(57) **ABSTRACT**

A social networking system determines common location information included in a set of posts between a set of users. Using the determined common location information, the social networking system generates a message interface for grouping a set of messages into a conversation thread. For example, the messages may be grouped into a conversation thread based on common location information in the messages and being associated with participants sharing a social relationship. When a group conversation is created, the social networking system presents a message interface containing the conversation thread to one or more participants of the thread. The social networking system adds the set of messages to the conversation thread based on social information about the social relationships among the participants of the conversation thread. The social networking system then presents the message interface for display to one or more of the participants.

FIG. 1

**FIG. 2**

FIG. 3

FIG. 4

FIG. 5

1

CREATION OF REAL-TIME CONVERSATIONS BASED ON SOCIAL LOCATION INFORMATION

BACKGROUND

This disclosure relates generally to social networking systems, and more specifically to a social networking system that organizes and presents messages as a conversation based on location information.

Social networking systems provide various electronic message channels to allow users to share information, including status updates including a current location of a user, or plans to attend a social event. For example, users can share information by updating their status, posting to another user's wall, or messaging a user using web-chat.

But the flexibility provided by sharing information using a variety of communication channels within the social networking system can create challenges for a user to discover related messages from other users with whom the user is connected to. For example, a user sharing messages over web-chat about attending a social event may be unaware of posts received from other users indicating an interest in attending the same social event, because the posts were buried in a listing of several unrelated posts from other users. In another example, a user may simply discover a message regarding the event too late. Thus, for many users of a social networking system, manually sorting through hundreds of messages in real-time to identify, group, and create messages associated with particular social information would be impractical.

SUMMARY

Embodiments of the invention facilitate the creation of real-time conversations based on social and location information. The creation of the real-time conversation may be triggered by and created based on posted content associated with a location. In an embodiment, the social networking system determines common location information from a set of posts between a set of users. Using the determined common location information, the social networking system generates a message interface for grouping a set of messages into a conversation thread. For example, the messages may be grouped into a conversation thread based on common location information in the messages and being associated with participants sharing a social relationship. When a group conversation is created, the social networking system presents a message interface containing the conversation thread to one or more participants of the thread. The social networking system adds the set of messages to the conversation thread based on social information about the social relationships among the participants of the conversation thread. The social networking system then presents the message interface for display to one or more of the participants.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a high-level block diagram of a computing environment for social networking, according to one embodiment.

FIG. 2 illustrates a flow chart of a method for presenting a message interface for presenting a conversation thread to a user, according to an embodiment.

FIG. 3 illustrates a message interface including a listing of conversation threads, according to an embodiment.

2

FIG. 4 illustrates a message interface for a conversation thread among more than two users, according to an embodiment.

FIG. 5 illustrates another message interface for a conversation thread among more than two users, according to an embodiment.

The figures depict various embodiments of this disclosure for purposes of illustration only. One skilled in the art will readily recognize from the following discussion that alternative embodiments of the structures and methods illustrated herein may be employed without departing from the principles of this disclosure.

DETAILED DESCRIPTION

FIG. 1 is a high-level block diagram of a computing environment 10 for social networking according to an embodiment. The computing environment 10 includes a social networking system 100, multiple client devices 140, and third party website 160 coupled to communication using network 150. Social networking system 100, client devices 140, and third party website 160 each comprise of one or more computers. Additionally, client devices 140 may comprise any other type of computing device, such as a mobile phone, laptop, netbook, tablet, set top box, television, in-vehicle infotainment system, etc.

A user of social networking system 100 uses client device 140 to interact with social networking system 100 via an application, such as a web browser or a native application, to perform operations such as browsing content, posting and sending messages, retrieving and sorting messages received from other users, and the like. The application may load a message interface provided by social networking system 100 to send and receive messages. Messages can be sent or received through different electronic message channels/formats. Generally speaking, a social networking channel is any technology that may be used for delivering electronic messages to a user of the social networking system. Examples of social networking channels include web-chat (e.g., a chat application of a web-page hosted by social networking system 100), e-mail, extensible social networking and presence protocol (XMPP), short message service (SMS) texting and mobile chat (e.g., via an application installed on a mobile client 140). Messages may contain plain text, or other content such as an image, video, audio, or other attachment.

In an embodiment, social networking system 100 comprises an object store 110, graph information store 132, application programming interface (API) 130, conversation thread index 134, and message grouping module 136. Through API 130, third party website 160 may interact with the social networking system 100. For example, in an embodiment, third party website 160 performs operations supported by API 130, such as delivering messages to social networking system 100, retrieving messages stored by social networking system 100, and obtaining social information about users of social networking system 100. Social information about users of social networking system 100 includes information describing relationships among users and interactions of users with other users and objects on social networking system 100. Interactions of users with objects on social networking system 100 include historical information, such as a previous check-in at a location, tagging a photo, sharing a link, or indicating a preference for an object (e.g., liking a band, a song, a video, a merchant location, etc.).

Object store 110 stores information on various objects of social networking system 100. These objects represent a variety of things with which a user of social networking system

100 may interact in social networking system 100, including, without limitation, other users (e.g., user objects 112) of social networking system 100 (represented, e.g., as a profile object for the user), application objects 114 (e.g., a game playable within social networking system 100), event objects 116 (e.g., a concert that a user attends, plans to attend, or is invited to attend), group objects 118 to which users may belong, page or hub objects 120 (e.g., pages constituting a particular organization's presence on the system), media item objects 122 (e.g., pictures, videos, audio, text, or any other type of media content), location objects 124 associated with a user (e.g., "Santa Clara, Calif., USA"), and even concept objects 126 or other terms (e.g., "monetary policy"). Object store 110 may further store objects representing other data routinely produced by users of social networking system 100, such as message objects 128, status updates, photos, and videos.

Message objects 128 includes content and metadata associated with a message, such as a, web-chat, SMS message, e-mail, or post. A post includes any content or information received from the user that indicates a location, including check-ins, photos with tagged locations, invitation to attend an event, etc. Content may include text, images, video, or references to other content. Metadata may include location information, temporal information, or network information associated with the sender or recipient, or any component of the communication channel associated with transmitting or receiving the message. Location information includes information as specific as latitude and longitude coordinates, street address, entity name (e.g., Yoshi's San Francisco), event (e.g., Carnival, Louis' New Years Eve party, Burning Man, Sturgis, etc.), or structure (e.g., Golden Gate Bridge, Coit Tower, or Eiffel Tower). Location information also includes information as broad as a country, city, or geographic region (e.g., Isla de San Andrés, or Pacific Northwest).

An object in object store 110 may represent a business entity. In an embodiment, the business entity creates a page on social networking system 100 to enable users of social networking system 100 to express interest in web pages hosted on third party websites 160 external to social networking system 100. For example, pages may be represented as page objects in social networking system 100 as a result of embedding a widget, social plug-in, programmable logic or code snippet into the webpage such as an inline frame ("iframe").

Object store 110 also stores metadata associated with the objects, such as a name describing the object (e.g., "Charles Williams" for a person, "Birthday Reminder" for an application, or "Lowell High School San Francisco Alumni" for a group), an image representing the object (e.g., a user or entity profile picture), one or more labels assigned to the object by users (e.g. the textual strings "game", "crime", and "strategy" for a strategy game application), or different e-mail addresses of a user object (e.g., "jeremy1234@gmail.com" and "jeremy1234@yahoo.com"). Different types of objects may have different types of metadata, such as a set of associated user objects 112 for a group object 118, a media type (e.g., "video") for media item object 122, and a unique user ID and name tokens (e.g., separate first and last names "Charles" and "Williams") for user object 112.

Graph information store 132 stores information on the relationships of the objects in object store 110. In an embodiment, graph information store 132 represents the objects of object store 110 as nodes that are linked together in a "social graph." A social graph includes nodes connected by edges stored on social networking system 100. Nodes include users and objects of social networking system 100, such as web pages embodying concepts and entities, and edges connect

the nodes. Any concept that can be embodied in a web page may become a node in the social graph. As a result, users may interact with many objects external to social networking system 100 that are relevant to a keyword or keyword phrase, such as "Cowboys Stadium." Social networking system 100 records each of the interactions with an object relevant to keyword or keyword phrase as an edge. For example, using keyword phrase "Cowboys Stadium," interactions may include a user purchasing tickets to attend the 2012 Cotton Bowl, attaching an image or video of highlights from a Dallas Cowboys football game to a message, a user message discussing where to park for an upcoming Dallas Cowboys game, or a user message inviting a connected user to attend an informal get together to watch a Dallas Cowboys game at a user's home.

Edges represent a particular interaction between two nodes, such as when a user expresses an interest in a news article shared by another user about "America's Cup." The social graph may record interactions between users of social networking system 100 as well as interactions between users and objects of social networking system 100 by storing information in the nodes and edges that represent these interactions.

Various examples of edges in the social graph include: an edge between two user objects representing that the users have a relationship in social networking system 100 (e.g., are friends, or have communicated, viewed the other's profile, or interacted in some way), an edge between a user object and an application object representing that the user has used the application, an edge between a user object and a group object representing that the user belongs to the group, and an edge between a user object and a page object representing that the user has viewed the page, to name just a few. For example, if one user establishes a relationship with another user in the social networking system, the two users are each represented as a node, and the edge between them represents the established relationship; the two users are then said to be connected in the social network system. Continuing this example, one of these users may send a message to the other user within the social networking system. This act of sending the message is another edge between those two nodes, which can be stored and/or logged by the social networking system. The message itself may be treated as a node.

In another example, one user may tag another user in an image that is maintained by the social networking system. This tagging action may create edges between the users as well as an edge between each of the users and the image, which is also a node. In yet another example, if a user confirms attending an event, the user and the event are nodes, where the indication of whether or not the user will attend the event is the edge.

In yet another example, if a user confirms attending an event, the user and the event are nodes, where the indication of whether or not the user will attend the event is the edge. Using a social graph, therefore, a social networking system may keep track of many different types of objects and edges (the interactions and connections among those objects), thereby maintaining an extremely rich store of socially relevant information.

Custom graph object types and graph action types may be defined by third-party developers as well as administrators of the social networking system to define attributes of the graph objects and graph actions. For example, a graph object for a movie may have several defined object properties, such as a title, actors, directors, producers, year, and the like. A graph action type, such as "purchase," may be used by a third-party developer on a website external (e.g., third party website 160)

5

to social networking system **100** to report custom actions performed by users of social networking system **100**. In this way, the social graph may be “open,” enabling third-party developers to create and use the custom graph objects and actions on external websites.

In an embodiment, edges in graph information store **132** have associated metadata, such as a label describing the type of relationship (e.g., “friend” as the label between two user objects, “family” as the label between brother and sister), or an affinity value quantifying the strength of the relationship. Affinity may be determined, for example, from positive and negative interactions between two objects. Further, a relationship degree, or “distance,” between any two objects can be ascertained by determining the number of edges on the shortest path between the objects. For example, two user objects that have an edge between them (e.g., denoting a friendship relationship) have a relationship degree (or “distance”) of one and are considered first-order connections. Similarly, if a user object A is a first-order connection of user object B but not of user object C, and B is a first-order connection of C, then objects A and C have a relationship degree of two, indicating that C is a second-order connection of A (and vice-versa).

In an embodiment, social networking system **100** adds information to graph information store **132** when it observes events taking place indicating relationships between the various objects, such as a user object **112** interacting with an event object **116**. Alternatively and/or additionally, graph information store **132** may be created based on existing stored information from which relationships can be inferred. For example, the friend list of a user object **112** might indicate that the user has a friend relationship with another user, or the data for group object **118** might indicate that some set of users has a membership relationship with that group, and this information could be reflected in graph information store **132**.

Conversation thread index **134** stores information about a large number of “conversation threads.” Each conversation thread is associated with a collection of posts that include common location information sent between the participants of the conversation thread. For example, one conversation thread may include messages discussing preference for particular restaurant sent between user Adam and user Bob, and messages sent between user Bob and user Charlie, discussing plans to visit the restaurant. In this example, Adam and Bob are connected as friends, and Bob and Charlie are also connected as friends. Adam and Charlie, however, are not connected as friends. From Adam’s perspective, a conversation thread concerning the restaurant includes messages exchanged between Bob and Charlie because the subject matter of their message concerns the restaurant and because Adam’s social proximity with Bob and Charlie. That is, Adam is a first-order connection of Bob, but not of Charlie. Bob is a first-order connection of Charlie, which makes Adam a second-order connection of Charlie (and vice-versa).

In an embodiment, social networking system **100** stores message objects **128** in object store **110**. Conversation thread index **134** links each conversation thread to message objects **128** that are part of a conversation thread. As conversation threads can include many message objects **128**, each conversation thread may be linked to several different message objects **128**. Other information stored in conversation thread index **134** for each thread may include, for example, participants of the thread, a folder or category (e.g., location or event) that the thread belongs to, a state of the thread, timestamps of the posts in the thread, an electronic message channel associated with each post, as well as other types of information that are appropriate for indexing.

6

Message grouping module **136** accesses conversation thread index **134** to retrieve information about conversation threads, update information about conversation threads, and to generate new conversation threads. Message grouping module **136** may also access object store **110** and graph information store **132** to retrieve information about the objects of social networking system **100**. Additionally, message grouping module **136** receives, organizes, and presents messages to/from users of social networking system **100** via an interactive message interface. The message interface can be, for example, a webpage that is viewed by a user at a client device **140** with a web browser.

The functionality provided by message grouping module **136** is described in greater detail in conjunction with FIGS. 2-5. Examples of the functionality provided by message grouping module **136** include organizing messages into conversation threads using location information and social network information, providing a reply interface, adding contextual information to messages, among others.

Organizing Messages into Conversations

In an embodiment, message grouping module **136** aggregates messages into conversation threads that include messages sent between connected users of social networking system **100** that include content associated with common location information. For example, assume that Adam and Bob are connected users of the social networking system **100**. If Adam sends a message to Bob inviting Bob to attend a sporting event with Adam, and Bob replies to Adam indicating that he would like to attend the event, message grouping module **136** creates a new conversation thread in conversation thread index **134** to capture the discussion about the sporting event. Each time Adam or Bob exchange messages concerning the sporting event, message grouping module **136** adds the new message to the existing “sporting event” conversation thread. Also, each time another users connected to Adam or Bob posts a message, that message is also added to the existing “sporting event” conversation thread.

More generally, message grouping module **136** creates a conversation thread from a plurality of messages that share common location and social information, which are exchanged by a threshold number of users over a predetermined threshold period of time. For example, message grouping module **136** may create a conversation thread when at least four messages that include common location information (e.g., discuss plans to go hiking at a local park) are exchanged between at least three users that share a social connection over a thirty minute period of time. In another example, message grouping module **136** may create a conversation thread based on receiving at least two messages that include common location information (e.g., a check-in by a first user at a Las Vegas resort and a post by a second user including an image of a second user at the same resort), and exchanged between at least two users that share a social connection during a predetermined period of time threshold of at least thirty minutes, or other threshold suitable to indicate that received messages are part of the same conversation.

As discussed in the previous example, message grouping module **136** determines location information by identifying content, including text or images, included in a message associated with a location. Message grouping module **136** also determines location information directly from a message, such as from a post associated with a check-in. And more generally, message grouping module **136** further determines location information of a post based on geographic information about a user’s location received by social networking system **100**. For example, social networking system **100** may receive a user’s location information from a mobile

device used by a user to access social networking system **100**. In another example, social networking system **100** may receive a user's location information from a third-party, such as a location-based service, or network provider by which the user accesses social networking system **100**.

Message grouping module **136** also groups messages into conversation threads by adding new messages to a previously grouped conversation thread. For example, messaging grouping module **136** updates the conversation thread to include new messages generated by participants of the conversation thread that include common location information. In another example, messaging grouping module **136** updates the conversation thread to include new messages that include common location information generated by other users who are connected to participants of the conversation thread. To provide a real-time conversation experience, message grouping module **136** continually updates the conversation thread in real-time, or substantially contemporaneous with a determination that a new message shares common location information with the messages of an existing conversation thread. Along with a further determination that the new message is associated with a user that has an existing social relationship with the existing participants of the conversation thread.

Message grouping module **136** further groups messages by adding messages to an existing conversation thread not previously grouped, such as a conversation thread initiated by a user to exchange messages with another user using a web-chat. In this case, message grouping module **136** identifies the subject matter of the messages to determine if the messages include common location information as previously discussed. Message grouping module **136** also access social information about the participants of the existing thread to determine if other users with which the participants have a social relationship are exchanging messages that also include the determined common location information. To access social information, social networking system **100** may traverse the social graph to identify other users to add the conversation thread based in part on interactions with the participants or other objects that have an edge to one or more participants. With additional users identified, message grouping module **136**, may in turn, add one or more of the identified users to an existing conversation when these identified users exchange messages about common location information (e.g., attending a concert, meeting a rally, impromptu study group at an on-campus library, etc.) presently discussed in the existing conversation thread.

Message grouping module **136** further organizes grouped messages within a conversation thread using social information from graph information store **132**. As previously discussed, social information is indicative of social relationships between the users of a conversation thread and allows the messages within a conversation thread to be organized by their social relevancy. When a user has a large number of messages in a conversation thread, organizing messages within a conversation thread using social networking information helps to avoid information overload.

In an embodiment, organizing includes categorizing messages within a conversation thread by applying a set of heuristic rules to order messages and/or determine how a message is displayed. For example, one rule may be that if a certain type of social relationship (e.g., friends, family) exists between the participants of a thread, messages associated with participants sharing that certain type of relationship may be listed before messages from other types of participants in the conversation thread. Alternatively or additionally, messages associated with participants sharing a certain type of relationship may be continually displayed with greater per-

sistence compared to other messages within the same conversation thread. In an embodiment, if a social relationship does not exist at all, the message is not included in the conversation thread. Another rule may be that if an affinity between the thread participants exceeds a threshold, the associated messages are displayed before and/or with greater persistence compared to messages from other participants that do not exceed the threshold. Similarly, a further rule may be that if a distance (e.g. degrees of separation) between the participants is less than a threshold, the associated messages are displayed before and/or with greater persistence compared to messages from other participants that do not exceed the threshold.

In an embodiment, message grouping module **136** may organize messages within a conversation thread based in part on a calculated relationship score. For example, the relationship score may be calculated by social networking system **100** as a function of affinity such that a higher affinity results in a higher relationship score. Higher scores (i.e., indicating a strong social relationship between users) indicate that a message is socially relevant, whereas lower scores (i.e., indicating a weak social relationship between users) indicate that a message is less relevant. Messages with relationship scores exceeding a threshold may be ordered or displayed in a position of greater prominence and/or greater persistence within a conversation thread. Messages with scores under a threshold are displayed in a position of lesser prominence and/or lesser persistence, and all other messages are not included in the conversation thread.

In an embodiment, organizing messages within a conversation threads also includes filtering messages within a conversation thread according to social networking information. For instance, a user may select only to view messages within a conversation thread that involve "friends" of the user. In response, for a selected conversation thread, message grouping module **136** presents messages where one or more participants of the thread are friends of the user. Other messages not involving participants that are "friends" are hidden from view.

When a thread has more than two participants, the type of social information used to organize messages for a selected conversation thread may depend directly on which participant the thread is being presented to. For example, if user A, B, and C are participants of a thread, the social relationship between user A and user B may be used to organize messages within the thread for presentation to user A. Additionally or alternatively, the social relationship between user A and user C may also be used to organize messages within a thread for presentation to user A. The social relationship between user B and user C may not be used to organize the messages within a thread for user A because that relationship is irrelevant to user A.

Message grouping module **136** also considers other factors, either alone or in combination with the social information when organizing messages within a conversation thread. These factors may include, but are not limited to:

- Whether any messages in the conversation thread contain known spam.

- Whether a message is sent by a sender with a bad reputation. A sender may have a bad reputation if the sender has been blocked by other users of social networking system **100**.

- Whether the message is initiated by an object (e.g., user, page, event, or group) of social networking system **100**.
- Whether the conversation thread includes messages with attachments.

- Whether the message is sent from an e-mail address that the mailbox owner has white-listed or black-listed.

FIG. 2 illustrates a flow chart of an exemplary method for presenting a message interface for presenting a real-time conversation thread to a user, according to an embodiment. Social networking system **100** maintains **202** a plurality of messages. Each message is associated with a participant and includes content and metadata as previously described.

To group messages based on location information, social networking system **100** determines **204** common location information from the plurality of messages. In an embodiment, message grouping module **136** observes the content of the received messages, including content referred to (e.g., links) in the messages. In observing the content of the messages, message grouping module **136** semantically analyzes the number and types of words, phrases, sentences, and paragraphs formed by the characters included in the message to determine location information associated with the content. For example, a message sent by user A to user B may be a web-chat that includes content describing the New Year's Eve Masquerade Ball hosted by the San Francisco Symphony. In this example, grouping module **136** identifies the phrase "New Year's Eve Masquerade Ball hosted by the San Francisco Symphony" as location information. And, in turn, groups messages from user A and other users connected to user A and related to the New Year's Eve Masquerade Ball into a conversation thread based on this common location information.

In another embodiment, social networking system **100** determines **204** common location information based in part on geographic information about the user. For example, social networking system may access geographic information about a computing device (e.g., smart phone, tablet computer, desktop computer, etc.) used by the user to access social networking system **100**. In another example, social networking system **100** determines common location information by accessing geographic information about the user from a third-party, including a location-based service or network provider providing services over network **150**.

Message grouping module **136** groups **206** the set of messages having determined common location information into a conversation thread. The grouped messages are associated with participants that have established a social relationship in social networking system **100**. For example, the social relationship represents social information including, an affinity between two or more participants, a type of connection between two or more participants (e.g., personal relationship, familial relationship, professional relationship, etc.). Social information also includes historical information about an interaction between a participant and an object included in the social networking system. For example, historical information may include previous check-in information associated with the location of an event discussed in messages from participants included in the real-time conversation thread. Historical information also includes interaction with a previously grouped conversation thread that included messages from the same or similar group of participants. The social information may be directly retrieved from social graph information store **132**. Alternatively, it may be retrieved from a pre-built index of social information that allows for faster retrieval of the social information in graph information store **132**.

Message grouping module **136** groups **206** messages into conversation threads when receiving a set of messages from a threshold number of users over a predetermined threshold period of time as previously described in reference to FIG. 1. In some embodiments, message grouping module **136** groups **206** messages, sharing common location information, from a set of participants that have a social relationship on social

networking system **100** into a previously existing conversation thread. The previously existing conversation thread will include messages from at least a subset of those participants that have a social relationship with the newly added participants, whose messages include location information common to at least some of the messages included in the previously existing conversation thread.

For example, for a first participant of a conversation thread, message grouping module **136** adds a set of messages to a conversation thread based on social information about the social relationship between the first participant and another participant of the conversation thread. For example, to present a conversation thread about a location socially relevant to a viewing user (i.e., the user to whom a message interface is presented), message grouping module **136** groups messages based in part on common location information and social information as previously described. Messages determined **204** to include common location information may be grouped, and then regrouped based on social information associated with the viewing user. For example, social information includes a degree of connection between the viewing user and another participant in the conversation thread and the viewing user's affinity to another participant in the conversation thread. Social information also includes whether the viewing user and another participant in the conversation thread have established a connection in the social networking system, and the type of connection between the viewing user and another participant of the conversation thread.

Message grouping module **136** adds **208** the conversation thread to a message interface to enable further communications in real-time among the participants. In one embodiment, message grouping module **136** adds **208** the conversation thread to the message interface as the messages are grouped by messaging grouping module **136**. And, because messages are grouped in real-time as previously discussed, messaging grouping module **136** may, in turn, add, maintain, and subsequently present a message interface that includes a real-time conversation thread. In another embodiment, message grouping module **136** allows a user to add a conversation thread to the message interface by allowing a user to create a new chat option. To allow a user to create a new chat option, message grouping module **136**, presents for display to a user a list of connect users associated with a particular location as determined by common location information included in messages associated with the list of connected users. The list of connected users may be presented to a user with the option for the user to arrange the lists by location or social proximity based on information from graph information store **132**.

Message grouping module **136** provides **210** the message interface for display to one or more of the participants of the conversation thread. In an embodiment, the message interface allows the viewing user to select a conversation thread from a list of conversation threads grouped based on location information. The message interface further allows the viewing user to add a message (e.g., a posts, web-chat, etc.) to a selected conversation thread. For example, message interface allows a viewing user to send a post to participants of the conversation thread using a third party application, SMS messages, e-mail, or the like. In an embodiment, message interface further allows a viewing user to create a new conversation thread by presenting the viewing user with a listing of friends sorted by location information. Like existing conversation threads, new conversation threads may also be sorted and/or ranked by location information or social proximity (i.e., by relationship degree relative to the viewing user).

An example message interface will be described in greater detail concerning FIGS. 3 and 4. In an embodiment, the

11

message interface provides selections for a user to list existing conversation threads, and to sort the conversation threads based on social information (i.e., friends or social proximity). In another embodiment, the message grouping module **136** organizes the conversation thread in the message interface using social information that is indicative of relationships between the participants of the thread. In an embodiment, message grouping module **136** also organizes the messages within a conversation thread using the social information. For example, organizing may include sorting or filtering the messages in a conversation thread based on the social information.

In the case where a participant in a conversation thread switches device types during a conversation (e.g., switches from a desktop computer to a mobile device while exchanging messages using web-chat), message grouping module **136** forwards the conversation thread to a message interface on the switched device. In one embodiment, message grouping module **136** switches devices automatically, and without user intervention. For example, social networking system **100** provides one or more signal to message grouping module **136** indicating when a session to access social networking system **100** was commenced and/or terminated by each device associated with a user. Message grouping module **136** may then evaluate these signals to determine whether the period of time between when a session was terminated and when a subsequent session was commenced meets a session switching threshold indicating a user switched devices. For example, a threshold may be less than five minutes between termination of a session and the commencement of a subsequent session. In another embodiment, in addition to the session switching threshold, message grouping module **136** switches devices automatically based in part on a change in location information associated with immediately subsequent sessions.

In another embodiment, message grouping module **136** switches devices based on receipt of a signal from the user indicating a request to switch the message interface to another device. For example, message grouping module **136** may receive a signal indicating that a participant in a conversation thread requests to switch the message interface to another device during a conversation. Responsive to receipt of the request signal, message grouping module **136** displays for selection to the user a list of devices previously used by the user to access social networking system **100**.

FIG. **3** illustrates an exemplary message interface including a listing of conversation threads, according to an embodiment. The message interface is for a user named Jon Perlow **302**. Jon has selected **304** to view his location-based messages, which opens up a list **306** of conversation threads (e.g., **308** and **310**). The first conversation thread **308** represents a conversation about Yoshi's San Francisco, a jazz club. The second conversation thread **310** represents a conversation about Ben's New Years Eve party, a small get together Ben's home.

For each conversation thread, a brief summary of the conversation is presented in the interface. In an embodiment, the summary includes the names or references to the common location information serving as the subject of the conversation thread, pictures (**312** and **314**). In another embodiment, and an excerpt (not shown) from the most recent message in the conversation is provided along with the summary. In an embodiment, the summaries are organized by time/date so that conversations with the most recent messages are placed higher in within a list of conversations in the interface.

Message interface also includes header region **320** for receiving a selection from the viewing user to create a new thread **322**, perform actions (e.g., sort threads based on social

12

information, hide threads, select persistence for a thread based on location or social information, among other things). Header region **320** also includes an interface **326** for searching for messages in a conversation thread. The interface allows messages to be searched through the use of textual search queries, by entering a query in a search box. Message grouping module **136** processes the query and identifies messages that match the query. The search results are then presented in a list to the viewing user. In an embodiment, the scope of the search can be limited through the use of search options. The search options can be entered in a number of ways, such as with an additional command in the search query or through a list of selectable options. Using the search options, the scope of the search can also be limited in a number of ways. For example, the search can be limited to particular conversation threads or can be an unrestricted search of a user's entire mailbox. Searches can also be restricted by time, user names, message channel (i.e., e-mail or web-chat), etc.

FIG. **4** illustrates an exemplary message interface for a conversation thread between more than two users, according to an embodiment. The user can reach this display by selecting one of the conversation threads in the interface of FIG. **3**. FIG. **4** shows a series of messages included in the Yoshi's San Francisco conversation between viewing user Jon Perlow and other users **402** connected to Jon. In an embodiment, the messages are presented in chronological order, the more recent messages listed below older messages. In another embodiment, messages may be listed by social proximity (e.g., by relationship degree), or by other social information (e.g., affinity, connection type, etc.) by selecting a message display mode using action pull down **324**.

Icons within each message indicate a message channel used to deliver the message. Icon **406** indicates that first message **412** is a web-chat message. Icon **408** indicates that the second message **414** is an e-mail message. Icon **410** indicates that the third message **416** is a SMS text message sent from a phone. In an embodiment, the conversation thread is updated in real-time as new messages are received. In operation, a conversation thread is akin to a historical record of correspondence about a location between a set of users sharing some social relationship. Through the interface, a viewing user can scroll backwards in time to view the entire history of the messages in the conversation thread. In an embodiment, some of the messages can have attachments such as pictures, videos, documents, etc. The pictures and video can be shown in the interface with a preview of the attachment instead of just a link to the attachment. For example, an attached picture can be shown in the interface with a thumbnail of the picture.

The conversation thread also includes both outgoing and incoming messages. For example, the conversation thread in FIG. **4** includes message **418**, which is a message sent by the viewing user Jon Perlow. The conversation thread also includes message **422**, which is a message sent to user Mike Matas from user Jen Elstrott in response to Mike's message **420**. Mike having a first-order connection with Jen, and Jen having a first-order connection with Jon.

In an embodiment, conversation threads that have more than two participants behave like chat rooms. A conversation participant can send a message to the conversation thread, which is then distributed by message grouping module **136** to all conversation participants. In an embodiment, object store **110** includes a profile for each user that comprises a profile name, an e-mail address, a profile picture, and other identifying information. In an embodiment, the name of a participant as displayed in the summary is identified from the par-

13

participant's profile. For example, an e-mail received from Lucy.Zhang@yahoo.com can be identified from information in object store 110 as being an e-mail from the user Lucy Zhang.

When a conversation thread has a large number of participants, in an embodiment only a sub-set of the participant names are presented to simplify the summary. The sub-set can be any number of participants from the conversation. For example, conversation thread 308 has fourteen participants. Only the names of four conversation participants (Lucy Zhang, Jon Perlow, Mike Matas, and Jen Elstrott) are displayed. The name of the mailbox owner is not shown in the summary. The names of the other two participants are grouped together and presented as "14 others." Message grouping module 136 selects the sub-set of names in any of a number of ways. For example, the sub-set may include the names of the participants who created the most recent messages in the conversation, the name of the participant who started the conversation, or the names of the participants that the viewing user has the strongest affinity for or social relationship with.

In an embodiment, the brief excerpt 422A may be extracted from the content of the most recent message in the conversation thread. For example, in conversation thread 308, the excerpt 422A includes the text "I will see you there," which is the most recent message from this conversation thread 308. In other embodiments, the brief excerpt is extracted from other information that is not message content, such as metadata associated with the message. For example, the brief excerpt could be the title of the most recent e-mail message in the conversation.

In an embodiment, the message interface also includes quick reply bar 426 for sending messages and adding messages to a conversation thread. For example, quick reply bar 426 is used for sending either text-based messages or attachments to participants of a conversation thread. As shown in FIG. 4, quick reply bar 426 is placed below a conversation thread at the bottom of the interface. In an embodiment, quick reply bar 426 is placed anywhere in the interface and does not necessarily have to be placed directly below the conversation thread.

Quick reply bar 426 includes a text entry box 428 and a mode selection box 430. Text entry box 428 is an element of the interface that accepts message text for updating the conversation thread. The quick reply bar can operate in two different messaging modes: quick reply mode or standard mode. The mode can be selected by toggling mode selection box 430 in quick reply bar 426. Mode selection box 430 thus allows a user to switch between the quick reply mode and the standard mode or to select a particular mode of operation. In other embodiments, more than two message modes are supported by quick reply bar 426, and mode selection box 430 allows the user to switch between any of the modes. In other embodiments, text entry box 428 and mode selection box 430 have a different appearance than that shown in FIG. 4.

The quick reply mode is similar to an instant messaging mode for sending messages. When operating in quick reply mode, a user can enter a message in text entry box 428 and send it by pressing the enter key. This allows for messages to be sent with keyboard-based input without requiring the user to switch between a keyboard and a mouse, allowing for a quicker reply. The message is sent to message grouping module 136 for adding the message to the conversation thread and updating the message interface with the new message. Any message text in the text entry box 428 is also cleared out to allow the user to start typing a new message.

14

In an embodiment, when operating in non-quick reply (standard mode), reply all button 432 is provided for sending messages. Reply all button 432 is an interface element that can be selected with a mouse click. In an embodiment, reply all button 432 is only be shown when operating in the standard mode but hidden during the quick reply mode.

When operating in a non-quick reply (standard) mode, pressing the enter key does not send the message. Instead, pressing the enter key has the effect of generating a carriage return and moves the cursor below the current line of text in the text entry box 428, similar to how pressing the enter key when writing an e-mail creates another line of text. This method of sending messages may be slower because it requires the use of a mouse, but is preferable for some users. Additionally, this also allows for the creation of more complex and longer messages that have multiple lines of text and spaces in-between the lines.

In an embodiment, the settings for quick reply bar 426 are persistent. As the viewing user moves from one conversation thread to the next, the settings for the quick reply bar 426 are maintained. For example, if the mailbox owner sets the quick reply bar 426 to a standard mode when viewing one conversation thread and then switches to viewing a different conversation thread, quick reply bar 426 will remain in standard mode. Additionally, to add a new message to a conversation thread, the viewing user may select new message 424, which generates an interface to compose a message to a current participant in the conversation thread or a non-participant, which has a social relationship with the viewing user. In an embodiment, the generated interface may be any suitable interface to send a message to another user of social networking system 100.

FIG. 5 illustrates another exemplary message interface for a conversation thread between more than two users, according to an embodiment. As shown in FIG. 5, the viewing user has selected the text for the fourteen other participants 502 in the conversation thread. In response, a list of participants is displayed. Each participant is displayed along with a name, a picture, and other identifying information such as an employer and college. As the entire list of fourteen participants is too long to be displayed at once, only a sub-set of seven participants is presented in the interface.

Additional Considerations

The foregoing description of the embodiments has been presented for the purpose of illustration; it is not intended to be exhaustive or to limit the embodiments to the precise forms disclosed. Persons skilled in the relevant art can appreciate that many modifications and variations are possible in light of the above disclosure.

Some portions of this description describe the embodiments in terms of algorithms and symbolic representations of operations on information. These algorithmic descriptions and representations are commonly used by those skilled in the data processing arts to convey the substance of their work effectively to others skilled in the art. These operations, while described functionally, computationally, or logically, are understood to be implemented by computer programs or equivalent electrical circuits, microcode, or the like. Furthermore, it has also proven convenient at times, to refer to these arrangements of operations as modules, without loss of generality. The described operations and their associated modules may be embodied in software, firmware, hardware, or any combinations thereof.

Any of the steps, operations, or processes described herein may be performed or implemented with one or more hardware or software modules, alone or in combination with other devices. In one embodiment, a software module is imple-

15

mented with a computer program product comprising a non-transitory computer-readable medium containing computer program code, which can be executed by a computer processor for performing any or all of the steps, operations, or processes described.

Embodiments may also relate to an apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, and/or it may comprise a general-purpose computing device selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a non-transitory computer readable storage medium or any type of media suitable for storing electronic instructions, and coupled to a computer system bus. Furthermore, any computing systems referred to in the specification may include a single processor or may be architectures employing multiple processor designs for increased computing capability.

Finally, the language used in the specification has been principally selected for readability and instructional purposes, and it may not have been selected to delineate or circumscribe the inventive subject matter. It is therefore intended that the scope of the embodiments to be limited not by this detailed description, but rather by any claims that issue on an application based hereon. Accordingly, this disclosure is intended to be illustrative, but not limiting, of the scope of the embodiments, which is set forth in the following claims.

What is claimed is:

1. A method comprising:

receiving a first set of one or more messages between a first set of participants from a plurality of message channels associated with a social networking system, each message channel having a message channel type, wherein the first set of participants are users of the social networking system;

receiving a second set of one or more messages between a second set of participants from the plurality of message channels, wherein the second set of participants are users of the social networking system;

determining common location information from the first and second sets of messages;

selecting messages having common location information from the first and second sets of messages based on the determining;

combining the selected messages from the first and the second sets of messages into a conversation thread;

identifying one or more messages from the conversation thread associated with participants from the first set or from the second set who have established a social relationship with a viewing participant of the conversation thread in the social networking system;

sorting the identified messages based on a social relationship between the viewing participant and two or more participants associated with identified messages;

adding the identified messages to a message interface for presentation to the viewing participant of the conversation thread, the message interface enabling further communications between the participants associated with the identified messages in the conversation thread, the message interface providing an indication of a message channel type associated with each identified message; and

providing the message interface for display to the viewing participant of the conversation thread.

2. The method of claim 1, further comprising:

determining common location information based on content included in the first and second sets of messages.

16

3. The method of claim 1, further comprising:

receiving user location information associated with one or more the first or second sets of participants; and determining common location information based on the received user location information.

4. The method of claim 1, further comprising:

combining the first and second sets of messages into the conversation when the first and second sets of messages are associated with a threshold number of users and received over a predetermined threshold period of time.

5. The method of claim 4, wherein the conversation thread is a previously existing conversation thread that includes messages from a subset of the first and second sets of participants.

6. The method of claim 1, further comprising sorting the messages included in the message interface based on social information.

7. The method of claim 6, wherein the social information comprises a type of connection between two or more participants associated with messages included in the message interface.

8. The method of claim 6, wherein the social information comprises historical information about an interaction between a participant associated with one or more messages included in the message interface and an object included in the social networking system.

9. The method of claim 6, wherein the social information comprises an affinity between two or more participants associated with messages included in the message interface.

10. The method of claim 1, further comprising:

sorting the messages included in the message interface based on common location information.

11. The method of claim 1, wherein the message interface includes a list of conversation threads.

12. The method of claim 1, wherein the message interface is a chat interface.

13. The method of claim 1, further comprising:

receiving a selection of at least one conversation thread; responsive to receiving the selection of the at least one conversation thread, presenting one or more message included in the at least one conversation thread; and

receiving, from an additional participant, a message to include in the at least one conversation thread, the received message including common location information and being associated with the additional participant.

14. The method of claim 13, wherein the additional participant having one degree of separation from a first subset of the first and second sets of participants, and having greater than one degree of separation from a second subset of the first and second sets of participants.

15. The method of claim 1, wherein the message channel type is a web-chat.

16. The method of claim 1, wherein the message channel type is a text message.

17. The method of claim 1, wherein the message channel type is a post.

18. The method of claim 1, wherein the message channel type is selected from a group consisting of a web-chat, a text message, an e-mail, and a post.

19. A computer program product comprising a non-transitory computer readable storage medium having instructions encoded thereon that, when executed by a processor, cause the processor to:

receive a first set of one or more messages between a first set of participants from a plurality of message channels associated with a social networking system, each message channel having a message channel type, wherein the first set of participants are users of the social networking system;

17

receive a second set of one or more messages between a second set of participants from the plurality of message channels, wherein the second set of participants are users of the social networking system;

determine common location information from the first and second sets of messages;

identify one or more messages from the conversation thread associated with participants from the first set or from the second set who have established a social relationship with a viewing participant of the conversation thread in the social networking system;

add the identified messages from the conversation thread to a message interface for presentation to the viewing participant of the conversation thread, the message interface enabling further communications between the participants associated with identified messages in the conversation thread, the message interface providing an indication of a message channel type associated with each identified message; and

provide the message interface for display to the viewing participant of the conversation thread.

20. The computer program product of claim **19**, wherein the non-transitory computer readable storage medium further has instructions encoded thereon that, when executed by the processor, cause the processor to:

determine common location information based on content included in the first and second sets of messages.

21. The computer program product of claim **19**, wherein the non-transitory computer readable storage medium further has instructions encoded thereon that, when executed by the processor, cause the processor to:

18

receive user location information associated with one or more the first and second sets of participants; and determine common location information based on the received user location information.

22. The computer program product of claim **19**, wherein the non-transitory computer readable storage medium further has instructions encoded thereon that, when executed by the processor, cause the processor to:

combine the first and the second sets of messages into the conversation when the first and second sets of messages are associated with a threshold number of users and received over a predetermined threshold period of time.

23. The computer program product of claim **19**, wherein the non-transitory computer readable storage medium further has instructions encoded thereon that, when executed by the processor, cause the processor to:

receive a selection of at least one conversation thread; responsive to receiving the selection of the at least one conversation thread, present one or more message included in the at least one conversation thread; and receive, from an additional participant, a message to include in the at least one conversation thread, the received message including common location information and being associated with the additional participant.

24. The computer program product of claim **23**, wherein the additional participant have one degree of separation from a first subset of the first and second sets of participants, and have greater than one degree of separation from a second subset of the first and second sets of participants.

* * * * *
