, ‘C9’, ‘0C’, ‘0’, ‘01’, ‘0B’, ‘14’, ‘C9’, ‘51’, ‘0’, ‘01’, ‘0B’, ‘14’.

NOTE 2—The following example Country element describes U.S. operation for an 80+80 MHz BSS using Table E-4 classes 116, 128 and 130 at a 100 mW limit for 40 MHz. The contents (in decimal) are '07' [Country element ID], '18' [Length], '85', '83', '04' [Country string indicating United States and Table E-4], '201', '116', '0' [Operating Triplet field for 20/40 MHz with the primary 20 MHz channel on the lower 20 MHz], '36', '1', '20' [Subband triplet field indicating 20 dBm on the 40 MHz channel 36+40], '201','128', '0' [Operating Triplet field for 80 MHz], '201', '130', '0', '201', '128', '0' [Pair of Operating Triplet field indicating 80+80 MHz]. Although the Operating Triplet fields for 80 MHz and 80+80 MHz only express BSS bandwidths rather than specific regulatory permissions (so are optional), they are included in this example.

Vendor Specific operating classes are used to carry information not defined in this standard within a single defined format, so that reserved operating classes are not usurped for nonstandard purposes and so that interoperability is more easily achieved in the presence of nonstandard information.

E.2 Band-specific operating requirements

E.2.1 General

Subclause E.2 contains requirements specific to particular bands and regulatory domains.

E.2.2 3650–3700 MHz in the United States

The registration authority is the FCC’s Universal Licensing System (ULS).

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Regulations specify the following:

— Certified mobile and portable STAs do not need to be registered, but they "must" operate under the control of an enabling STA (using DSE procedures).
— A registered STA "must" be a fixed STA.
— A registered STA "must" not operate as an enabling STA until the licensee has registered it as a "base station" in ULS.

Enabling STAs and fixed STAs are registered STAs. Dependent non-AP STAs and dependent APs are dependent STAs.

A STA shall use the following:

— CCA-ED
— CS/CCA
— TPC
— DFS

For OFDM PHY operation in this specific band, the CCA-ED thresholds shall be less than or equal to –72 dBm for 20 MHz channel widths, –75 dBm for 10 MHz channel widths, and –78 dBm for 5 MHz channel widths (minimum sensitivity for BPSK, R=1/2 + 10 dB in Table 17-18).

No STA shall use channel switch announcement.

No station may transmit for more than 4 ms without carrier sensing, whether transmitting fragments or frames, unless it is controlled by another STA.

A STA shall have the following equal to true:

— dot11LCIDSERequired
— dot11SpectrumManagementRequired
— dot11MultiDomainCapabilityActivated
— dot11ExtendedChannelSwitchActivated

A STA shall be capable of receiving all channels associated with operating classes 13–15.

A STA shall be capable of transmitting on all channels associated with operating class 15.

A STA shall set the value of dot11DSETransmitDivisor to 256 and the other dot11DSE timer values as shown in Table E-6.

Table E-6—DSE timer limits

Parameter	Seconds
dot11DSEEnablementTimeLimit	32
dot11DSEEnablementFailHoldTime	512
dot11DSERenewalTime	60

E.2.3 5.9 GHz band in the United States (5.850–5.925 GHz)

STAs operating with a behavior limit of ITS_nonmobile_operations in Table D-2 are required to be registered with the FCC ULS. The registration includes the following:

— Classification by coverage size, which is defined by EIRP, and
— Identification of channels the STA is permitted to use.

A STA shall be classified for operation in this band by their maximum transmit power capability, as listed in Table D-3 in D.2.2. A STA shall be compliant with the spectral emission requirements for their class listed in D.2.3.

A STA shall have dot11OCBActivated equal to true.

EPD as defined in IEEE Std 802-2014 shall be used for transmission of all MSDUs.

E.2.4 5.9 GHz band in Europe (5.855–5.925 GHz)

A STA shall have dot11OCBActivated equal to true.

EPD as defined in IEEE Std 802-2014 shall be used for transmission of all MSDUs.

E.2.5 TVWS band in the United States and Canada (54 MHz to 698 MHz)

Each GDD enabling STA and AP in TVWS determines the available TV channels at its location using its own geographic location identification and TV bands database access capabilities. Each GDD dependent STA in TVWS receives an available TV channel list from the STA that enables its operation.

The registration authorities are FCC designated TV bands administrators (FCC 47 CFR [B9], sections 15.713-715).

NOTE—IEEE 802.11 terms differ from FCC 47 CFR [B9], section 15.703, in many particulars. However, generally, a GDD enabling STA is Fixed or Mode II TVBD, and each GDD dependent STA has only one GDD enabling STA at any time. Generally, GDD dependent STAs are Mode I TVBDs. Each Fixed or Mode II TVBD is required to contact an authorized TV bands device database and operate based on the information received from that TV bands database. Fixed and Mode II TVBDs are certified to operate with specific TV bands databases using protocols specified by TV bands database administrators. FCC regulations require an encrypted Contact Verification Signal be received by Mode I TVBD to verify the integrity of the list of available channels FCC 47 CFR, section 15.711. Canadian regulation RSS-196 allows Remote Rural Broadband operation at transmit powers to 125 W in 6 MHz. The Canadian Minister of Industry held a consultation documented in SMSE-012-12, wherein a decision to act in concert with FCC license-exempt low power regulations was taken. It is expected that Canadian RSS-210 will be revised to align with FCC 47 CFR, Part 15, Subpart H-Television Band Devices.

STAs operating in TVWS shall use

— CS/CCA
— DFS

No STA operating in TVWS shall use Channel Switch Announcement.

STAs operating in TVWS shall have the following equal to true

— dot11GDDActivated
— dot11OperatingClassesRequired
— dot11SpectrumManagementRequired

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

— dot11MultiDomainCapabilityActivated
— dot11ContactVerificationSignalActivated

For GDD dependent STA operation in TVWS, the GDD enabling signal (see 11.44.2) is received directly from a GDD enabling STA and is a Beacon frame or Probe Response frame containing a Geodatabase Inband Enabling Signal field indicating that enablement in the frequency band is possible.

All GDD dependent STAs shall set the dot11GDD timer values as shown in Table E-7.

Table E-7—TVWS GDD timer limits

Parameter	Seconds
dot11GDDEnablementTimeLimit	32
dot11GDDEnablementFailHoldTime	512
dot11ContactVerificationSignalInterval	60
dot11GDDEnablementValidityTimer	60

NOTE—Be aware that most protocols above the MAC operate in the opposite endianness from what is used in Table E-8 and Table E-9.

The Device Identification Information format is shown in Table E-8.

Table E-8—Device Identification Information Value fields

Name	Type	Length (octets)	Value	Scope/ Country code
FCC ID	4	14	The device identification contains the 14-octet FCC ID of the device.	US
Industry Canada ID	5	11	The device identification contains the 11-octet Industry Canada ID of the device. This value not present in the United States.	CA
Device Serial Number	6	4	The Device Serial Number field contains the manufacturer's serial number. This field is present only if the Device Class field (Table 9-264) is equal to 2 (GDD AP) or 3 (GDD fixed STA); otherwise, this field is not present.	US

The WSM Information Value fields format is shown in Table E-9. In some regulatory domains, an AP can retrieve the WSM information from the GDB through the upper layer protocol (e.g., IETF Protocol to Access WS database 'paws-protocol'). When the AP retrieves the WSM information from the upper layer, it may translate it to the WSM Information field format shown in Table E-9, which is the link-layer-specific information.

NOTE—In the United States, an example of full Map 1 for a U.S. GDD non-AP STA describing two available channels with power limits of 100 mW and 40 mW is shown as 85, 0x06, 0x00, 0x03, 0x15, 0x28, 0x33, 0x20. Type is 85, Length is 0x06, Device Class is 0x00, a full map with MapID 1 is 0x03, TV channel 21 is 0x15, 20 dBm Maximum Power Level is 0x28, TV channel 51 is 0x33, 16 dBm Maximum Power Level is 0x20.

Table E-9—WSM Information Value fields

Name	Length (octets)	Value	Scope/ Country code
Device Class	1	Single octet TLV comprising fields in Table 9-264.	WSM
Map ID	1	Bit 0: The Type bit, which indicates whether the following channel list is a full channel list or a partial channel list. If the Type bit is 1, the following channel list is a full channel list; and if the Type bit is 0, the following channel list is a partial channel list. Bits 1–7: The Map version field, which identifies the version of the WSM.	WSM
Channel Number	1	The Channel Number field is a positive integer value as defined in E.1 that indicates the available TV channel for WLAN operation. When the Channel Number field and Maximum Power Level field pairs are repeated, they are listed in ascending TV channel order.	WSM, US
Maximum Power Level	1	The Maximum Power Level field indicates the maximum power, in units of 0.5 dBm, allowed to be transmitted on the channel indicated in the Channel Number field.	WSM, US

E.2.6 TVWS band in Europe

Each GDD enabling STA and AP in TVWS determines the available TV channels at its location using its own geographic location identification and TV bands database access capabilities. Each GDD dependent STA in TVWS receives an available TV channel list from the STA that enables its operation.

The Harmonized Standard for unlicensed device operation in TVWS is EN 301 598.

STAs operating in TVWS shall use:

— CS/CCA
— DFS

No STA operating in TVWS shall use Channel Switch Announcement.

STAs operating in TVWS shall have the following equal to true

— dot11GDDActivated
— dot11OperatingClassesRequired
— dot11SpectrumManagementRequired
— dot11MultiDomainCapabilityActivated
— dot11ContactVerificationSignalActivated

For GDD dependent STA operation in TVWS, the GDD enabling signal (see 11.44.2) is received directly from a GDD enabling STA and is a Beacon frame or Probe Response frame containing a Geodatabase Inband Enabling Signal field indicating that enablement in the frequency band is possible.

Annex G

(normative)

Frame exchange sequences

G.1 General

The allowable frame exchange sequences are defined using an extension of the EBNF format as defined in ISO/IEC 14977:1996 [B49]. The elements of this syntax that are used here are as follows:

- [a] = a is optional.
- {a} = a is repeated zero or more times.
- n{a} = a is repeated n or more times. For example, 3{a} requires 3 or more "a". This notation is an extension to ISO/IEC 14977 and equivalent to n*a{a} as defined in that standard.
- a|b|c|... = selection between mutually exclusive alternatives, a, b, c ....
- ( ) = grouping, e.g., "a (b|c)" is equivalent to "a b | a c".
- (* a *) = “a” is a comment. Comments are placed before the text they relate to.
- < > = order of frames not relevant. For example, <a b> is either "a b" or "b a."
- A rule is terminated by a semicolon ";"
- The meaning of whitespace is changed from ISO/IEC 14977. The name of terminals do not contain whitespace, and the concatenate-symbol (comma in ISO/IEC 14977) is replaced by white space. Whitespace appearing between the names of terminals indicates concatenation. Otherwise, whitespace is not significant and is used to highlight the nesting of grouped terms.

Two types of terminals are defined:

- **Frames.** The name of a frame is shown in **bold** and identified by its type/subtype (e.g., **Beacon**, **Data**). Frames are shown with an initial capital letter.
- *Attributes.* The name of attributes are shown in *italic*. An attribute is introduced by the "+" character. The attribute specifies a condition that applies to the frame (or alternatively, for the attributes that start +mu, the A-MPDU) that precedes it. Where there are multiple attributes applied, they are generally ordered in the same order of the fields in the frame to which they refer. The syntax a+(b|c) where b and c are attributes is equivalent to (a+b) | (a+c).

In this syntax the names of nonterminals are shown in a normal font, i.e., a sequence of words joined by hyphens (e.g., cf-frame-exchange-sequence).

The attributes are defined in Table G-1.

Table G-1—Attributes applicable to frame exchange sequence definition

Attribute	Description
a-mpdu	Frame is part of an A-MPDU aggregate. See NOTE 2.
a-mpdu-end	Frame is the last frame in an A-MPDU aggregate. See NOTE 2.
block-ack	QoS Data frame has ack policy equal to Block Ack.
broadcast	Frame RA is the broadcast address.

Table G-1—Attributes applicable to frame exchange sequence definition *(continued)*

Attribute	Description
CF	Beacon contains a CFP element.
CF-Ack	Data type CF-Ack subtype bit (Frame Control field B4) equal to 1 or CF-End +CF-Ack frame.
CF-Poll	Data type CF-Poll subtype bit (Frame Control field B5) equal to 1.
csi	An Action frame carrying channel state feedback (i.e., CSI, uncompressed beamforming, or compressed beamforming feedback matrices).
csi-request	A +HTC frame with the Feedback Request field equal to a value > 0.
delayed	BlockAck or BlockAckReq frame under a delayed policy.
delayed-no-ack	BlockAck or BlockAckReq frame has the BA Ack Policy or BAR Ack Policy field, respectively, equal to No Acknowlegement.
DTIM	Beacon is a DTIM.
frag	Frame has its More Fragments subfield equal to 1.
group	Frame RA has i/g bit equal to 1.
HTC	+HTC frame, i.e., a frame that contains the HT Control field, including the Control Wrapper frame. See NOTE.
implicit-bar	QoS Data frame in an A-MPDU with Normal Ack policy.
individual	Frame RA has i/g bit equal to 0.
last	Frame has its More Fragments subfield equal to 0.
L-sig	L-sig duration not equal to PPDU duration.
action-no-ack	Management frame of subtype Action No Ack.
mfb	A +HTC frame with the MFB field is not equal to all 1s.
more-psmp	A PSMP frame with the More PSMP field equal to 1.
mrq	A +HTC frame with the MRQ subfield equal to 1.
mu-ppdu-end	This attribute delineates the end of a VHT MU PPDU. See NOTE 3 and NOTE 4.
mu-user-respond	The preceding frame or A-MPDU is part of a VHT MU PPDU and is addressed to a user from which an immediate response is expected. See NOTE 3 and NOTE 4.
mu-user-not-respond	The preceding frame or A-MPDU is part of a VHT MU PPDU and is addressed to a user from which no immediate response is expected. See NOTE 3 and NOTE 4.
ndp-announce	A +HTC frame with the HT NDP Announcement subfield equal to 1.
no-ack	QoS Data frame with the Ack Policy subfield equal to No Ack.
no-more-psmp	A PSMP frame with the More PSMP field equal to 0.
normal-ack	QoS Data frame with the Ack Policy subfield equal to Normal Ack.
non-QAP	Frame is transmitted by a non-AP QoS STA.
non-stbc	PPDU TXVECTOR STBC parameter is equal to 0.
null	Data type Null Data subtype bit (Frame Control field B6) equal to 1.
pifs	Frame is transmitted following a PIFS.
psmp-ack	Ack Policy field of QoS Data frame is equal to PSMP Ack.

Table G-1—Attributes applicable to frame exchange sequence definition *(continued)*

Attribute	Description
QAP	Frame is transmitted by a QoS AP.
QoS	Data type QoS subtype bit (Frame Control field B7) equal to 1.
RD	Frame includes an HT Control field in which the RDG/More PPDU subfield is equal to 1.
self	Frame RA = TA.
sounding	PPDU TXVECTOR SOUNDING parameter is present and equal to SOUNDING.
stbc	PPDU TXVECTOR STBC parameter is equal to a value >0.
to-ap	Frame is addressed to the AP.
trq	Frame is a +HTC frame with the TRQ field equal to 1.

NOTE 1—A Control frame that contains the HT Control field is always transmitted using the Control Wrapper frame.

NOTE 2—In the case of VHT single MPDU, a single MPDU is carried in a A-MPDU, but the attributes *+a-mpdu* and *+a-mpdu-end* are not used.

NOTE 3—*+mu-ppdu-end*, *+mu-user-respond* and *+mu-user-other* are used in productions that generate VHT MU PPDUs, according to the pattern: ["an A-MPDU (which might contain a VHT single MPDU) needing a response" *+mu-user-respond*] {"an A-MPDU (which might contain a VHT single MPDU) not needing a response" *+mu-user-not-respond*} *+mu-ppdu-end*. There is at least one of *+mu-user-respond* or *+mu-user-not-respond* in a VHT MU PPDU.

NOTE 4—In the sequence **A***+mu-user-respond* **B***+mu-user-not-respond* … *+mu-ppdu-end*, although the terms **A**, **B** … (which represent one or more frames) are listed sequentially in these productions, the per-user sequence of frames represented by **A**, **B**, ... are transmitted simultaneously per-user using a VHT MU PPDU.

G.2 Basic sequences

An allowable frame exchange sequence is defined by the rule frame-exchange-sequence. Except where modified by the *pifs* attribute, frames are separated by a SIFS or RIFS.

(* This rule defines all of the allowable frame exchange sequences *)
frame-exchange-sequence =

([**CTS**] (**Management** *+broadcast* | **Data** *+group*)) |
([**CTS** | **RTS CTS** | **PS-Poll**] {frag-frame **Ack**} last-frame **Ack**) |
(**PS-Poll Ack**) |
([**Beacon** *+DTIM*] {cf-sequence} [**CF-End** [*+CF-Ack*]])|
hcf-sequence |
mcf-sequence;

(* A frag-frame is a nonfinal part of an individually addressed MSDU or MMPDU *)
frag-frame = (**Data** | **Management**) *+individual +frag*;

(* This is the last (or only) part of a an individually addressed MSDU or MMPDU *)
last-frame = (**Data** | **Management**) *+individual +last*;

(* A cf-sequence expresses all of the sequences that may be generated within a contention free period. The first frame in this sequence is sent by the AP. *)
cf-sequence =

(**BlockAck**+*HTC*+*ndp-announce NDP*);

(* During operation of explicit transmit beamforming (explicit-txbf), there are three encodings of feedback information. These are not distinguished here and are all identified by the *csi* attribute. The feedback position may be immediate, aggregate, or delayed. Immediate feedback follows a SIFS after the sounding PPDU (identified by the *sounding* attribute) or the NDP. Aggregate feedback occurs during an aggregate within the same TXOP and may accompany Data frames in the same PPDU. Delayed feedback occurs during a subsequent TXOP during which the CSI responder is TXOP initiator. Only immediate feedback is described in the syntax below. The frame indicating any *csi-request* is carried in a sounding PPDU or followed by an NDP. The CSI response is carried in an Action No Ack frame, which may be aggregated with a response that is a BlockAck or Ack frame.
There are also two sets of sequences "staggered" and "NDP" that use either staggered sounding, or NDP sounding respectively.*)

Annex H

(normative)

Usage of Ethertype 89-0d

The Ethertype 89-0d frame body is specified in Figure H-1, omitting any possible security header and trailer.

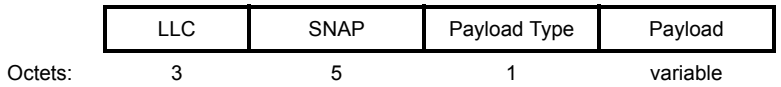

Figure H-1—Ethertype 89-0d frame body

LLC is defined in ISO/IEC 8802-2:1998.

SNAP is defined in IEEE Std 802-2014. The formatting of the SNAP header is according to IETF RFC 1042. The Ethertype is set to 89-0d.

The Payload Type field is set to one of the values in Table H-1.

Table H-1—Payload Type field values

Protocol name	Payload type	Subclause
Remote Request/Response	1	13.10.3
TDLS	2	11.23.2
FST	3	11.33.5
RLQP	4	11.25.3.4
Reserved	5–255	

The Payload depends on the value inside the Payload Type field and is defined in the subclauses listed in Table H-1.

Annex I

(informative)

Examples of encoding a frame for OFDM PHYs and DMG PHYs

I.1 Example 1 - BCC encoding

I.1.1 Introduction

The purpose of this annex is to show an example of encoding a frame for the OFDM PHY, as described in Clause 17. This example covers all of the encoding details defined by this standard.

The encoding illustration goes through the following stages:

a) Generating the short training sequence section of the preamble;
b) Generating the long preamble sequence section of the preamble;
c) Generating the SIGNAL field bits;
d) Coding and interleaving the SIGNAL field bits;
e) Mapping the SIGNAL field into frequency domain;
f) Pilot insertion;
g) Transforming into time domain;
h) Delineating the data octet stream into a bit stream;
i) Prepending the SERVICE field and adding the pad bits, thus forming the DATA;
j) Scrambling and zeroing the tail bits;
k) Encoding the DATA with a convolutional encoder and puncturing;
l) Mapping into complex 16-QAM symbols;
m) Pilot insertion;
n) Transforming from frequency to time and adding a circular prefix;
o) Concatenating the OFDM symbols into a single, time-domain signal.

In the description of time domain waveforms, a complex baseband signal at 20 Msample/s shall be used.

This example uses the 36 Mb/s data rate and a message of 100 octets. These parameters are chosen in order to illustrate as many nontrivial aspects of the processing as possible:

— Use of several bits per symbol (4 in this case);
— Puncturing of the convolutional code;
— Interleaving, which uses the LSB–MSB swapping stage;
— Scrambling of the pilot subcarriers.

In each Annex I table that has “Binary value” columns, the bit positions of the binary values are specified in the header of the table.

I.1.2 The message for the BCC example

The message being encoded consists of the first 72 characters (shown in **bold** and including line breaks) of the well-known "Ode to Joy" by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header and an FCS is added. The resulting 100 octet PSDU is shown in Table I-1.

Table I-1—The message for the BCC example

The single period of the short training sequence is extended periodically for 161 samples (about 8 μs), and then multiplied by the window function:

$$W(k) = \begin{bmatrix} 0.5 & k = 0 \\ 1 & 1 \le k \le 159 \\ 0.5 & k = 160 \end{bmatrix}$$

The last sample serves as an overlap with the following OFDM symbol. The 161 samples vector is shown in Table I-4. The time-windowing feature illustrated here is not part of the normative specifications.

Table I-4—Time domain representation of the short sequence

The time domain representation is derived by performing IFFT on the contents of Table I-5, cyclically extending the result to get the cyclic prefix, and then multiplying with the window function given in I.1.3.1. The resulting 161 points vector is shown in Table I-6. The samples are appended to the short sequence section by overlapping and adding element 160 of Table I-4 to element 0 of Table I-6.

Table I-6—Time domain representation of the long sequence

I.1.4 Generation of the SIGNAL field

I.1.4.1 SIGNAL field bit assignment

The SIGNAL field bit assignment follows 17.3.4 and Figure 17-5. The transmitted bits are shown in Table I-7, where bit 0 is transmitted first.

Table I-7—Bit assignment for SIGNAL field

##	Bit	Meaning		##	Bit	Meaning
0	1	RATE: R1		12	0	—
1	0	RATE: R2		13	0	—
2	1	RATE: R3		14	0	—

I.1.4.2 Coding the SIGNAL field bits

The bits are encoded by the rate 1/2 convolutional encoder to yield the 48 bits given in Table I-8.

Table I-8—SIGNAL field bits after encoding

##	Bit		##	Bit		##	Bit		##	Bit		##	Bit		##	Bit
0	1		8	1		16	0		24	0		32	0		40	0
1	1		9	0		17	0		25	0		33	1		41	0
2	0		10	1		18	0		26	1		34	1		42	0
3	1		11	0		19	0		27	1		35	1		43	0
4	0		12	0		20	0		28	1		36	0		44	0
5	0		13	0		21	0		29	1		37	0		45	0
6	0		14	0		22	1		30	1		38	0		46	0
7	1		15	1		23	0		31	0		39	0		47	0

I.1.4.3 Interleaving the SIGNAL field bits

The encoded bits are interleaved according to the interleaver of 17.3.5.7. A detailed breakdown of the interleaving operation is described in I.1.6.2. The interleaved SIGNAL field bits are shown in Table I-9.

Table I-9—SIGNAL field bits after interleaving

##	Bit		##	Bit		##	Bit		##	Bit		##	Bit		##	Bit
0	1		8	1		16	0		24	1		32	0		40	1
1	0		9	1		17	0		25	0		33	0		41	0
2	0		10	0		18	0		26	0		34	1		42	0
3	1		11	1		19	1		27	0		35	0		43	1
4	0		12	0		20	0		28	0		36	0		44	0
5	1		13	0		21	1		29	0		37	1		45	1
6	0		14	0		22	0		30	1		38	0		46	0
7	0		15	0		23	0		31	1		39	0		47	0

I.1.4.4 SIGNAL field frequency domain

The encoded and interleaved bits are BPSK modulated to yield the frequency domain representation given in Table I-10. Locations –21, –7, 7, and 21 are skipped and are used for pilot insertion.

Four pilot subcarriers are added by taking the values {1.0,1.0,1.0,–1.0}, multiplying them by the first element of sequence $p_{0\ldots126}$, given in Equation (17-22) (in 17.3.5.10), and inserting them into location {–21, –7,7,21}, respectively. The resulting frequency domain values are given in Table I-11.

I.1.4.5 SIGNAL field time domain

The time domain representation is derived by performing IFFT on the contents of Table I-11, extending cyclically, and multiplying by the window function

$$W(k) = \begin{bmatrix} 0.5 & k = 0 \\ 1 & 1 \le k \le 79 \\ 0.5 & k = 80 \end{bmatrix}$$

The resulting 81 samples vector is shown in Table I-12. Note that the time-windowing feature illustrated here is not a part of the normative specifications.

The SIGNAL field samples are appended with one sample overlap to the preamble, given in Table I-6.

I.1.5 Generating the DATA bits for the BCC example

I.1.5.1 Delineating, SERVICE field prepending, and zero padding

The transmitted message shown in Table I-1 contains 100 octets or, equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits and are appended by 6 tail bits. The resulting 822 bits are appended by some number of bits with value 0 to yield an integer number of OFDM symbols. For the 36 Mb/s mode, there are 144 data bits per OFDM symbol; the overall number of bits is $\lceil 822/144 \rceil \times 144 = 864$. Hence, $864 - 822 = 42$ zero bits are appended.

The DATA bits are shown in Table I-13.

I.1.5.2 Scrambling the BCC example

The 864 bits are scrambled by the scrambler defined in 17.3.5.5. The initial state of the scrambler is the state 1011101. The generated scrambling sequence is given in Table I-14.

Table I-14—Scrambling sequence for seed 1011101

##	Bit	##	Bit	##	Bit	##	Bit	##	Bit	##	Bit	##	Bit	##	Bit
0	0	16	1	32	0	48	1	64	0	80	0	96	0	112	1
1	1	17	0	33	1	49	1	65	1	81	0	97	0	113	0

I.1.6.2 Interleaving the DATA bits

The interleaver is defined as a two-permutation process. The index of the coded bit before the first permutation shall be denoted by k; i shall be the index after the first and before the second permutation; and j shall be the index after the second permutation, just prior to modulation mapping. The mapping from k to i is shown in Table I-17, and the mapping from i to j is shown in Table I-18.

As a specific example, consider the case of $k = 17$ (the 18th bit after encoding and puncturing). It is mapped by the first permutation to $i = 13$ and by the second permutation to $j = 12$ (the 13th bit before mapping).

The interleaved bits are shown in Table I-19.

I.1.6.3 Mapping into symbols

The frequency domain symbols are generated by grouping 4 coded bits and mapping into complex 16-QAM symbols according to Table 17-14 (in 17.3.5.8). For instance, the first 4 bits (0 1 1 1) are mapped to the complex value, –0.316 + 0.316j, inserted at subcarrier #26.

Four pilot subcarriers are added by taking the values {1.0,1.0,1.0,–1.0}, multiplying them by the second element of sequence p, given in Equation (17-22) (in 17.3.5.10), and inserting them into location {–21,–7,7,21}, respectively.

The frequency domain is shown in Table I-20.

The time domain samples are produced by performing IFFT, cyclically extending, and multiplying with the window function in the same manner as described in I.1.4.5. The time domain samples are appended with one sample overlap to the SIGNAL field symbol.

I.1.7 Generating the additional DATA symbols

The generation of the additional five data symbols follows the same procedure as described in Clause 4. Special attention should be paid to the scrambling of the pilot subcarriers. Table I-21 lists the polarity of the pilot subcarriers and the elements of the sequence $p_{0\ldots126}$ for the DATA symbols. For completeness, the pilots in the SIGNAL are included as well. The symbols are appended one after the other with a one-sample overlap.

Table I-21—Polarity of the pilot subcarriers

i	OFDM symbol	Element of p_i	Pilot at #–21	Pilot at #–7	Pilot at #7	Pilot at #21
0	SIGNAL	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
1	DATA 1	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
2	DATA 2	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
3	DATA 3	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
4	DATA 4	–1	–1.0 +0 j	–1.0 +0 j	–1.0 +0 j	1.0 +0 j
5	DATA 5	–1	–1.0 +0 j	–1.0 +0 j	–1.0 +0 j	1.0 +0 j
6	DATA 6	–1	–1.0 +0 j	–1.0 +0 j	–1.0 +0 j	1.0 +0 j

I.1.8 The entire packet for the BCC example

The packet in its entirety is shown in the tables in this subclause. These tables illustrate the short training sequence section (Table I-22), the long training sequence section (Table I-23), the SIGNAL field (Table I-24), and the six DATA symbols (Table I-25 to Table I-30).

Table I-22—Time domain representation of the short training sequence

I.2 Generating encoded DATA bits—LDPC example 1

LDPC example 1 is similar to the BCC example. This example illustrates LDPC shortening, encoding, and puncturing of a single codeword.

Input TXVECTOR parameters for LDPC example 1:

- FEC_CODING = LDPC_CODING = 1 (LDPC encoder; not BCC)
- CH_BANDWIDTH = HT_CBW20 = 0 (CH_BANDWIDTH = 0 => 20 MHz)
- MCS = 4 (MCS = 4; QAM 16; Coding rate = 3/4)
- Coding rate R = 3/4
- LENGTH = 100 octets (with 16-bit SERVICE field becomes 102 Octets = 816 bits to scramble and encode)
- STBC = 0 (STBC = 0 => OFF; m_STBC=1)

I.2.1 The message for LDPC example 1

The message being encoded consists of the first 72 characters (shown in **bold** and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header, and an FCS is added. The resulting 100 octet PSDU is shown in Table I-31.

NOTE 1—The message for LDPC example 1 is identical to the message for the BCC example; in other words, the FCS field (octets 97–100) has the same value.

NOTE 2—The DurationID field (i.e., octets 3 and 4) remains 0x02E = 46 μs.

Table I-31—Message for LDPC example 1

Octet ##	Value	Value	Value	Value	Value

I.2.2 Prepending the SERVICE field for LDPC example 1

The transmitted message shown in Table I-31 contains 100 octets, or equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits (bits 0–15 in Table I-32), as defined in 19.3.11.2, but tail bits and padding bits are not appended as in the BCC example. The resulting 816 bits are shown in Table I-32.

Table I-32—DATA bits for LDPC example 1 before scrambling

I.2.3 Scrambling LDPC example 1

The 816 bits are scrambled by the scrambler defined in 17.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D). The scrambled sequence is given in Table I-33.

NOTE—The scrambled entries for the correct FCS field value are given in bits 784–815.

Table I-33—DATA bits for LDPC example 1 after scrambling

Bit ##	Binary value B0 B7	Binary value B8 B15	Binary value B16 B23	Hexadecimal value	Hexadecimal value	Hexadecimal value

I.2.4 Inserting shortening bits for LDPC example 1

The equations of 19.3.11.7.5 are solved to calculate the following derived parameters for LDPC example 1 from the input TXVECTOR parameters:

— $N_{CW} = 1$ (number of codewords)
— $L_{LDPC} = 1944$ (size of codeword)
— $N_{CBPS} = 208$ (number of coded bits per symbol)
— $N_{avbits} = 1248$ (number of available bits)
— $N_{shrt} = 642$ (number of bits to be shortened)
— $N_{punc} = 54$ (number of bits to be punctured)
— $N_{SYM} = 6$ (number of OFDM symbols)
— $N_{rep} = 0$ (number of bits to be repeated)

The results of applying shortening bits, as prescribed in paragraph (c) of 19.3.11.7.5, is given in Table I-34.

NOTE—$N_{shrt} = 642$ shortening bits have been inserted as 0s in bits 816–1457.

Table I-34—DATA bits for LDPC example 1 after insertion of shortening bits

I.2.5 Encoding data for LDPC example 1

The DATA with shortening bits are LDPC encoded as a single (N_{CW}=1) codeword (L_{LDPC}=944; R=3/4) as prescribed by paragraph (c) of 19.3.11.7.5. The results are given in Table I-35.

NOTE—The LDPC encoder appends 486 bits (i.e., bits 1458–1943) after the shortening bits.

I.2.6 Removing shortening bits and puncturing for LDPC example 1

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 19.3.11.7.5. Finally, either puncturing is applied as described in paragraph (d) of the same subclause, or the copying of repeated bits is applied as described in paragraph (e) of the same subclause. In LDPC example 1, because N_{punc} = 54 is nonzero and N_{rep} = 0, puncturing is prescribed and completes the LDPC encoding process.

The results are given in Table I-36.

NOTE—The N_{shrt} = 642 shortening bits have been removed, and the N_{punc} = 54 bits have been punctured from Table I-35 to produce bits 816–1247 of Table I-36.

Table I-36—DATA bits after puncturing and removal of shortening bits

Bit ##	Binary value B0 B7	Binary value B8 B15	Binary value B16 B23	Hexadecimal value	Hexadecimal value	Hexadecimal value

I.3 Generating encoded DATA bits—LDPC example 2

LDPC example 2 exercises the alternative branches of the LDPC encoding procedure not exercised in LDPC example 1. Example 2 also exhibits LDPC shortening, encoding, and padding by repetition and employs multiple codewords and diversifies the TXVECTOR parameters—all without making the length of this example cumbersome.

The length of the text of the message is increased by 40 octets, from 72 characters to 112 characters, in order to illustrate padding (rather than puncturing) and encoding of multiple codewords.

Input TXVECTOR parameters for LDPC example 2:

- FEC_CODING = LDPC_CODING = 1 (LDPC encoder; not BCC)
- CH_BANDWIDTH = HT_CBW40 = 1 (CH_BANDWIDTH = 1 => 40 MHz)
- MCS = 1 (MCS = 1; QPSK; coding rate = 1/2)
- Coding rate R = 1/2
- LENGTH = 140 octets (with 16-bit SERVICE field becomes 142 octets = 1136 bits to scramble and encode)
- STBC = 1 (STBC = 1 => ON; m_STBC = 2)

I.3.1 The message for LDPC example 2

The message being encoded consists of the first 112 characters (shown in **bold** and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.

Thy magic power re-unites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

The message is converted to ASCII; then it is prepended with an appropriate MAC header and an FCS is added. The resulting 140 octet PSDU is shown in Table I-37.

Because of the additional 40 characters, note that the message for LDPC example 2 has a different FCS field (octets 137–140) than the previous examples and that the DurationID field (i.e., octets 3 and 4) changes to 0x036 = 54 μs.

Table I-37—Message for LDPC example 2

I.3.2 Prepending the SERVICE field for LDPC example 2

The transmitted message shown in Table I-37 contains 140 octets, or equivalently, 1120 bits. The bits are prepended by the 16 SERVICE field bits (bits 0–15 in Table I-38), as defined by 19.3.11.2, but tail bits and padding bits are not appended as in the BCC example. The resulting 1136 bits are shown in Table I-38.

I.3.3 Scrambling LDPC example 2

The 1136 bits are scrambled by the scrambler defined in 17.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D). The scrambled sequence is given in Table I-39.

Table I-39—DATA bits for LDPC example 2 after scrambling

Bit ##	Binary value B0 B7	Binary value B8 B15	Binary value B16 B23	Hexadecimal value	Hexadecimal value	Hexadecimal value

I.3.4 Inserting the shortening bits for LDPC example 2

The equations of 19.3.11.7.5 are solved to calculate the following derived parameters for LDPC example 2 from the input TXVECTOR parameters:

— $N_{CW} = 2$ (number of codewords)
— $L_{LDPC} = 1296$ (size of codeword)
— $N_{CBPS} = 216$ (number of coded bits per symbol)
— $N_{avbits} = 2592$ (number of available bits)
— $N_{shrt} = 160$ (number of bits to be shortened)
— $N_{punc} = 0$ (number of bits to be punctured)
— $N_{SYM} = 12$ (number of OFDM symbols)
— $N_{rep} = 160$ (number of bits to be repeated)

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The results of applying shortening bits, as prescribed in paragraph (c) of 19.3.11.7.5, is given in Table I-40.

NOTE—N_{shrt} = 160 shortening bits have been inserted as 0s: 80 0s at bits 568–647 and 80 0s at bits 1216–1295; this order equally distributes the shortening bits across the N_{CW} = 2 codewords.

Table I-40—DATA bits for LDPC example 2 after insertion of shortening bits

I.3.5 Encoding the data for LDPC example 2

The DATA with shortening bits are LDPC encoded as two (N_{CW} = 2) codewords (L_{LDPC} = 1296; R = 1/2) as prescribed by paragraph (c) of 19.3.11.7.5. The results are given in Table I-41.

NOTE—The LDPC encoder appends 648 bits as follows: bits 648–1295 after the first shortened codeword and another 648 bits (bits 1944–2591) after the second shortened codeword.

I.3.6 Removing shortening bits and repetition for LDPC example 2

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 19.3.11.7.5. Finally, either puncturing is applied as described in paragraph (d) of the same subclause, or the copying of repeated bits is applied as described in paragraph (e) of the same subclause. In LDPC example 2, because N_{punc} = 0 and N_{rep} = 160 are nonzero, repetition is prescribed and completes the LDPC encoding process.

The results are given in Table I-42.

NOTE—The first 80 shortening bits (bits 568–647 from Table I-41) have been removed from the first codeword between bits 567 and 568 of Table I-42, and the second 80 shortening bits (bits 1864–1943 of Table I-41) have been removed between bits 1215 and 1216 of Table I-42. Also, 80 bits have been repeated from the beginning of the first codeword (bits 0–79) to the end of the first codeword (bits 1216–1295), and 80 bits have been repeated from the beginning of the second codeword (bits 1296–1375) to end of the second codeword (bits 2512–2591) in Table I-42.

Table I-42—DATA bits after removal of shortening bits and copying of repetition bits

I.4 DMG example data vectors

Subclauses I.5 to I.8 contain example data vectors for the DMG PHY (see Clause 20).

For each described node, there is a cross-reference in this annex that is of the form

Reference: <**filename.txt**>

where the named file is one of the text files contained in the DMGEncodingExamples.zip file embedded in the IEEE 802.11 Working Group document 11-12/0751r0, located at https://mentor.ieee.org/802.11/dcn/12/11-12-0751-00-00ad-dmg-encoding-examples.docx).

Depending on the node being illustrated, the text file might represent bit data, symbol data, or sample data:

- For bit data, the text file contains a time ordered sequence of 1 and 0 characters, separated by spaces and without any carriage control characters.
- For symbol data, the text file contains a time ordered sequence of signed integers, separated by spaces and without any carriage control characters.
- For sample data, the text file contains a time ordered sequence of complex values, formatted as ±<real>±<imag>j, separated by spaces and without any carriage control characters.

When referencing specific bits, symbols, or samples in the files, they are considered to be numbered starting from 1.

This formatting of the text files has been chosen to facilitate import into other tools. For example, the files can be read using the MATLAB `dlmread('filename')` command.

For DMG control mode, SC mode and low-power (LP) SC mode modulation samples, no spectrum shaping has been applied to the data because the implementation of spectrum shaping is not defined in this standard. For DMG OFDM mode modulation samples, no symbol shaping has been applied to the data because the implementation of OFDM symbol shaping is not defined in this standard.

I.5 DMG Example 1 – DMG control mode encoding

I.5.1 DMG control mode preamble

The DMG control mode preamble Short Training field (STF) and Channel Estimation field (CEF) are each constructed from a concatenation of real valued bipolar Golay sequences that is π/2-BPSK modulated, as shown in Figure I-1.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

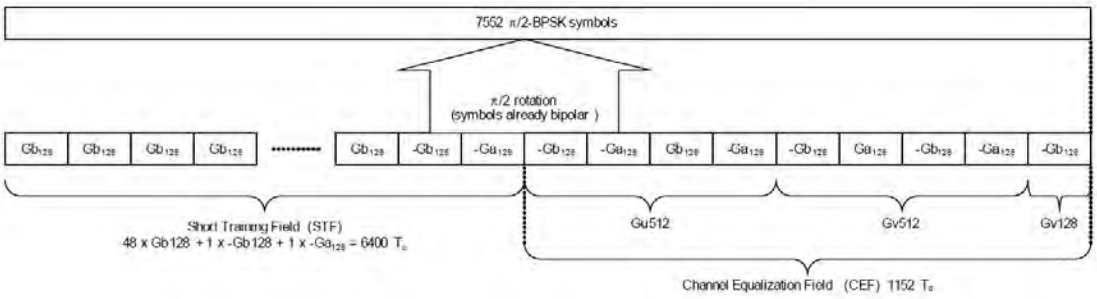

Figure I-1—DMG control mode preamble expressed in Ga_{128} and Gb_{128} sequences

The DMG control mode preamble is 7552 samples long.

Reference: **CPHY_Preamble Samples.txt**

I.5.2 Control mode header

The DMG control mode header coding and modulation are shown in Figure I-2.

I.5.2.1 DMG control mode header and payload bits

Figure I-2 node ①. The 5 octets of header data followed by the payload data. The first 6 octets of the data payload are used to complete the construction of the single LDPC codeword of the DMG control mode header. For this example, the DMG control mode header bit fields are set as listed in Table I-43.

Table I-43—DMG control mode header settings

Field	Value
Scrambler Initialization	2
Length	120
Packet Type	0
Training Length	0
Turnaround	0
Reserved bits	0

The data payload octets are provided by a count, modulo 256, starting at 0. The resulting header and payload sequence is 1000 bits long, of which the first 88 bits are encoded in the header modulation block. For this example, with a payload of 120 octets, $L_{DPFCW} = 88$, $L_{DPCW} = 152$ and $L_{DPLCW} = 152$.

These numbers illustrate that the payload is not simply packed 168 bits at a time into the LDPC encoding, with the last few bits (modulo 168) in the last packet getting disproportionate coding gain. The specified calculation spreads the excess coding gain evenly across all of the packets, so the number of payload bits in each packet varies between approximately 120 and the maximum 168.

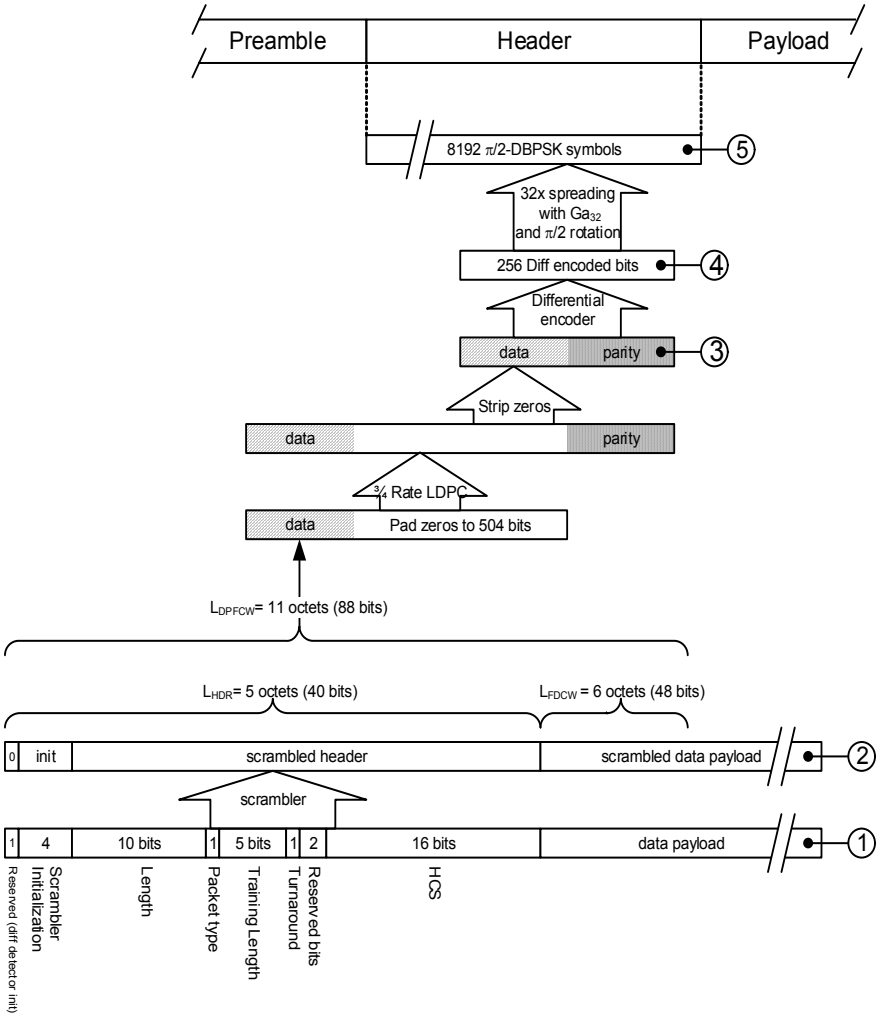

Figure I-2—DMG control mode header coding and modulation

I.5.2.2 DMG control mode scrambled header and payload bits

Figure I-2 node ②. The 5 header plus 6 data = 11 octets after scrambling.

Reference: Bits 1 to 88 of the file **CPHY_Scrambled Header and Payload bits.txt**

I.5.2.3 DMG control mode LDPC encoded header bits

Figure I-2 node ③. In this example there are 7 LDPC codewords. The number of bits produced by the first codeword after zero stripping is 88 + 168 = 256, and the number of bits produced by each of the remaining 6 codewords is 152 + 168 = 320. The total number of bits after LDPC encoding is 256 + 6 x 320 = 2176, of which the first 256 bits correspond to the LDPC encoded header.

Reference: Bits 1 to 256 of the file **CPHY_LDPC Encoded Header and Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.5.2.4 DMG control mode differentially encoded header symbols

Figure I-2 node ④. The 256 LDPC encoded header bits are differentially encoded.

Reference: Symbols 1 to 256 of the file **CPHY_Diff Encoded Header and Payload symbols.txt**

I.5.2.5 DMG control mode header samples

Figure I-2 node ⑤. The 256 differentially encoded bipolar symbol values are spread using the Ga_{32} Golay sequence, then $\pi/2$ rotated to produce 8192 chips at F_c = 1760 MHz.

Reference: Samples 1 to 8192 of the file **CPHY_Header and Payload samples.txt**

I.5.3 DMG control mode payload

The DMG control mode payload coding and modulation are shown in Figure I-3.

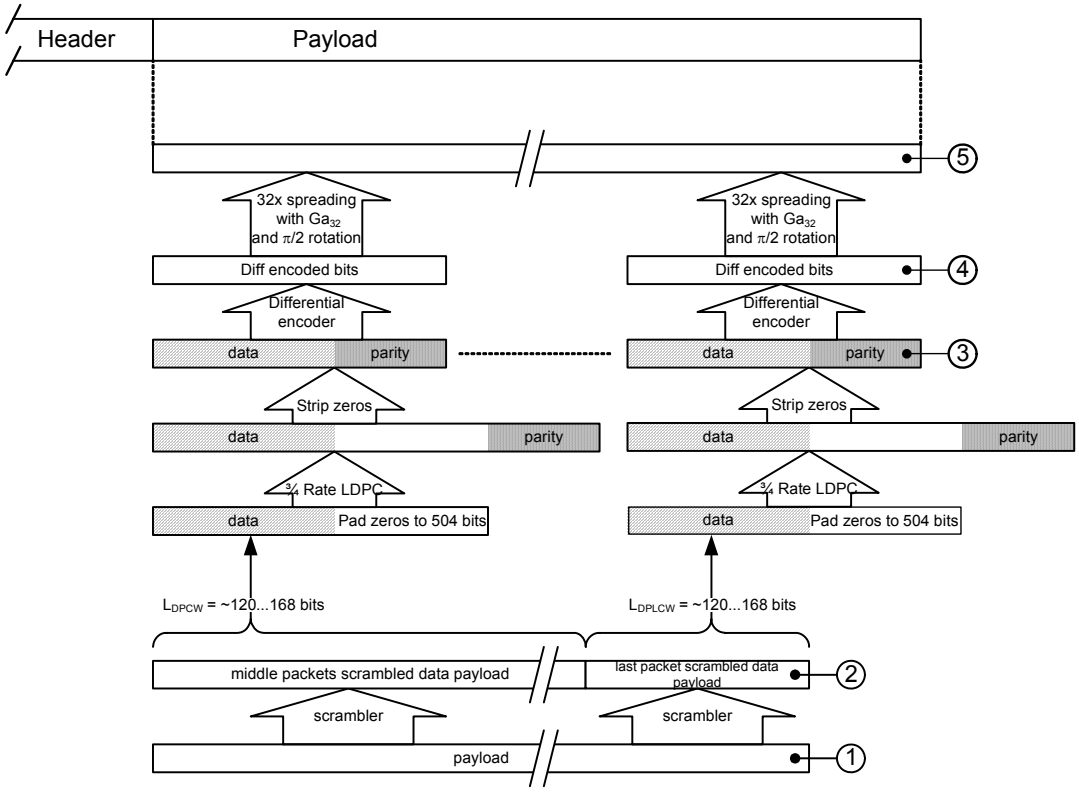

Figure I-3—DMG control mode payload coding and modulation

I.5.3.1 DMG control mode payload bits

Figure I-3 node ①.

Reference: Bits 89 to 1000 of the file **CPHY_Header and Payload bits.txt**

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.5.3.2 DMG control mode scrambled payload bits

Figure I-3 node ②.

Reference: Bits 89 to 1000 of the file **CPHY_Scrambled Header and Payload bits.txt**

I.5.3.3 DMG control mode LDPC encoded payload bits

Figure I-3 node ③.

Reference: Bits 257 to 2176 of the file **CPHY_LDPC Encoded Header and Payload bits.txt**

I.5.3.4 DMG control mode differentially encoded payload symbols

Figure I-3 node ④.

Reference: Symbols 257 to 2176 of the file **CPHY_Diff Encoded Header and Data symbols.txt**

I.5.3.5 DMG control mode payload samples

Figure I-3 node ⑤.

In this example, the 320 differentially encoded bipolar symbol values from each of the 6 payload bearing LDPC codewords, including the last one, gives a total of 6 x 320 = 1920 symbols which are then spread using the Ga_{32} Golay sequence and π/2 rotated to produce 61 440 chips at Fc = 1.76 GHz.

Reference: Samples 8193 to 69 632 of the file **CPHY_Header and Payload samples.txt**

I.6 DMG Example 2 – DMG SC mode encoding

I.6.1 DMG SC mode preamble

The DMG SC mode preamble Short Training field (STF) and Channel Estimation field (CEF) are each constructed from a concatenation of real valued bipolar Golay sequences that is π/2-BPSK modulated, as shown in Figure I-4.

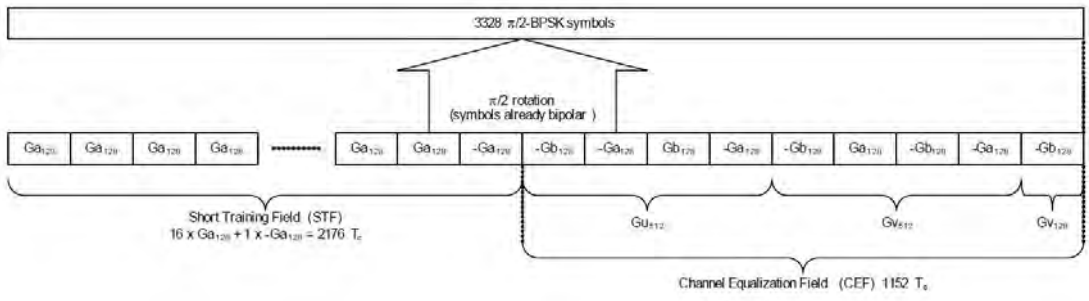

Figure I-4—DMG SC mode preamble expressed in Ga_{128} and Gb_{128} sequences

The preamble is 3328 samples long.

I.6.2.4 DMG SC mode LDPC data shortened bits

Figure I-5 node ④. The dimension of DMG SC mode modulation blocks requires that the CS1 and CS2 sequences are each 224 bits long; this in turn requires that, in addition to the zeros, some of the parity bits are discarded in order to shorten the LDPC codewords to 224 bits.

The data for the second shortened LDPC codeword is given as they are before they are scrambled to provide CS2.

Reference: **SCPHY_MCS2_Shortened LDPC for CS1 bits.txt**

Reference: **SCPHY_MCS2_Shortened LDPC for CS2 bits.txt**

I.6.2.5 DMG SC mode CS1/CS2 sequence bits

Figure I-5 node ⑤. The 448 bit concatenated CS1/CS2 sequence including the PN scrambling of CS2.

Reference: **SCPHY_MCS2_Final CS1 CS2 Sequence bits.txt**

I.6.2.6 DMG SC mode header samples

Figure I-5 node ⑥. The fully modulated signal after BPSK mapping, duplication (with negation), guard interval addition and $\pi/2$ rotation are applied.

The 448 header bits are BPSK mapped to 448 modulation symbols and increased to 512 symbols by the addition of a 64 symbol guard interval. A second, negated, copy of the 448 modulation symbols is also increased to 512 symbols by the addition of a 64 symbol guard interval. The two 512 symbol blocks are concatenated and $\pi/2$ rotated to create 1024 samples.

Reference: **SCPHY_MCS2_Header Samples.txt**

I.6.3 DMG SC mode payload

The DMG SC mode payload coding and modulation are shown in Figure I-6 (for MCS1) and Figure I-7 (for MCS2–MCS12).

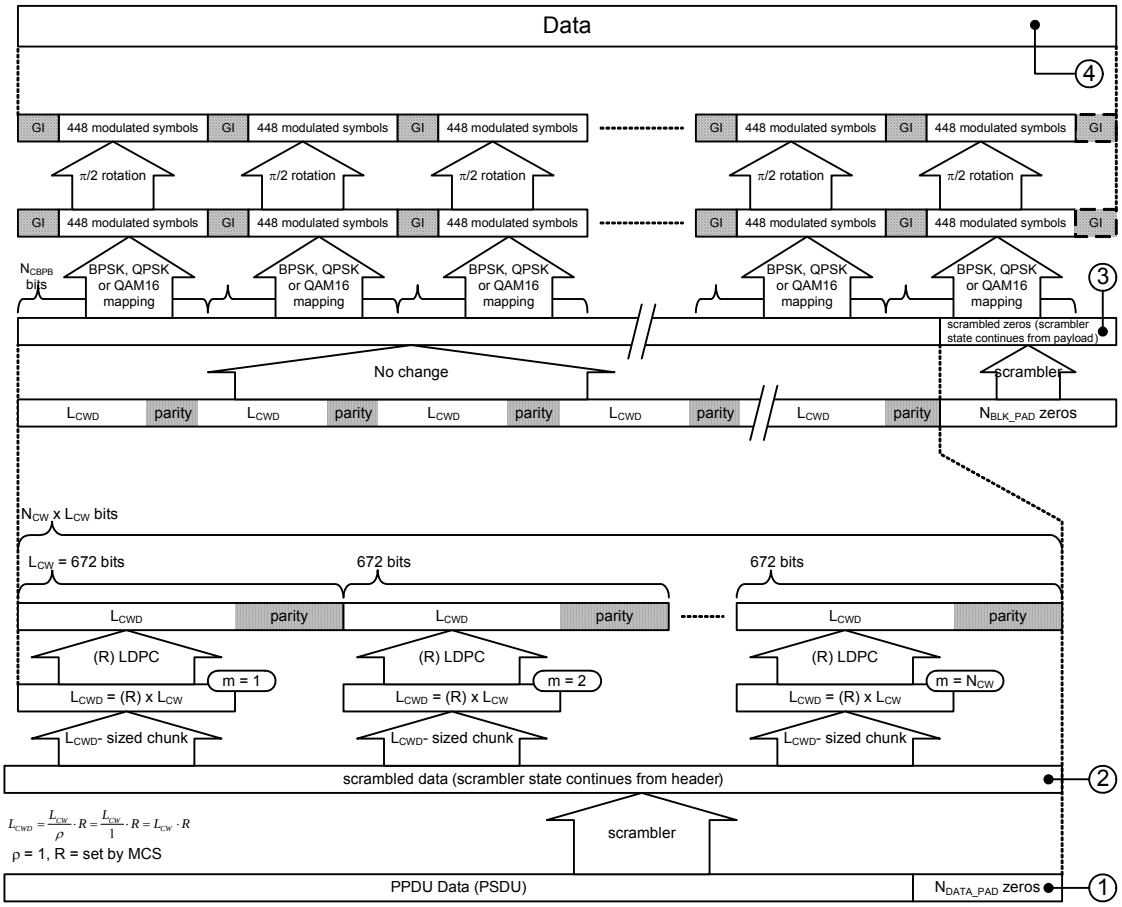

Figure I-7—DMG SC mode MCS2—MCS12 payload coding and modulation

I.6.3.1 DMG SC mode MCS1 payload

I.6.3.1.1 Payload bits

Figure I-6 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS1 each rate 1/2 LDPC codeword encodes 168 bits (with $\rho = 2$ repetition) so the payload padding calculation gives $N_{CW} = 48$ and $N_{DATA_PAD} = 64$.

There are 1000 × 8 = 8000 payload bits plus 64 padding bits giving a total of 8 064 bits.

Reference: **SCPHY_MCS1_Payload bits.txt**

I.6.3.1.2 Scrambled payload bits

Figure I-6 node ②. All 8 064 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS1_Scrambled Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.6.3.1.3 Rate 1/2 LDPC encoded bits before scrambled duplication

Figure I-6 node ③. The rate 1/2 LDPC encoding of each block of L_z = 168 scrambled payload bits plus L_z = 168 padding zero bits. In this example, the 8064 actual payload bits are doubled, by repetition, to an effective payload of 16 128 bits, then doubled again to 32 256 bits by LDPC encoding.

This node, unique to MCS1, is the raw LDPC encoded payload bits before scrambled duplication.

Reference: **SCPHY_MCS1_LDPC Encoder Output bits.txt**

I.6.3.1.4 Rate 1/2 LDPC encoded bits after scrambled duplication

Figure I-6 node ④. The LDPC codewords after the L_z = 168 zeros have been replaced by the L_z = 168 re-scrambled data octets. The data at this node also includes the appended N_{BLK_PAD} scrambled zeros; however, in this example, N_{BLK_PAD} = 0, so there are still 32 256 bits.

Each 448 bits in the reference file is the N_{CBPB} = 448 bits required to build a modulation block of the MCS1 payload.

Reference: **SCPHY_MCS1_LDPC Encoded Payload Bits.txt**

I.6.3.1.5 Payload samples

Figure I-6 node ⑤. The modulated signal after BPSK mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 32 256 encoded bits are divided into 72 × 448 bit blocks. BPSK mapping converts this to 72 × 448 modulation symbols which the guard interval increases to 72 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 72 × 512 + 64 = 36 928 payload samples.

Reference: **SCPHY_MCS1_Payload Samples.txt**

I.6.3.2 DMG SC mode MCS5 payload

I.6.3.2.1 Payload bits

Figure I-7 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS5 each rate 13/16 LDPC codeword encodes 546 bits so the payload padding calculation gives N_{CW} = 15 and N_{DATA_PAD} = 190.

There are 1000 × 8 = 8000 payload bits plus 190 padding bits giving a total of 8 190 bits.

Reference: **SCPHY_MCS5_Payload bits.txt**

I.6.3.2.2 Scrambled payload bits

Figure I-7 node ②. All 8 190 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS5_Scrambled Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.6.3.2.3 Rate 13/16 LDPC encoded payload bits

Figure I-6 node ③. The rate 13/16 LDPC encoding of each block of L_{CWD} = 546 scrambled payload bits. In this example, the 8 190 payload bits are increased to 10 080 bits by the LDPC encoding.

The data at this node also includes the appended N_{BLK_PAD} scrambled zeros. In this example, N_{BLK_PAD} = 224, so the total number of bits is 10 080 + 224 = 10 304.

Reference: **SCPHY_MCS5_LDPC Encoded Payload Bits.txt**

I.6.3.2.4 Payload samples

Figure I-7 node ④. The modulated signal after BPSK mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 10 304 encoded bits are divided into 23 × 448 bit blocks. BPSK mapping converts this to 23 × 448 modulation symbols which the guard interval increases to 23 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 23 × 512 + 64 = 11 840 payload samples.

Reference: **SCPHY_MCS5_Payload Samples.txt**

I.6.3.3 DMG SC mode MCS7 payload

I.6.3.3.1 Payload bits

Figure I-7 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS7 each rate 5/8 LDPC codeword encodes 420 bits so the payload padding calculation gives N_{CW} = 20 and N_{DATA_PAD} = 400.

There are 1000 × 8 = 8000 payload bits plus 400 padding bits giving a total of 8 400 bits.

Reference: **SCPHY_MCS7_Payload bits.txt**

I.6.3.3.2 Scrambled payload bits

Figure I-6 node ②. All 8 400 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS7_Scrambled Payload bits.txt**

I.6.3.3.3 Rate 5/8 LDPC encoded payload bits

Figure I-7 node ③. The rate 5/8 LDPC encoding of each block of L_{CWD} = 420 scrambled payload bits. In this example, the 8 400 payload bits are increased to 13 440 bits by the LDPC encoding.

The data at this node also includes the appended N_{BLK_PAD} scrambled zeros. In this example, N_{BLK_PAD} = 0, so there are still a total of 13 440 bits.

Reference: **SCPHY_MCS7_LDPC Encoded Payload Bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.6.3.3.4 Payload samples

Figure I-7 node ④. The modulated signal after QPSK mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 13 440 encoded bits are divided into 15 × 896 bit blocks. QPSK mapping converts this to 15 × 448 modulation symbols which the guard interval increases to 15 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 15 × 512 + 64 = 7 744 payload samples.

Reference: **SCPHY_MCS7_Payload Samples.txt**

I.6.3.4 DMG SC mode MCS12 payload

I.6.3.4.1 Payload bits

Figure I-7 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS12 each rate 3/4 LDPC codeword encodes 504 bits so the payload padding calculation gives $N_{CW} = 16$ and $N_{DATA_PAD} = 64$.

There are 1000 × 8 = 8000 payload bits plus 64 padding bits giving a total of 8 064 bits.

Reference: **SCPHY_MCS12_Payload bits.txt**

I.6.3.4.2 Scrambled payload bits

Figure I-7 node ②. All 8 064 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS12_Scrambled Payload bits.txt**

I.6.3.4.3 Rate 3/4 LDPC encoded payload bits

Figure I-7 node ③. The rate 3/4 LDPC encoding of each block of $L_{CWD} = 504$ scrambled payload bits. In this example, the 8 064 payload bits are increased to 10 752 bits by the LDPC encoding.

The data at this node also includes the appended N_{BLK_PAD} scrambled zeros. In this example, $N_{BLK_PAD} = 0$, so there are still a total of 10 752 bits.

Reference: **SCPHY_MCS12_LDPC Encoded Payload Bits.txt**

I.6.3.4.4 Payload samples

Figure I-7 node ④. The modulated signal after 16-QAM mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 10 752 encoded bits are divided into 6 × 1 792 bit blocks. 16-QAM mapping converts this to 6 × 448 modulation symbols which the guard interval increases to 6 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 6 × 512 + 64 = 3 136 payload samples.

Reference: **SCPHY_MCS12_Payload Samples.txt**

I.7 DMG Example 3 – DMG OFDM mode encoding

I.7.1 DMG OFDM mode preamble

Figure I-8 illustrates that the DMG OFDM mode preamble is similar to the DMG SC mode preamble, but with the Gu_{512} and Gv_{512} parts of the CEF reversed. It is also resampled from 1.76 GSa/s to 2.64 GSa/s using the specified process of interpolation, resampling, and decimation.

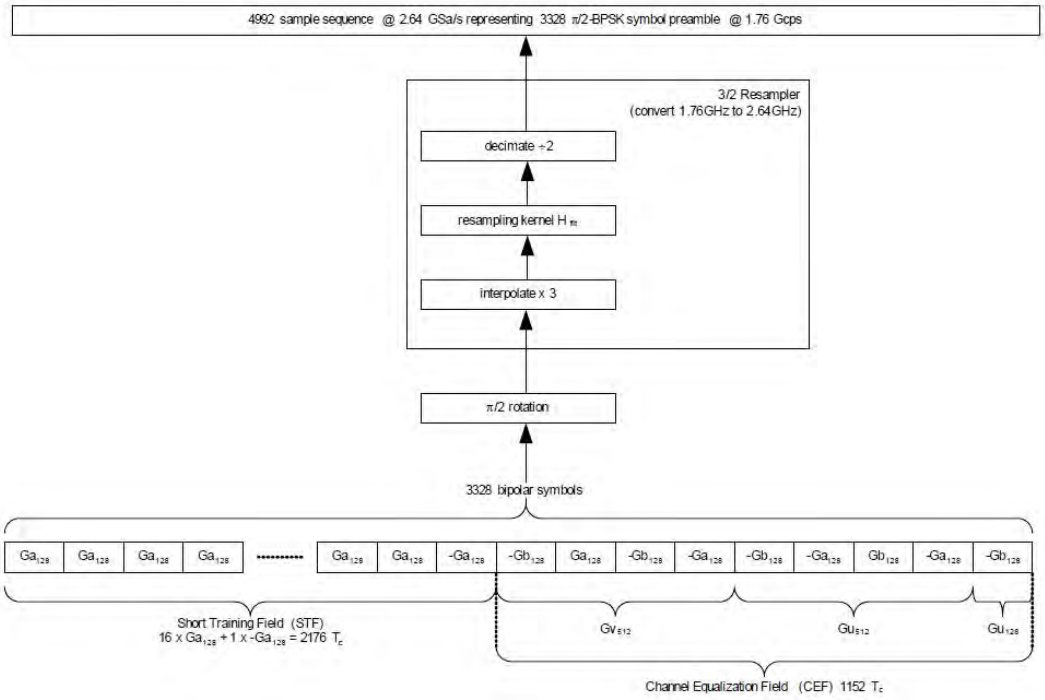

Figure I-8—DMG OFDM mode preamble

Thus the DMG OFDM mode preamble sample count increases from 3 328 to 4 992.

Reference: **OFDMPHY_Preamble Samples.txt**

I.7.2 DMG OFDM mode header

The DMG OFDM mode header coding is shown in Figure I-9.

I.7.2.1 DMG OFDM mode header bits

Figure I-9 node ①. The 8 octets of header data.

For this example, the DMG OFDM mode header bit fields are set as listed in Table I-45.

Figure I-9 node ②. The header bits after scrambling bits 8 to 64 of the header using the seed 66 (0x42).

Reference: **OFDMPHY_MCS13_Scrambled Header bits.txt**

I.7.2.3 DMG OFDM mode LDPC encoded header bits

Figure I-9 node ③. The scrambled header bits after LDPC encoding but prior to zero stripping.

Reference: **OFDMPHY_MCS13_LDPC Encoded Header Bits.txt**

I.7.2.4 DMG OFDM mode LDPC data shortened bits

Figure I-9 node ④. The dimension of DMG OFDM mode modulation symbols requires that the CS1, CS2, and CS3 sequences are each 224 bits long; this in turn requires that, in addition to the zeros, some of the parity bits are discarded in order to shorten the LDPC codewords to 224 bits.

The data for the second and third shortened LDPC codewords are given as they are before they are scrambled to provide CS2 and CS3.

Reference: **OFDMPHY_MCS13_Shortened LDPC for CS1 bits.txt**

Reference: **OFDMPHY_MCS13_Shortened LDPC for CS2 bits.txt**

Reference: **OFDMPHY_MCS13_Shortened LDPC for CS3 bits.txt**

I.7.2.5 DMG OFDM mode CS1/CS2/CS3 sequence bits

Figure I-9 node ⑤. The 672 bit concatenated CS1/CS2/CS3 sequence including the PN scrambling of CS2 and CS3.

I.7.3 DMG OFDM mode header modulation

The DMG OFDM mode header modulation is shown in Figure I-10.

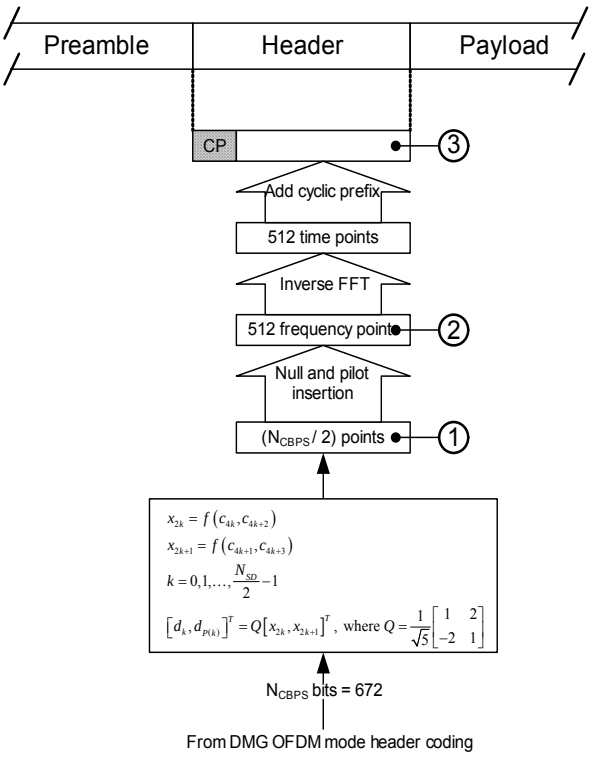

Figure I-10—DMG OFDM mode header modulation

I.7.3.1 Constellation mapped data points

Figure I-10 node ①. The LDPC encoded data is converted in the specified manner to 336 QPSK constellation point values prior to assignment to data carriers (in the same order as the data they were derived from). Note that because of the action of the *Q* matrix, these points look like 16-QAM when plotted.

Reference: Samples 1 to 336 of the file **OFDMPHY_MCS13_Constellation Mapped Data Points.txt**

I.7.3.2 IFFT input samples including data, pilot, DC and null carriers

Figure I-10 node ②. At this node the data points have been mapped to the data carriers, the pilots, DC and null carriers have been assigned, and the resulting 512 point frequency domain vector is in the correct order for input to the inverse Fourier transform, i.e., with positive frequencies in the first 256 locations and negative frequencies in the second 256 locations.

Reference: Samples 1 to 512 of the file **OFDMPHY_MCS13_FFT Input Samples.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.7.3.3 Header samples

Figure I-10 node ③. At this node the signal has been inverse Fourier transformed to produce a time record and the cyclic prefix has been appended to create the 640 sample OFDM symbol.

Reference: **OFDMPHY_MCS13_Header Samples.txt**

I.7.4 DMG OFDM mode payload coding

As illustrated in Figure I-11, the LDPC encoding for the DMG OFDM mode case is identical to the DMG SC mode case, so no additional LDPC vectors are strictly necessary. However, the equations for computing the zero padding at the end of the payload are different from the DMG SC mode case so bit vectors for nodes 1, 2, and 3 are provided.

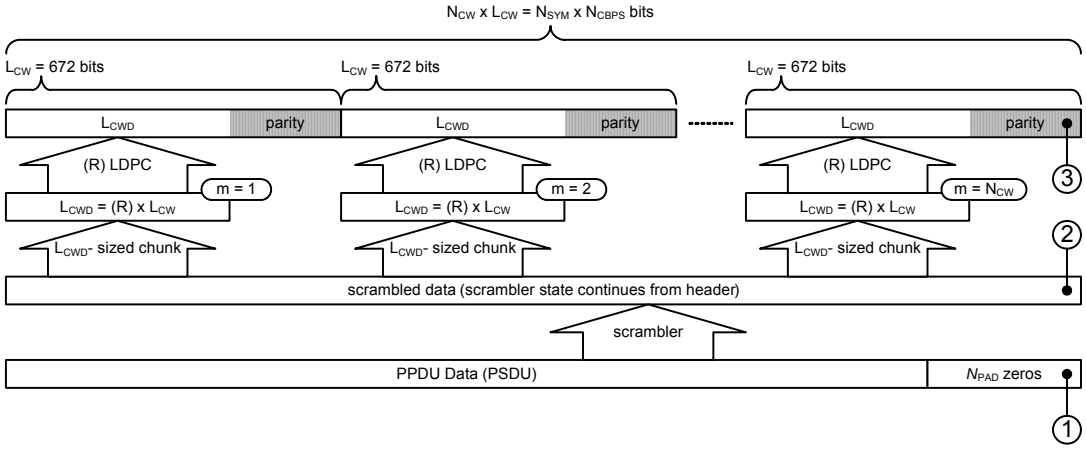

Figure I-11—DMG OFDM mode payload coding

I.7.5 DMG OFDM mode MCS14 payload modulation

The DMG OFDM mode SQPSK payload modulation is shown in Figure I-12.

I.7.5.1 Payload bits

Figure I-11 node ①. The payload comprises 1000 × 8 bits. With $N_{\mathrm{CBPS}} = 336$ and rate 5/8 LDPC coding the DMG OFDM mode zero padding $N_{PAD} = 400$, so the padded payload comprises 8 400 bits.

Reference: **OFDMPHY_MCS14_ Payload bits.txt**

I.7.5.2 Scrambled payload bits

Figure I-11 node ②. All 8 400 bits are scrambled according to a scrambler initialization value of 66.

Reference: **OFDMPHY_MCS14_Scrambled Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

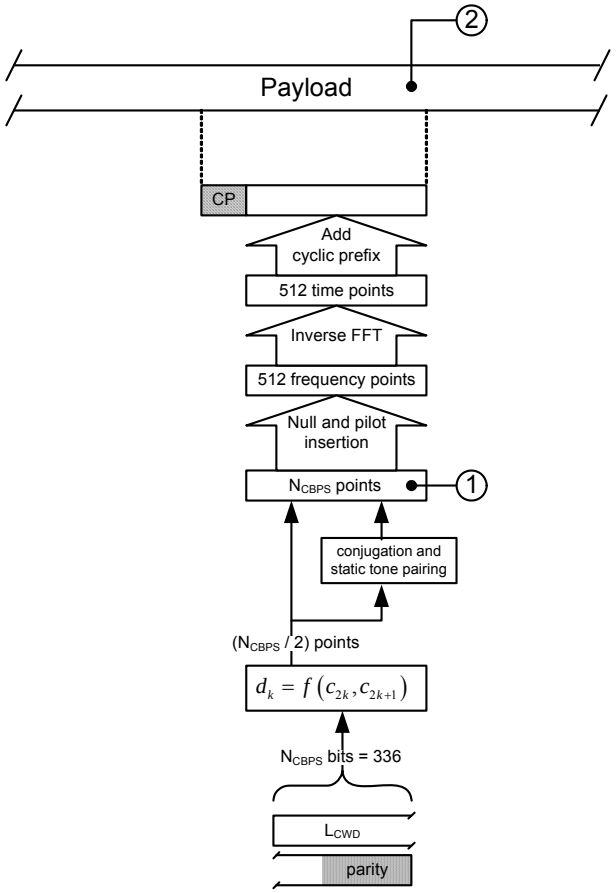

Figure I-12—DMG OFDM mode SQPSK payload modulation

I.7.5.3 LDPC encoded payload bits

Figure I-11 node ③. For this example, with N_{CBPS} = 336 and rate 5/8 LDPC coding there are 20 LDPC codewords or 20 × 672 = 13 440 bits at this node.

Reference: **OFDMPHY_MCS14_LDPC Encoded Payload bits.txt**

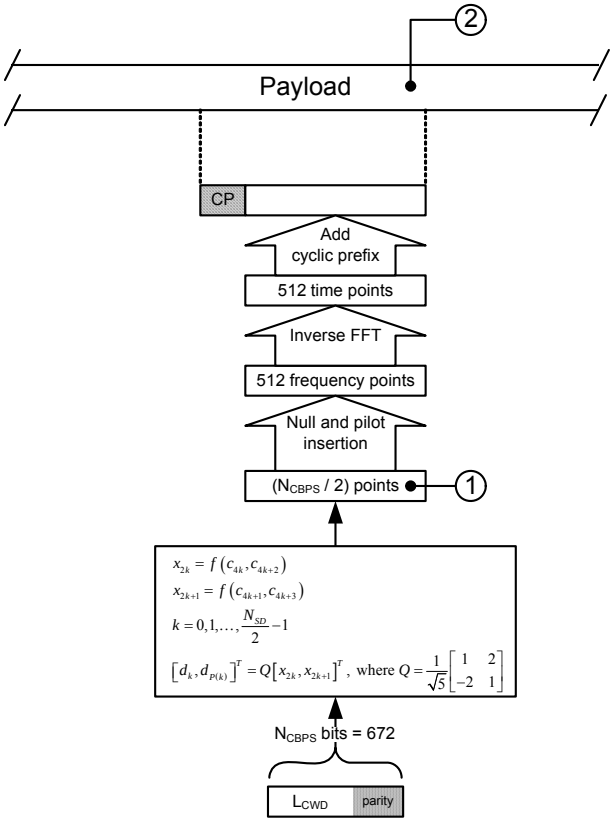
I.7.5.4 SQPSK constellation mapped data points

Figure I-12 node ①. For SQPSK modulation, each block of N_{CBPS} = 336 LDPC encoded bits is converted in the specified manner to 168 QPSK constellation point values and their complex conjugates prior to assignment to data carriers, in the same order as the data they were derived from.

There are 336 constellation points for each block of 336 LDPC encoded bits, so there are 40 sets of 336 constellation points (13 440 point in total) at this node.

Reference:
Samples 337 to 13 776 of the file **OFDMPHY_MCS14_Constellation Mapped Data Points.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.



I.7.5.5 Payload samples

Figure I-12 node ②. Each set of 336 constellation points is mapped to 512 frequency domain points then inverse Fourier transformed to 512 time domain points; adding the cyclic prefix creates a 640 sample OFDM symbol. There are 40 OFDM symbols in this example payload, giving a total of 40 × 640 = 25 600 samples.

Reference: **OFDMPHY_MCS14_Payload Samples.txt**

I.7.6 DMG OFDM mode MCS17 payload modulation

The DMG OFDM mode QPSK payload modulation is shown in Figure I-13.

For QPSK, 1 LDPC codeword is used for each OFDM symbol

Figure I-13—DMG OFDM mode QPSK payload modulation

I.7.6.1 Payload bits

Figure I-11 node ①. The payload comprises 1000 × 8 bits. With N_{CBPS} = 672 and rate 3/4 LDPC coding the DMG OFDM mode zero padding N_{PAD} = 64, so the padded payload comprises 8 064 bits.

Reference: **OFDMPHY_MCS17_ Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.7.6.2 Scrambled payload bits

Figure I-11 node ②. All 8 064 bits are scrambled according to a scrambler initialization value of 66.

Reference: **OFDMPHY_MCS17_Scrambled Payload bits.txt**

I.7.6.3 LDPC encoded payload bits

Figure I-11 node ③. For this example, with N_{CBPS} = 672 and rate 3/4 LDPC coding there are 16 LDPC codewords or 16 × 672 = 10 752 bits at this node.

Reference: **OFDMPHY_MCS17_LDPC Encoded Payload bits.txt**

I.7.6.4 QPSK constellation mapped data points

Figure I-13 node ①. For QPSK modulation, each block of N_{CBPS} = 672 LDPC encoded bits is converted in the specified manner to 336 QPSK constellation point values prior to assignment to data carriers, in the same order as the data they were derived from.

There are 336 constellation points for each block of 672 LDPC encoded bits, so there are 16 sets of 336 constellation points (5 376 point in total) at this node.

Reference:
Samples 337 to 5 712 of the file **OFDMPHY_MCS17_Constellation Mapped Data Points.txt**

I.7.6.5 Payload samples

Figure I-13 node ②. Each set of 336 constellation points is mapped to 512 frequency domain points then inverse Fourier transformed to 512 time domain points; adding the cyclic prefix creates a 640 sample OFDM symbol. There are 16 OFDM symbols in this example payload giving a total of 16 × 640 = 10 240 samples.

Reference: **OFDMPHY_MCS17_Payload Samples.txt**

I.7.7 DMG OFDM mode MCS19 payload modulation

The DMG OFDM mode 16-QAM payload modulation is shown in Figure I-14.

I.7.7.1 Payload bits

Figure I-11 node ①. The payload comprises 1000 × 8 bits. With N_{CBPS} = 1 344 and rate 5/8 LDPC coding the DMG OFDM mode zero padding N_{PAD} = 400, so the padded payload comprises 8 400 bits.

Reference: **OFDMPHY_MCS19_ Payload bits.txt**

I.7.7.2 Scrambled payload bits

Figure I-11 node ②. All 8 400 bits are scrambled according to a scrambler initialization value of 66.

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.7.7.5 Payload samples

Figure I-14 node ②. Each set of 336 constellation points is mapped to 512 frequency domain points then inverse Fourier transformed to 512 time domain points; adding the cyclic prefix creates a 640 sample OFDM symbol. There are 10 OFDM symbols in this example payload giving a total of 10 × 640 = 6 400 samples.

Reference: **OFDMPHY_MCS19_Payload Samples.txt**

I.7.8 DMG OFDM mode MCS23 payload modulation

The DMG OFDM mode 64-QAM payload modulation is shown in Figure I-15.

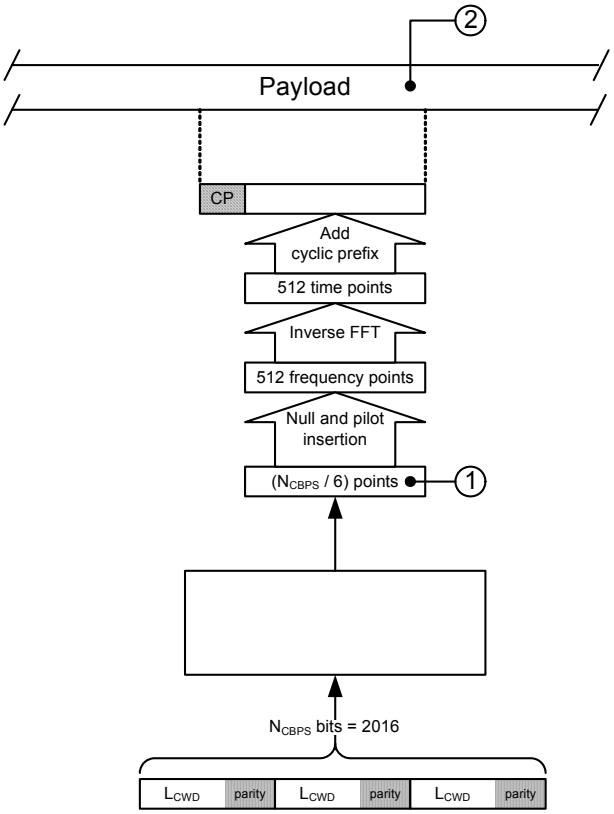

Figure I-15—DMG OFDM mode 64-QAM payload modulation

I.7.8.1 Payload bits

Figure I-11 node ①. The payload comprises 1000 × 8 bits. With N_{CBPS} = 2 016 and rate 3/4 LDPC coding the DMG OFDM mode zero padding N_{PAD} = 1 072, so the padded payload comprises 9 072 bits.

Reference: **OFDMPHY_MCS23_ Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.7.8.2 Scrambled payload bits

Figure I-11 node ②. All 9 072 bits are scrambled according to a scrambler initialization value of 66.

Reference: **OFDMPHY_MCS23_Scrambled Payload bits.txt**

I.7.8.3 LDPC encoded bits

Figure I-11 node ③. For this example, with N_{CBPS} = 2 016 and rate 3/4 LDPC coding there are 18 LDPC codewords or 18 × 672 = 12 096 bits at this node.

Reference: **OFDMPHY_MCS23_LDPC Encoded Payload bits.txt**

I.7.8.4 64-QAM constellation mapped data points

Figure I-15 node ①. For 64-QAM modulation, each block of N_{CBPS} = 2 016 LDPC encoded bits is converted in the specified manner to 336 64-QAM constellation point values prior to assignment to data carriers, in the same order as the data they were derived from.

There are 336 constellation points for each block of 2 016 LDPC encoded bits, so there are 6 sets of 336 constellation points (2 016 points in total) at this node.

Reference:
Samples 337 to 2352 of the file **OFDMPHY_MCS23_Constellation Mapped Data Points.txt**

I.7.8.5 Payload samples

Figure I-15 node ②. Each set of 336 constellation points is mapped to 512 frequency domain points then inverse Fourier transformed to 512 time domain points; adding the cyclic prefix creates a 640 sample OFDM symbol. There are 6 OFDM symbols in this example payload giving a total of 6 × 640 = 3 840 samples.

Reference: **OFDMPHY_MCS23_Payload Samples.txt**

I.8 DMG Example 4 – DMG low-power SC mode encoding

I.8.1 DMG low-power SC mode preamble

The DMG low-power SC mode preamble is identical to the DMG SC mode preamble.

I.8.2 DMG low-power SC mode header

The DMG low-power SC mode header fields are the same as the DMG SC mode header fields. The DMG low-power SC mode header is encoded and modulated in the same way as the DMG SC mode header.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.8.3 DMG low-power SC mode MCS26 payload

The DMG low-power SC mode payload coding and modulation are shown in Figure I-16.

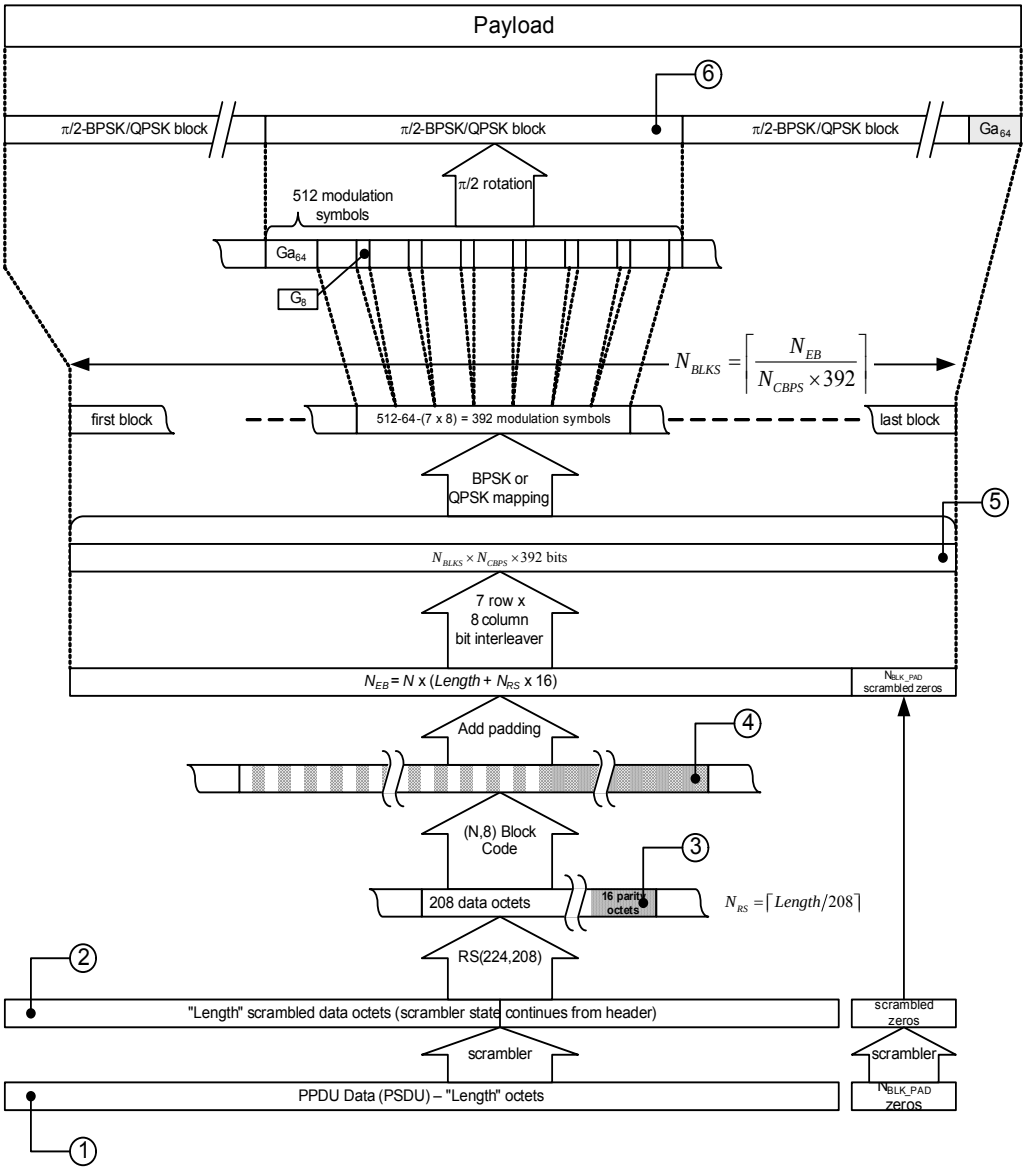

Figure I-16—DMG low-power SC mode payload coding and modulation

I.8.3.1 Payload bits

Figure I-16 node ①. The payload at node is a count, modulo 256, starting at 0.

For MCS26, the DMG low-power SC mode payload padding calculation gives $N_{\mathrm{DATA_PAD}} = 368$; however, unlike the other modes, this padding data is not appended before FEC computation.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 11,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

So there are just 1000 × 8 = 8000 payload bits.

Reference: **LPSCPHY_MCS26_Payload bits.txt**

I.8.3.2 Scrambled payload bits

Figure I-16 node ②. All 8000 bits are scrambled according to a scrambler initialization value of 66.

Reference: **LPSCPHY_MCS26_Scrambled Payload bits.txt**

I.8.3.3 RS(224,208) encoded payload bits

Figure I-16 node ③. In this example, there are 4 RS(224,208) codewords and one shortened RS(184,168) codeword, giving a total of (4 × 224 + 1 × 184) × 8 = 8 640 bits at this node.

Reference: **LPSCPHY_MCS26_RS(224,208) Output bits.txt**

I.8.3.4 (12,8) block coded payload bits

Figure I-16 node ④. The (12,8) block coder increases the effective bits from 8 640 to 12 960.

Reference: **LPSCPHY_MCS26_Block Coded Payload bits.txt**

I.8.3.5 Interleaved payload bits

Figure I-16 node ⑤. Before interleaving the block coder output is padded with N_{DATA_PAD} = 368 scrambled zeros to give 13 328 bits (34 x 392). The interleaver then redistributes these bits in time, as specified.

Reference: **LPSCPHY_MCS26_RS Encoded and Interleaved Payload bits.txt**

I.8.3.6 Payload samples

Figure I-16 node ⑥. Each block of 392 bits from the interleaver output is BPSK mapped to 392 modulation symbols, prepended with a Ga_{64} sequence as a guard interval and punctuated by G_8 (last 8 samples of Ga_{64}) guard intervals, then π/2 rotated, thus resulting in a 512 symbol π/2-BPSK modulation block.

In this example, there are 34 modulation blocks and, as specified, the last one is followed by a terminating Ga_{64} guard interval sequence, so there are 34 × 512 + 64 = 17 472 samples at this node.

Reference: **LPSCPHY_MCS26_Payload Samples.txt**

I.8.4 DMG low-power SC mode MCS30 payload

I.8.4.1 Payload bits

Figure I-16 node ①. The payload at node is a count, modulo 256, starting at 0.

For MCS30, the DMG low-power SC mode payload padding calculation gives N_{DATA_PAD} = 472; however, unlike the other modes, this padding data is not appended before FEC computation.

So there are just 1000 × 8 = 8000 payload bits.

Reference: **LPSCPHY_MCS30_Payload bits.txt**

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

I.8.4.2 Scrambled payload bits

Figure I-16 node ②. All 8000 bits are scrambled according to a scrambler initialization value of 66.

Reference: **LPSCPHY_MCS30_Scrambled Payload bits.txt**

I.8.4.3 RS(224,208) encoded payload bits

Figure I-16 node ③. In this example, there are 4 RS(224,208) codewords and one shortened RS(184,168) codeword, giving a total of $(4 \times 224 + 1 \times 184) \times 8 = 8\,640$ bits at this node.

Reference: **LPSCPHY_MCS30_RS(224,208) Output bits.txt**

I.8.4.4 Spc(9,8) block coded payload bits

Figure I-16 node ④. The (9,8) block coder increases the effective bits from 8 640 to 9 720.

Reference: **LPSCPHY_MCS30_Block Coded Payload bits.txt**

I.8.4.5 Interleaved payload bits

Figure I-16 node ⑤. Before interleaving the block coder output is padded with $N_{DATA_PAD} = 472$ scrambled zeros to give 10 192 bits (26×392). The interleaver then redistributes these bits in time, as specified.

Reference: **LPSCPHY_MCS30_RS Encoded and Interleaved Payload bits.txt**

I.8.4.6 Payload samples

Figure I-16 node ⑥. Each block of 784 bits from the interleaver output is QPSK mapped to 392 modulation symbols, prepended with a Ga_{64} sequence as a guard interval and punctuated by G_8 (last 8 samples of Ga_{64}) guard intervals, then $\pi/2$ rotated, thus resulting in a 512 symbol $\pi/2$-BPSK modulation block.

In this example, there are 13 modulation blocks and, as specified, the last one is followed by a terminating Ga_{64} guard interval sequence, so there are $13 \times 512 + 64 = 6\,720$ samples at this node.

Reference: **LPSCPHY_MCS30_Payload Samples.txt**

***********************************************************************
* Routine: Phase 2 -- generate ARC4KEY, given TK, P1K, IV16
*
* Inputs:
*     TK[]      = Temporal Key                        [128 bits]
*     P1K[]     = Phase 1 output key                  [ 80 bits]
*     IV16      = low 16 bits of IV counter           [ 16 bits]
* Output:
*     ARC4KEY[]  = the key used to encrypt the frame  [128 bits]
*
* Note:
*     The value {TA,IV32,IV16} for Phase1/Phase2 shall be unique
*     across all frames using the same key TK value. Then, for a
*     given value of TK[], this TKIP48 construction guarantees that
*     the final ARC4KEY value is unique across all frames.
*
* Suggested implementation optimization: if PPK[] is "overlaid"
*     appropriately on ARC4KEY[], there is no need for the final
*     for loop below that copies the PPK[] result into ARC4KEY[].
*

J.2 Michael reference implementation and test vectors

J.2.1 Michael test vectors

J.2.1.1 Introduction

Test vectors are provided below in order to support correct implementation of michael. These test vectors still have to be confirmed by an independent implementation.

J.2.1.2 Block function

Table J-1 gives some test vectors for the block function.

Table J-1—Test vectors for block function

Input	# times	Output
(00000000, 00000000)	1	(00000000, 00000000)
(00000000, 00000001)	1	(c00015a8, c0000b95)
(00000001, 00000000)	1	(6b519593, 572b8b8a)
(01234567, 83659326)	1	(441492c2, 1d8427ed)
(00000001, 00000000)	1000	(9f04c4ad, 2ec6c2bf)

The first four rows give test vectors for a single application of the block function *b*. The last row gives a test vector for 1000 repeated applications of the block function. Together these should provide adequate test coverage.

J.2.1.3 Michael

Table J-2 gives some test vectors for michael.

Table J-2—Test vectors for michael

Key	Message	Output
0000000000000000	""	82925c1ca1d130b8
82925c1ca1d130b8	"M”	434721ca40639b3f
434721ca40639b3f	"Mi “	e8f9becae97e5d29
E8f9becae97e5d29	"Mic"	90038fc6cf13c1db

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Table J-2—Test vectors for michael

Key	Message	Output
90038fc6cf13c1db	"Mich"	D55e100510128986
D55e100510128986	"Michael"	0a942b124ecaa546

Note that each key is the result of the previous line, which makes it easy to construct a single test out of all of these test cases.

J.2.2 Sample code for michael

```
//
// Michael.h    Reference implementation for michael

//
// A michael object implements the computation of the MIC.
//
// Conceptually, the object stores the message to be authenticated.
// At construction the message is empty.
// The append() method appends bytes to the message.
// The getMic() method computes the MIC over the message and returns the
// result.
// As a side-effect it also resets the stored message
// to the empty message so that the object can be reused
// for another MIC computation.

class Michael
{

public:
    // Constructor requires a pointer to 8 bytes of key
    Michael( Byte * key );

    // Destructor
    ~Michael();

    // Clear the internal message,
    // resets the object to the state just after construction.
    void clear();

    // Set the key to a new value
    void setKey( Byte * key );

    // Append bytes to the message to be MICed
```

J.4 Suggested pass-phrase-to-PSK mapping

J.4.1 Introduction

The RSNA PSK consists of 256 bits, or 64 octets when represented in hexadecimal. It is difficult for a user to correctly enter 64 hexadecimal characters. Most users, however, are familiar with passwords and pass-phrases and feel more comfortable entering them than entering keys. A user is more likely to be able to enter an ASCII password or pass-phrase, even though doing so limits the set of possible keys. This suggests that the best that can be done is to introduce a pass-phrase to PSK mapping.

This subclause defines a pass-phrase–to–PSK mapping that is the recommended practice for use with RSNAs. This pass-phrase mapping was introduced to encourage users unfamiliar with cryptographic concepts to enable the security features of their WLAN.

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Keys derived from the pass-phrase provide relatively low levels of security, especially with keys generated form short passwords, since they are subject to dictionary attack. Use of the key hash is recommended only where it is impractical to make use of a stronger form of user authentication. A key generated from a pass-phrase of less than about 20 characters is unlikely to deter attacks.

The pass-phrase mapping defined in this subclause uses the PBKDF2 as defined in IETF RFC 2898 section 5.2.

$$PSK = \text{PBKDF2}(passPhrase, ssid, 4096, 256/8)$$

Here, the following assumptions apply:

— passPhrase is a sequence of between 8 and 63 ASCII-encoded characters. The limit of 63 comes from the need to distinguish between a pass-phrase and a PSK displayed as 64 hexadecimal characters.

— Each character in the pass-phrase has an encoding in the range 32 to 126 (decimal).

— *ssid* is the SSID of the ESS or IBSS where this pass-phrase is in use, encoded as an octet string used in the Beacon and Probe Response frames for the ESS or IBSS.

— 4096 is the number of times the pass-phrase is hashed.

— 256 is the number of bits output by the pass-phrase mapping.

J.4.2 Test vectors

```
Test case 1
passPhrase = “password”
ssid = { ‘I’, ‘E’, ‘E’, ‘E’ }
PSK = f42c6fc52df0ebef9ebb4b90b38a5f90 2e83fe1b135a70e23aed762e9710a12e

Test case 2
passPhrase = “ThisIsAPassword”
ssid = { ‘T’, ‘h’, ‘i’, ‘s’, ‘I’, ‘s’, ‘A’, ‘S’, ‘S’, ‘I’, ‘D’ }
PSK = 0dc0d6eb90555ed6419756b9a15ec3e3 209b63df707dd508d14581f8982721af

Test case 3
passPhrase = “aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa”
ssid = {‘Z’,‘Z’,‘Z’,‘Z’, ‘Z’,‘Z’,‘Z’,‘Z’, ‘Z’,‘Z’,‘Z’,‘Z’, ‘Z’,‘Z’,‘Z’,‘Z’,
             ‘Z’,‘Z’,‘Z’,‘Z’, ‘Z’,‘Z’,‘Z’,‘Z’, ‘Z’,‘Z’,‘Z’,‘Z’,‘Z’,‘Z’,‘Z’,‘Z’}
PSK = becb93866bb8c3832cb777c2f559807c 8c59afcb6eae734885001300a981cc62
```

Note that the passPhrase does not have a terminating null.

J.5 Suggestions for random number generation

J.5.1 General

In order to properly implement cryptographic protocols, every platform needs the ability to generate cryptographic-quality random numbers. IETF RFC 4086 explains the notion of cryptographic-quality random numbers and provides advice on ways to harvest suitable randomness. It recommends sampling multiple sources, each of which contains some randomness, and by passing the complete set of samples through a PRF. By following this advice, an implementation can usually collect enough randomness to distill into a seed for a PRNG whose output is unpredictable.

This clause suggests two sample techniques that can be combined with the other recommendations of IETF RFC 4086 to harvest randomness. The first method is a software solution that can be implemented on most

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

hardware; the second is a hardware-assisted solution. These solutions are expository only, to demonstrate that it is feasible to harvest randomness on any IEEE 802.11 platform. They are not mutually exclusive, and they do not preclude the use of other sources of randomness when available, such as a noisy diode in a power circuit; in this case, the more the merrier. As many sources of randomness as possible should be gathered into a buffer, and then hashed, to obtain a seed for the PRNG.

J.5.2 Software sampling

Due to the nature of clock circuits in modern electronics, there is some lack of correlation between two clocks in two different pieces of equipment, even when high-quality crystals are used—crystal clocks are subject to jitter, noise, drift, and frequency mismatch. This randomness might be as little as the placement of the clock waveform edges. Even if one entity were to attempt to synchronize itself to another entity's clock, the correlation cannot be perfect due to noise and uncertainties of the synchronization.

Two clock circuits in the same piece of equipment might synchronize in frequency, but again the correlation is not perfect due to the noise and jitter of the circuits.

The randomness between the two clocks might not be much per sample—a tenth of a bit or less—but enough samples might be collected to gather enough randomness to form a seed.

A device can use software methods to take advantage of this lack of synchronization, to collect randomness from different sources. As an example, an AP might measure the frame arrival times on Ethernet wireless ports. There is always some amount of traffic on modern Ethernets: ARPs, DHCP requests, NetBIOS advertisements, etc. The sample algorithm in this subclause uses this traffic. In the example, an AP obtains randomness from the available traffic. If Ethernet traffic is available, the AP utilizes that for a source of randomness. Otherwise, it waits for the first association and creates traffic from which it can obtain randomness.

The clocks used to time the frames should be the highest resolution available, preferably 1 ms resolution or better. The clock used to time frame arrival should not be related to the clock used for frame serialization.

```
Initialize result to empty array
LoopCounter = 0
Wait until Ethernet traffic or association
Repeat until global key counter "random enough" or 32 times {
    result = PRF-256(0, "Init Counter",
    Local Mac Address || Time || result || LoopCounter)
    LoopCounter++
    Repeat 32 times {
        If Ethernet traffic available then {
            Take least significant octet of the timestamp when Ethernet packet is received
            Concatenate this octet onto result
        } else {
            Start 4-way handshake; after receipt of message 2, deauthenticate
            Take least significant octet of the timestamp of when message 1 is sent
            Take least significant octet of the timestamp of when message 2 is received
            Take the least significant octet of RSSI from message 2
            Take SNonce from message 2
            Concatenate the sent time, received time, RSSI and SNonce octets onto result
        }
```

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

```
        }
    }
    Global key counter = result = PRF-256(0, "Init Counter",
    Local Mac Address || Time || result || LoopCounter)
```

NOTE—The Time is set to 0 if it is not available.

J.5.3 Hardware-assisted solution

The sample implementation in this subclause uses hardware ring oscillators to generate randomness, as depicted in Figure J-1.

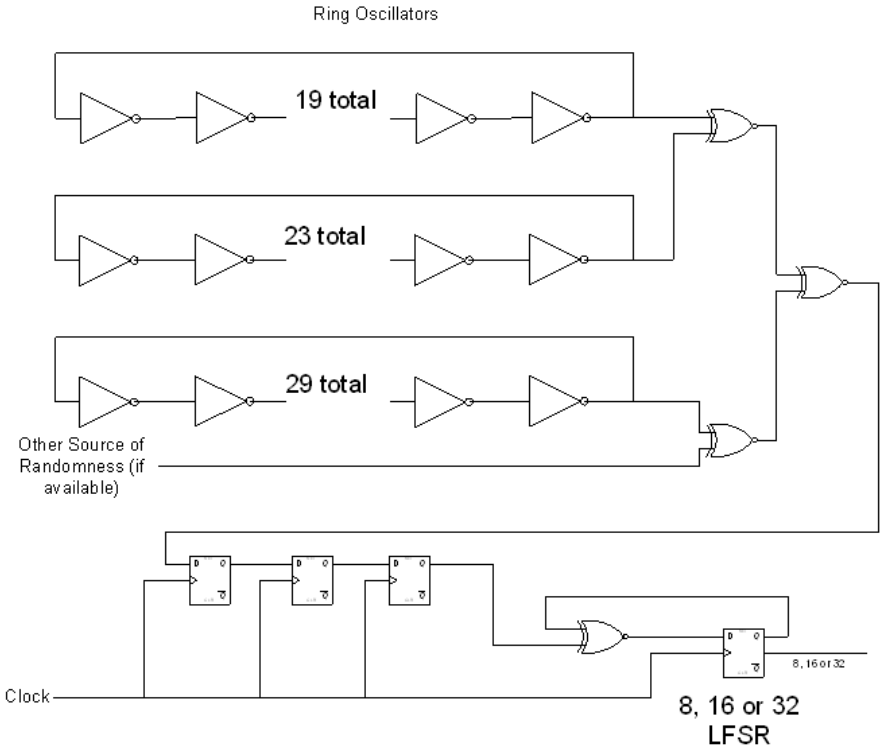

Figure J-1—Randomness generating circuit

The circuit in Figure J-1 generates randomness. The clock input should be about the same frequency as the ring oscillator's natural frequencies. The LFSR should be chosen to be one that is maximal length. Sample LFSRs can be found in Arazi [B6].

The three ring oscillators should be isolated from each other as much as possible to avoid harmonic locking between them. In addition, the three ring oscillators should not be near any other clock circuitry within the system to avoid these ring oscillators' locking to system clocks. The oscillators should be tested to verify that their output is not correlated.

The output of the LFSR is read by software and concatenated until enough randomness is collected. As a rule of thumb, reading from the LFSR 8 to 16 times the number of bits as the desired number of random bits is sufficient.

```
    Initialize result to empty array
```

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

```
Repeat 1024 times {
    Read LFSR
    result = result | LFSR
    Wait a time period
}
Global key counter = PRF-256(0, "Init Counter", result)
```

J.6 Additional test vectors

J.6.1 Notation

In the examples that follow in J.6, frames are represented as a stream of octets, each octet in hexadecimal notation, sometimes with text annotation. The order of transmission for octets is left to right, top to bottom. For example, consider the following representation of a frame in Table J-3.

Table J-3—Notation example

Description #1	00 01 02 03 04 05
Description #2	06 07 08

The frame consists of 9 octets, represented in hexadecimal notation as “00”, “01”, ..., “08”. The octet represented by “00” is transmitted first, and the octet represented by “08” is transmitted last. Similar tables are used for other purposes, such as describing a cryptographic operation.

J.6.2 WEP cryptographic encapsulation

The discussion in this subclause represents an ARC4 encryption using a table that shows the key, plaintext input, and cipher text output. The MPDU data, prior to WEP cryptographic encapsulation, is shown in Table J-4.

Table J-4—Sample plaintext MPDU

MPDU data	aa aa 03 00 00 00 08 00 45 00 00 4e 66 1a 00 00 80 11 be 64 0a 00 01 22 0a ff ff ff 00 89 00 89 00 3a 00 00 80 a6 01 10 00 01 00 00 00 00 00 00 20 45 43 45 4a 45 48 45 43 46 43 45 50 46 45 45 49 45 46 46 43 43 41 43 41 43 41 43 41 43 41 41 41 00 00 20 00 01

ARC4 encryption is performed as shown in Table J-5.

The plaintext consists of the MPDU data, followed by a 4-octet CRC-32 calculated over the MPDU data.

The expanded MPDU, after WEP cryptographic encapsulation, is shown in Table J-6.

The IV consists of the first 3 octets of the ARC4 key, followed by an octet containing the Key ID value in the upper 2 bits. In this example, the Key ID value is 2. The MPDU data consists of the cipher text,

J.6.5 PRF test vectors

A set of test vectors are provided for each size of PRF function used in this subclause. See Table J-9 to Table J-12. The inputs to the PRF function are strings for key, prefix, and data. The length can be any multiple of 8, but the values 192, 256, 384, and 512 are used in this subclause. The test vectors were taken from IETF RFC 2202 [B28] with additional vectors added to test larger key and data sizes.

J.7 Key hierarchy test vectors for pairwise keys

J.7.1 General

The test vectors in this subclause provide an example of PTK derivation for both CCMP-128 and TKIP.

Pairwise keys are derived from the PMK, AA, SPA, SNonce, and ANonce. The values in Table J-13 are used as input to the pairwise key derivation test vectors.

Table J-13—Sample values for pairwise key derivations

PMK	0d c0 d6 eb 90 55 5e d6 41 97 56 b9 a1 5e c3 e3 20 9b 63 df 70 7d d5 08 d1 45 81 f8 98 27 21 af
AA	a0 a1 a1 a3 a4 a5
SPA	b0 b1 b2 b3 b4 b5
SNonce	c0 c1 c2 c3 c4 c5 c6 c7 c8 c9 d0 d1 d2 d3 d4 d5 d6 d7 d8 d9 da db dc dd de df e0 e1 e2 e3 e4 e5
ANonce	e0 e1 e2 e3 e4 e5 e6 e7 e8 e9 f0 f1 f2 f3 f4 f5 f6 f7 f8 f9 fa fb fc fd fe ff 00 01 02 03 04 05

J.7.2 CCMP-128 pairwise key derivation

Using the values from Table J-13 for PMK, AA, SPA, SNonce, and ANonce, the key derivation process for CCMP generates a temporal key as shown in Table J-14.

Table J-14—Sample derived CCMP-128 temporal key (TK)

TK	b2 36 0c 79 e9 71 0f dd 58 be a9 3d ea f0 65 99

J.7.3 TKIP pairwise key derivation

Using the values from Table J-13 for PMK, AA, SPA, SNonce, and ANonce, the key derivation process for TKIP generates the values shown in Table J-15.

Annex K

(informative)

TSPECs and Admission control

K.1 Example use of TSPEC for admission control

Admission control, in general, depends on vendors' implementations of schedulers, available channel capacity, link conditions, retransmission limits, and the scheduling requirements of a given TSPEC. However, for any given channel capacity, link conditions, and retransmission limits, some TSPEC constructions might be categorically rejected because a scheduler cannot create a meaningful schedule for that TSPEC. There needs to be, for example, be a minimum number of specified fields in the TSPEC in order for the admission control mechanism to create a valid TSPEC. Table K-1 below lists the valid TSPEC fields that need to be present for all admission control algorithms to admit a TSPEC. This represents a set of necessary parameters in order for TSPEC to be admitted; it is not sufficient in and of itself to guarantee TSPEC admittance, which depends upon channel conditions and other factors. Such TSPECs are said to be *admissible*. In the table, S means specified, X means unspecified, and Opt means "optional."

Table K-1—Admissible TSPECs

TSPEC parameter	Continuous time QoS traffic (HCCA)	Controlled-access CBR traffic (HCCA)	Bursty traffic (HCCA)	Contention based traffic (EDCA)
Nominal MSDU Size	S	S	X	S
Minimum Service Interval	S	Nominal MSDU size/mean data rate, if specified (VoIP typically uses this)	S Usually set to 0 or a small number (e.g., 1)	X
Maximum Service Interval	S	Same as Minimum SI	S	Opt (Used to indicate aggregation limit)
Inactivity Interval	Always specified			X
Suspension Interval	Opt			
Minimum Data Rate	Specified if peak data rate is specified	Equal to mean data rate	X	Specified if peak data rate is specified
Mean Data Rate	S	S	Opt	S
Burst Size	X	X	S	Opt
Minimum PHY Rate	Always specified			
Peak Data Rate	Opt Should be specified if Minimum Data Rate is specified	Equal to Mean Data Rate	Opt	Opt Should be specified if Minimum Data Rate is specified

Table K-1—Admissible TSPECs *(continued)*

TSPEC parameter	Continuous time QoS traffic (HCCA)	Controlled-access CBR traffic (HCCA)	Bursty traffic (HCCA)	Contention based traffic (EDCA)
Delay Bound	S	S	Opt	Opt
Surplus Bandwidth Allow-ance	Is specified if the delay bound is present			S
Medium Time	(not specified by non-AP STA; only an output from the HC)			

K.2 Recommendation for implementation of contention based admission control

K.2.1 Use of ACM (admission control mandatory) subfield

It is recommended that admission control not be required for the access categories AC_BE and AC_BK. The ACM subfield for these categories should be set to 0. The AC parameters chosen by the AP should account for unadmitted traffic in these ACs.

When dot11SSPNInterfaceActivated is true, it is recommended that any STA authenticated through an SSPN interface use admission control to access categories AC_VO and AC_VI to produce network utilization consistent with the policy imposed by the SSPN for admission. AC parameters chosen by the AP should further account for any unadmitted traffic in AC_VO and AC_VI that might be reserved for users of a particular SSPN.

K.2.2 Deriving medium time

An AP should use the following procedure to derive the value of the Medium Time field in its ADDTS Response frame.

There are two requirements to consider: 1) the traffic requirements of the application, and 2) the expected error performance of the medium.

The application requirements are captured by the following TSPEC fields: Nominal MSDU Size and Mean Data Rate. Note that the Nominal MSDU Size field is the nominal A-MSDU size, where A-MSDU aggregation is employed.

The medium requirements are captured by the following TSPEC fields: Surplus Bandwidth Allowance and Minimum PHY Rate.

The following formula describes how Medium Time, in units of 32 μs periods per second, can be calculated:

$$\text{Medium Time} = \left\lceil \frac{\text{Surplus Bandwidth Allowance} \times \text{Packets Per Second} \times \text{Frame Exchange Time}}{0\text{x}2000 \times 32} \right\rceil$$

where

a) if A-MPDU aggregation is not employed (i.e., TS Info Ack Policy = 00 (Normal Acknowledg-ment)):

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

$$\text{Packets Per Second} = \frac{\text{Mean Data Size}}{8 \times \text{Nominal MSDU Size}}$$

Frame Exchange Time =
duration (Nominal MPDU Size, Minimum PHY Rate)
+ SIFS
+ duration (Ack Size, Ack Rate)

Nominal MPDU Size =
MAC Header Size
+ Nominal MSDU Size
+ Security Encapsulation Size
+ FCS Size

b) if A-MPDU aggregation is employed (i.e., TS Info Ack Policy = 11 (Block Ack)):

$$\text{Packets Per Second} = \left\lceil \frac{\text{Mean Data Rate}}{8 \times \text{Nominal MSDU Size} \times \text{Nominal MSDUAggregation}} \right\rceil$$

Frame Exchange Time =
duration (Nominal A-MPDU Size, Minimum PHY Rate)
+ SIFS
+ duration (BlockAck Size, BlockAck Rate)

Nominal A-MPDU Size =
Nominal MSDU Aggregation
× Nominal A-MPDU Subframe Size
– Padding Size

Nominal A-MPDU Subframe Size =
MPDU Delimiter Size
+ MAC Header Size
+ Nominal MSDU Size
+ Security Encapsulation Size
+ FCS Size
+ Padding Size

Padding Size =
3
– (MAC Header Size
+ Nominal MSDU Size
+ Security Encapsulation Size
+ 3)
mod 4

and where

Sizes are in octets; Rates are in b/s; durations and Times are in μs; Surplus Bandwidth Allowance is the unsigned integer value passed
MAC Header Size = 26
MPDU Delimiter Size = 4
Security Encapsulation Size = 16 (CCMP), 20 (GCMP and TKIP), 8 (WEP) or 0 (open system)
Ack Size = 14

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

BlockAck Size = 32
FCS Size = 4
SIFSIFS = 10 when operating in the 2.4 GHz band, 16 when operating in the 5 GHz band, 3 when operating in the 60 GHz band
Ack/BlockAck Rate is the rate used for the Ack/BlockAck frame, given the Minimum PHY Rate, subject to the corresponding multirate rules
duration () is the PLME-TXTIME primitive defined in clauses 6.5.5 and 6.5.6 that returns the duration of a PPDU based on the PSDU size and the PHY data rate and PHY employed, e.g., clauses 16.3.4, 17.4.3, 18.5.3.2, 19.4.3 and 20.12.3

Notes:

— Division does not truncate.
— Any signal extension is included, even for the acknowledgment frame which ends the frame exchange.
— If protection frames are used, then they are included in the Frame Exchange Time too. Each frame contributes an additional term:

Frame Exchange Time +=
duration (Protection Frame Size, Protection Frame Rate)
+ SIFS

where

RTS Protection Frame Size = 20
CTS Protection Frame Size = 14
Protection Frame Rate is the rate used for the protection frame, given the Minimum PHY Rate, subject to the corresponding multirate and protection rules

An AP assumes that a STA will use CTS-to-self protection if an ERP element directs use of protection.

— The assumption is made that HT Control headers and beamforming frames are not normally used and so their contribution to Medium Time is negligible.
— The Nominal A-MPDU Subframe Size can be increased by the AP where necessary to account for the Minimum MPDU Start Spacing. For example, if the Minimum PHY Rate is 65 Mb/s and the Minimum MPDU Start Spacing is 16 μs then the minimum Nominal A-MPDU Subframe Size is 132 octets (including 2 octets of pad).
— A STA might request TSPEC fields that would result in violation of other applicable constraints such as the receiver's maximum A-MSDU or A-MPDU size, any maximum PPDU duration, or, for uplink or bidirectional TSPECs, any nonzero TXOP limit. An AP receiving such a request is likely to reject it. An AP might also reject requests that cannot be satisfied for reasons that the STA is not always aware of, such as, for uplink or bidirectional TSPECs, the AP's maximum Block Ack Buffer Size.
— Where A-MPDU aggregation is employed, HT-immediate Block Ack is assumed.

K.3 Guidelines and reference design for sample scheduler and admission control unit

K.3.1 Guidelines for deriving service schedule parameters

The HC establishes the SI for each admitted TS for a STA to derive the aggregate minimum SI contained in the STA's service schedule. The SI for each TS is equal to the maximum SI contained in the TSPEC, if it

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

exists; otherwise, it is the nominal MSDU size divided by the mean data rate. The SI contained in the service schedule is equal to the smallest SI for any TSPEC.

The HC can use an aggregate "token bucket specification" to police a STA's admitted flows. The HC derives the aggregate mean data rate and aggregate burst size to establish the aggregate token bucket specification. The aggregate mean data rate is equal to the sum of the mean data rates of all of the STA's admitted TSs. The aggregate burst size is equal to the sum of the burst size of all of the STA's admitted TSs. An aggregate token bucket is initialized with the aggregate burst size. Tokens are added to the token bucket at the aggregate mean data rate. Alternatively the method of summing TSPECs for statistical multiplexing, as described in T.2.3, can be used.

When dot11SSPNInterfaceActivated is true, the HC polices all traffic flows from a non-AP STA authenticated against the maximum authorized data rates stored in the dot11InterworkingTable. Each SSPN-authenticated STA is given a maximum bandwidth allowance by the SSPN for each access category as well as scheduled access. The AP polices the SSPN-authenticated STA traffic flows to the maximum bandwidth allowance provided by the SSPN.

K.3.2 Reference design for sample scheduler and admission control unit

K.3.2.1 General

This subclause provides the guidelines for the design of a simple scheduler and admission control unit (the unit that administers admission policy in the HC's SME) that meet the minimum performance requirements as specified in 10.22.4.3. The scheduler and admission control unit use the minimum set of mandatory TSPEC fields as specified in 10.22.4.3.

K.3.2.2 Sample scheduler

This subclause includes the reference design for a sample scheduler. This scheduler uses the mandatory set of TSPEC fields to generate a schedule: Mean Data Rate, Nominal MSDU Size, and Maximum Service Interval or Delay Bound. If both Maximum Service Interval and Delay Bound parameters are specified in the TSPEC, the scheduler uses the Maximum Service Interval parameter for the calculation of the schedule.

The schedule generated by the scheduler satisfies the requirements specified in 10.22.4.3. The schedule for an admitted stream is calculated in two steps. The first step is the calculation of the scheduled SI. In the second step, the TXOP duration for a given SI is calculated for the stream.

The calculation of the scheduled service interval is done as follows: First, the scheduler calculates the minimum of all maximum SIs for all admitted streams. Let this minimum be *m*. Second, the scheduler chooses a number lower than *m* that is a submultiple of the beacon interval. This value is the scheduled SI for all STAs with admitted streams. See Figure K-1.

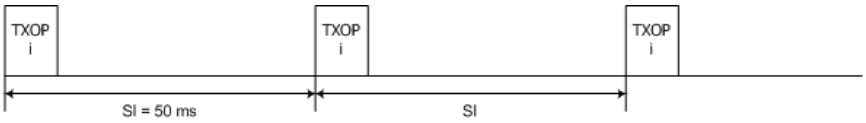

Figure K-1—Schedule for stream from STA *i*

For the calculation of the TXOP duration for an admitted stream, the scheduler uses the following parameters: Mean Data Rate and Nominal MSDU Size; and from the negotiated TSPEC, the Scheduled Service Interval calculated above, Physical Transmission Rate, Maximum Allowable Size of MSDU, and

Copyright © 2016 IEEE. All rights reserved.

Overhead. The Physical Transmission Rate is the minimum PHY rate negotiated in the TSPEC. If the minimum PHY rate is not committed in the ADDTS Response frame, the scheduler can use the observed PHY rate as the Physical Transmission Rate. The Overhead includes IFSs, Ack frames and CF-Poll frames. For simplicity, details for the Overhead calculation are omitted in this description. The TXOP duration is calculated as follows: First, the scheduler calculates the number of MSDUs that can arrive at the Mean Data Rate during the SI:

$$N_i = \left\lceil \frac{SI \times \rho_i}{L_i} \right\rceil$$

where

SI is the Scheduled Service Interval
ρ is the Mean Data Rate
L is the Nominal MSDU Size

Then the scheduler calculates the TXOP duration as the maximum of

— Time to transmit N_i frames at R_i and
— Time to transmit one maximum size MSDU at R_i (plus overhead):

$$TXOP_i = max(\frac{N_i \times L_i}{R_i} + O, \frac{M}{R_i} + O)$$

where

R is the Physical Transmission Rate
M is the maximum possible size of MSDU
O is the Overhead in time units

An example is shown in Figure K-1. Stream from STA *i* is admitted. The beacon interval is 100 ms and the maximum SI for the stream is 60 ms. The scheduler calculates a scheduled SI (SI) equal to 50 ms using the steps explained above is this annex.

The same process is repeated continuously while the maximum SI for the admitted stream is larger than the current SI. An example is shown in Figure K-2.

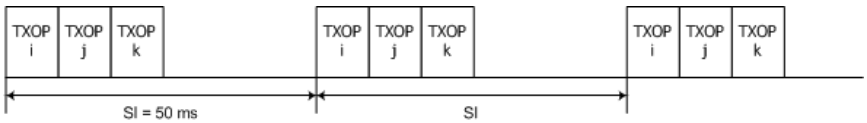

Figure K-2—Schedule for streams from STAs *i* to *k*

If a new stream is admitted with a maximum SI smaller than the current SI, the scheduler needs to change the current SI to a smaller number than the maximum SI of the newly admitted stream. Therefore, the TXOP duration for the current admitted streams needs also to be recalculated with the new SI.

If a stream is dropped, the scheduler might use the time available to resume contention. The scheduler might also choose to move the TXOPs for the STAs following the STA dropped to use the unused time. An example is shown in Figure K-3, when the stream for STA *j* is removed. However, this option might require the announcement of a new schedule to all STAs.

Figure K-3—Reallocation of TXOPs when a stream is dropped

Different modifications can be implemented to improve the performance of the minimum scheduler. For example, a scheduler might generate different scheduled SIs (SI) for different STAs, and/or a scheduler might consider accommodating retransmissions while allocating TXOP durations.

K.3.2.3 Admission control unit

This subclause describes a reference design for an admission control unit (ACU) that administers admission of TS. The ACU uses the same set of parameters that the scheduler uses in K.3.2.2.

When a new stream requests admission, the admission control process is done in three steps. First, the ACU calculates the number of MSDUs that arrive at the mean data rate during the scheduled SI. The scheduled SI (*SI*) is the one that the scheduler calculates for the stream as specified in K.3.2.2. For the calculation of the number of MSDUs, the ACU uses the equation for N_i shown in K.3.2.2. Second, the ACU calculates the TXOP duration that needs to be allocated for the stream. The ACU uses the equation for $TXOP_i$ shown in K.3.2.2. Finally, the ACU determines that the stream can be admitted when the following inequality is satisfied:

$$\frac{TXOP_{k+1}}{SI} + \sum_{i=1}^{k} \frac{TXOP_i}{SI} \leq \frac{T - T_{CP}}{T}$$

where

k is the number of existing streams
$k + 1$ is used as index for the newly arriving stream
T indicates the beacon interval
T_{CP} is the time used for EDCA traffic

Subclause 10.22.3.3 requires that the ACU complies with the dot11CAPlimit, i.e., the scheduler does not allocate TXOPs that exceed dot11CAPlimit. The ACU might also consider additional time to allow for retransmissions.

The ACU allows admitted streams to have an allocated access to the channel. Any modification can be implemented for the design of the ACU. For example, UP-based ACU is possible by examining the UP field in TSPEC to decide whether to admit, retain, or drop a stream. If the UP is not specified, a default value of 0 is used. If a higher UP stream needs to be serviced, an ACU might drop lower UP streams.

K.4 TSPEC construction

TSPECs are constructed at the SME from application requirements supplied via the SME and with information specific to the MAC layer. However, in this subclause a description is given of how and where certain parameters can be chosen. The following parameters typically arise from the application: Nominal MSDU Size, Maximum MSDU Size, Minimum Service Interval, Maximum Service Interval, Inactivity Interval, Minimum Data Rate, Mean Data Rate, Burst Size, Peak Data Rate, and Delay Bound. The

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

following parameters are generated locally within the MAC: Minimum PHY Rate and Surplus Bandwidth Allowance, although the Maximum Service Interval and Minimum Service Intervals can be generated within the MLME as well. This subclause describes how the parameters that are typically generated within the MAC can be derived.

Note that a TSPEC can also be generated autonomously by the MAC without any initiation by the SME. However, if a TSPEC is generated subsequently by the SME, the TSPEC generated autonomously by the MAC might be overridden (see 11.4.4.5).

Typically, TSPEC fields not determined by the application are built upon the assumption that the following exist:

— A probability *p* of not transmitting the frame (because it would have exceeded its delay bound)
— An MSDU length (which can be considered fixed for constant-bit-rate applications)
— Application throughput and delay requirements
— A channel model of error, in particular a channel error probability for the (fixed) frame length
— Possibly country-specific limits on TXOP limits

K.4.1 Surplus Bandwidth Allocation

Typically, it can be assumed that the scheduler would attempt to schedule TXOPs distributed throughout a small multiple of beacon intervals (if not a single beacon interval). In addition, TXOP limits would typically be chosen to be as short as possible (within the constraints of the minimum PHY rate, acknowledgment policy, and so forth), consistent with the goal of maximizing throughput. In other words, because of overhead, not to mention the requirements for transmitting a single Poll frame, MPDU, and possibly Ack frame, the TXOPs need to be at least of a certain duration.

The channel model implies an error ratio and an assumption about dependency (joint probability distribution of channel errors sequentially, i.e., burst error probabilities).

For example, if the channel causes errors independently from frame to frame and the error probability is the same for all frames of the same length at all times, this channel would be said to be an independent, identically distributed error channel. With p as the probability of dropping the frame, and p_e as the probability of the frame not being transmitted successfully (i.e., either the Data frame or the Ack frame associated with it is in error), let N_p be the number of retries required to maintain the probability of dropping the frame to be p.

The probability of any given packet being dropped in such a channel after N_p retries is given by

$$p_{\text{drop}} = (p_e)^{N_p + 1}$$

For example, in such a channel, if $p_e = 0.1$ and $p_{\text{drop}} = 10^{-8}$, then up to seven retries within the delay bound are required, and the scheduler should consider these retransmissions in the cumulative TXOP allocations.

The Surplus Bandwidth Allowance (SBA) parameter causes the requesting STA to be allocated a minimum amount of excess time by the scheduler so that the application dropped packet rates are bounded.

The probability of not successfully transmitting *k* packets is given by the cumulative distribution function of the Binomial Distribution.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The binomial probability mass function is

$$b(k, n, p) = \frac{n!}{k!(n-k)!} p^k (1-p)^{n-k}$$

where

n is the number of trials
p is the probability of success for each trial.

The binomial cumulative distribution function is

$$B(k, n, p) = \sum_{y=0}^{n} b(y, n, p)$$

Assuming a certain packet error ratio (PER), P_e, the number of extra packets, *N,* that are required in order to have a probability, P_{ns}, of not successfully transmitting *S* packets is given:

$$B(S, S+N, 1-P_e) = \sum_{y=0}^{n} b(y, S+N, 1-P_e)$$

Then

$SBA = (S+N)/S$

Now, if just one packet is lost, then the lost packet ratio, L_{PR}, is $L_{PR} = 1/(S+N)$

The condition where $P_{ns} < L_{PR}$ represents a practical point for determining the value of *N*.

Medium Time used for EDCA Admission Control is based upon one second periods and HCCA Medium time, used to aggregate TSPECs (see T.2.3) also uses the one second period. Hence, for each application, *S* is the number of packets that are desired to be sent in each one second period.

For example, consider a voice application:

PER, $P_e = 0.1$ or probability of success is $1 - P_e = 0.9$

Number of packets per second, $S = 50$

Probability of not having 50 successful packets, $P_{ns} = 0.87\%$ for $N = 13$

Lost packet ratio for 1 lost packet, $L_{PR} = 1.59\%$

$SBA = 1.26$

Take the example of a video stream at 380 packets per second (about 4 Mb/s):

Number of packets per second, $S = 380$

Probability of not having 380 successful packets, $P_{ns} = 0.2\%$ for $N = 64$

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Lost packet ratio for 1 lost packet, $L_{PR} = 0.23\%$

$SBA = 1.168$

It can be seen that the value for SBA varies with *S*, the number of required packets per second.

A reasonable estimate for *SBA* is given by

$SBA = -0.033 \ln(S) + 1.37$

Table K-2 is a table of *SBA* for various values of *S*, and the *SBA* estimate derived by using the formula above.

Table K-2—SBA *vs* Packets/s

***S* Packets/s**	***SBA***	**Estimated *SBA***
50	1.26	1.241
95	1.221	1.220
190	1.189	1.197
285	1.179	1.183
380	1.168	1.174
475	1.164	1.167
570	1.160	1.161
665	1.156	1.156
760	1.154	1.151
855	1.151	1.147
950	1.151	1.144
1900	1.139	1.121

The values for *SBA* as shown in Table K-2 are based upon a one second time period and hence are what should be used in the TSEC for EDCA Admission Control. The value used in an HCCA TSPEC might be different, as will now be explained.

In an HCCA TSPEC the *SBA* relates the overhead required in each scheduled period. A voice stream, for example, only sends one packet every 20 ms. Obviously an *SBA* of 1.26 is meaningless as it does not allow even one retry. To allow just one retry, the minimum *SBA* is 2.0, Similarly for a video example of say 6 packets per schedule period, to allow at least one retry would require an *SBA* of (6+1)/6 = 1.167

Hence, for an HCCA TSPEC:

Calculate packets per SI:

$$PPSI = \frac{R_m}{S_n \times 8 \times SI}$$

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

where

R_m is the mean data rate (b/s)
S_n is the nominal MDSU size (octets)
SI is the service interval (seconds)

Then Minimum HCCA $SBA = \text{MAX}\left(SBA, \frac{PPSI + 1}{PPSI}\right)$.

Table K-3 shows the recommended SBA values for HCCA TSPECs for various video streams.

Table K-3—Table HCCA SBA for video streams

Video, Mb/s	Pkts per SI	Min HCCA SBA	SBA, (1 sec)	HCCA SBA
1	1	2.000	1.221	2.000
2	3	1.333	1.189	1.333
3	4	1.250	1.179	1.250
4	6	1.167	1.168	1.168
5	7	1.143	1.164	1.164
6	9	1.111	1.160	1.160
7	10	1.100	1.156	1.156
8	12	1.083	1.154	1.154
9	13	1.077	1.151	1.151
10	15	1.067	1.151	1.151
20	30	1.033	1.139	1.139

In summary, the suggested value for SBA is derived as follows:

— Calculate Packets per sec, *PPS*

$$PPS = \frac{R_m}{S_n \times 8}$$

where

R_m is the mean data rate (b/s)
S_n is the nominal MDSU size (octets)
NOTE—Nominal MSDU = MDSU or A-MSDU

— Calculate *SBA*

$SBA = -0.033 \text{ Ln } (PPS) + 1.37$

EDCA Admission Control TSPEC and Medium Time calculation uses SBA.

For HCCA TSPEC:

— Calculate packets per SI, PPSI

$$PPSI = \frac{R_m}{S_n \times 8 \times SI}$$

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

where

R_m is the mean data rate (b/s)
S_n is the nominal MDSU size (octets)
SI is the service interval (seconds)

— HCCA $SBA = \mathrm{MAX}\left(SBA, \frac{PPSI + 1}{PPSI}\right)$

HCCA Medium Time uses SBA in place of HCCA SBA, if different.

K.4.2 Minimum and Maximum Service Interval

K.4.2.1 Scheduled traffic

The HC uses the Maximum Service Interval for the calculation of the schedule.

The value of the Minimum Service Interval is an indication that the traffic is CBR or VBR.

For CBR traffic the minimum and maximum Service Intervals should be set to the same value. For example, most voice traffic requires a minimum and maximum service interval value of 20 ms.

In the case of VBR traffic, such as video, Minimum Service Interval should be set to 0 and the Maximum Service Interval set to the service interval required by the application, e.g., to correspond to the codec that is to be used For example, Maximum Service Interval is set to 16 ms for many real time video applications.

K.4.2.2 Use of Maximum Service Interval with Aggregation of Packets

Aggregation of MPDUs or MSDUs introduces delay to the packets, but the use of aggregated packets is to be encouraged because of the increased efficiency. In the case of scheduled traffic, the aggregation of packets is such that the number of MSDUs that are aggregated into a single packet (A-MSDU or A-MPDU) does not exceed the scheduling service interval. Consider the following example:

— Video packet = 1316B (7*188 MPEG2-TS)
— Nominal MSDU Size = 1364 (octets)
— Mean Data Rate = 4 Mb/s
— Maximum Service Interval = 16 ms

$$\text{Nominal MSDUs per SI} = \left\lfloor \frac{4 \times 10^6}{1364 \times 8} \right\rfloor = 3$$

Hence, to comply with the 16 ms SI, the limit for aggregation is 3, (an A-MSDU of 3 MSDUs, or an A-MPDU consisting of 3 MSDUs).

In the case of EDCA Admission Control, where regular scheduling is not used, the value of the Maximum Service Interval is used to indicate the limit of aggregation of nominal MSDUs and the acceptable latency between packets. Using aggregation reduces the Medium Time and Used Time required.

For example, assuming a minimum PHY Rate of 39 Mb/s for the example used above, the accurate Medium Time returned by the AP would be 13 783 μs. If the AP assumed that A-MPDUs were to be used, then the accurate Medium Time would be 11 681 μs, a 15% reduction. Hence, an AP could ‘force’ a STA to use aggregation, or alternatively could assume aggregation when it is considering the total traffic as part of its admittance policy.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The Nominal MSDU Size is the size of the MSDU or A-MSDU belonging to the TS.

Consider another example:

— Video packet = 1316B (7*188 MPEG2-TS)
— Nominal MSDU Size = 4137 (A-MSDU of 3 MSDUs)
— Mean Data Rate = 10 Mb/s
— Maximum Service Interval = 16 ms

$$\text{Nominal MSDUs per SI} = \left\lfloor \frac{10 \times 10^6}{4137 \times 8} \right\rfloor = 4$$

Hence, further aggregation is possible and an A-MPDU consisting of 4 A-MSDUs could be sent and still comply with the latency or SI requirement.

Note that the TSPEC is invalid if the Nominal MSDUs per Maximum Service Interval is less than 1.

K.4.3 Minimum, Mean, and Peak Data Rate

In an HCCA TSPEC, for CBR traffic the Minimum, Mean and Maximum Data Rate fields should contain the same value but it is allowable to just specify the Mean Data Rate noting that the Minimum and Maximum Service Intervals are the same.

In an EDCA TSPEC, for CBR traffic the Minimum, Mean and Maximum Data Rate fields should contain the same value but it is allowable to just specify the Mean Data Rate.

For VBR traffic it is desirable to populate the Minimum, Mean and Peak data rate fields.

If a TSPEC has the Minimum Data Rate (R_{min}) and Peak Data Rate (R_{max}) fields populated, then the standard deviation of that stream, σ, can be estimated as:

$$\sigma = 0.25(R_{max} - R_{min})$$

If a TSPEC has the Mean Data Rate (R_{mean}) and Peak Data Rate fields populated, then the standard deviation of that stream, σ, can be estimated as:

$$\sigma = 0.5(R_{max} - R_{mean}))$$

If there are *n* streams, the values of the mean μ and standard deviation σ, of the total stream traffic should be calculated using:

$$\mu = \sum \mu_n$$

$$\sigma_{tot} = \sqrt{\sum \sigma_n^{\,2}}$$

This is of particular use to EDCA admission control policy. When summing streams for EDCA Admission Control, the EDCA Overhead Factor needs to be taken into account; see T.2.7.

Annex L

(informative)

Examples and sample code for encoding a TIM Partial Virtual Bitmap

L.1 Introduction

The purpose of this annex is to show an examples of encoding a Partial Virtual Bitmap field of the TIM element, as described in 9.4.2.6. Sample C code is provided in L.3.

L.2 Examples

The following examples help clarify the use of TIM values, both with and without the multiple BSSID capability.

The first example is one in which there are no group addressed MSDUs buffered in the AP but there is traffic for two STAs queued in the AP. STAs with AID 2 and AID 7 have data buffered in the AP. Figure L-1 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example.

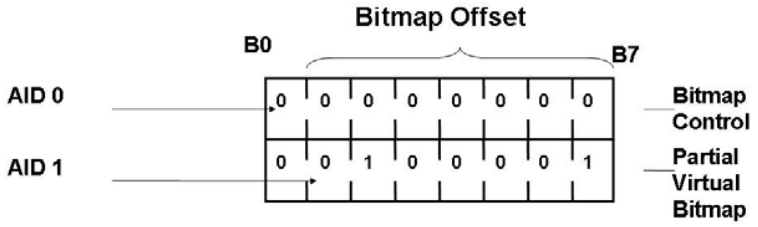

Figure L-1—Partial Virtual Bitmap example #1

The next example is one in which group addressed MSDUs are buffered in the AP as well as traffic for STAs. The DTIM Count field in the TIM element equals 0. STAs with AID 2, AID 7, AID 22 and AID 24 have data buffered in the AP. Figure L-2 shows the values of the Bitmap Control and Partial Virtual Bitmap fields.

Another example is one in which group addressed MSDUs are buffered in the AP as well as traffic for STAs. The DTIM Count field in the TIM element equals 0. Only the node with AID 24 has data buffered in the AP. In this example, the Bitmap Offset is used to start the Partial Virtual Bitmap at the third octet. Figure L-3 shows the values of the Bitmap Control and Partial Virtual Bitmap fields.

The three examples listed above describe the construction of the Partial Virtual Bitmap when multiple BSSID operation is not supported. The following three examples demonstrate how to construct the Partial Virtual Bitmap, when multiple BSSID operation is supported.

Figure L-2—Partial Virtual Bitmap example #2

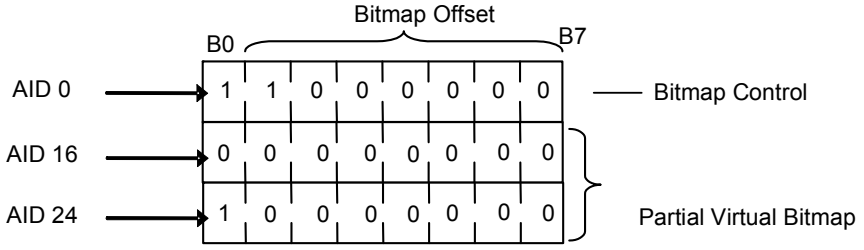

Figure L-3—Partial Virtual Bitmap example #3

The first example showing multiple BSSID operation is one in which there are eight BSSIDs and the lowest possible AID that can be assigned to any STA in this example is 8. There are no group addressed frames buffered in the AP for any of the eight BSSIDs. However, STAs with AID 9 and AID 11 have an individually addressed frames buffered in the AP. Figure L-4 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when either Method A or Method B is used. It is noted that Method B reduces to Method A in this example.

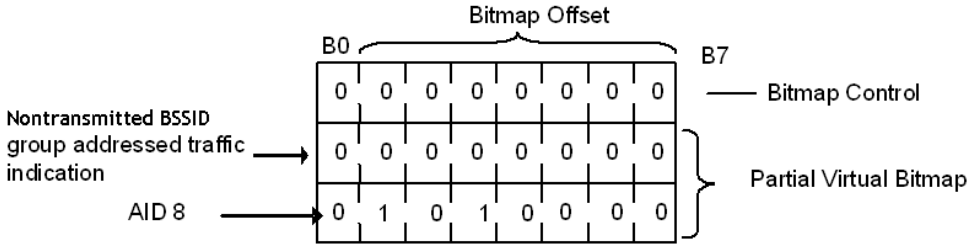

Figure L-4—Partial Virtual Bitmap example #4, Method A and Method B

In the next example, there are eight BSSIDs and the lowest possible AID that can be assigned to any STA in this example is 8. There are group addressed frames buffered at the AP for the transmitted BSSID, and the DTIM Count field in the TIM element of the transmitted BSSID is 0. The nontransmitted BSSID with BSSID Index 3 also has the DTIM Count field set to 0 and has buffered group addressed frames. All other nontransmitted BSSIDs have no buffered group addressed frames. In addition, STAs with AID 12, AID 17,

Copyright © 2016 IEEE. All rights reserved.

AID 22 and AID 24 have data buffered at the AP. Figure L-5 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when either Method A or Method B is used. It is noted that Method B reduces to Method A in this example.

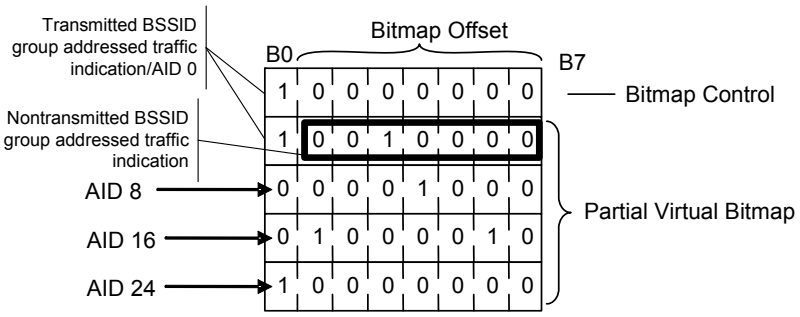

Figure L-5—Partial Virtual Bitmap example #5, Method A or Method B

In the third example, there are sixteen BSSIDs and the lowest possible AID that can be assigned to any STA is 16 (n=4, k=15, see 9.4.2.6. There are no group addressed frames buffered at the AP for the transmitted BSSID, and the DTIM Count field in the TIM element of the transmitted BSSID is 0. The nontransmitted BSSID Index 3 also has the DTIM Count field set to 0 and has group addressed frames buffered at the AP. All other nontransmitted BSSIDs have no buffered group addressed frames. In addition, the STA with AID 39 has individually addressed frames buffered at the AP. Figure L-6 and Figure L-7 show the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when Method A ($N2$=4, see 9.4.2.6) and Method B ($N0$=2, $N1$=4, $N2$=4, see 9.4.2.6) are used, respectively.

Annex M

(informative)

Integration function

M.1 Introduction

The purpose of this annex is to guide the implementor of an ESS's infrastructure that includes a portal that integrates the ESS's infrastructure with a wired LAN.

M.2 Ethernet V2.0/IEEE 802.3 LAN integration function

It is recommended that any ESS's infrastructure that logically incorporates a portal that integrates the ESS's infrastructure with an Ethernet V2.0/IEEE 802.3 LAN use the procedures defined in ISO/IEC Technical Report 11802-5:1997 (previously known as IEEE Std 802.1H-1997), with the two-entry selective translation table (STT) shown in Table M-1, to perform the integration service. Note that the majority of such IEEE 802.11 implementations currently use this STT, rather than the single-entry STT recommended in Annex A of IEEE Std 802.1H-1997 [B24].

Table M-1—IEEE 802.11 integration service STT

Protocol use	Ethernet type value	Encoding in Type field	
		First octet	Second octet
AppleTalk Address Resolution Protocol	0x80F3	80	F3
Novell NetWare Internetwork Packet exchange (IPX)	0x8137	81	37

M.3 Example

The tables below illustrate the translations performed by the integration service using the encapsulation/ decapsulation procedures defined in ISO/IEC Technical Report 11802-5:1997 with the IEEE 802.11 integration service STT. These tables show how the octets in an IEEE 802.11 MSDU correspond to the octets in the Ethernet/IEEE 802.3 MSDU that represents the same LLC SDU on the integrated Ethernet/ IEEE 802.3 LAN. Table M-2 shows the encapsulation example, and Table M-3 shows the decapsulation example.

In the tables below the rows that have a 81-00 Type/Length field value represent bridging between an Ethernet/IEEE 802.3 LAN and an IEEE 802.11 LAN. Both LANs are carrying VLAN-tagged MSDUs (User Priority=4, DEI=0, VLAN ID=1893).

Table M-2—Ethernet/IEEE 802.3 to IEEE 802.11 translation

Protocol	Type / Length	LLC header	IEEE 802.11 LLC header
IP	08-00	—	AA-AA-03-00-00-00-08-00
IP 802.3[a]	length	AA-AA-03-00-00-00-08-00	AA-AA-03-00-00-00-08-00
IP ARP	08-06	—	AA-AA-03-00-00-00-08-06
AppleTalk (1)	80-9B	—	AA-AA-03-00-00-00-80-9B
AppleTalk (2)	length	AA-AA-03-08-00-07-80-9B	AA-AA-03-08-00-07-80-9B
AppleTalk AARP (1)	80-F3	—	AA-AA-03-00-00-F8-80-F3
AppleTalk AARP (2)	length	AA-AA-03-00-00-00-80-F3	AA-AA-03-00-00-00-80-F3
IPX Ethernet II	81-37	—	AA-AA-03-00-00-F8-81-37
IPX SNAP	length	AA-AA-03-00-00-00-81-37	AA-AA-03-00-00-00-81-37
IPX 802.2	length	E0-E0-03	E0-E0-03
IPX 802.3[b]	length	FF-FF	FF-FF
VLAN-tagged IP	81-00	87-65-08-00	AA-AA-03-00-00-00-81-00-87-65-AA-AA-03-00-00-00-08-00[c]

[a]This format of IP packet over IEEE Std 802.3 is deprecated, and the change to the canonical Ethernet IP format is not considered harmful.

[b]The use of this nonstandard format happens to work with these rules, even though the FF-FF is not actually a valid LLC header value. (The broadcast LSAP is not valid as a source SAP in LLC. See IEEE Std 802.2.)

[c]The sequence of octets AA-AA-03-00-00-00-81-00-87-65 represents the SNAP-encoded VLAN header. The sequence of octets AA-AA-03-00-00-00-08-00 represents the IEEE 802.1H™-translated Type/Length field, using the same translation as the untagged IP MSDU on the first line of Table M-2.

Table M-3—IEEE 802.11 to Ethernet/IEEE 802.3 translation

Protocol	IEEE 802.11 LLC header	Type / Length	LLC header
IP	AA-AA-03-00-00-00-08-00	08-00	—
IP 802.3[a]	AA-AA-03-00-00-00-08-00	length	—
IP ARP	AA-AA-03-00-00-00-08-06	08-06	—
AppleTalk (1)	AA-AA-03-00-00-00-80-9B	80-9B	—
AppleTalk (2)	AA-AA-03-08-00-07-80-9B	length	AA-AA-03-08-00-07-80-9B
AppleTalk AARP (1)	AA-AA-03-00-00-F8-80-F3	80-F3	—
AppleTalk AARP (2)	AA-AA-03-00-00-00-80-F3	length	AA-AA-03-00-00-00-80-F3
IPX Ethernet II	AA-AA-03-00-00-F8-81-37	81-37	—

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Table M-3—IEEE 802.11 to Ethernet/IEEE 802.3 translation *(continued)*

Protocol	IEEE 802.11 LLC header	Type / Length	LLC header
IPX SNAP	AA-AA-03-00-00-00-81-37	length	AA-AA-03-00-00-00-81-37
IPX 802.2	E0-E0-03	length	E0-E0-03
IPX 802.3	FF-FF	length	FF-FF
VLAN-tagged IP ARP	AA-AA-03-00-00-00-81-00-87-65-AA-AA-03-00-00-00-08-06	81-00	87-65-08-06

[a]This format of IP packet does not survive the trip across the non-IEEE-802.3 LAN intact.

M.4 Integration service versus bridging

There are a number of differences between the IEEE 802.11 integration service and the service provided by an IEEE 802.1D bridge [B23]. In the IEEE 802.11 architecture a portal provides the minimum connectivity between an IEEE 802.11 WLAN and a non-IEEE-802.11 LAN. Requiring an IEEE 802.1D bridge in order to be compliant with IEEE Std 802.11 would unnecessarily render some implementations noncompliant.

The most important distinction is that a portal has only one "port" (in the sense of IEEE Std 802.1D, for example) through which it accesses the DS. This renders it unnecessary to update bridging tables inside a portal each time a STA changes its association status. In other words, the details of distributing MSDUs inside the IEEE 802.11 WLAN need not be exposed to the portal.

Another difference is that the DS is not an IEEE 802 LAN (although it carries IEEE 802 LLC SDUs). Requiring that the DS implements all behaviors of an IEEE 802 LAN places an undue burden on the architecture.

Finally, it is an explicit intent of this standard to permit transparent integration of an IEEE 802.11 WLAN into another non-IEEE-802.11 LAN, including passing bridge PDUs through a portal. While an implementer might wish to attach an IEEE 802.1D bridge to the portal (note that the non-IEEE-802.11 LAN interface on the bridge need not be any particular type of LAN), it is not an architectural requirement of this standard to do so.

Annex N

(informative)

AP functional description

N.1 Introduction

This informative annex seeks to clarify the AP functional description. At times there is some confusion surrounding the term *AP* and the relation of that term to the AP functions and common implementations of AP devices. The core IEEE 802.11 conceptual definitions that surround the AP (refer to Clause 4) are abstract (and can sometimes cause confusion), but Clause 4 definitions are crafted to be flexible and hence serve to allow the adaptation and extension of this standard in a wide variety of ways.

In this annex a wireless local area network (WLAN) system is a system that includes the distribution system (DS), access point (AP), and portal entities. It is also the logical location of distribution and integration service functions of an extended service set (ESS). A WLAN system contains an optional portal and one or more APs in addition to the DS.

N.2 Terminology

An enhanced description of these access entities begins with clarification of several terms.

This standard defines an entity called a *STA*. STAs can operate in different modes. The possible operational modes of a STA are:

a) Infrastructure mobile STAs
b) Independent mobile STAs
c) Access control mode STAs
d) Mesh STAs

The mobile STAs are the STA entities that are ordinarily moving around, but might also be in a fixed location. The mobile adjective prefix often helps in visualizing the type of STA under discussion.

Infrastructure mobile STAs operate in infrastructure BSS mode, i.e., they are the users of an AP. Devices that incorporate an infrastructure mobile STA are referred to in this annex by the term mobile unit. A mobile unit device might consist of just a mobile STA implementation, but also likely includes an SME and a client. The exact configuration of the mobile unit it is not relevant to the descriptions in this annex.

Independent mobile STAs operate in IBSS mode. Independent mobile STAs form autonomous networks that do not require an AP.

A STA can also form an integral part of an AP. To do so, the STA operates in access control mode. This type of STA is called an *access control mode STA* (ACM_STA).

The primary function of an AP is to provide the mobile units with access to the DS, as shown in the Unified Modeling Language (UML) use case diagram in Figure N-1. Complete UML specifications can be found in Rumbaugh [B57]. The UML diagram shows a system boundary box containing a single use case (ellipse). Entities that are outside the system boundary box are shown as stick people. These external entities represent the actors (formal term), or users, of the system. Since the actors are outside the system boundary, their

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

internal behavior is not described (i.e., it is out of scope for the current view). Instead, references to the external entities are limited to descriptions of their interactions with, and expectations of, the system, which is accomplished by describing the use cases and scenarios (i.e., functions) of the system and later (in Figure N-4) a decomposition of the entities (objects and behaviors) within the system that provide that functionality. The use case diagram employs connecting lines to indicate relationships between the various artifacts present in the diagram. Relationship lines lacking arrows on both ends indicate that there is a bidirectional relationship between the artifacts.

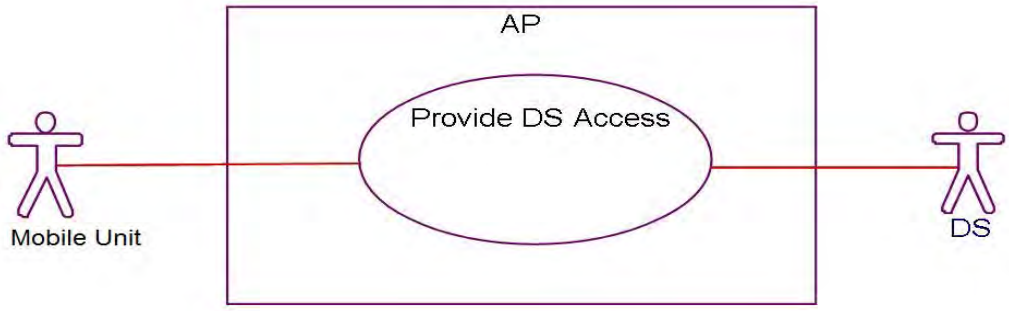

Figure N-1—Very high level UML use case diagram for the AP

The DS enables communication between mobile units and the construction of collections of APs. To enable communication between mobile units and a non-IEEE-802.11 LAN entity requires the presence of a (logical) portal from the DS to the non-IEEE-802.11 LAN.

Often the functions of an AP (which includes an ACM_STA), a DS, and a portal, are combined into a single device, referred to in this annex as an *access unit* (AU). While reference to that basic implementation is commonplace, it is helpful to discuss the abstract case: a WLAN system. The WLAN system includes the DS, an optional portal, APs, and the AP's STAs. It is also the logical location of distribution and integration service functions of an ESS. An infrastructure WLAN system contains one or more APs and zero or one portal in addition to the DS.

The primary function of a WLAN system is to provide the mobile units with access to the non-IEEE-802.11 LAN, as shown in Figure N-2. A secondary function is to provide the mobile units with access to each other.

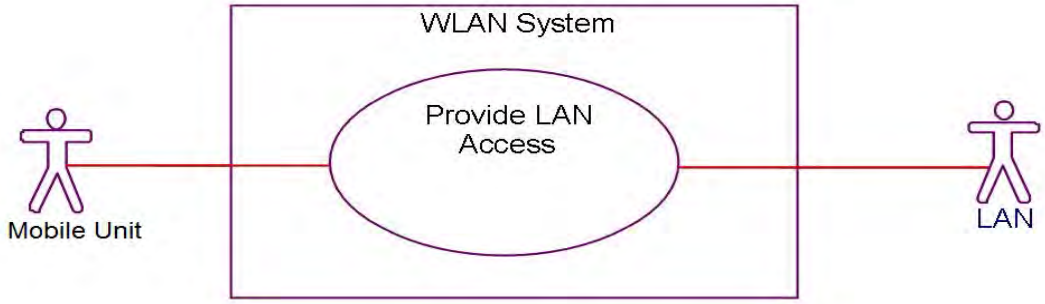

Figure N-2—Very high level UML use case diagram for the WLAN system

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The primary functions of the WLAN system can be further characterized as follows:

a) Provide non-IEEE-802.11 LAN access.
   1) Includes mobile unit validation.
   2) Includes moving data between the mobile units and the non-IEEE-802.11 LAN.
      i) Uses a special data movement function called *filtering data*.

b) Configure the system.

Those high-level use cases of the WLAN system are shown in the UML use case diagram in Figure N-3. The UML diagram shows multiple use cases with two types of relationships between those use cases: include and generalization. The include relationship "includes" functionality in one use case that is described by another use case. The "provide LAN Access" use case includes the functionality of the "Validate mobile unit" use case. The generalization relationship indicates that one use case is a more general form of another use case. The relationship line with a hollow triangle at the end indicates that the "Move Data" use case is a more generalized form of the "Filter Data" use case. Or, equivalently, "Filter Data" is a more specialized form of "Move Data." The constraint artifact (in the lower left corner of the diagram) requires the WLAN system and the mobile units to be set to the same SSID.

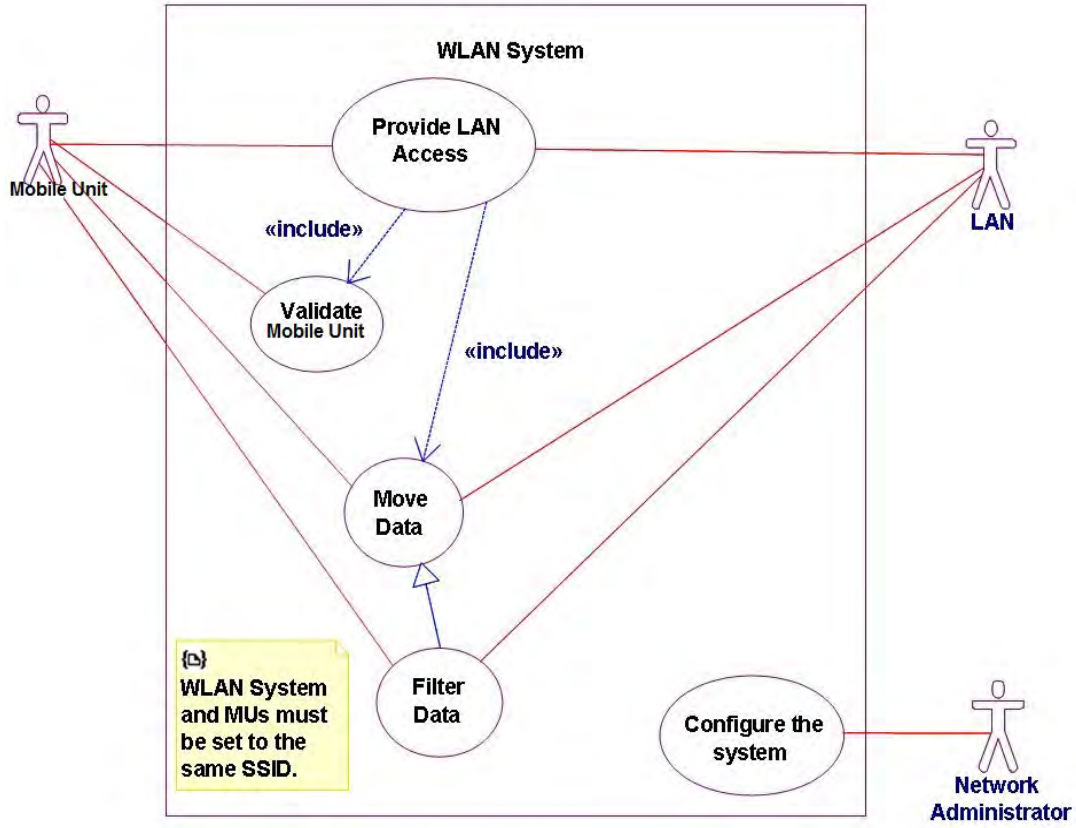

Figure N-3—High-level UML use case diagram for the WLAN system

The primary functions of the WLAN system, depicted in the UML object model diagram in Figure N-4, are provided by the AP, and DS entities, the latter via the DSSs. The portal is merely a conceptual link from the DS to the non-IEEE-802.11 LAN. The UML object model diagram shows a package containing a set of object classes. References to the actors (external entities) are limited to descriptions of their interactions

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

with, and expectations of, the object classes, which is accomplished by describing the attributes and behaviors of the class entities. The object model diagram uses connecting lines to indicate interfaces (called *associations* in UML terminology) between the various artifacts present in the diagram. UML association lines lacking arrows on both ends indicate that there is a bidirectional interface between the artifacts. The UML association lines are annotated with multiplicity counts to indicate the how many entities might fill the position at that end of the association.

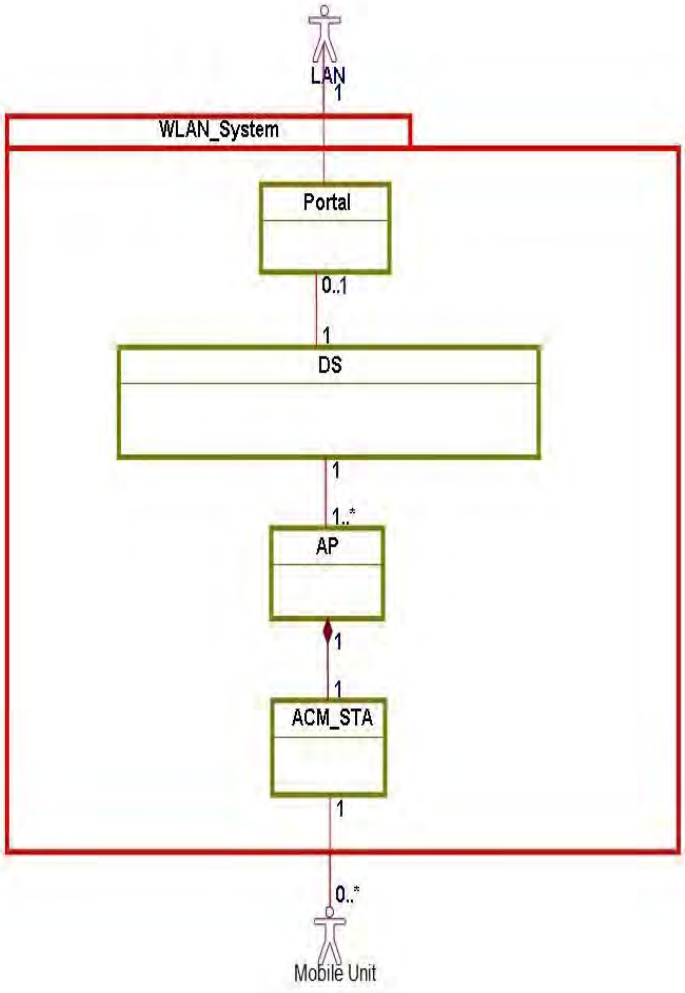

Figure N-4—High-level UML entity diagram for the WLAN system

Figure N-4 also shows the relationships between the WLAN system entities. There exists a bidirectional association between zero or more [0..*] mobile units and a single (given) ACM_STA. The solid diamond terminated line indicates that there is a composition relationship between the ACM_STA and the AP, i.e., the AP is composed of (or always has an) ACM_STA. Hence there is a one-to-one mapping between APs and ACM_STAs. This composition and one-to-one relationship can also be drawn as shown in Figure N-5. These two forms are equivalent. There are one or more [1..*] APs connected to a single DS. The DS in turn connects to zero or one [0..1] portal. The portal connects to a single non-IEEE-802.11 LAN.

Figure N-5—AP UML composition diagram (alternate syntax)

N.3 Primary ACM_STA functions

The primary functions of an ACM_STA are as follows:

a) Instantiate the infrastructure BSS.
b) Move data between the mobile units and the AP.

Instantiating the infrastructure BSS consists of advertising the BSS and defining timing for the entire BSS (i.e., infrastructure mode TSF). Advertising the BSS includes creating an infrastructure mode Beacon frame, transmitting that Beacon frame, and replying to mobile unit probe requests with corresponding probe response transmissions. Beacon frames and probe responses provide a way for the mobile units to find, join with the ACM_STA, and (subsequently) associate with the AP. This includes, for example, the AP providing channel, regulatory, and country information to the mobile units.

Moving data between the mobile units and the AP consists of translating between MSDUs and MPDUs, buffering data, and transmitting/receiving MPDUs via an IEEE 802.11 PHY.

N.4 Primary AP functions

The primary functions of an AP are as follows:

a) Provide DS access for the mobile units.
    1) Includes mobile unit validation and extends (in some cases) to notifying the DS.
    2) Includes moving data between the mobile units and the DS.
        i) Uses a special data movement function called *data filtering*.
b) Configure the AP (both the AP itself and the included ACM_STA).

Those high-level use cases of the AP are shown in the UML use case diagram in Figure N-6. The UML extend relationship “extends” a use case with optional functions provided by another use case that are applied only in some scenarios. In Figure N-6, the “Notify the DS” use case extends the “Validate mobile unit” use case in some scenarios.

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

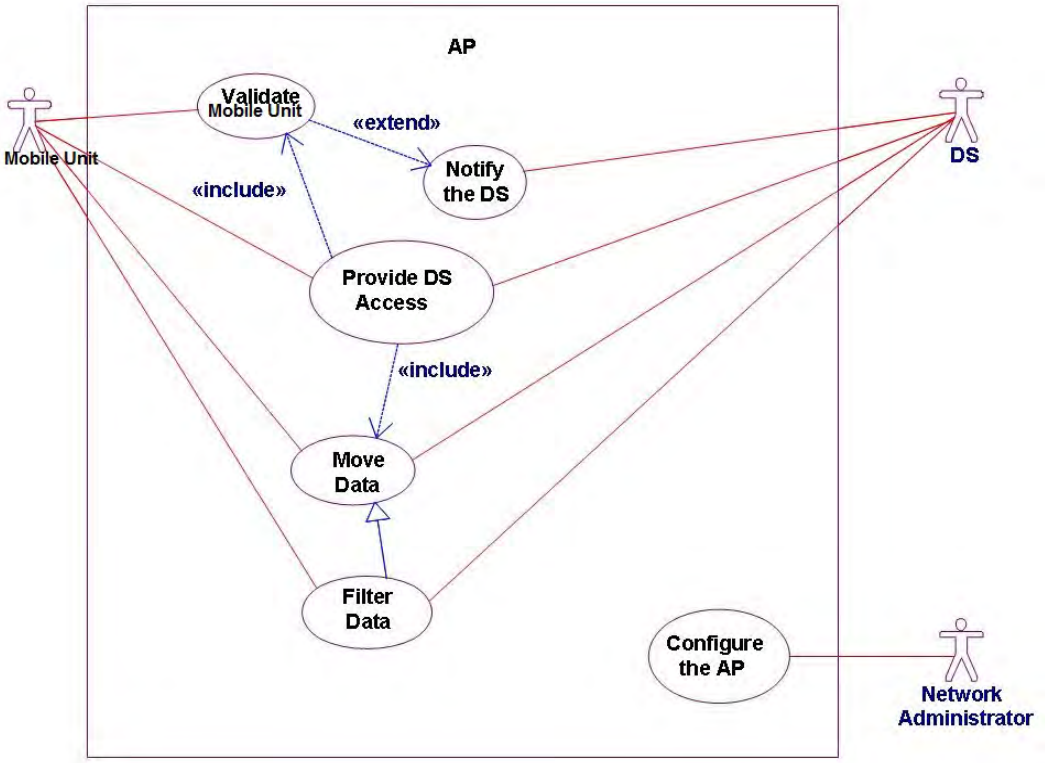

Figure N-6—High-level UML use case diagram for the AP

The AP provides DS access for the mobile units, including validating the mobile units (e.g., via STA and/or client authentication) and providing access and admission control (e.g., via the association process). An AP is literally a point of access to the DS (and, by extension, to the non-IEEE-802.11 LAN beyond). Upon validating a mobile unit, the AP updates the DS mapping of the mobile unit to the AP. DS mapping updates can, for example, be based on (re)association requests (received from the ACM_STA) or aging of inactive links (based on session timers). An AP might also receive access control updates directly from other APs, via a protocol outside the scope of this standard, in the form of inter-AP notifications of mobile unit association events and transitions. In this way, mobile unit validation and subsequent changes in mobile unit access control lead to adjustments in how data are allowed to move through the AP (i.e., between the mobile units and the DS).

Providing DS access for the mobile units also includes moving data between the mobile units and the DS, which is accomplished by moving MSDUs between the ACM_STA and the DS (bidirectionally).

The moving data function includes “filtering data.” The filtering data function controls which MSDUs (if any) are moved between the DS and the mobile units. For example, filtering of data to and from a particular mobile unit is adjusted based on the various stages of validation of that mobile unit.

The AP also provides a function for configuration. Configuring the AP includes configuring the AP itself as well as the included ACM_STA. For example, configuration might include setting the local values of the SSID, PHY channel, beacon interval, and so on.

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

N.5 Primary DS functions

The primary functions of the DS (i.e., the DSSs) are as follows:

a) Map mobile unit to AP (for DS-to-mobile unit traffic delivery).
b) Move data.

The DS's mobile unit-to-AP map determines which AP is to be used for a given mobile unit's data delivery. This function includes mapping update adjustments, which are based on notification from the APs, of changes in mobile unit access control.

Moving data consists of moving MSDUs among the APs (including returning MSDUs to the source AP for mobile unit-to-mobile unit communications) and between the APs and the portal.

N.6 Primary portal function

The primary function of a portal is as follows:

a) Move data with a special data movement function called *data transformation*.

Moving data consists of moving MSDUs between the DS and the external non-IEEE-802.11 LAN. Moving data through the portal transforms the MSDUs using the integration function. The integration function translates external non-IEEE-802.11-LAN MSDUs to and from IEEE 802.11 MSDUs using, for example, the procedures defined in Annex M.

Annex O

(informative)

Additional VHT and HT information

O.1 VHT and HT waveform generator tool

As an informative extension to this standard, waveform generator tools have been written to model the PHY transmission process described in Clause 17, Clause 18, Clause 19, and Clause 21.

The waveform generator can be downloaded from the public IEEE 802.11 document website. The waveform generator code that includes Clause 17, Clause 18, and Clause 19 is contained in document 11-06/1715, and the waveform generator description is contained in document 11-06/1714 (HT code). A description of the waveform generator that includes Clause 17, Clause 19, and Clause 21 and the waveform generator code itself may be found in document 11-11/0517 (VHT code).

The purpose of these tools is to promote common understanding of complex PHY algorithms, facilitate device interoperability by providing reference test vectors, and assist researchers in industry and academia to develop next generation wireless solutions.

The code is written in the MATLAB computing language and can be configured to generate test vectors for most PHY configurations, defined by this standard. Instructions on how to configure and run the tools are specified in the referenced documents.

A command line interface is used to configure the VHT code tool. For consistency with this standard, the configuration interface is made very similar to the TXVECTOR parameters defined in 21.2.2.

A command line interface and graphic user interface (GUI) exist to configure the HT code tool. For consistency with this standard, the configuration interface is made very similar to the TXVECTOR parameters defined in 19.2.2.

The waveform generator tool produces test vectors for all transmitter blocks, defined in Figure 19-2 and Figure 19-3, generating reference samples in both frequency and time domains. Outputs of the tool are time domain samples for all transmitting chains.

O.2 A-MPDU deaggregation

This subclause contains a description of the deaggregation process. Other implementations are also possible.

The receiver checks the MPDU delimiter for validity based on the CRC. It can also check that the length indicated is within the value of the LENGTH parameter indicated in RXVECTOR.

If the MPDU delimiter is valid, the MPDU is extracted from the A-MPDU. The next MPDU delimiter is expected at the first multiple of 4 octets immediately after the current MPDU. This process is continued until the end of the PPDU is reached.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

If the MPDU delimiter is not valid, the deaggregation process skips forward 4 octets and checks to see whether the new location contains a valid MPDU delimiter. It continues searching until either a valid delimiter is found or the end of the PSDU is reached based on the value of the LENGTH parameter indicated in the RXVECTOR.[62]

An A-MPDU parsing (deaggregation) algorithm is expressed (as a C programming language snippet) in Figure O-1.

```
void Parse_A_MPDU (int length)
{
  int offset = 0; /* Octet offset from start of PSDU */
  while (offset+4 < length)
  {
    if (valid_MPDU_delimiter(offset) &&
        get_MPDU_length(offset) <= (length -(offset+4)))
    { /* Valid delimiter */

      /* Receive the MPDU */
      Receive_MPDU(offset+4, get_MPDU_length(offset));

      /* advance by MPDU length rounded up to a multiple of 4 */
      offset += 4 + 4*((get_MPDU_length(offset)+3)/4);
    }
    else /* Invalid delimiter */
    {
      /* Advance 4 octets and try again */
      offset += 4;
    }
  }
}
```

NOTE 1—This algorithm is not optimized for efficiency.

NOTE 2—The delimiter signature can be used to reduce the amount of computation required while scanning for a valid delimiter. In this case, the receiver tests each possible delimiter for a matching Delimiter Signature field. Only when a match is discovered does it then check the CRC.

Figure O-1—A-MPDU parsing

[62] This procedure occasionally wrongly interprets a random bit-pattern as a valid delimiter. When this happens, the MAC attempts to interpret a random MPDU. The MAC discards it with a high probability based on a check of the FCS field.

O.3 Example of an RD exchange sequence

Figure O-2 shows an example of the operation of the RD rules, defined in 10.28.

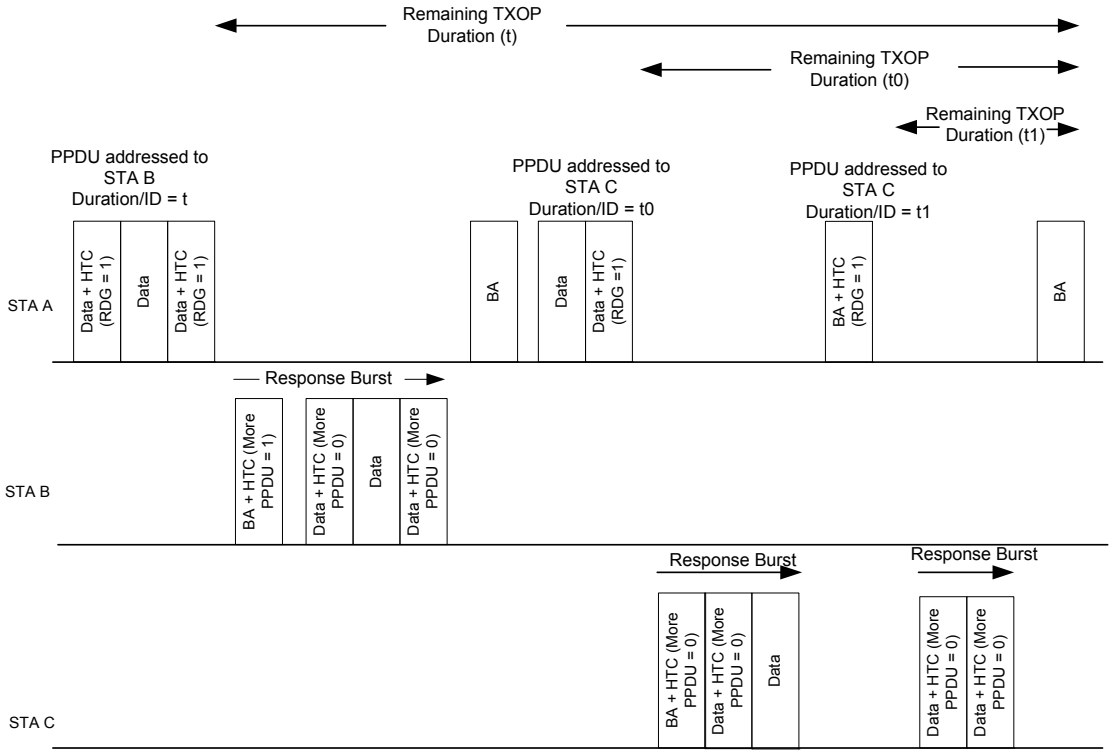

Figure O-2—Example of RD exchange sequence showing response burst

The following is a summary of Figure O-2:

a) STA A (acting as RD initiator) transmits a PPDU containing MPDUs addressed to STA B (acting as RD responder). The Ack Policy field of the QoS Data frames in this PPDU is set to Implicit Block Ack Request. One or more MPDUs within this PPDU include an HT Control field with the RDG/ More PPDU subfield set to 1, indicating an RDG. The Duration/ID field of MPDUs within the PPDU contains the remaining duration of the TXOP, t μs.

b) STA B (the RD responder) responds with the transmission of a +HTC BlockAck frame in which the RDG/More PPDU subfield is set to 1, indicating that another PPDU will follow a SIFS or RIFS after the end of the PPDU containing the BlockAck frame.

c) STA B transmits a PPDU (the second PPDU of an RD response burst) to STA A, with the Ack Policy field of its QoS Data frames set to Implicit Block Ack Request and containing one or more +HTC MPDUs in which the RDG/More PPDU subfield is set to 0, indicating that this is the last PPDU in the response burst.

d) STA A (the RD initiator) regains control of the TXOP and transmits a BlockAck frame addressed to STA B to acknowledge the MPDUs transmitted by STA B in the RD response burst.

e) STA A (the RD initiator) transmits a PPDU containing MPDUs addressed to STA C (acting as RD responder). The Ack Policy field of the QoS Data frames in this PPDU is set to Implicit Block Ack. This PPDU includes one or more +HTC MPDUs in which the RDG/More PPDU subfield is set to 1, indicating an RDG. The Duration/ID field of MPDUs in the PPDU contains the remaining duration of the TXOP, t0 μs.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

f) STA C (the RD responder) transmits a PPDU to STA A, containing one or more +HTC MPDUs with the RDG/More PPDU subfield set to 0, indicating that this is the last PPDU in the response burst. This PPDU contains a BlockAck frame that is a response to the implicit block ack request of the previous PPDU, plus QoS Data frames with the Ack Policy field set to Implicit Block Ack.

g) STA A (the RD initiator) regains control of the TXOP and transmits a BlockAck frame to STA C that acknowledges the MPDUs transmitted by STA C. This PPDU contains one or more +HTC MPDUs with the RDG/More PPDU subfield set to 1, indicating an RDG. The Duration/ID field of MPDUs in the PPDU contains the remaining duration of the TXOP, t1 μs.

h) STA C (the RD responder) transmits a PPDU to STA A, containing QoS data +HTC MPDUs with the Ack Policy field set to Implicit Block Ack Request and the RDG/More PPDU subfield set to 0. This is the only PPDU in the RD response burst.

i) STA A transmits a BlockAck frame to STA C that acknowledges the MPDUs transmitted by STA C in the RD response burst.

O.4 Illustration of determination of NDP addresses

Determination of NDP SA and DA are illustrated in Figure O-3 and Figure O-4.

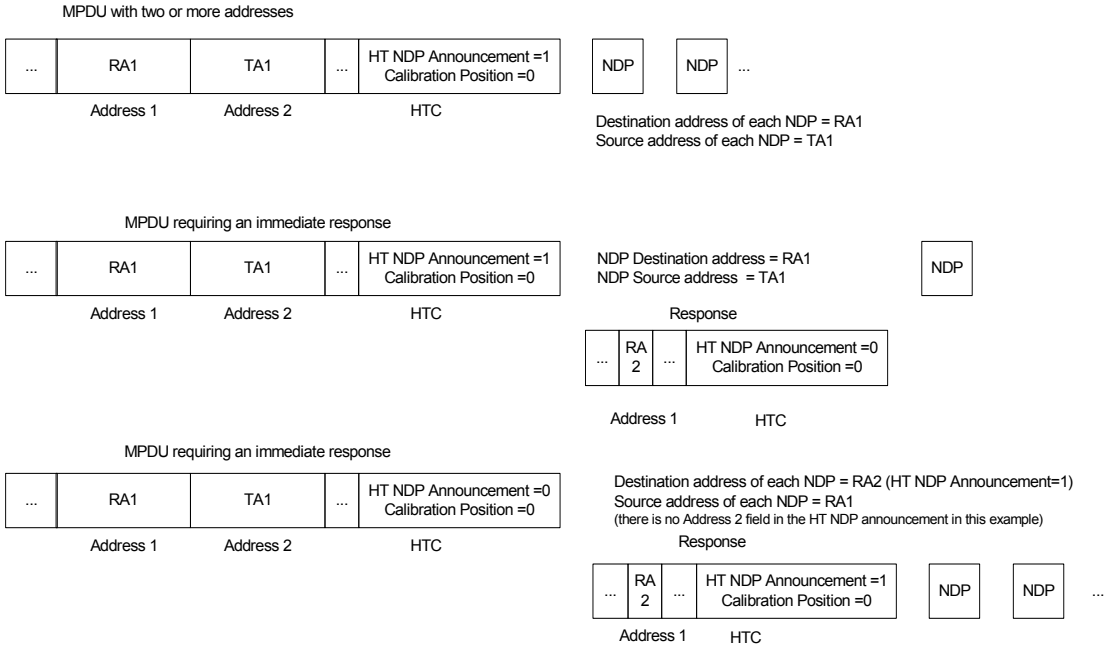

Figure O-3—Determination of NDP source and destination for unidirectional NDP sequences

Figure O-4—Determination of NDP source and destination for bidirectional NDP sequence

O.5 20/40 MHz BSS establishment and maintenance

O.5.1 Signaling 20/40 MHz BSS capability and operation

A BSS that occupies 40 MHz of bandwidth and that is administered by an HT AP is called a *20/40 MHz BSS*.

An HT AP that has dot11FortyMHzOperationImplemented equal to true sets the Supported Channel Width Set subfield of the HT Capabilities element to a nonzero value. The AP might also operate a 20/40 MHz BSS. The Supported Channel Width Set subfield of the HT Capabilities element that is transmitted by the AP indicates the possible operating mode of the BSS and of the AP, but the value in this field is not an indication of the current BSS bandwidth of either the AP or the BSS.

An HT AP signals the operating width of the BSS through the Secondary Channel offset field of the HT Operation element. A nonzero value in this field indicates that a secondary channel exists; in other words, the BSS is a 20/40 MHz BSS. A value of 0 in this field indicates that the BSS is operating as a 20 MHz BSS.

An HT AP that has dot11FortyMHzOperationActivated equal to true sets its STA Channel Width field of the HT Operation element to a nonzero value. This field signals the current operating mode of the AP, not the BSS. An HT AP might operate a 20/40 MHz BSS while it is operating as a 20 MHz device. Such a situation would support, for example, 40 MHz bandwidth DLS traffic among associated STAs, but only 20 MHz bandwidth traffic between STAs and the AP.

O.5.2 Establishing a 20/40 MHz BSS

Before starting a 20/40 MHz BSS, a 40MC HT AP is required by the rules defined in 11.16.5 to examine the channels of the current regulatory domain to determine whether the operation of a 20/40 MHz BSS might unfairly interfere with the operation of existing 20 MHz BSSs. The AP (or some of its associated HT STAs) is required to scan all of the channels of the current regulatory domain in order to ascertain the operating channels of any existing 20 MHz BSSs and 20/40 MHz BSSs. This type of scanning is called *OBSS scanning*. The particulars of OBSS scanning are controlled by the following MIB attributes:

— dot11FortyMHzOptionImplemented
— dot112040BSSCoexistenceManagementSupport
— dot11FortyMHzIntolerant
— dot11BSSWidthTriggerScanInterval
— dot11BSSWidthChannelTransitionDelayFactor
— dot11OBSSScanPassiveDwell
— dot11OBSSScanActiveDwell

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

— dot11OBSSScanPassiveTotalPerChannel
— dot11OBSSScanActiveTotalPerChannel
— dot11OBSSScanActivityThreshold

Specific values for these MIB attributes are provided to set minimum scan times for passive scanning of each channel, and a separate minimum time is provided for active scanning of each channel. A total minimum amount of scanning per channel is required before a determination can be made to allow the operation of a 20/40 MHz BSS.

The rules that are applied when determining whether a 20/40 MHz BSS can be established are intended to avoid a full or partial overlap of the secondary channel of the 20/40 MHz BSS with an existing primary channel of either a 20 MHz BSS or a 20/40 MHz BSS. The lack of partially overlapping channels in the 5 GHz band allows these rules to be written as recommendations, while in the 2.4 GHz band, they are requirements.

An additional constraint on establishing a 20/40 MHz BSS includes the allowance for any IEEE 802.11 device to explicitly prohibit the operation of the 20/40 BSS mode due to other considerations. For example, if an IEEE 802.15.1™ WPAN device is operating in the area, that device is likely to be unable to communicate successfully with a paired receiver if the number of available IEEE 802.15.1 WPAN channels falls below a given threshold. Operation of a 20/40 MHz BSS in the 2.4 GHz band can contribute to the reduction of the number of available IEEE 802.15.1 WPAN channels, possibly pushing the available channels below that threshold.

To promote sharing of the spectrum resource under such circumstances, it might be desirable to prohibit the operation of a 20/40 MHz BSS. As such, the 20/40 BSS coexistence mechanism allows a STA to transmit Management frames containing a value of 1 for the Forty MHz Intolerant field. (The MIB attribute dot11FortyMHzIntolerant determines the setting of the value of the Forty MHz Intolerant field in transmitted frames, and the setting of the value of the MIB attribute is beyond the scope of this standard.) Receivers of such frames on any channel in the band are not allowed to establish a 20/40 MHz BSS anywhere in the band for a duration of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds. To effect this requirement, monitoring STAs and APs maintain a countdown timer to indicate that a prohibition is in force. The countdown timer is reloaded with the value dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds each time that the STA or AP observes a Management frame containing a value of 1 for the Forty MHz Intolerant field. STAs communicate changes in their countdown counter (i.e., transitions between a zero value and a nonzero value) to their associated AP through the 20 MHz BSS Width Request field of the 20/40 BSS Coexistence Management frame.

O.5.3 Monitoring channels for other BSS operation

Some of the STAs that are associated with a 20/40 MHz BSS perform monitoring so that the conditions which allowed the establishment of the 20/40 MHz BSS do not change to conditions that would disallow the existence of the 20/40 MHz BSS.

Monitoring STAs keep a local record of channels that are in use by other BSSs. STAs that receive Beacon frames determine the primary channel by examining the DSSS Parameter Set element. Secondary channel existence and channel information are determined by examining the Secondary Channel Offset field of the 20/40 BSS Coexistence element. Monitoring STAs also record receptions of frames that contain a value of 1 for the Forty MHz Intolerant field. Any changes to the local record that would create a prohibition against 20/40 MHz BSS operation are immediately reported to the associated AP through the transmission of a 20/40 BSS Coexistence Management frame (i.e., with the 20 MHz BSS Width Request field set to 1). The reception of a 20 MHz BSS Width Request field equal to 1 at the AP causes the AP to switch the BSS to 20 MHz operation immediately.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Any change of a channel in use that had not previously been in use is also reported immediately within a 20/40 BSS Coexistence Management frame. The AP examines the new in-use channel information to determine whether any changes in BSS width operation are required (i.e., to see if any changes have occurred that indicate an overlap of the secondary channel). If a change to 20 MHz BSS operation is required, the change occurs immediately.

Conditions that prevent the operation of a 20/40 MHz BSS might be transient. If the number of channels in use is reduced or all STA signaling 40 MHz intolerance leave the area, an AP might choose to revert to 20/40 MHz operation, if allowed to do so. However, the conditions that allow 20/40 MHz BSS operation have to persist for a period of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTrigger-ScanInterval seconds before a STA can signal that the conditions have changed, and the same period of time has elapsed before an AP can resume 20/40 MHz BSS operation.

STAs that do not monitor channels through OBSS scanning and do not report any channel information or received Forty MHz Intolerant field information to their associated AP are listed here:

— Non-HT STAs
— HT STAs that are exempt from scanning as specified in 11.16.6
— HT APs, once the 20/40 MHz BSS is established
— HT STAs that are associated with an AP whose BSS is operating on a channel that is not in the 2.4 GHz band
— HT STAs that are associated with an HT AP that is not 40-MHz-capable (as indicated by a value of 0 in the Supported Channel Width Set subfield of the HT Capabilities element)

All other HT STAs that are associated with a 40-MHz-capable HT AP whose BSS is operating on a channel in the 2.4 GHz band monitor channels through OBSS scanning and report any channel information or received Forty MHz Intolerant field information to their associated AP.

All MIB attributes that are employed by the 20/40 BSS Coexistence mechanism are maintained by the AP, which has the ability to provide updates to the MIB attribute values to the associated STA by transmitting an OBSS Scan Parameters element.

Annex P

(informative)

Location and Time Difference accuracy test

P.1 Location via Time Difference of arrival

The location of a device might be determined using multiple methods, including:

- Signal strength at different sensors
- Time of flight between the device and different sensors
- Time difference of arrival between the device and pairs of sensors

A typical implementation of the time difference of arrival method requires that the sensors are co-channel, have synchronized clocks, and receive the same transmission from the device. The sensor's time of arrival measurements are shared, and the device location is determined via multilateration, i.e., each pair of sensor measurements provides a time difference of arrival measurement that represents a hyperbola in 2D space of most likely candidate locations, and the overlap of the multiple hyperbola from multiple pairs of sensors leads to the location estimate. The single time of departure is not relevant in this typical multilateration implementation as it is canceled out when time differences of arrival are computed.

When the sensors are on different channels, such as APs in a typical multi-channel deployment, the device transmits on each channel and thus with multiple times of departure. In this environment it is necessary for the device to advertise each time of departure so that it can be subtracted from the times of arrivals measured by sensors on different channels. Furthermore, the device's clock frequency typically does not match the clock frequency of the synchronized sensors, and so the device should transmit on the same channel multiple widely spaced times in order for the sensors to estimate the device's clock frequency relative to themselves and to be able to suitably scale the device's advertised times of departure.

An example transmission sequence comprises frames transmitted on channels 1, 6, 11, 1 at 2.4 GHz. From this, the device's clock frequency can be determined relative to the synchronized APs on channel 1, and all APs on channels 1, 6, and 11 can measure a time of arrival. These four transmissions enable a single location calculation. The Time of Departure Accuracy test in P.2 is designed to measure errors within such a transmission sequence that would degrade a multi-channel time difference of arrival location scheme.

P.2 Time Difference of departure accuracy test

The Time Difference of Departure accuracy test is an informative description of how time difference of departure accuracy can be measured for any parameterizable PHY waveform. This accuracy test does not apply when the Time of Departure timestamps are exclusively used for timing measurement (see 11.24.5).

The Time Difference of Departure accuracy test is parameterized by the following test parameters:

- TIME_OF_DEPARTURE(j,i), $1 \le j \le 500$, $1 \le i \le I$ (scalar entries)
- MULTICHANNEL_SAMPLING_RATE (scalar)
- FIRST_TRANSITION_FIELD(j,i), $1 \le j \le 500$, $1 \le i \le I$ (waveform entries)
- SECOND_TRANSITION_FIELD(j,i), $1 \le j \le 500$, $1 \le i \le I$ (waveform entries)
- TRAINING_FIELD(j,i), $1 \le j \le 500$, $1 \le i \le I$ (waveform entries)
- TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH (scalar)

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

TIME_OF_DEPARTURE(j,i) is exposed externally through the TOD Timestamp field in the Time of Departure subelement in Location Track Notification frames.

The Time Difference of Departure accuracy test is performed as follows or in an equivalent or more accurate manner.

The Time Difference of Departure accuracy test is performed by instrumentation capable of converting signals transmitted on one or more channels into a stream of complex samples at f_s sample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, etc, and at a fixed delay from the transmitter. The minimum sampling rate is MULTICHANNEL_SAMPLING_RATE sample/s respectively. A possible embodiment of such a setup is converting the signal to a low IF frequency with a cabled microwave synthesizer, sampling the signal with a digital oscilloscope and decomposing it digitally into quadrature components. The sampled signal is processed in a manner similar to an actual time of arrival processor, according to the following steps:

a) Repeat steps b) to j) indexed by $j = 1, \ldots, 500$

b) Repeat steps c) to i) indexed by $i = 1, \ldots, I$

c) Start of frame is detected.

d) Channel number, coarse and fine frequency offsets are estimated.

e) The packet is derotated according to estimated frequency offsets.

f) The transition from FIRST_TRANSITION_FIELD(j,i) to SECOND_TRANSITION_FIELD(j,i) is detected; and fine timing (with one sample resolution) is established.

g) The TRAINING_FIELD(j,i) of the derotated signal is up-sampled to meet the TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH requirement. For example, a TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH of 1 ns requires up-sampling of at least 1 GHz.

h) The up-sampled signal is cross-correlated with a reference waveform of the TRAINING_FIELD(j,i)

i) The measured time of departure $x_{j,i}$ is determined from the time of the peak of the magnitude of the cross-correlation.

NOTE—The time of the peak of the magnitude of the cross-correlation is actually a time of arrival measurement that equals the time of departure up to a fixed delay. Since the fixed delay is removed within step j), the fixed need not be known or explicitly compensated for.

j) Having repeated steps c) to i) I times, the (j,i)th time of departure error $e_{j,i}$ is calculated as TIME_OF_DEPARTURE(j,i) minus the synchronized time of departure. Defining $x_j = [x_{j,1},..,x_{j,I}]^T$ as the I measured times of departure, y = [TIME_OF_DEPARTURE(j,1), … TIME_OF_DEPARTURE(j,I)]^T, $e_j = [e_{j,1}, e_{j,I}]^T$ are the I time of departure errors and $X_j = [1_{I\times1}, x_j]$, where $1_{I\times1}$ is an $I\times1$ matrix of 1s, then the relative clock intercept, rci_j, and slope, rcs_j, between device and instrumentation are determined as the linear least squares line of best fit: i.e., $[rci_j, rcs_j]^T = (X_j^T X_j)^{-1} X_j^T y^j$. With these definitions and calculations, the synchronized time of departure $s_j = [s_{j,1},..,s_{j,I}]^T$ equals $rcs_j \times x_j + rci_j \times 1_{I\times1}$, and so the I time of departure errors equal $e_j = y_j - s_j$.

k) Having repeated steps b) to j) 500 times, there are $500 \times I$ values of the time of departure errors $e = [e_{1,1}, e_{500,I}]$

l) The Time Difference of Departure accuracy test is passed if both of the following conditions are met:

   1) The RMS value of e is less than aTxPHYTxStartRMS.

   2) aTxPHYTxStartRMS is less than TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH, where the units of e, aTxPHYTxStartRMS, and TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH are properly accounted for.

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—One possible implementation of a time of departure measurement system is a free-running oscillator clocking (a) the digital-to-analog converter(s) used to transmit the packet, (b) a 32-bit continuously counting counter and (c) a hardware finite state machine such that PHY-TXSTART.request primitive causes a transition within the finite state machine that in turn causes frame transmission at the DACs a fixed number of cycles later; where the time of departure is recorded as the value of the counter at that transition minus aTxPHYTxStartRFDelay (using TIME_OF_DEPARTURE_ClockRate), where aTxPHYTxStartRFDelay can vary by channel. In this implementation, the principal source of time of departure error is short-term oscillator imperfection (e.g., phase noise) and RF group delay variation across channels uncompensated by aTxPHYTxStartRFDelay.

NOTE 2—1 ns of time of departure error corresponds to approximately 0.3 m of distance error, so high location accuracy depends upon a tight time of departure standard deviation.

P.3 Differential Distance Computation using Fine Timing Measurement frames

In Figure P-1 the Observing STA is able to listen to the Fine Timing Measurement frame exchange between the Sending and Receiving STAs. The time of flight of a line of sight transmission between the Sending and Receiving STAs is denoted as *T*. At the Observing STA, the time of Arrival (ToA) of message M and its Ack frame are respectively t_{c1} and t_{c2}. At the Sending STA, the time of departure (ToD) of message M and the ToA of its Ack frame are t_1 and t_4 respectively.

The differential distance between the Observing STA and each of the Sending and Receiving STAs, denoted as D_{SR}, is defined as:

$$D_{SR} = c \times (T_{SO} - T_{RO})$$

where

c is speed of the light.
T_{SO} is the time of flight between the Sending STA and the Observing STA
T_{RO} is the time of flight between the Receiving STA and the Observing STA

D_{SR} can now be computed as:

$$D_{SR} = c \times (t_{c1} - t_{c2} - T - (t_1 - t_4))$$

An Observing STA can use the ToA and the time stamps (t_1 and t_4) received in the following messages in the message exchange to refine its computation of the differential distance to the Sending and Receiving STAs.

In Figure P-1 the Receiving and Sending STAs can be APs. The APs can learn about neighboring APs that support the FTM protocol and an AP can initiate a FTM message exchange on a periodic basis (e.g., the beacon interval or a multiple of the beacon interval) with its neighbor APs. Monitoring and receiving these messages can enable Observing STAs to estimate their differential distance with the AP pairs. An Observing STA that is able to determine its differential distance to at least three pairs of Sending and Receiving STAs can determine its location using the principle of hyperbolic navigation. An Observing STA can potentially determine its location by monitoring the FTM exchanges of a single AP (Sending STA) if there are three or more neighbor APs of the Sending STA that support FTM.

Annex Q

(informative)

Example use of the Destination URI for Event and Diagnostic Reports

Q.1 Destination URI payload

An example of the payload used to transmit Event and Diagnostic reports shown in Table Q-1. The protocol used to transport the Destination URI payload is beyond the scope of this standard. An example use of the Destination URI is given in Q.2.

Table Q-1—Destination URI payload

Size (octets)	Information
6	BSSID
6	Reporting STA Address
variable	Event or Diagnostic Report frame contents

Q.2 Use of HTTP (or HTTPS) for Destination URI of Event and Diagnostic Reports

Under certain conditions a non-AP STA might need to send Event and Diagnostic reports to an AP using the Destination URI advertised by the AP in the request frame. A suitable higher layer protocol that could be used to transport the Event or Diagnostic report is HTTP or HTTPS.

For example, consider the following:

1) IT is investigating a WLAN coverage problem and uses a non-AP STA with a WLAN and Ethernet adapters to collect some additional information.
2) The non-AP STA with MAC 00-ff-fd-00-00-01 has received a request for a Diagnostic report from AP 00-ff-fe-00-00-10 and is in fringe coverage. The non-AP STA has an Ethernet adapter that is connected.
3) The AP includes an Alternate Destination URI of http://www.myserver.mycompany.com in the Diagnostic Report frame.
4) The non-AP STA loses WLAN connectivity while trying to transmit a Diagnostic Report frame to the AP and the non-AP STA's SME determines that it can use the Alternate Destination URI to send the Diagnostic Report frame using the Ethernet link.
5) The non-AP STA POSTs the Diagnostic report as follows:

   POST /wnm/msg/00-ff-fd-00-00-01/msg1 HTTP/1.1

   Host: http://www.myserver.mycompany.com

   Content-Type: application/octet-stream

   Content-Encoding-Type: base64

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Content-Length: i (length of data as specified in Figure 9-697 in 9.6.14.5)

<encoded data = 00 ff fe 00 00 10 00 ff fd 00 00 01 …>

In the HTTPS case, the non-AP STA would need to be provisioned with credentials to establish the TLS connection prior to posting the message over HTTP. The HTTP post would work as described previously.

Annex R

(informative)

Interworking with external networks

R.1 General

The purpose of this informative annex is to describe and clarify the support for interworking with external networks including the support for network discovery and selection, QoS mapping, SSPN interface, and emergency services and to provide some background information and recommended practices.

R.2 Network discovery and selection

R.2.1 General

Interworking service provides features to support the network discovery and selection process a STA uses to choose the network with which to associate. GAS provides a non-AP STA access to an advertisement server (e.g., an access network server or an IEEE 802.21 information server), which can provide a rich set of information to aid the network discovery and selection process. In addition, interworking service provides lightweight features that also facilitate this process. The following subclauses describe several use cases illustrating how these features can be used to aid in network discovery and selection:

— **Airport:** A traveling businesswoman needs to connect via an airport hotspot to her enterprise network to download email and information from the customer database.
— **Shopping:** A shopper visits a shopping mall and wants to use a smartphone to discover items on sale.
— **Sales meeting:** A salesman visiting a customer accesses his guest network.
— **Museum:** A visitor to a museum uses a smartphone to obtain virtual docent service.
— **Emergency call:** A traveler needs to make an emergency call while in another country.
— **Emergency alert:** A traveler, having enabled the display of emergency alerts, arrives at a new destination.

R.2.2 Airport

A traveling businesswoman arrives for the first time at an airport having a WLAN. This user wants to download email onto her laptop utilizing the airport's hotspot, a chargeable network. Once associated, the woman needs to connect via VPN connection back to her company's servers to access email and information from the customer database. This is performed as follows:

a) The laptop's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Chargeable Public Network." In response, it receives Probe Response frames from several of the airport's APs, in the immediate neighborhood, for the SSID "Narita Hotspot."
b) The Probe Response frame received by the laptop indicated the following capabilities:
    1) Extended Capabilities element indicates: AP provides interworking service.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

2) Interworking element indicates: venue group = 1 (Assembly) and venue type = 3 (passenger terminal), Internet = 1 (Internet access available), ASRA = 1 (there is an additional step required for network access).
3) Advertisement Protocol element including the Advertisement Protocol ID set to MIH Information Service.
4) Roaming Consortium element present containing an OI for "Hotspot Roaming International."
5) There is no RSNE present in the received Beacon frame.

c) Since the laptop's SME does not recognize the Roaming Consortium OI, it invokes the GAS protocol to query the network's IEEE 802.21 IS. The IEEE 802.21 IS's response indicates the roaming partners for "Narita Hotspot" and the laptop have security credentials for one of them.
d) Since the AP indicated ASRA = 1, the SME again invokes the GAS protocol to retrieve the Network Authentication Type ANQP-element. The response indicates that https redirection is in use and provides the Redirect URL of hotspot.narita.co.jp. Note that this is helpful since some networks use conditional redirection—that is, access to a walled garden is provided for free, but a subscription fee is required to access the Internet.
e) Since the laptop's SME now knows it should be able to successfully authenticate with the network, the STA associates to the AP.
f) The following operations are then carried out by higher layers operating within the laptop:
1) The laptop's SME autonomously launches an http client and provides to it the URL of hotspot.narita.co.jp, which provides the proper security credentials to the network and thereby successfully authenticates it to the network.
2) The VPN client is autonomously launched and a secure session to the user's corporate network is established. Then the user launches the email application to download email and other required information.

R.2.3 Shopping

A shopper visits a shopping mall and wants to use a smartphone to discover items on sale. In this mall, the mall's IT department is providing WLAN facilities for all of the stores in the mall; therefore, there is only one SSID for shoppers (i.e., there is not a different SSID for each store in the mall). The user arrives at the mall and taps an icon on the screen to put the smartphone in "shopping mode." The smartphone's shopping application causes the non-AP STA to carry out the following steps:

a) The smartphone's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Free Public Network." In response, it receives Probe Response frames from several of the mall's APs, but only one SSID is provided, which is "Silicon Valley Mall." The mall's APs did not transmit Probe Response frames for the SSIDs "Engineering," "Deliveries," and "Janitorial" since their access network type is "Private network."
b) The Probe Response frame received by the smartphone indicated the following capabilities:
1) Extended Capabilities element indicates: AP provides interworking service.
2) Interworking element indicates: venue group = 6 (mercantile) and venue type = 4 (shopping mall), Internet = 0 (unspecified).
3) RSNE indicates: IEEE 802.1X authentication.
c) Since the AP indicated Interworking service is available, the smartphone's non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 9.4.5.3). In the Capability List ANQP-element, the AP has indicated support for Venue Name and Domain Name. Subsequent to receipt of the Capability List ANQP-element, the non-AP STA invokes the MLME-GAS.request primitive to retrieve the other two lists.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

d) Next, the non-AP STA's supplicant searches the received Domain Name list to determine whether it has any stored credentials for these domains. If so,
   1) The smartphone autonomously associates to the "Silicon Valley Mall Shopping" SSID and displays the following information:
      i) Venue name: Silicon Valley Mall, 1234 Main Street, Rownhams, CA 98765-1234
      ii) SSID: Silicon Valley Mall
      iii) Venue type: Shopping Mall
   2) The supplicant autonomously provides the security credentials for the selected domain.
e) Higher layer protocols then download discount coupons being offered for items on sale.

R.2.4 Sales meeting

A salesman travels across town to a meeting at ACME Manufacturing. While there, this user needs to send email to get a document from engineering. On his laptop, he requests the WLAN via the laptop's UI to search for guest networks. The laptop performs the following steps:

a) The laptop's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Private Network with Guest Access." In response, it receives Probe Response frames from several of ACME Manufacturing's APs, but only one SSID is provided, which is "Guest." ACME Manufacturing's APs did not transmit Probe Responses for the SSIDs "Engineering" and "Finance" since their access network type is "Private network."
b) The Probe Response frame received by the laptop indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: Internet is available, venue group = 2 (Business) and venue type = 8 (Research and Development Facility).
   3) RSNE indicates: IEEE 802.1X authentication with CCMP-128 pairwise and group cipher suites.
c) Since the AP indicated interworking service is available, the laptop's non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 9.4.5.3). In the Capability List ANQP-element, the AP has indicated support for venue name. Upon receipt of the Capability List ANQP-element, the non-AP STA again invokes the MLME-GAS.request primitive to retrieve the venue name.
d) The laptop's UI displays the following information and automatically associates to the network:
   1) SSID: Guest (Type: Private network with Guest access)
   2) Venue name: ACME Manufacturing, 1234 Main Street, Rownhams, CA 98765-1234
   3) Venue type: Research and Development Facility
   4) Internet is available
e) Upon prompt, the user enters the username and password supplied by his point of contact from ACME Manufacturing and is then able to send and receive email.

R.2.5 Museum

A visitor enters a museum that is advertising virtual docent service (audio tracks describing each of the major exhibits). The visitor taps an icon on a smartphone and requests it to search for free networks. The smartphone then carries out the following:

a) The smartphone's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Free Public Network." In response, it receives Probe Response frames from several of the

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

museum's APs, but only one SSID is provided, which is "Visitors." The museum's APs did not transmit Probe Response frames for the SSID "Maintenance" since its access network type is "Private network."

b) The Probe Response frame received by the smartphone indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: venue group = 1 (assembly), venue type = 9 (museum), and ASRA = 0 (no additional steps are required for access).

c) Since the AP indicated interworking service is available, the smartphone's non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 9.4.5.3). In the Capability List ANQP-element, the AP has indicated support for venue name. Upon receipt of the Capability List ANQP-element, the non-AP STA again invokes the MLME-GAS.request primitive to retrieve the venue name.

d) The smartphone's UI displays the following information, asking the user whether they wish to connect to the network:
   1) Venue name: Museum of Modern Art (MOMA)
   2) SSID: Visitors
   3) Venue type: Museum
   4) No authentication required

e) The user taps the "Connect" icon on the smartphone's display. Note that the smartphone's non-AP STA knows that the network uses Open System authentication since there is no RSNE present in the beacon and ASRA = 0.

R.2.6 Emergency call

A traveler needs to make an emergency call while in another country. The traveler might not be aware of the emergency call numbers that are used in that country. Being in this new location for the first time, the traveler is not aware of which local access points provide access for emergency calling. (Note that emergency calling requires higher layer application(s) that are outside the scope of this standard.) This is performed as follows:

a) The traveler's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element. (If the non-AP STA is already associated with an AP that has indicated support for emergency service in its beacon, the probe request would not be necessary.)

b) In response, it receives Probe Response frames from one or more APs indicating support for emergency service in the Access Network Options field of the Interworking element.
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Emergency services reachability is indicated by the ESR and UESA fields in the Access Network Options field in the Interworking element.
   3) A dedicated emergency services network is indicated by the Access Network Type field in the Interworking element.

c) The traveler's non-AP STA then requests the Emergency Call Number ANQP-element with a GAS Initial Request frame.

d) The GAS Initial Response frame from the AP provides the Emergency Call Number, for example the sequence of digits "911" or an emergency service URN label, URI pair "urn:service:sos.fire, tel:112;sip:+15555551002@fire.com" [B46].

e) This information is passed to the higher layer application in the traveler's non-AP STA.

f) The traveler's non-AP STA then associates with the AP.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

g) The traveler's non-AP STA then places the emergency call, with an expedited bandwidth request (EBR) in an ADDTS frame to provide priority to the emergency call.

R.2.7 Emergency alert

A traveler has enabled the display of emergency alerts on a wireless device (non-AP STA) by appropriately setting the higher layer emergency alert application on the device. The traveler arrives at a new destination and turns on the device. The device, when switched on, will perform a search and then associate with an AP to which the traveler has a subscription or associate with an open AP (if the traveler has enabled the device to do that). During the steps leading up to association, the device, when it becomes aware of an emergency alert, will obtain and display it. The emergency alert will likely be obtained from the AP that has the service to which the traveler has subscribed, but the device might also obtain the emergency alert from other APs, if an AP to which the traveler has a subscription is not available. This is performed as follows:

a) The traveler's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID. If it is associated with an AP, it checks the beacon.

b) In response, it receives Probe Response frames from one or more APs, which it checks (or, alternately, checks the beacon) for the subscription and also whether the Emergency Alert element indicates that there are emergency alert message(s).

c) If there are one or more emergency alert messages to be downloaded, the Emergency Alert Identifier element provides an Alert Identifier Hash value.

d) The device uses the hash of each of the available emergency message(s) to determine whether that message has already been received or whether it is a new message that needs to be downloaded.

e) If there are one or more emergency alert messages to be downloaded, the device forms the EAS Message URI by concatenating the Emergency Alert URI with the hexadecimal numerals of the Alert Identifier Hash, using the specified method.

f) Should the device be unassociated with an AP when it determines that a new emergency alert is available, it retrieves the EAS message using either GAS procedures with Advertisement Protocol ID field set to the value for EAS. If the device is associated with the AP, it retrieves the EAS message using either GAS procedures with Advertisement Protocol ID field set to the value for EAS or, for example, using HTTP.

R.3 QoS mapping guidelines for interworking with external networks

R.3.1 General

The EDCA and HCCA mechanism defined in 10.22 provide QoS control at the MAC layer. However, the QoS control parameters used by the EDCA and HCCA cannot match directly with other QoS control parameters of the interworked external networks, e.g., SSPN. For example, the SSPN could have different metrics for defining the QoS levels. Destination Network 1 (DN1) and DN2 can use DSCP values differently, in which case, STA1 and STA2 would require different QoS mapping information. Therefore, mapping from these external QoS control parameters to the QoS parameters of this standard is necessary.

The QoS parameters mapping can be used for both uplink and downlink data transmission:

— For uplink: at the non-AP STA, external QoS parameters are mapped to IEEE 802.11 QoS parameters, e.g., DSCP to IEEE 802.11 User Priority and in turn to EDCA ACs. This mapping helps the non-AP STA to construct correct QoS requests to the AP, e.g., the ADDTS Request frame and to transmit frames at the correct priority.

— For downlink: at the AP, DSCP values are mapped to EDCA UPs. Optionally, the non-AP STA can use TSPEC and TCLAS elements in an ADDTS Request frame to set up a traffic stream in the BSS.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

In this method, the User Priority is specified in the TCLAS element. The policy used by the AP to choose a specific method to map frames to user priorities is outside the scope of this standard.

Different external networks can use different DSCP sets for the same services as described in R.3.3. For example, a 3GPP network can use different code points from that of an enterprise network. The QoS Map distribution mechanism defined in 11.25.9 provides means to communicate to the STA's mapping information from the network.

R.3.2 Determination of the mapping for a STA

The QoS mapping to be applied depends upon the network the non-AP STA is accessing. In an interworking IEEE 802.11 infrastructure setting, the same physical AP can serve non-AP STAs from different SSPNs on different BSSIDs. As such, these STAs are separated into different BSSs. Figure R-1 presents an example of the scenario using authentication, authorization, and accounting (AAA). In Figure R-1, AAA Server 1 controls access to DN-1 and AAA Server 2 controls access to DN-2.

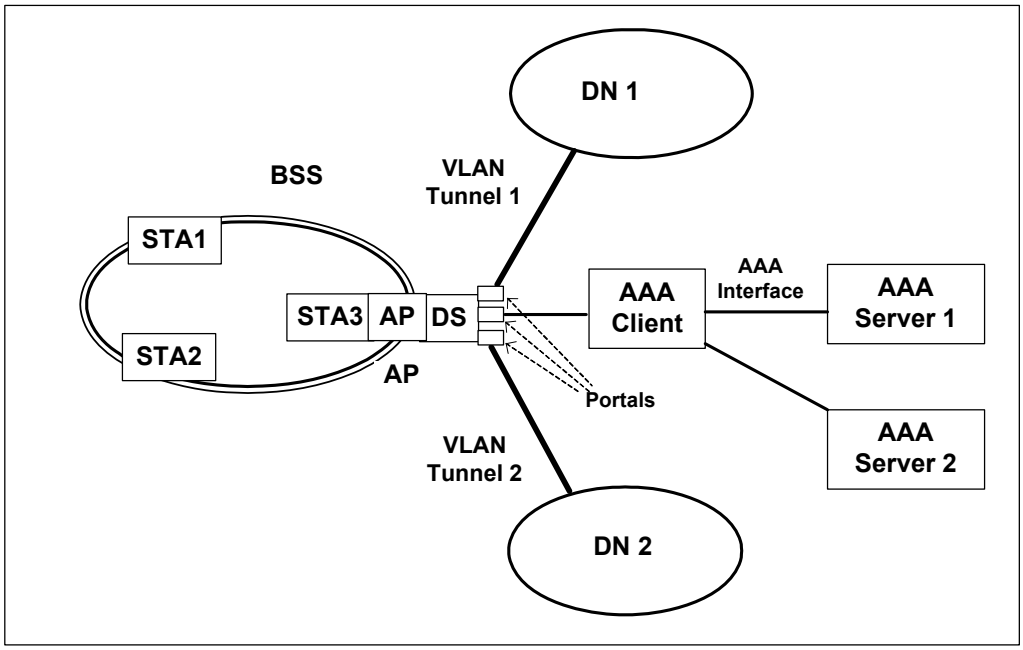

Figure R-1—Interworking IEEE 802.11 infrastructure supporting multiple SSPNs

R.3.3 Example of QoS mapping from different networks

IEEE 802.1D UPs map to EDCA ACs, as described in Table 10-1. The use of DSCP sets differs from network to network. Table R-1 shows examples of DCSP mappings.

NOTE—The mapping of the DSCP to 3GPP Traffic Class is available in GSMA, IR.34 v4.6 [B16] (similar to that of GSMA IREG34). See TR 21.905 [B2] for definition of general packet radio service (GPRS) roaming exchange. Table R-1 is extended to cover the EDCA ACs mapping. This mapping can also apply to other networks that adopt the 3GPP QoS definitions, e.g., 3GPP2.

Table R-1—Mapping table of DSCP to 3GPP QoS information and EDCA ACs

3GPP QoS Information		DiffServ PHB	DSCP	QoS Requirement on GPRS Roaming Exchange				EDCA Access Category	UP (as in IEEE Std 802.1D)
Traffic Class	THP			Max Delay	Max Jitter	MSDU Loss	MSDU Error Ratio		
Conversational	N/A	EF	101110	20 ms	5 ms	0.5%	10^{-6}	AC_VO	7, 6
Streaming	N/A	$AF4_1$	100010	40 ms	5 ms	0.5%	10^{-6}	AV_VI	5, 4
Interactive	1	$AF3_1$	011010	250 ms	N/A	0.1%	10^{-8}	AC_BE	3
	2	$AF2_1$	010010	300 ms	N/A	0.1%	10^{-8}	AC_BE	3
	3	$AF1_1$	001010	350 ms	N/A	0.1%	10^{-8}	AC_BE	0
Background	N/A	BE	000000	400 ms	N/A	0.1%	10^{-8}	AC_BK	2,1

Table R-2 shows an example mapping based on application classes defined in IETF RFC 4594. Mapping between DSCP and UP can be done using Exception fields or by range. The use of DSCP Exception fields will map a DSCP to a UP according to Table R-2. Mapping by range will require the setting of DSCP ranges as shown in Table R-3.

Table R-2—Example Enterprise DSCP to UP/AC mapping

Application Class	Per-hop behavior (PHB)	IEEE 802.1D) User Priority	Access Category
Network Control	CS6	7	AC_VO
Telephony	EF	6	AC_VO
RT Interactive	CS4	6	AC_VO
Multimedia Conference	AF4x	5	AC_VI
Signaling	CS5	5	AC_VI
Broadcast Video	CS3	4	AC_VI
Multimedia Stream	AF3x	4	AC_VI
Low Latency Data	AF2x	3	AC_BE
High Throughput Data	AF1x	2	AC_BK
OAM	CS2	3	AC_BE
Standard	DF	0	AC_BE
Low Priority/Background	CS1	1	AC_BK

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Table R-3—UP to DSCP range mapping example

UP Range	DSCP Low	DSCP High
UP 0 Range	0	0
UP 1 Range	1	9
UP 2 Range	10	16
UP 3 Range	17	23
UP 4 Range	24	31
UP 5 Range	32	40
UP 6 Range	41	47
UP 7 Range	48	63

Furthermore mapping by range will require an additional exceptional element to map DSCP 32 to UP 6.

NOTE—Twenty-one DSCP Exception fields are provided to give more flexibility in defining the QoS mapping. This number is equal to the number of FIBs (Forwarding Information Bases) defined by IETF RFC 3222.

R.4 Interworking and SSPN interface support

R.4.1 General

The interworking service architecture defines the scope of the SSPN interface. This interface is provided by the IEEE 802.11 MAC to support the interworking service. In an interworking scenario, the IEEE 802.11 infrastructure is operating in infrastructure mode.

Figure R-2 shows an example implementation of the control aspect of the Interworking Interface. As shown in the figure, the Interworking Interface consists of two parts: the generic SSPN Interface between the AP and the AAA Client; and the AAA Interface between the AAA Client and the corresponding AAA Server in the SSPN. Depending on the implementation the AAA Client can be collocated with the AP or stand alone serving as a proxy or translation agent between the SSPN Interface and AAA Interface. The AAA Interface serves as a transparent carrier of the SSPN interface.

The possible interactions over the SSPN interface are defined in 11.25.5. The information transferred over the SSPN Interface is defined in R.4.2. This interface results in parameters being set in the dot11InterworkingTable MIB. The AP's SME thereafter uses these parameters to permit or deny, as appropriate, services to non-AP STAs.

Figure R-2—Basic architecture of the interworking service

R.4.2 SSPN interface parameters

The parameters for each associated non-AP STA defined in this clause cross the SSPN Interface, i.e., between AP and AAA Client as shown in Table R-4.

Table R-4—SSPN Interface information or permission parameters

Information or permission name	From AN to SSPN	From SSPN to AN	Per non-AP STA entry
Non-AP STA MAC	+		+
Non-AP STA User ID	+	+	+
Non-AP STA Interworking Capability	+		+
Link Layer Encryption Method	+		+
Authorized Priority		+	+
Authorized Rate		+	+
Authorized Delay		+	+
Authorized Service Access Type		+	+
Authorized Service Access Information		+	+
Non-AP STA Transmission Count	+		+
Non-AP STA Location Information	+		+
Non-AP STA State Information	+		+

The SSPN Interface parameters are stored in the AP with corresponding MIB attributes as defined in Annex C, and are used by the Interworking Service Management function in the SME. The MIB variables themselves, which are used by the AP SME, are read only.

R.4.2.1 Non-AP STA MAC

This parameter is the MAC address of the non-AP STA accessing the interworking service through the AP. It can be requested by the external network, e.g., a 3GPP network, for fraud prevention. The non-AP STA MAC address is normally available through MLME SAP, e.g., MLME-ASSOCIATE.indication primitive, and should be forwarded by the AS to the AAA Server entity in the SSPN through the AAA Interface.

The following MIB attribute is used:

— dot11NonAPStationMacAddress

R.4.2.2 Non-AP STA User ID

This parameter contains the subscriber information of the non-AP STA for the interworking service. It is provided by the non-AP STA through the RSNA establishment process to the AAA Server; in turn, the AAA Server provides it back to the AP via the SSPN interface. It is in the form of an NAI, i.e., it contains both the user's identity and its SSP information.

NOTE—The reason the AAA Server provides the user identity back to the AP is that some EAP methods use encrypted tunnels to maintain confidentiality of the user and thus the AP might not otherwise be able to learn the user's identity.

The following MIB attribute is used:

— dot11NonAPStationUserIdentity

R.4.2.3 Non-AP STA Interworking Capability

This parameter is derived from the non-AP STA's Extended Capabilities element, which is included in (Re)Association Request frames.The AP SME obtains this information from the MLME SAP, e.g., MLME-ASSOCIATE.indication primitive. This information needs to be passed over the SSPN interface since the service authorization decisions can depend on the non-AP STA capabilities.

The following MIB attribute is used:

— dot11NonAPStationInterworkingCapability

R.4.2.4 Link Layer Encryption Method

This parameter indicates the link layer encryption method selected during the RSNA establishment process for protecting the unicast communication between the non-AP STA and the AP. The cipher suite format of this parameter is drawn from the RSNE defined in 9.4.2.25. The AP obtains this information about the STA via the MLME SAP.

In the interworking service, the SSPN also participates in the selection of the cipher suite selection, as described in 11.25.5. Therefore, the link layer encryption method selected will meet or exceed the security requirement of the SSPN.

NOTE—In interworking, the SSPN can require visibility and configurability of the STA access.

With this information available to the SSPN, the operator would be able to have better control, e.g., barring access to IEEE 802.11 networks if null encryption is used. This is also related to the operator network's configuration, e.g., if preauthentication should be supported.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The following MIB attribute is used:

— dot11NonAPStationUnicastCipherSuite

R.4.2.5 Authorized Priority

This parameter is used for admission control and user-priority policing at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. The Authorized Priority specifies the authorized User Priorities that the non-AP STA is allowed to use during the Interworking access. It also specifies whether the non-AP STA can use HCCA.

For EDCA operation, the following MIB attribute is used:

— dot11NonAPStationAuthAccessCategories MIB attribute after mapping the priority according to Table 10-1.

For HCCA operation, the following MIB attribute is used:

— dot11NonAPStationAuthHCCAHEMM

R.4.2.6 Authorized Maximum Rate

This parameter is used for admission control decisions or policing actions at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. For EDCA operation, this parameter contains a list of four MaxRate values indicating the maximum rate allowed for each of the access categories. For HCCA operation, there is one MaxRate value. Each of the MaxRate values is an unsigned integer and in the unit of kilobits per second. An additional value provides the maximum rate at which a non-AP STA can source group addressed frames.

The following MIB attributes are used:

— dot11NonAPStationAuthMaxVoiceRate,
— dot11NonAPStationAuthMaxVideoRate,
— dot11NonAPStationAuthMaxBestEffortRate,
— dot11NonAPStationAuthMaxBackgroundRate,
— dot11NonAPStationAuthMaxHCCAHEMMRate
— dot11NonAPStationAuthMaxSourceMulticastRate.

R.4.2.7 Authorized Service Access Type

This per-non-AP STA parameter indicates the access type allowed for the non-AP STA based on the SSPN decision. The AP will use this information for authorization requests from the STA, e.g., allow or disallow direct link operation and group addressed services. The parameter uses truth values to indicate the service type authorized.

The following MIB attributes are used:

— dot11NonAPStationAuthDls is to authorize a non-AP STA to use DLS
— dot11NonAPStationAuthMaxSourceMulticastRate is to authorize a non-AP STA to source group addressed stream(s) to toward the network

R.4.2.8 Authorized Delay

This parameter is used for admission control decisions at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. This parameter is used only for HCCA operation, and contains one value. An AP should deliver frames to a non-AP STA within the time

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

period specified in this attribute. Furthermore, when a non-AP STA requests admission control, the requested delay is approved only if it is greater than or equal to the value stored in the corresponding parameter. Each parameter is an unsigned integer that measures delay in units of microseconds.

The following MIB attribute is used:

— dot11NonAPStationAuthHCCAHEMMDelay

R.4.2.9 Authorized Service Access Information

This parameter contains the relevant information for the AP to enforce the authorized service access type indicated in the Authorized Service Access Type parameter. The Authorized Service Access parameters provide the VLAN assignment (VLAN ID and VLAN Name) to which frames to or from the non-AP STA are bridged.

The following MIB attributes are used:

— dot11NonAPStationVLANId

— dot11NonAPStationVLANName

R.4.2.10 Non-AP STA Transmission Count

This parameter indicates the count of the data traffic transmitted to and received from a non-AP STA. Such information would be used by the on-line charging and accounting function, especially for the IEEE 802.11 WLAN local service, where the data traffic does not necessarily go through the SSPN network. In such cases, Layer 3 accounting/charging information is not reliable since addresses could be spoofed. Layer 2 would be a better place to collect such information since due to the cryptographic security association that exists between the non-AP STA and AP.

The following MIB attributes are used:

— dot11NonAPStationVoiceMSDUCount,

— dot11NonAPStationVideoMSDUCount,

— dot11NonAPStation-BestEffortMSDUCount,

— dot11NonAPStationBackgroundMSDUCount,

— dot11NonAPStationHCCAHEMMMSDUCount,

— dot11NonAPStationMulticastMSDUCount,

— dot11NonAPStationVoiceOctetCount,

— dot11NonAPStationVideoOctetCount,

— dot11NonAPStationBestEffortOctetCount,

— dot11NonAPStationBackgroundOctetCount,

— dot11NonAPStationHCCAHEMMOctetCount,

— dot11NonAPStationMulticastOctetCount MIB attributes

R.4.2.11 Non-AP STA Location Information

This parameter provides information about the STA's location to the SSPN. It is required by the SSPN applying location based service control. In the IEEE 802.11 network, the non-AP STA location is approximated using the AP's location information. This parameter includes two type of formats, Geospatial and Civic Location.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The following MIB attributes are used:

— dot11APLCITable,

— dot11APCivicLocationTable

R.4.2.12 Non-AP STA State Information

This parameter indicates whether the power management mode of the non-AP STA is either active mode or PS mode.

The following MIB attributes are used:

— dot11NonAPStationPowerManagementMode

R.5 Interworking with external networks and emergency call support

R.5.1 General

Emergency services define the IEEE 802.11 functionality to support an emergency call (e.g., E911) service as part of an overall multi-layer solution, specifically capability advertisement and access to emergency services by STAs not having proper security credentials. “Multi-layer” indicates that emergency services will be provided by protocols developed in part by other standards bodies; see IETF ECRIT [B25], 3GPP TS 23.167 [B1], and 3GPP TS 22.067 [B3]. Three features of interworking with external networks support emergency call services.

The first feature is a mechanism for a non-AP STA to signal to an AP that a call is an emergency call. This is useful in the case where the access category to be used to carry the emergency call traffic (typically AC_VO) is configured for mandatory admission control. If the WLAN is congested, then the AP can deny the TSPEC request for bandwidth to carry the call. However, if the AP is able to determine that the call is an emergency call, then it can invoke other options to admit the TSPEC request.

The second and third features provide the means for a client without proper security credentials to be able to place an emergency call. The second feature makes use of the Interworking element, which can be included in Association Request frames in order to bypass the IEEE 802.1X port at an AP for unauthenticated access to emergency services. This is described further in R.5.5. The third feature makes use of an SSID configured for Open Authentication to provide emergency services and is described in R.5.3.

The STA has the burden to confirm the availability of emergency services from the IEEE 802.11 network, including that the network is authorized for emergency services. The time it takes for a client to find an authorized emergency services network is related to the speed of forward progress the authorized network can make over the air with the STA, relative to all of the other networks (attackers as well), and is inversely related to the number of false advertisements. A STA can confirm the availability of emergency services by observing the value of the access network type, ESR and UESA fields in the Interworking element of any received Beacon or Probe Response frame.

R.5.2 Background on emergency call support over IEEE 802.11 infrastructure

Special handling for emergency service calls is required over IEEE Std 802.11. To use a public hotspot a user will go typically through an authentication process (e.g., EAP-based, or http/https redirect or DNS redirection) before being able to use it for emergency calls.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

There is a need to support these emergency services both when the user has a relationship with the IEEE 802.11 network (credentials to access the network) and when it does not have any relationship with the IEEE 802.11 network.

The former case requires no changes to the authentication process—the user, having already been authenticated to and associated with the WLAN, simply dials the emergency number thereby placing the call.

In the latter case, the non-AP STA will be able to gain access to the network without using security credentials and make an emergency call.

Another difficulty is that once the user gains access to the network, there is no mechanism to prioritize their emergency traffic in the IEEE 802.11 MAC over that of other users, even with IEEE 802.11 QoS capability.

Supporting emergency services, such as E911 calling, requires a multi-layer solution with support at various protocol layers. Apart from MAC level access and support for transfer of data between non-AP STA and AP with appropriate QoS at layer 2, there is a clear need, above this layer, to set up the call, conduct call control and management, and use an appropriate audio codec.

One specific example is when a user arrives in a new country and needs to make an emergency call in a public hotspot where there is no prior relationship with the available WLAN network or WLAN hotspot operator.

NOTE—The callback feature, if required in a regulatory domain, is dealt with at a higher layer.

R.5.3 System aspects for emergency call support

An IEEE 802.11 infrastructure by itself cannot ensure that all factors are compatible for an emergency service call to actually take place. The client device might have to register with a call manager (SIP agent or some other signaling endpoint) for the call to be placed successfully. Different signaling systems such as SIP, H.323, etc., can be deployed for supporting emergency service calling. Higher layers can also verify an emergency service call is being placed so that appropriate level of resources can be granted to the emergency call. Voice endpoints (e.g., non-AP STAs) can use different codecs such as G.711, AMR, and iLBC. All these functionalities are outside the scope of this standard.

IEEE Std 802.11 can provide priority for emergency traffic both for the initial call establishment and during an ongoing emergency call, which assumes advertisement of this functionality supported in the BSS.

This subclause describes general design assumptions to support emergency services with IEEE Std 802.11:

a) It is assumed that there is a higher layer (above IEEE 802.11 Layer 2) protocol (or protocol suite) for making emergency calls or using any other emergency services.
b) In order to make the emergency call procedure work properly, the non-AP STA has the following responsibilities:
    1) Recognize the user’s request to make an emergency call.
    2) Select an AP that supports QoS and EBR capability.
    3) Non-AP STA will associate with the AP if it is not already done so. In an RSN, if the user does not have valid authentication credentials for network access then non-AP STA can bypass the RSN that will provide access to the network to make emergency calls.
    4) If location information is required in a particular regulatory domain, request location information from the WLAN. If the STA cannot determine its own location by its own means, then Location information should be obtained from the network prior to initiating the

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

emergency call request. There are two methods a non-AP STA can use to obtain location services from the IEEE 802.11 network:

i) If the non-AP STA can use location information in geospatial format (i.e., latitude, longitude and altitude), then the LCI report procedures (11.11.9.6) can be used to obtain this information. The AP advertises its capability for the LCI report procedures by setting the LCI Measurement Capability Enabled field to 1 in the RM Enabled Capabilities field in the RM Enabled Capabilities element, and the non-AP STA transmits an LCI request to the AP.

NOTE—The non-AP STA can receive an LCI report with the incapable field set. According to the procedures in 11.11.9.6, the non-AP STA can resubmit an LCI request with a location subject of "remote." If the AP still responds with incapable, then location services are not available from the AP via the LCI report procedures.

ii) If the non-AP STA requires location information in Civic or geospatial formats, then an AP's wireless network management capability can be used. In this case, an AP advertises its ability to provide its location in Civic or geospatial format by setting the Civic Location or Geospatial Location field in the Extended Capabilities element to 1 respectively in the Beacon frame. A non-AP STA can also request its location using the procedures in 11.25.7. An AP that advertises its ability to provide its location in civic or geospatial format does not return an "incapable" response if a requesting STA requests the "remote" location.

5) Selects one of possibly several SSPNs advertising support for emergency services and VoIP service.

c) There are two methods described in this annex by which a user lacking security credentials can gain access to the network. The method selected in any particular deployment is at the discretion of the IEEE 802.11 infrastructure provider, SSPN or system administrator as appropriate. The AP and non-AP STA should permit users lacking security credentials to gain access to a network using one of two methods:

1) Using an emergency services association (see 9.4.2.92) in a BSS configured for RSNA. Using this type of association means the AP and non-AP STA will exchange unprotected frames for emergency service access only during the lifetime of the association. In this situation, cryptographic keys are not exchanged, the IEEE 802.1X uncontrolled port is bypassed without invoking the IEEE 802.1X state machine. Since protection is used for authenticated STAs, their traffic is protected.

2) Using an SSID configured for Open System authentication. Network elements necessary to complete an emergency call are reachable via this SSID. How to reach these network elements (e.g., a call manager) and which protocol to use (e.g., SIP) are outside the scope of this standard.

d) The AP can separate the backhaul of emergency services traffic from other traffic, typically via a dedicated VLAN.

To ease burden of implementation on the network side, some basic means should exist to allow easy filtering, routing and basic access control of "regular" BSS traffic and emergency-type BSS traffic. This can be assisted by the downloading of emergency call number information, as described in 9.4.5.5.

R.5.4 Description of the Expedited Bandwidth Request element

For access categories configured for mandatory admission control, a non-AP STA requests bandwidth using a TSPEC element in an ADDTS Request frame. The TSPEC Request includes parameters describing the characteristics of the traffic stream, but no information on the use of the traffic stream. The Expedited Bandwidth Request (EBR) element describes the "use" of a traffic stream. To use this element, it is the responsibility of the station to transmit this element in response to certain call signaling messages. How this

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

is done is outside the scope for the interworking service. The following bandwidth uses are provided in the EBR element:

— Emergency call, defined in NENA 08-002 [B56]
— Public first responder (e.g., fire department)
— Private first responder (e.g., enterprise security guard)
— Multi-level precedence and preemption (MLPP)

MLPP services are provided by other voice networking technologies such as 3GPP (see 3GPP TS 22.067 [B3]), H.323 (see ITU-T H4.60.14) and other proprietary signaling protocols. MLPP is used as a subscription service to provide differentiated levels of consumer service; it is also used by military organizations so that commanding officers will not get a network busy signal.

If the AP is provided additional information regarding the nature of the Traffic Stream, it can invoke additional policy that can be configured on the AP to accept the TSPEC request when it would be otherwise denied. Policy configured at AP defines how bandwidth is allocated. Specification of these policies is outside the scope of interworking with external networks. Policy examples include the following:

— No action
— Preemptive action: delete a TS of lower priority if necessary to make room for new TS
— Use capacity allocated for nonvoice services if priority is above a certain value (assuming TSPEC is for AC_VO)
— Interpret MLPP codes as defined 3GPP specification
— Interpret MLPP codes as defined in proprietary specification

R.5.5 Access to emergency services in an RSN

If an infrastructure BSS requires authentication and encryption with RSN, a non-AP STA placing an emergency call associates and authenticate to the network by using an emergency services association (see 9.4.2.92). If the non-AP STA has user credentials that allow it to use a particular network, the non-AP STA can use its credentials to authenticate to the SSPN through the IEEE 802.11 infrastructure.

When a mesh STA has an emergency services association, and it receives a Mesh Peering Open frame that includes the Interworking element, with ASRA bit equal to 1 and UESA bit equal to 0, and the Authenticated Mesh Peering Exchange element (see 9.4.2.118) it allows access to emergency services. If the mesh STA has user credentials that allow the accessing mesh STA to use the mesh network, the mesh STA can use its credentials to authenticate with the accessing mesh peer.

In order to use an emergency services association in an infrastructure BSS, a STA lacking security credentials can associate with a BSS in which emergency services are accessible by including an Interworking element with the UESA field set to 1 in a (Re)Association Request frame. An AP receiving this type of (re)association request recognizes this as a request for unauthenticated emergency access. The AP can look up the VLAN ID to use with a AAA Server, or it can have an emergency services VLAN configured. The STA can either have, policies configured locally for quality-of-service parameters and network access restrictions, or it can look them up through external policy servers. When a mesh STA has an emergency services association, and it receives a Mesh Peering Open frame, from a mesh STA lacking security credentials, that includes the Interworking element, with ASRA bit equal to 1 and UESA bit equal to 1, and the Mesh Peering Management element (see 9.4.2.102) it allows access to emergency services.

When an emergency services association is used, an infrastructure BSS or an MBSS should be designed to restrict access to emergency services only (or alternatively prioritize the emergency services to the highest level of access). Methods of such restriction are beyond the scope of this standard, but can include an isolated VLAN for emergency services, filtering rules in the AP or network entity (e.g., router) in an

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

external network to limit network access to only network elements involved in emergency calls, and per-session bandwidth control to place an upper limit on resource utilization.

R.6 Peer information

Peer information allows TDLS peer STAs to discover their capabilities. An example of peer information could be expressed in an XML format as follows:

```
<Peer information>
    <mode> tdls </mode>

    <wireless info>
        <mac address> 00-01-02-03-04-05 </mac address>
        <bssid> 00-0a-0b-0c-0d-0e </bssid>
    </wireless info>

    < network info>
        < DHCP> No</DHCP>
        < IP address>192.168.2.1 </IP address>
        < Subnet> 255.255.255.0 </subnet>
        <Hostname> myphone </Hostname>
    </network info>
</Peer information>
```

The minimum required peer information for TDLS is contained in “wireless info.” The “mac address” field contains the MAC address of the transmitting STA and the “bssid” identifies the BSS in which the STA is a member. The “network info” could optionally be used to aid the peer devices in establishing a TDLS link.

R.7 Calculating Estimated Throughput

In response to the receipt of MLME-ESTIMATED-THROUGHPUT.request, ESP STAs can determine values for EstimatedThroughputInbound and EstimatedThroughputOutbound for each AC of a current or potential link to another STA using Equation (R-1):

$$EstimatedThroughput = \frac{EST_{AirtimeFraction} \times MPDU_{pPPDU} \times A_MSDU_B \times 8}{PPDU_{Dur}} \quad \text{(R-1)}$$

where

$EstimatedThroughput$	is in bits/second
$PPDU_{Dur}$	is the expected duration of a single PPDU, in seconds
$EST_{AirtimeFraction}$	is dimensionless. It is the estimated portion of airtime that is available for outbound transmissions for this link as indicated in the Estimated Service Parameters element received from the STA with the MAC address that matches the PeerMACAddress in the MLME-ESTIMATED-THROUGHPUT.request primitive
min(x,y)	is the minimum of x and y
max(x,y)	is the maximum of x and y

$MPDU_{pPPDU}$ = min(BA_WIN_Size, max(1,$MPDU_pA_MPDU$))

BA_WIN_Size = min($BA_WIN_Size_{TX}$,$BA_WIN_Size_{RX}$)

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

$BA_WIN_Size_{TX}$ is the expected block ack window size of the transmitter of the PPDUs containing MPDUs with the Type field equal to Data

$BA_WIN_Size_{RX}$ is the expected block ack window size of the receiver of the PPDUs containing MPDUs with the Type field equal to Data

$$MPDU_pA_MPDU = \min\left(\left\lceil \frac{PPDUR}{MPDU_{SS}} \right\rceil, \left\lceil \frac{PPDUR \times DataRate}{(MAC_{Hdr} + A_MSDU_B) \times 8} \right\rceil\right)$$

MPDU_pA_MPDU is dimensionless

$PPDUR = DPDUR - PHDUR$

PPDUR is the PPDU payload duration, in seconds

DPDUR is the Data PPDU duration target of the transmitter of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds

PHDUR is the PHY header duration, estimated based on the expected PPDU format of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds

$MPDU_{SS}$ is the minimum MPDU start spacing of the receiver of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds

MAC_{Hdr} is the number of octets of MAC header information for an A-MSDU

$A_MSDU_B = \min(A_MSDU_B_{TX}, A_MSDU_B_{RX})$

$A_MSDU_B_{TX}$ is the maximum A-MSDU size of the transmitter of the PPDUs containing MPDUs with the Type subfield equal to Data, in octets

$A_MSDU_B_{RX}$ is the maximum A-MSDU size of the receiver of the PPDUs containing MPDUs with the Type subfield equal to Data, in octets

$$PPDU_{Dur} = \left\lceil \frac{(MAC_{Hdr} + A_MSDU_B) \times MPDU_{pPPDU} \times 8}{DataRate \times DSYM_{DUR}} \right\rceil \times DSYM_{DUR} + PHDUR$$

$DSYM_{DUR}$ is the duration of one PPDU payload symbol for the expected PHY format of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds. If multiple symbol durations are possible, then the shortest symbol duration is assumed

DataRate is calculated using equation Equation (R-2), in b/s

$$DataRate = \min(\log_2(1 + SNR_tone), MaxBitsPerSc) \times \frac{NSS_max \times Ntone}{DSYM_{DUR}} \quad \text{(R-2)}$$

where

$$SNR_tone = 10^{\frac{RSSI + P_{adjust}}{10}}$$

RSSI is the RSSI of Beacon or Probe Response frames received from the STA with the MAC address that matches the PeerMACAddress in the MLME-ESTIMATED-THROUGHPUT.request primitive, in dBm

P_adjust is the implementation specific power adjustment parameter used to convert RSSI into SNR, as well as take into account potential transmit power differences between Beacon/Probe Response frames to data frames, in dBm.

NSS_max is the maximum number of spatial streams allowed in the link based on the capabilities of the two STAs

Ntone is N_SD × N_Seg if the expected PPDU format is VHT, and N_SD otherwise, where N_SD is defined as number of subcarriers in Table 17-16 for non-HT format, NSD in Table 19-6 for HT format and NSD in Table 21-5 for VHT format. If multiple PPDU bandwidths are available, the N_SD of the widest

possible PPDU bandwidth allowed between the two STAs based on capabilities is assumed.

$$MaxBitsPerSc = \begin{cases} \frac{40}{6}, \text{ if 256-QAM 5/6 modulation is allowed in the link} \\ 6, \text{ if 256-QAM 3/4 modulation is allowed in the link} \\ \quad \text{but 256-QAM 5/6 modulation is not} \\ 5, \text{ otherwise} \end{cases}$$

Note that some of the parameters of Equation (R-2) have values that are AC dependent.

Annex S

(informative)

Mesh BSS operation

S.1 Clarification of mesh Data frame format

A mesh Data frame consists of MAC header, frame body, and the FCS. The fields in the MAC header are described in 9.2.3.

In a mesh Data frame containing a single MSDU, the Mesh Control field is placed immediately before the Data (PDU) in the encrypted Frame Body. The Data (PDU) comprises the LLC/SNAP headers and the higher layer data. This is shown in the example frame format for a CCMP-128-encrypted mesh Data frame containing a single MSDU in Figure S-1.

When the mesh Data frame is fragmented, only the first fragment contains the Mesh Control field.

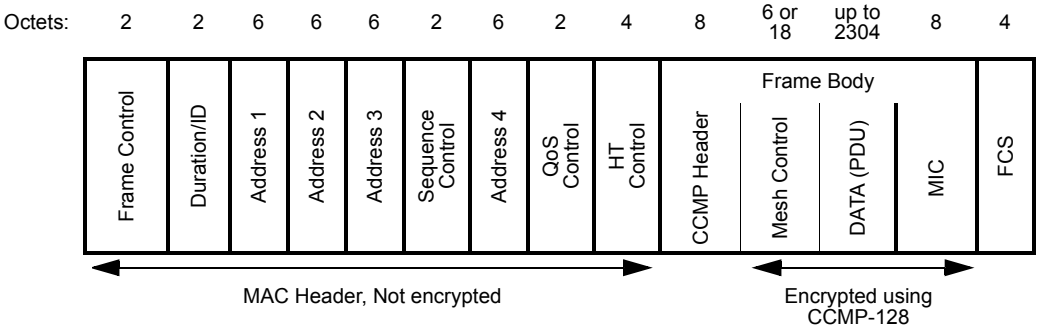

Figure S-1—Format of a CCMP-128-encrypted mesh Data frame containing a single MSDU

NOTE—A DMG STA does not send mesh Data frames, and all other STAs have a maximum MSDU size of 2304 octets (see Table 9-19).

S.2 Operational considerations for interworking

S.2.1 Formation and maintenance of the IEEE 802.1D spanning tree

No special action is required to support formation of the IEEE 802.1D spanning tree. Spanning tree control messages are typically delivered to bridges in group addressed frames. These messages are Data frames from the point of view of the mesh BSS.

S.3 Power save parameters selection

S.3.1 General

Power save mechanisms enable mesh STA operation in doze state. In doze state a mesh STA might set the transceivers off. The power save mechanism might adjust the mesh power management mode of a mesh STA for various reasons that are beyond the scope of the standard, including but not limited to traffic load or scanning and network maintenance needs.

This annex specifies recommendations on how a mesh STA selects mesh power management modes based on traffic load, recommendations on how to do scanning in mesh BSSs that might contain mesh STAs in light or deep sleep mode, and recommended default values for power save related parameters.

S.3.2 Selecting the mesh power management mode based on traffic load

A mesh STA might adjust its mesh power management mode based on the traffic load or the QoS requirements of the forwarded traffic. If a mesh STA has high traffic load or if a mesh STA is congested, the mesh STA should operate in active mode on the corresponding mesh peering to reduce delays or overhead that might be created by the operation in light or deep sleep mode.

A mesh STA might consider staying in active mode for all peer mesh STAs, even if only a single link is congested. When mesh STA operates in active mode, the mesh STA might receive frames at any time and mesh peer service periods might be triggered on demand, as in case of an AP that receives a trigger frame at times controlled by a non-AP STA.

If traffic load is moderate or low and best effort data is transmitted, a mesh STA might consider staying in light sleep mode for all or some mesh peerings. The mesh STA in light sleep mode for a mesh peering receives beacons from the peer mesh STA with periodic indication of buffered traffic.

If traffic load is low or no traffic is transmitted, a mesh STA might consider staying in deep sleep mode for a mesh peering. The mesh STA does not need to wake up to receive a beacon from the peer mesh STA to which it is in deep sleep mode.

The mesh STA might use deep sleep mode to control the number of times it enters the awake state to receive Beacon frame from a peer mesh STA. If the mesh STA is in deep sleep mode for all of its mesh peering, the mesh STA needs only to remain in awake state during its own beacon transmission and mesh awake window.

The mesh STA that forwards real time traffic (AC3 or AC2 with EDCA) should be in active mode for the corresponding link. A mesh STA forwarding real time traffic with EDCA might stay in light or deep sleep mode for the corresponding link, if the mesh STA is capable of initiating mesh peer service periods frequently and the other forwarding peer mesh STAs are in active mode. Poor handling of the mesh power management modes might result to delays and inappropriate QoS of the forwarded MSDUs.

S.3.3 Scanning of mesh BSSs

A mesh BSS might have mesh STAs that alternate awake state and doze state. With active scanning only devices in awake state at the transmission time of Probe Request frame might be found. However, with passive scanning also mesh STAs in light or deep sleep mode for a mesh peering can be found.

Since mesh STAs in light or deep sleep mode might transmit beacons at long intervals, a mesh STA seeking for candidate mesh STAs for a new mesh peerings should perform passive scanning relatively for a longer

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

time compared to passive scanning in BSS infrastructure mode. Mesh STAs in light or deep sleep mode with long DTIM interval might not be discovered with short scanning durations. Mesh STAs that operate in light or deep sleep mode for a mesh peering might use a short DTIM interval, if they intend to establish new mesh peerings.

S.3.4 Default parameters

The following are the recommended default values for power save related parameters for mesh STAs:

Table S-1—Default parameters for mesh STAs that intend to operate in light or deep sleep mode for mesh peerings

	For moderate power save	For aggressive power save
Beacon period	200 TU	800 TU
DTIM Period	4	1
Mesh awake window	10 TU	10 TU

A mesh STA that is eager to conserve power and likely to remain in deep sleep mode with most of the mesh peerings should utilize the value from aggressive power save parameters.

Although mesh STAs might utilize individual parameters regardless of the parameters used by neighbor mesh STAs or peer mesh STAs, each implementer should recognize balance between the power save efficiency and delay in the service initiation.

S.3.5 MSDU forwarding in an MBSS containing mesh STAs in light or deep sleep mode

The battery powered mesh STAs should avoid forwarding MSDUs, to avoid power consumption and possible additional delays and inefficiencies that power save mechanisms might cause. If a light or deep sleep mode mesh STA forwards MSDUs, it should select its mesh power management mode based on the traffic load and the traffic type as described in S.3.2.

A mesh STA might save power by selecting the light or deep sleep mode for a mesh peering as follows:

— A mesh STA that is “mains powered” might apply light or deep sleep mode if it does not have MSDUs to forward

— A mesh STA that is “battery powered” might freely use all mesh power management modes

Mesh STAs that are in light or deep sleep mode for a mesh peering might degrade the corresponding link metric value. The use of worse metric values reduces the probability of a link being used for MSDU forwarding. If the mesh STA will operate in active mode for the link in forwarding path, it should apply the link metric value without degradation.

S.3.6 Synchronization maintenance of mesh STAs in deep sleep mode

A mesh STA in deep sleep mode for a mesh peering might not receive Beacon frames from the corresponding peer mesh STA, but the mesh STA is required to maintain synchronization with the neighbor peer mesh STAs. Neighbor offset synchronization method imposes the maintenance of TSF offset values

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

between neighbor peer mesh STAs, which generally requires the reception of Beacon frame or Probe Response frame. The simplest way to maintain the synchronization is that the mesh STA in deep sleep mode for a mesh peering listens to the corresponding peer mesh STA's Beacon frame for certain periods and check the TSF offset value.

S.5 Airtime link metric usage example

The airtime cost constants (Table 14-4) and estimates of the average data rate and frame error rate will vary from one implementation and configuration of the IEEE 802.11 PHY and MAC to the other. While no mechanism is defined to measure the average data rate and the frame error rate, numeric values are not expected to exhibit large variations in amplitude over the lifetime of a path. Unstable measurements might cause path selection instabilities.

An example of an airtime link metric is provided to illustrate how it might be calculated.

Assume a DSSS PHY with an average data rate of 1 Mb/s to a given neighbor and a frame size of 8192 bits.

The overhead O for the Data frame comprises the PHY preamble (144 μs) and the PHY header (48 μs). The payload Bit is 8192 bits at an r of 1 Mb/s, or 8192 μs. The data transmission time is therefore 8416 μs. Other transmission times for different frame types are calculated in the same way (based on their size, rate, and overhead).

If RTS/CTS is used, the data transmission time (including PHY preamble and header) is 8416 μs, the RTS transmission time (including PHY preamble and header) is 352 μs, the CTS frame transmission time (including PHY preamble and header) is 304 μs, the Ack frame transmission time (including PHY preamble and header) is 304 μs and the interframe spacing overhead is 390 μs. The total time, including overhead, is 9766 μs.

This airtime and overhead value is converted to units of 0.01 TU (10.24 μs), i.e., 953.71 (rounded to 954).

If the frame error rate to the neighbor is 0%, the metric is 954. If the frame error rate is 80%, the metric is 4769 (i.e., 953.71/(1–0.8), rounded).

S.6 Generation of proactive PREP elements in the proactive PREQ mechanism of HWMP

S.6.1 General

In the proactive PREQ mechanism of HWMP, the generation of a proactive PREP element in response to the receipt of a proactive PREQ element depends on the value of the Proactive PREP subfield in the received proactive PREQ element (see 14.10.4.2). Furthermore, if the Proactive PREP subfield is 0, the mesh STA

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

might respond with the proactive PREP element in case it needs a bidirectional path between the root mesh STA and itself. This is usually the case if the mesh STA has data to be sent to the root mesh STA. This clause provides a unified mechanism that controls the generation of proactive PREP elements in the proactive PREQ mechanism of HWMP.

A proactive PREQ element is defined by all of the following:

— The Target Address is set to all 1s; and

— The TO subfield in the Per Target Flags field is 1.

S.6.2 Additions to forwarding information

The forwarding information to a root mesh STA contains two additional Boolean information fields. The Proactive PREP field indicates whether the mesh STA will generate a proactive PREP element to the root mesh STA in response to a proactive PREQ element (Proactive PREP = 1) or not (Proactive PREP = 0). The Proactive PREP Sent field indicates whether the mesh STA has sent a proactive PREP element to the root mesh STA (Proactive PREP Sent = 1) or not (Proactive PREP Sent = 0). Both fields are initialized with 0.

S.6.3 Actions when sending Data frames as source mesh STA

If a mesh STA receives proactive PREQ elements with the Proactive PREP subfield set to 0, the recipient mesh STA sends a proactive PREP element before sending a Data frame as source mesh STA only if the mesh STA has data to send to the root mesh STA, which requires establishing a bidirectional path with the root mesh STA and the field Proactive PREP Sent of the forwarding information to the root mesh STA is not set (=0).

If the mesh STA sends a Data frame as source mesh STA to the root mesh STA, the mesh STA sets the field Proactive PREP of the forwarding information to 1.

S.6.4 Actions on receipt of a proactive PREQ element

If the mesh STA receives a proactive PREQ element, the field Proactive PREP Sent of the forwarding information to the root mesh STA is set to 0. If the field Proactive PREP of the forwarding information to the root mesh STA is 1, the mesh STA generates a proactive PREP element to the root mesh STA (see 14.10.10.3 Case D), sets the field Proactive PREP of the forwarding information to 0, and sets the field Proactive PREP Sent of the forwarding information to 1.

If the Proactive PREP subfield of the Flags field of the received proactive PREQ element is 1, the mesh STA sets the field Proactive PREP of the forwarding information to the root mesh STA to 1.

S.6.5 Generation of proactive PREP elements

A mesh STA will generate a proactive PREP element according to 14.10.10.3 Case D if one of the following applies:

— [The mesh STA has received a proactive PREQ element] AND [in the forwarding information to the root mesh STA of the proactive PREQ element, field Proactive PREP is set to 1 AND field Proactive PREP Sent is set to 0].

— [The mesh STA has data to send to the root mesh STA, which requires establishing a bidirectional path with the root mesh STA] AND [the field Proactive PREP Sent of the forwarding information to the root mesh STA is not set (=0)].

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

If the mesh STA generates a proactive PREP to the root mesh STA, the field Proactive PREP Sent of the forwarding information is set to 1 and the field Proactive PREP of the forwarding information is set to 0.

S.7 Generation of PREQ elements in proactive RANN mechanism of HWMP

S.7.1 General

In the proactive RANN mechanism of HWMP, the generation of a PREQ element for root path confirmation in response to the receipt of a RANN element depends on the path metric from the mesh STA to the root mesh STA as computed by the RANN element propagation. However, the RANN mechanism does not set up the necessary forwarding information. This is done with individually addressed PREQ elements. This clause provides further details to the generation of individually addressed PREQ elements in the proactive RANN mechanism of HWMP.

An individually addressed PREQ element is defined by the following:

— The Addressing Mode subfield in the Flags field is 1 (individually addressed).

S.7.2 Additions to forwarding information

The forwarding information to a root mesh STA contains an additional address field. The RANN element Sender Address field contains the MAC address of the neighbor peer mesh STA that has sent the RANN element with the best metric.

S.7.3 Actions when sending Data frames as source mesh STA

If the mesh STA sends a Data frame as source mesh STA to the root mesh STA, the mesh STA uses the forwarding information to the root mesh STA. The RANN element Sender Address is not used for forwarding mesh Data frames to the root mesh STA.

S.7.4 Actions on receipt of proactive RANN element

If the mesh STA receives a proactive RANN element, the field RANN element Sender Address of the forwarding information to the root mesh STA is set to the sender of the RANN element if the metric to the root mesh STA is better than the path metric of the existing mesh path in the forwarding information.

In this case, the mesh STA generates an individually addressed PREQ element to the root mesh STA—see 14.10.10.3 Case D (Root Path Confirmation (Original Transmission)). This individually addressed PREQ element is not sent according to the general forwarding information. Instead, it is sent to the neighbor peer mesh STA indicated in the RANN element Sender Address field.

Since all mesh STAs between the mesh STA and the root mesh STA have already a value in the RANN element Sender Address field, the individually address PREQ element will eventually reach the root mesh STA. Since the TO subfield in the Per Target Flags field is 1, only the root mesh STA will generate a PREQ element as reply to the individually addressed PREQ element.

The individually addressed PREQ elements will set up forwarding information (that can be used for forwarding mesh Data frames) from the root mesh STA toward the mesh STA that initiated the root path confirmation in all intermediate mesh STAs according to the normal HWMP procedures.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Note, since the PREQ element is sent in an individually addressed frame, every sender of the individually addressed PREQ element will be able to determine whether the next mesh STA toward the root mesh STA has received the PREQ element.

The root mesh STA will generate a PREP element according to the normal HWMP procedures—see 14.10.10.3 Case A (Original Transmission).

S.7.5 Actions on receipt of a PREP element

The PREP element generated by the root mesh STA will be forwarded on the mesh path from the root mesh STA to the mesh STA as set up by the individually addressed PREQ element. The PREP element will be propagated and will eventually reach the mesh STA. The PREP element will set up forwarding information (that can be used for forwarding mesh Data frames) toward the root mesh STA in the mesh STA that initiated the root path confirmation and in all intermediate mesh STAs on this path according to the normal HWMP procedures.

After establishing the forwarding information (mesh path) toward the root mesh STA, the path to the root mesh STA is updated to the better one.

Note that since the PREP element is sent in an individually addressed frame, every sender of the PREP element will be able to determine whether the next mesh STA has received the PREP element.

Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

Annex T

(informative)

Overlapping BSS (OBSS) management

T.1 Introduction

When two or more BSSs overlap, the available bandwidth is shared and hence reduced for each BSS. The basic access mechanism, such as DCF, is able to work across OBSSs. Similarly, if EDCA is used, the OBSS might be considered a larger network, and access to the WM is basically shared according to the EDCA access mechanism. Note that for both DCF and EDCA overlapping networks, the sharing is affected by the relative traffic; and if more than two APs are sharing, the problem of "neighbor capture" might occur. The neighbor capture effect might occur when a BSS is in the middle of two other BSSs that are hidden from each other, where it might suffer a disproportionate degradation in throughput, relative to the total traffic in all three BSSs. A particular problem arises when there is some expectation of QoS. If EDCA admission control is in use, then it can be used to regulate the QoS traffic on its own BSS, but it might not take into account the EDCA admitted traffic on an OBSS. The result is that the QoS is compromised if each BSS admits traffic up to its local maximum. Similarly a BSS using HCCA might schedule traffic in its own BSS, to "guarantee" a service, but, if not controlled, this might suppress overlapping EDCA admission control BSS. Furthermore, if two HCCA BSSs overlap and they do not coordinate their scheduled TXOPs, then a degradation of QoS might result. The features described in this annex have been introduced in order to allow a degree of management for OBSSs and for mitigation of the basic problems outlined above.

T.2 QLoad Report element

T.2.1 General

The fields and their uses in the QLoad Report element are as follows:

— Potential Traffic Self field value represents the potential QoS traffic load that this AP is expecting and is provided as an indication to other APs that might be considering selecting the same channel and for sharing when an OBSS situation occurs. The Potential Traffic Self field also includes the peak number of AC_VO and AC_VI EDCA streams.

— Allocated Traffic Self field value represents the total QoS traffic and the numbers of AC_VI and AC_VO streams that are active at that time. This field is provided to enable an on-demand sharing scheme. It might be used by the other APs in OBSSs to determine if the AP has either overallocated in a proportional sharing scheme or is using an on-demand sharing scheme.

— Allocated Traffic Shared field contains the sum of the Allocated Traffic Self field values for OBSSs and is used to protect an AP from the neighbor capture effect where an AP that has neighbors that are hidden from each other. It indicates to other APs in OBSSs if this AP has either overallocated in a proportional sharing scheme, or might be using an on-demand sharing scheme.

— EDCA Access Factor field value represents the total QoS traffic bandwidth requirement for all of the APs in OBSSs and is used to indicate potential overallocation. It also enables a proportional sharing scheme. The Potential Traffic Self fields from QLoad Report elements of nearby co-channel APs are used for estimating the overhead bandwidth required due to EDCA contention and is used in the determination of the EDCA Access Factor.

— HCCA Peak field value represents the total peak HCCA TXOP requirement for the BSS and is provided so that other overlapping APs can determine whether the AP has overallocated.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

— HCCA Access Factor field contains the sum of all of the HCCA Peak field values in all of the QLoad Reports of all of the overlapping APs, including its own. This value is used when HCCA APs are sharing as defined in 11.28.2.

— Overlap field value is the number of other APs that are on the same channel and from which Beacon frames are being regularly received. It might be used to aid the channel selection process.

T.2.2 Calculating medium time

This annex uses the function defined in Equation (T-1) for calculating and estimating medium times in both ACM and non-ACM QoS modes:

$$\text{mediumTime}(s,d,m,p) = s \times pps \times MPDUExchangeTime \quad \text{(T-1)}$$

where

$$pps = \left\lceil \frac{d}{8 \times m} \right\rceil \quad \text{(T-2)}$$

$$MPDUExchangeTime = \text{duration}(m,p) + SIFS + \text{duration}(14,p) \quad \text{(T-3)}$$

duration() is the PLME-TXTIME primitive that returns the duration of a frame based on its payload size and the PHY data rate employed.

s, *d*, *m* and *p* are parameters that are passed in to the mediumTime function

(Also see the definition of MPDUExchangeTime in 10.22.4.2.3.)

T.2.3 Calculation of potential traffic self

The Potential Traffic Self field value represents the sum of all of the streams derived from all of the potential EDCA admission control and HCCA QoS traffic. The individual TSPEC elements provided by the non-AP STAs are used by the AP to calculate mean, maximum, and minimum values for

— Medium time, in multiples of 32 μs per second, in the case of EDCA admission control

— HCCA medium time, in the case of HCCA; where HCCA medium time is the TXOP time scheduled by the HC converted to multiples of 32 μs over a 1 s period, by dividing the scheduled TXOP time by the SI that the HC has allocated

The AP maintains a <mean, standard deviation, AC_VO, AC_VI> tuple that contains the maximum values from Allocated Traffic Self field. The values of this tuple are calculated using

a) The mean and standard deviation from the Allocated Traffic Self field that had the largest value of the Mean subfield

b) The AC_VO Streams subfield from the Allocated Traffic Self field that had the largest value

c) The AC_VI Streams subfield from the Allocated Traffic Self field that had the largest value

This <mean, standard deviation, AC_VO, AC_VI> tuple is calculated over fixed, consecutive seven-day periods and is reset at the start of each new period. If, at any time, any of the maximum values in the tuple are greater than those in the corresponding subfields of the Potential Traffic Self field, then those fields in the Potential Traffic Self field are set to the value(s) in the tuple. If the AP refuses an ADDTS request due to a perceived overallocation (for example, step b) 4) in the proportional sharing scheme described in T.4.2.2), then the AP adds the TSPEC values of the rejected request to the tuple.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

At the end of each seven-day period, if any of the maximum values in the tuple are less than those in the corresponding subfields of the Potential Traffic Self field, then those subfields in the Potential Traffic Self fields are set to the value(s) in the tuple.

NOTE—It is not required that the start and end of the seven-day periods be synchronized across OBSSs. After the first seven-day period, each AP advertises its correct potential load irrespective of its start time.

TSPECs provide for mean, maximum, and minimum bit rate values, which allow for statistical multiplexing of streams. The result of summing multiple streams is a composite stream, which should be reported in the Potential Traffic Self field. The summing of streams to produce a composite stream is achieved by using the mean and standard deviation of each stream.

The mean (MEAN), maximum (MAX), and minimum (MIN) values of the medium time or HCCA medium time should be calculated using the values provided in the individual TSPECs, as follows:

For a TSPEC for stream, i, the mean value, μ, is:

$$MIN_i = \text{mediumTime}(\textit{Surplus Bandwidth Allowance, Nominal MSDU Size, Minimum Data Rate, Minimum PHY Rate}) \quad \text{(T-4)}$$

$$MEAN_i = \text{mediumTime}(\textit{Surplus Bandwidth Allowance, Nominal MSDU Size, Mean Data Rate, Minimum PHY Rate}) \quad \text{(T-5)}$$

$$MAX_i = \text{mediumTime}(\textit{Surplus Bandwidth Allowance, Nominal MSDU Size, Peak Data Rate, Minimum PHY Rate}) \quad \text{(T-6)}$$

$$\mu_i = MEAN_i \quad \text{(T-7)}$$

If the Minimum Data Rate and Peak Data Rate fields were provided in the TSPEC element, σ is:

$$\sigma_i = 0.25(MAX_i - MIN_i) \quad \text{(T-8)}$$

Else if the Peak Data Rate field was provided in the TSPEC element, σ is:

$$\sigma_i = \frac{MAX_i - MIN_i}{2} \quad \text{(T-9)}$$

Otherwise:

$$\sigma_i = 0 \quad \text{(T-10)}$$

When the non-AP STA does not have any active TSPECs, the should AP monitor the mean and maximum frame reception and transmission rates for AC_VI and AC_VO (for example, by regular sampling of changes to dot11QosMPDUsReceivedCount and dot11QosTransmittedFrameCount of each AC) to calculate the potential load information as follows:

For a QoS traffic capability, the mean value, μ, is:

$$\mu_0 = \text{mediumTime}(\text{dot11DefaultSurplusBandwidthAllowance}/100, \text{dot11STAStatisticsAverageMSDUSizeVideo}, \textit{MAXt[VI]},\text{dot11STAStatisticsAverageBitrateVideo}) \quad \text{(T-11)}$$

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

μ_1 = mediumTime(dot11DefaultSurplusBandwidthAllowance/100,
dot11STAStatisticsAverageMSDUSizeVoice,
MAXt[VO],
dot11STAStatisticsAverageBitrateVoice) (T-12)

and the standard deviation, σ, is:

$\sigma_0 = 0$ (T-13)

$\sigma_1 = 0$ (T-14)

The values reported in the Potential Traffic Self field represent the composite stream of all of the individual streams of all associated STAs, and this composite stream should be calculated as follows:

Potential traffic self mean is:

$\mu_{tot} = \Sigma\mu_i$ (T-15)

Potential traffic self standard deviation:

$\sigma_{tot} = \sqrt{\sum \sigma_i^2}$ (T-16)

T.2.4 Calculation of allocated traffic self

The Allocated Traffic Self field value represents the total BSS load of all streams that the AP has allocated at any one time and the number of AC_VI and AC_VO streams that make up that total. The AP should calculate the mean and standard deviation using the Minimum Data Rate, Mean Data Rate, and Peak Data Rate fields of admitted TSPECs and to recalculate the Allocated Traffic Self field value as each TS is added or deleted. The values of the Mean and Standard Deviation subfields placed in the Allocated Traffic Self field for *i* allocated streams should be calculated using Equation (T-17) to Equation (T-24).

MIN_i = mediumTime(*Surplus Bandwidth Allowance, Nominal MSDU Size, Minimum Data Rate, Minimum PHY Rate*) (T-17)

$MEAN_i$ = mediumTime(*Surplus Bandwidth Allowance, Nominal MSDU Size, Mean Data Rate, Minimum PHY Rate*) (T-18)

MAX_i = mediumTime(Surplus Bandwidth Allowance, Nominal MSDU Size, *Peak Data Rate, Minimum PHY Rate*) (T-19)

If $TSPEC_i$ has the Minimum Data Rate and Peak Data Rate fields populated, σ is:

$\sigma_i = 0.25(MAX_i - MIN_i)$ (T-20)

Else if $TSPEC_i$ has the Mean Data Rate and Peak Data Rate fields populated, σ is:

$$\sigma_i = \frac{MAX_i - MEAN_i}{2} \quad \text{(T-21)}$$

Otherwise:

$\sigma_i = 0$ (T-22)

$$\text{Mean} = \Sigma\mu_i \tag{T-23}$$

$$\text{Standard deviation} = \sqrt{\sum\sigma_i^2} \tag{T-24}$$

When admission control is not used, the AP should monitor the mean and maximum frame reception and transmission rates for AC_VI and AC_VO (for example, by regular sampling of changes to dot11QosMPDUsReceivedCount and dot11QosTransmittedFrameCount of each AC). The MAX, MEAN, and standard deviation (STDEV) at time t for access category AC are as given in Equation (T-25), Equation (T-26), and Equation (T-27).

$$MEAN_i = o\ (\text{duration}(s, b) + \text{SIFS} + \text{duration}(14,b))\ p_t \tag{T-25}$$

MAX_t is the maximum value of $MEAN_t$ since MLME-START.confirm

$$STDEV_t = \frac{MAX_t - MEAN_t}{2} \tag{T-26}$$

where

$$p_t = \frac{d}{dt}(dot11QosMPDUsReceivedCount[AC] + dot11QosTransmittedFrameCount[AC] - dot11QosFrameDuplicateCount[AC]) \tag{T-27}$$

o = dot11DefaultSurplusBandwidthAllowance

s = dot11STAStatisticsAverageMSDUSizeVideo

b = dot11STAStatisticsAverageBitrateVideo

duration() is the PLME-TXTIME primitive that returns the duration of a packet based on its payload size and the PHY data rate employed

NOTE—The differentiation above calculates the frames per second for the given AC.

T.2.5 Calculation of allocated traffic shared

The Allocated Traffic Shared field value is the sum of the values expressed in the Allocated Traffic Self fields of all APs in OBSSs, including in its own Allocated Traffic Self field. The values of the mean μ and standard deviation σ, placed in the Allocated Traffic Shared field, for n OBSSs should be calculated using Equation (T-28) and Equation (T-29).

$$\mu = \Sigma\mu_n \tag{T-28}$$

$$\sigma = \sqrt{\sum\sigma_n^2} \tag{T-29}$$

T.2.6 Calculation of EDCA Access Factor

The EDCA Access Factor is the total traffic requirement for all of the OBSSs. The value of EDCA Access Factor might be greater than 1. The EDCA Access Factor should be calculated from the addition of all of the Potential Traffic Self fields of the APs that are overlapping as follows:

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

First calculate the overlap traffic for all of the APs in OBSSs. Each AP notes the reported Potential Traffic Self fields for every OBSS, including the AP's own Potential Traffic Self field, and calculates the maximum traffic of the composite stream, using Equation (T-30), Equation (T-31), and Equation (T-32).

$$\text{Overlap traffic} = \mu_{tot} + 2\,\sigma_{tot} \tag{T-30}$$

where, for *i* Potential Traffic Self fields

$$\mu_{tot} = \Sigma\mu_i \tag{T-31}$$

$$\sigma_{tot} = \sqrt{\sum \sigma_i^{\,2}} \tag{T-32}$$

This overlap traffic value is in multiples of 32 μs per second.

The following procedure should be used to calculate the EDCA Access Factor:

a) Sum the AC_VI and AC_VO priority streams reported in the Potential Traffic Self fields of its own QLoad report and all of the QLoad reports of APs in OBSSs, and determine the EDCA Overhead Factor as recommended in T.2.7.
b) Multiply the overlap traffic and the resulting EDCA Overhead Factor together. This value represents the total overlap traffic requirement for the OBSSs in multiples of 32 μs per second.
c) Convert the total overlap traffic to a fraction (seconds per second) by multiplying by 32×10^{-6}.
d) Round the resulting fraction value rounded down to a multiple of 1/64.

For example, if the total overlap traffic is 74 268 (32 μs/s), this is 2.376 576 (seconds/second). Now 2.376 576 × 64 = 152.1 rounded to 152. Hence, the EDCA Access Factor octet, in this case, would be 1001100 (152 in decimal, representing the fraction 152/64).

T.2.7 EDCA Overhead Factor

The Potential Traffic Self field also includes the number of AC_VI and AC_VO streams that make up the composite stream. The recommended calculation for medium time for an admitted EDCA is given in K.2.2. This value includes the duration of the packet plus SIFS and Ack frame times. The medium time, therefore, does not include the access time. For example, for a single stream, between each transmitted packet, there is a time period due to SIFS, AIFSN, and contention window, and for two or more streams, there is also the time when each packet is delayed while another packet is being transmitted. Hence, in order to calculate the total time or bandwidth required to service multiple EDCA streams, an overhead is present.

A fixed value of 1.34 should be used for EDCA Overhead Factor. The value of the EDCA Overhead Factor is dependent upon many factors, including

— Number and mix of streams, voice and video
— Mixture of PHY rates and PHYs
— Mixture of streams' data rates
— Use and mix of aggregated MSDUs
— Choice of EDCA parameters including different settings in OBSSs

Based on a range of simulations, the value of EDCA Overhead Factor is normally in the range 1.26 to 1.43. These simulations, however, were not exhaustive and did not include the effects of hidden nodes and non-IEEE 802.11 interference.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

T.2.8 Calculation of HCCA Access Factor

The HCCA Access Factor should be calculated as follows:

a) Sum the HCCA Peak field values in all of the QLoad reports of all of the APs in OBSSs, including its own.
b) Convert the total peak traffic to a fraction (seconds per second) by multiplying by 32×10^{-6}.
c) Round the resulting fraction value to the nearest 1/64 and enter the result into the HCCA Access Factor field.

For example, if the total overlap traffic is 74 268 (32 μs/s), this is 2.376 576 (seconds/second). Now 2.376 576 × 64 = 152.1 rounded to 152. Hence, the HCCA Access Factor octet, in this case, would be 152 (representing the fraction 152/64).

T.3 Channel selection using QLoad report

T.3.1 General

In addition to the channel selection described below, it is advised that other factors such as traffic from IBSSs, energy from non-IEEE-802.11 systems, and device constraints on the AP or STAs anticipated within the BSS be considered, and regulatory constraints need to be complied with.

The most effective mitigation to OBSS is for an AP to operate on channels that are free or that are occupied by another AP that is not fully loaded with QoS traffic. In the absence of a centralized channel assignment algorithm, an AP should use the Overlap and Potential Traffic Self fields of the QLoad Report element as part of its channel selection procedure. An AP might use the Overlap field and Potential Traffic Self field information when deciding the best channel to select. If there are sufficient channels for an AP to find a channel with no other APs within range, then an AP is advised to select one of them.

When selecting a channel, the AP should scan to see whether there is a free channel taking account of BSS channel width and channel spacing. If a free channel is not available, then it is advised to select channels that have the least number of QoS APs present. There might be more than one channel with the same number of QoS APs present. At this point, the AP is advised to select, in turn, the candidate channels and send a QLoad Request frame to each AP on that channel. The AP is advised to examine the Overlap and Potential Traffic Self fields of the QLoad Report element to make its final selection.

T.3.2 AP with admission control mandatory

If no “empty” channels are available, then an AP with the ACM (admission control mandatory) bit in the EDCA Parameter Set element set for AC_VI or AC_VO should implement a channel selection procedure to share with one or more APs, in the following preference order:

a) Non-QoS AP where the EDCA Parameter Set element is not present in the Beacon frame
b) QoS AP with the ACM bit set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
c) QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
d) QoS AP with an HC and with no indication of support for QLoad reporting
e) QoS AP with the ACM bit set for AC_VI or AC_VO and with no indication of support for QLoad reporting

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

f) QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM bit is not set for AC_VI or AC_VO

T.3.3 AP with an HC

If no "empty" channels are available, then an AP with an HC should implement a channel selection procedure to share with one or more APs, in the following preference order:

a) Non-QoS AP where the EDCA Parameter Set element is not present in the Beacon frame
b) QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM bit is not set for AC_VI or AC_VO
c) QoS AP with the ACM bit set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
d) QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
e) QoS AP with the ACM bit set for AC_VI or AC_VO and with no indication of support for QLoad reporting
f) QoS AP with an HC and with no indication of support for QLoad reporting

T.3.4 Channel selection procedures

Channel selection should be performed as follows:

a) Create a list of the available channels. Typically this is the list of channels allowed by regulation in the operating regulatory domain; however, this list might be modified by management policy (e.g., removing overlapping channels, avoiding radar detect channels).
b) Create an array for each available channel that allows the recording of the QoS AP count, ACM bit count, HC count, overlap count, and potential load for that channel.
c) Step through the list of available channels, listening for beacons for at least dot11OBSSScanPassiveTotalPerChannel TUs per channel.
d) Upon completion of the scan of a channel, process the beacons received on that channel, filtered to the set of unique BSSIDs:
    1) Using the capabilities signaled in the beacon, modify the QoS AP count, ACM bit count, HC count, overlap count, and potential load of the channel array for the primary channel indicated in the received beacon.
    2) If the AP is using a channel bandwidth that is greater than the channel spacing (e.g., when using the 2.4 GHz band or when the overlapping AP allows 40 MHz HT PPDUs in its BSS), also update the channel array for channels that are affected by this OBSS. For example, a beacon received on channel 2 indicating a 20 MHz BSS also affects channels 1, 3, and 4.
e) Upon completion of scanning all of the channels, the AP has information on the number of APs and the potential load of each channel, including co-channel BSSs.
f) If the channel array indicates that there are channels with no other APs, one of these "empty" channels should be chosen randomly.
g) Otherwise, create a list of candidate channels by selecting only the channels with the lowest number of QoS APs. For example, if the channel scan procedure indicated that there were two QoS APs on channel 3, three QoS APs on channel 6, and two QoS APs on channel 11, the list of candidate channels would contain 3 and 11.
    1) If this list contains one or more channels with non-QoS APs, then filter the list for the least number of APs.
    2) If this list contains more than one channel, one of these channels should be chosen randomly.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

h) If this list contains more than one channel and the AP has been configured to set the ACM bit for AC_VI or AC_VO:
   1) Filter the list for the minimum count of QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM bit is not set for AC_VI or AC_VO.
   2) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM bit set for AC_VI or AC_VO and with no indication of support for QLoad reporting.
   3) If this list contains more than one channel, filter the list for the minimum count of QoS AP with an HC and with no indication of support for QLoad reporting.
   4) If this list contains more than one channel, filter the list for the minimum count of QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
   5) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM bit set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
i) If this list contains more than one channel and the AP has an HC:
   1) Filter the list for the minimum count of QoS AP with an HC and with no indication of support for QLoad reporting.
   2) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM bit set for AC_VI or AC_VO and with no indication of support for QLoad reporting.
   3) If this list contains more than one channel, filter the list for the minimum count of QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
   4) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM bit set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
   5) If this list contains more than one channel, filter the list for the minimum count of QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM bit is not set for AC_VI or AC_VO.
j) If this list contains more than one channel, filter the list to the set of channels with the minimum overlap count.
k) If this list contains more than one channel, filter the list to the set of channels with the minimum potential load.
l) From the remaining channels in this list, randomly choose one of these channels.

T.4 Sharing in an OBSS situation

T.4.1 General

If the EDCA Access Factor is greater than one, then there is a potential overallocation of the WM. APs should avoid overallocation in the channel selection process, but if overallocation exists, then a sharing scheme should be used to provide each AP with a fair share of the bandwidth, but more importantly, so that any already admitted or scheduled QoS streams are not impaired by the addition of streams from any OBSS. The EDCA Access Factor, HCCA Access Factor, and Potential Traffic Self fields in the QLoad Report element are provided to enable sharing schemes to be used.

The sharing scheme also protects an AP from the neighbor capture effect where it has neighbors that are hidden from each other. A major objective of an OBSS sharing scheme is that if a QoS stream is allocated or scheduled, then it is not compromised by the addition of further streams from any OBSS that would cause the medium to be overallocated. This objective is achieved if the APs in OBSSs cooperate.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

T.4.2 Sharing schemes

T.4.2.1 General

Two sharing schemes are suggested: proportional sharing and on-demand sharing. In each sharing scheme, the purpose is to keep the total allocated traffic to a value where overallocation does not occur. The absolute maximum allocation is 1 s/s (100%). In the following descriptions of the two suggested sharing schemes, this value is referred to as the *maximum allocation value (MAV)*. It is suggested that in order to provide some protection to non-QoS traffic, each AP select a value for MAV:

$$MAV = (M + 1)/(M + N + 1) \text{ s/s} \quad \text{(T-33)}$$

where

M is the number of overlapping APs that are robust AV streaming STAs
N is the number of overlapping APs that are not robust AV streaming STAs

There is no requirement that each AP select the same MAV.

T.4.2.2 Proportional sharing scheme

The proportional sharing scheme described in this subclause is an example of a static sharing policy, as described in Table 9-226 and 11.28.2.2.

When using the proportional sharing scheme, the AP examines the sum of the EDCA Access Factors and HCCA Access Factors in the QLoad reports from each OBSS, including its own Qload report, and determines the maximum. This maximum value is termed the *combined access factor*. If the maximum value from the combined access factor is less than or equal to MAV, the AP is advised to allocate only up to its advertised potential traffic self traffic. If the maximum value from the combined access factor is greater than MAV, then the AP is advised to allocate only up to a value of its potential traffic self divided by the combined access factor, multiplied by MAV.

In the proportional sharing scheme, before an AP allocates a new medium time or schedules a new TXOP in response to an ADDTS Request frame, it checks that this addition does not exceed its sharing limit, as follows:

a) If the EDCA Access Factor is less than or equal to MAV, then the AP allocates up to its advertised potential traffic self, with the composite stream (MAX traffic) calculated as shown in Equation (T-34).

$$\text{MAX traffic} = \mu_{tot} + 2\,\sigma_{tot} \quad \text{(T-34)}$$

b) If the EDCA Access Factor is greater than MAV, the AP carries out the following:
   1) Calculate the peak traffic value of the potential traffic self using Equation (T-35).

$$Peak = \mu_{tot} + 2\,\sigma_{tot} \quad \text{(T-35)}$$

   2) Divide this value by the combined access factor and multiply by MAV. This value is termed the *maximum allowable potential traffic self traffic*.
   3) Calculate the resulting value of the allocated traffic self if the new TSPEC is accepted, as explained in Equation (T.2.4), and then calculate the resulting peak value using Equation (T-36).

$$Peak = \mu_{tot} + 2\,\sigma_{tot} \quad \text{(T-36)}$$

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

4) If the resulting peak value, calculated in step 3), is greater than the maximum allowable potential traffic self traffic, then the AP is advised to reject the ADDTS Request frame.
5) If the resulting peak value, calculated in step 3), is less than the maximum allowable potential traffic self traffic and the ADDTS Request frame is set for EDCA admission, then the AP is advised to accept the request.
6) The AP then checks that it is possible to schedule TXOPs using the HCCA TXOP advertisement as described in Equation (11.28.3).

If the new stream is allocated, then the AP updates the appropriate fields in its QLoad Report element.

T.4.2.3 On-demand sharing scheme

The on-demand sharing scheme described in this subclause is an example of a dynamic sharing policy, as described in Table 9-226 and 11.28.2.2.

The on-demand sharing scheme is as follows:

a) Before allocating a new stream, the AP examines the Allocated Traffic Shared field values in the QLoad reports from each OBSS, including its own Qload report, and selects the maximum Allocated Traffic Shared field value that has the highest peak value, using Equation (T-37).

$$Peak = \mu_{tot} + 2\,\sigma_{tot} \quad \text{(T-37)}$$

The AP also notes the number of AC_VI and AC_VO streams in this maximum Allocated Traffic Shared field.

b) The AP adds the requested new stream (*new*) to the selected maximum Allocated Traffic Shared field value (*max*) determined in step a), using Equation (T-38) and Equation (T-38).

$$\mu = \mu_{new} + Peak \quad \text{(T-38)}$$

$$\sigma = \sqrt{\sigma_{new}^2 + \sigma_{max}^2} \quad \text{(T-39)}$$

c) The AP then calculates the peak value for the new composite stream calculated in step b), using Equation (T-40).

$$Peak = \mu + 2\sigma \quad \text{(T-40)}$$

d) Using the values of the AC_VI and AC_VO streams noted in step a), plus the stream represented by the new stream, the AP determines the new EDCA Access Factor and then the combined access factor, as described in T.4.2.2.
e) Multiply the peak value calculated in step c) by the EDCA Access Factor, determined in step d). This value is the new peak traffic requirement.
f) If this peak traffic requirement value calculated in step e) is greater than MAV, then the AP is advised to refuse to allocate the new stream.
g) If the peak value calculated in step e) is less than or equal to MAV and the new allocation is for an EDCA admission ADDTS, then the AP allocates that new traffic.
h) If the peak value calculated in step d) is less than or equal to MAV and the new allocation is for an HCCA ADDTS, the AP checks that it is possible to schedule TXOPs using the HCCA TXOP advertisement as described in 11.28.3.

If the new stream is allocated, then the AP updates the appropriate fields in its QLoad Report element.

Copyright © 2016 IEEE. All rights reserved.
Authorized licensed use limited to: Penn State University. Downloaded on September 21,2023 at 00:33:22 UTC from IEEE Xplore. Restrictions apply.

The Allocated Traffic Self field in the QLoad Report element of a particular AP can be used by other APs as an indication of whether an AP has overallocated or is using an on-demand sharing scheme.

If, using either the proportional or on-demand sharing schemes, an AP determines that the acceptance of a TSPEC would exceed the available allocation, or if a non-AP STA has a TSPEC refused, the non-AP STA could always request a new TSPEC that represents a lower medium time or TXOP. This request might be used, for example, where the non-AP STA or AP has the ability to send a more compressed stream.

An AP might choose to use the on-demand sharing scheme until the maximum value of any access factor field in the QLoad Report elements from each OBSS reaches MAV. Once this condition has occurred, the AP could then use the proportional sharing for subsequent ADDTS requests.

T.5 Mitigating consequences of OBSS sharing in presence of noncollaborating devices

The performance of the channel selection and HCAA TXOP negotiation procedures described in this annex and 11.28 might become degraded by the presence of devices that willfully or accidentally behave in an uncooperative manner.

It is suggested that implementations use additional heuristics (e.g., a history of collaboration, traffic monitoring, device configuration, or a combination of such) to assess the accuracy of the information they receive from neighboring APs in order to determine an appropriate collaboration strategy.

An AP that maintains historical information of collaboration results with its neighboring APs could use this information to control its collaboration behavior. For example, an AP might choose to share a channel with an AP that had a history of successful collaboration. In another example, an AP might choose to avoid transmissions only during the HCCA TXOPs of neighboring APs with which it has a history of successful HCCA TXOP negotiation.

When using HCCA TXOP negotiation, it is suggested that an AP perform some monitoring of the channel to assess whether the HCCA AP with which it is collaborating is using its advertised HCCA TXOPs. If the monitoring AP does not detect HCCA traffic during these advertised HCCA TXOPs, such a lack of traffic might indicate that the neighboring AP is willfully or accidentally behaving in an uncooperative manner by advertising HCCA TXOPs that it is not using, possibly as a method to suppress traffic in neighboring BSSs. The monitoring AP might wish to ignore the HCCA TXOP advertisements from APs that do not appear to be collaborating.

Some of the OBSS procedures use unauthenticated Beacon frames and Public Action frames, which are susceptible to impersonation. If unauthenticated Beacon frames and Public Action frames are used, an AP might suffer a denial of service attack by another device impersonating the AP. This denial of service attack, due to the actions of the impersonating device, might cause neighboring APs to falsely ascertain the AP is not collaborating.

An AP could enable protected HCCA TXOP negotiation and protected QLoad reporting to provide protection against impersonation. The AP PeerKey protocol is used in the generation of the PMK to prove that an AP has the private key that corresponds to its public key. Impersonation of protected HCCA TXOP negotiation and protected QLoad report management from an AP is prevented while the AP maintains possession of this private key and this private key is not possessed by any other devices.

Annex U

(informative)

Functions of the centralized coordination service root (CCSR)

Via unspecified means over the DS, a centralized coordination service root (CCSR) performs the following functions:

- Allows APs to enroll or unenroll from the CCSS.
- Provides a directory service, wherein the CCSR responds to a directory service request that includes a MAC address with an indication of whether the MAC address is an S-AP within the CCSS.
- Configures the beacon interval, ClusterMaxMem, Beacon SP duration, TXSS offset, TXSS CBAP duration, and TXSS CBAP MaxMem (see 10.37.2.2) of each S-AP.
- Aligns the rate of increment of TSFs of S-APs within the CCSS.
- Configures the individual TSF offsets of each S-AP in order to minimize the temporal, spatial, and frequency overlap of BHIs of the BSSs in the same CCSS.
- Provides to each S-AP the cluster time offset availability information from nearby co-channel S-APs.
- Configures each S-AP with certain medium access policies for its centralized AP or PCP cluster (see 10.37.3.4). The CCSR is permitted to configure different S-APs with different medium access policies.
- Configures each S-AP with a list of one or more channels in an operating class that the S-AP is excluded from operating upon and that the S-AP advertises via the Channel Usage procedures (see 11.24.15). The excluded channels are available to STAs that are operating in the area covered by the ECAPC, yet are not within the ECAPC.

Annex V

(informative)

TSPEC aggregation for DMG BSSs

Examples of TSPEC aggregation include, but are not limited to, the following:

— Traffic streams between DMG STA A and DMG STA B, having an access policy of SPCA, even if they flow in opposite directions, sharing an SP allocation created with DMG STA A as Source AID and DMG STA B as Destination AID.

— Traffic streams between DMG STA A and other DMG STAs, having an access policy of EDCA, even if they flow in opposite directions (some having DMG STA A as source and some having DMG STA A as destination), sharing a CBAP allocation created with DMG STA A as Source AID and broadcast Destination AID.

Figure V-1 and Figure V-2 show examples of TSPEC aggregation in a DMG BSS. Note that TSPEC 3 in Figure V-1 (for both SPCA and EDCA cases) can flow only through an RD grant.
